Background and Aims:: Inherited cerebellar ataxia is a rare disabling disease that lead to early death. Here we describe clinical characteristics of a large Malagasy family with this disease, share our experience of its screening, our difficulties in assessing transmission pattern.

Methods:: It is a prospective study, in Analamanga region from 2011 to 2020. We did consultation and follow-up of index cases in our department, did home visit of other family members. Those who completed direct interview and clinical examination, with obtained informed consent, were included. They underwent interview with standardized questionnaires, clinical assessment, and brain CT scan. A family tree was built. Penetrance, clinical characteristics, inheritance pattern were analyzed.

Results:: From 5 generations, 148 persons were identified, 57 of them were studied (32 alive and 25 dead), with 18 patients with cerebellar ataxia. Cerebellar ataxia was present in each generation, in both sex, with an autosomal dominant pattern. Age of onset of ataxia were between 30 and 50 years old for the first 3 generations and between 7 and 28 years old for the fourth generation. From the first 3 generations 15 dead at their third or fourth decade. Non-cerebellar neurological signs were dominated by early onset of cognitive disorders (n=21). Nowadays all those who had cerebellar ataxia are dead so we are waiting for their descendence to present its signs.

Conclusions:: Cerebellar ataxia with probably dominant autosomal inheritance pattern was observed. International collaborations are needed when studying this disease in low income countries.
ANTI-YO ANTIBODY MEDIATED PARANEOPLASTIC CEREBELLAR DEGENERATION WITH BREAST CARCINOMA: RARE CASE REPORT

Dnyaneshwar Jadhav, Neeraj Jain, Sangeeta Ravat, Mayur Thakkar
Seth GSMC and KEM hospital Mumbai, Neurology, Mumbai, India

Background and Aims:: Paraneoplastic cerebellar degeneration is a rare, severely debilitating neurodegenerative syndrome with antibodies targeting Purkinje cells of the cerebellum. It has been associated with fever than 1% of cancers, including small cell carcinoma of the lung, breast cancer, Hodgkin lymphoma and gynaecologic malignancies. Anti-Yo antibody frequently associated with this syndrome and associated with poor prognosis. We are reporting a rare case report of anti-Yo antibody mediated cerebellar degeneration in patient with highly aggressive carcinoma of breast.

Methods:: A 48-year-old female presented with 6-month history of imbalance while walking followed by tremulousness of both upper limb and change in speech. There was no history of preceding systemic symptoms, drugs, hypothyroidism, stroke or encephalitis. Family history was negative. On examination she had small lump in right breast and palpable axillary lymph node. Neurological examination showed severe cerebellar ataxia, intentional tremor, scanning speech and titubation, suggestive of pancerebellar involvement. Rest of examination was unremarkable.

Results:: On evaluation, MRI brain showed moderate cerebellar atrophy. Paraneoplastic panel showed strongly positive anti-Yo antibody. Histopathology showed high grade carcinoma with medullary feature. Treated with surgery (MRM) followed by chemotherapy (adriamycin + cyclophosphamide), Steroid, PLEX, IVIG (2gm/kg). No clinical improvement was noted in patient at 6 months follow up.

Conclusions:: This case highlights that anti-Yo antibody mediated paraneoplastic cerebellar degeneration may present before their cancer diagnosis and associated with very poor prognosis. Early recognition followed by rapid initiation of treatment may be helpful.
HUMAN ALLOGENEIC BONE MARROW-DERIVED MESENCHYMAL STEM CELL THERAPY FOR CEREBELLAR ATAXIA: A CASE REPORT

Sangmin Park, Ho-Won Lee
Kyungpook National University Chilgok Hospital, Department Of Neurology, Daegu, Korea, Republic of

Background and Aims:: To date, there is no curable treatment option for non-hereditary degenerative cerebellar ataxia. Here we report the case of a patient with sporadic adult-onset ataxia (SAOA) who underwent allogeneic bone marrow-derived mesenchymal stem cell (MSC) therapy via the intrathecal route.

Methods:: A 60-year-old male patient visited our clinic complaining of progressive gait disturbance that commenced two years ago. Upon neurologic examination, the patient exhibited limb dysmetria and gait ataxia. Brain magnetic resonance imaging (MRI) revealed cerebellar atrophy whereas the autonomic function test was normal. The patient was diagnosed with SAOA. The medications that were initially prescribed had no significant effects on the course of this disease and the symptoms deteriorated progressively.

Results:: At the age of 64, the patient was treated with allogeneic bone marrow-derived MSC therapy. The subsequent K-SARA (Korean version of the Scale for the Assessment and Rating of Ataxia) scores demonstrated a distinct improvement up until 10 months post-administration. No adverse events were reported.

Conclusions:: The improved post-treatment K-SARA scores may suggest that the MSC therapy can have a neuroprotective effect and that stem cell therapy may serve as a potential therapeutic option for degenerative cerebellar ataxia.
VESTIBULO-OCULAR REFLEX IN SPINOCEREBELLAR ATAXIA: DOES IT HAVE A DIFFERENTIATING VALUE?

Jae-Myung Kim, Hyunsoo Kim, Sang-Jun Ko, Tai-Seung Nam, Seong-Min Choi, Seung-Han Lee
Chonnam National University Hospital, Neurology, Gwangju, Korea, Republic of

Background and Aims:: The differential diagnosis of spinocerebellar ataxia (SCA) is often difficult and usually dependent upon genetic testing since the clinical phenotypes of SCAs considerably overlap. SCA may present VOR impairments, though the previous studies have shown inconsistent results. We aimed to assess VOR of SCA patients with various subtypes using video head impulse test (HIT) device, and to determine whether they have differentiating value.

Methods:: 25 genetically confirmed SCA patients (SCA2=5, SCA3=3, SCA6=9, SCA7=8) were enrolled. Baseline demographics, vestibular performance, and combined ocular motor dysfunctions were investigated. Furthermore, correlation analyses were performed between clinical parameters and the VOR gains. Normative data were obtained from 40 age-matched healthy control.

Results:: Compared to normal control, the VOR gains were spared in SCA2, but globally decreased in SCA3. In vertical canals, SCA6 showed posterior canal-dominant gain impairments, but SCA7 exhibited impaired gains in both anterior and posterior canals. The gains for the horizontal canals in SCA6 and the vertical canals in SCA7 were negatively correlated with disease severity. Saccadic slowing associated with absent gaze-evoked nystagmus were prominent in SCA2 and SCA7. Spontaneous and evoked nystagmus were common in SCA6. Pursuit and optokinetic nystagmus impairments were frequent regardless of subtypes.

Conclusions:: VOR impairments are common in SCA, but their patterns were various according to the subtypes. Distinctive VOR performance for each subtype using video HITs may aid the differential diagnosis of the SCA genotypes and may lead to a better understanding of the neuropathology.
CEREBELLO-SPINAL STIMULATION IN NEURODEGENERATIVE ATAXIA: MOTOR AND COGNITIVE OUTCOMES.

Ilenia Libri, Alberto Benussi, Valentina Cantoni, Marta Manes, Valentina Dell'Era, Abhishek Datta, Chris Thomas, Camilla Ferrari, Alessio Di Fonzio, Mario Grassi, Alfredo Brusco, Antonella Alberici, Barbara Borroni

1University of Brescia, Neurology Unit, Department Of Clinical And Experimental Sciences, Brescia, Italy, 2Aulss2 Marca Trevigiana, Neurology Unit, Treviso, Italy, 3ASST Papa Giovanni XXIII, Department Of Neurology, Bergamo, Italy, 4Soterix Medical, Inc., Research & Development, New York, United States of America, 5University of Florence, Department Of Neuroscience, Psychology, Drug Research And Child Health (neurofarba), Florence, Italy, 6Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Neurology Unit, Milano, Italy, 7University of Pavia, Department Of Brain And Behavioural Sciences, Medical And Genomic Statistics Unit, Pavia, Italy, 8University of Torino, Department Of Medical Sciences, Torino, Italy

Background and Aims:: In this randomized, double-blind, sham-controlled trial, followed by an open-label phase, we investigated whether treatment with cerebello-spinal transcranial direct current stimulation (tDCS) could improve both motor and cognitive symptoms in patients with neurodegenerative ataxia, a still orphan disorder of any pharmacological intervention.

Methods:: Sixty-one patients were randomized in two groups for the first controlled phase. At baseline (T0), Group 1 received placebo stimulation (sham tDCS) while Group 2 received anodal cerebellar tDCS and cathodal spinal tDCS (real tDCS) for 5 days/week for two weeks (T1), with a 12-week (T2) follow-up. At the 12-week follow-up (T2), all patients received a second treatment of real tDCS for 5 days/week for two weeks, with a 14-week (T3), 24-week (T4), 36-week (T5) and 52-week follow-up (T6). At each time point, a clinical, neuropsychological and neurophysiological evaluation was performed. Cerebellar-motor cortex connectivity was evaluated using transcranial magnetic stimulation (TMS).

Results:: We observed a significant improvement in all motor scores, in cognition, in quality-of-life scores, in motor cortex excitability and in cerebellar inhibition after real tDCS compared to sham stimulation and compared to baseline (T0), both at short and long-term. We observed an addon-effect after two repeated treatments with real tDCS compared to a single treatment with real tDCS.

Conclusions:: Multiple sessions of cerebello-spinal tDCS repeated every 3 months, are an effective, non-invasive, painless, and easy to perform treatment to be considered in the spectrum of neurodegenerative ataxias, capable of improving both motor and cognitive functions with long-lasting effects.
Background and Aims:: Introduction Neuro-degeneration with brain iron accumulation (NBIA) is where early deposition of iron in the basal ganglia and the other deep grey matter is characteristically associated with movement disorders. Spinocerebellar ataxia (SCA) is characteristically a neurodegenerative disorder predominantly affecting the cerebellum and the cortico-spinal tracts. Rarely excess iron accumulation is reported in long standing SCA patients. We report a case of genetically proven SCA38 with evidence of excess iron deposition in the basal ganglia similar to a NBIA.

Methods:: Case report A 38 year old woman presented with difficulty in walking and maintaining her balance for 3 years. She didn’t complain of any sensory symptoms and denied any defect in the sense of smell or hearing. On examination she was ataxic and bradykinetic with parkinsonism. There was gaze evoked horizontal nystagmus. Appendicular rigidity was prominent with exaggerated reflexes and extensor planter responses. She didn’t have any evidence of pes cavas. She did not have KF rings. Ceruloplasmin, serum cooper, TSH, Serum Ferritin were normal.

Results:: MRI showed evidence of brain iron accumulation with prominent cerebellar atrophy. Her genetic studies showed heterozygous ELOVL5 gene mutation due to c.304C>T mutation characteristic of SCA 38.

Conclusions:: SCA38 is characterized by slowly progressive ataxia with prominent cerebellar signs. Evidence of brain iron accumulation which normally occurs with NBIA and Wilson’s disease (WD) is unusual in SCA. Brain iron accumulation was previously reported only in cases of SCA15. It has never
been reported before in SCA 38. A genetic evaluation in such cases is of paramount importance to make an accurate diagnosis distinguishing SCA from NBIA and WD.
Background and Aims:: Paraneoplastic cerebellar degeneration is rare and can be the presenting feature of an underlying malignancy

Methods:: A 75 year old retired police officer with type 2 diabetes and hypertension presented with gradually worsening unsteadiness since 2 weeks. He was a heavy smoker. He gave a history of recent onset loss of weight and loss of appetite. He denied any respiratory symptoms. Physical examination revealed bilateral cerebellar signs. He was wasted but didn’t have any other significant findings during the examination. His MRI brain was significant for marked cerebellar atrophy. Contrast enhanced CT scan of the chest showed 2 cm nodule in the right middle lobe. CT guided biopsy was performed which confirmed the diagnosis of small cell carcinoma of the lung. Anti neuronal antibodies were remarkable for a positive anti Hu antibody. His thyroid functions, serum vitamin B12 levels were normal. He was referred to oncology team following the diagnosis.

Results:: Paraneoplastic cerebellar ataxia is one of the most common paraneoplastic syndromes. Its characterized by rapid development of severe pancecerebellar dysfunction. Since it can precede the presentation of neoplasms by several months to years, a high degree of suspicion is needed. Lung, testicular, ovarian, breast carcinoma, Hodgkin’s lymphoma are the common types associated with paraneoplastic cerebellar degeneration.

Conclusions:: Paraneoplastic cerebellar degeneration should be considered in elderly patients presenting with constitutional symptoms and ataxia.
ANTI-MGLUR1 MEDIATED CEREBELLAR ATAXIA CASE REPORT & REVIEW OF LITERATURE

Osama Khojah1,2, Saeed Alghamdi3
1King Abdullah International Medical Research Center, King Abdullah International Medical Research Center, Jeddah, Saudi Arabia, 2King Saud Bin Abdulaziz University for Health Sciences, College Of Medicine, Jeddah, Saudi Arabia, 3King Abdulaziz Medical City, Ministry of National Guard Health Affairs, Division Of Neurology, Department Of Medicine, Jeddah, Saudi Arabia

Background and Aims: Immune-mediated neurological disorders literature is evolving like no other field of neurological illnesses. Many new antibodies and disorders have been described in the last decade. The cerebellum is one of the brain structures susceptible to these immune-mediated pathologies and anti-metabotropic glutamate receptor 1 (mGluR1) antibodies have a predilection to cerebellar tissue. Cerebellar ataxia associated with anti-mGluR1 is a rare autoimmune-mediated disorder. As about one-quarter of the reported cases have an associated malignancy, investigating for occult malignancies is important. We aim to describe the first case of anti-mGluR1 antibody-mediated cerebellar ataxia in the Middle East.

Methods: Case-report & review of literature

Results: We describe a case of non-paraneoplastic cerebellar ataxia associated with anti-mGluR1 antibodies in a 56-year-old female. She presented with cerebellar ataxia, dysarthria, tremors, and diplopia following a febrile illness. CSF analysis showed lymphocytic pleocytosis with positive oligoclonal bands. Brain MRI was initially unremarkable and six months later showed cerebellar atrophy. Serum and CSF anti-mGluR1 antibodies were positive. She was treated with pulse intravenous methylprednisolone, intravenous immunoglobulin (IVlg), and plasma exchange (PLEX) as acute treatment. For maintenance, she received IVlg, PLEX, rituximab, and azathioprine over the course of 3 years. She improved and is in remission until now; follow-up extensive workup showed no occult malignancy.

Conclusions: Anti-mGluR1 Cerebellar Ataxia is an immune-mediated disorder that warrants early diagnosis to initiate therapy promptly with the goal to achieve a better outcome. Testing for mGluR1 antibodies should be considered in any acute or subacute cerebellar ataxia especially when it follows a prodrome of febrile illness.
CEREBELLAR COGNITIVE AFFECTIVE SYNDROME IN PATIENT WITH CEREBELLAR INFARCTION

Mario Fuentealba¹, Fernando Andrade², Carolina Herrera¹
¹university of Concepcion, Neurology, Concepción, Chile, ²universidad de concepcion, Radiology, Concepción, Chile

Background and Aims:: Schmahmann (1998) described the ‘cerebellar cognitive affective syndrome’, (CCAS) reporting impairments in executive functions, disturbances in spatial cognition, language deficits and personality changes in subjects with cerebellar pathologies. the current CCAS literature consists of only small series of patients that are frequently biased by patient selection rather than consecutive inclusion. and is clear that stroke in the anterior lobe for occlusion of Anterior Inferior Cerebellar Artery (AICA) produced the motor syndrome but not the CCAS, whereas stroke in the posterior lobe posterior Inferior Cerebellar Artery (PICA) produced the CCAS. however is controversial the role of the Superior Cerebellar Artery (SCA) that included largest part of the deep white matter with most of or the whole dentate nucleus.

Methods:: revision of clinical record of case of a 56-year-old man with complete clinical, neurocognitive and imagenological evaluation is presented
Results: A cerebelar stroke for basilar-vertebral atheromatosis with MRI evidence show extensive infarction of the bilateral SCA and the left PICA without encephalic supratentorial damage Has severe motor cerebellum syndrome with BARS score of 17/30 and cognitive deficit in language functions, attention, visual construction and behavioral manifestations such as apathy. CCAS scale is applied with total score of 22/120 and 8/10 failed item

Conclusions: this case meets diagnostic criteria of CCAS with cognitive profile consistent with cognitive deficits in the stroke of PICA without cerebral compromise, also in this case the bilateral injury of SCA
probably contributes at the multidimensional cognitive deterioration for the damage of the cortical efferent pathways in the white matter and deep cerebellar nuclei.
A GUIDELINE ON THE DIAGNOSIS AND TREATMENT OF CHILDREN WITH ATAXIAS

Eleonora Lacorte¹, Paola Piscopo², Guido Bellomo¹, Francesco Della Gatta¹, Nicola Vanacore³, Guide-Line Working Group³
¹National Institute of Health, Rome, Italy, National Center For Disease Prevention And Health Promotion, Rome, Italy, ²National Institute of Health, Rome, Italy, Department Of Neurosciences, Rome, Italy, ³National Institute of Health, National Center For Disease Prevention And Health Promotion, Rome, Italy

Background and Aims:: The activities of the project “Pediatric ataxias and Public Health: epidemiological studies and disease registry, characterization of genetic determinants and implementation of protocols for diagnosis, management, and rehabilitation using innovative low cost, widely accessible technologies”, funded by the Ministry of Health, included the production of a guideline (GL) on the diagnosis and treatment of children with ataxias.

Methods:: The GL was produced using the GRADE approach. A systematic review (SR) of the literature was performed to gather available evidence on each clinical question included in the scope of the GL. Results from the SR were reported in summary of findings (SoF) tables and the multidisciplinary panel (MP), after discussing the evidence, produced clinical practice recommendation (CPR) along with their respective evidence-to-decision tables.

Results:: The GL included 28 clinical questions (2 on acute ataxias, 10 on the diagnosis of chronic ataxias, 12 on the pharmacological and habilitative/rehabilitative treatment of chronic ataxias, and 2 on care models). Specific SRs were carried out for each question. Selected evidence was qualitatively assessed and SoF tables were built, including a judgement of each body of evidence. Discussion with the MP lead to the definition of 39 CPR and 7 research recommendations. Following the NICE and the European Pathway association (EPA) models, a care pathway was also produced, in the form of an interactive pdf. An informative leaflet was also produced.

Conclusions:: To our knowledge, this is the first guideline produced using a standardized methodology and including evidence-based recommendation on these rare diseases.
METABOLIC IMAGING PATTERNS IN CEREBELLAR ATAXIA SYNDROMES

Ritu Verma¹, Rajeev Ranjan², Nikhil Seniaray¹, Ethel Belho¹
¹Sir Ganga Ram Hospital, Department Of Nuclear Medicine And Pet Ct, NEW DELHI, India, ²Sir Ganga Ram Hospital, Department Of Neurology, NEW DELHI, India

Background and Aims:: To elucidate the patterns of characteristic hypometabolism on 18F-FDG PET/CT in cerebellar ataxia syndromes.

Methods:: A retrospective analysis of 70 patients of clinically diagnosed ataxia syndrome was done. All the subjects were clinically analyzed and were further segregated into hereditary and acquired sub groups of SCA (n=10), MSA-C (n=40), Normal pressure hydrocephalous (NPH) (n=20) and 5 subjects diagnosed with autoimmune cerebellar degeneration. All the subjects underwent 18F-FDG PET/CT and 99mTc TRODAT-1 SPECT studies. The FDG uptake patterns were recorded and areas of hypometabolism that were two standard deviations from the mean were considered as abnormal.

Results:: 99mTc TRODAT-1 scan was abnormal in all the subjects of suspected MSA-C, establishing degenerative Parkinsonism. 99mTc TRODAT-1 scan was normal in all subjects of SCA and NPH. On FDG PET, the subjects of SCA showed diffuse mild to moderate hypometabolism involving the bilateral cerebellar hemispheres, cerebellar peduncles, sensori-motor and insular cortices, whereas the subjects of MSA-C had diffuse moderate to severe hypometabolism involving the bilateral cerebellar cortices, cerebellar vermis, sensori-motor cortices, basal ganglia and brain stem. The subjects with NPH showed global cortical and sub cortical hypometabolism. Among the 5 subjects with autoimmune cerebellar degeneration, 3 had anti-yo positive para neoplastic degeneration and showed diffuse cerebellar hypometabolism, while 2 had anti-GAD positive autoimmune encephalitis with areas of hypometabolism and hypermetabolism.

Conclusions:: Characteristic patterns of hypometabolism may help in differentiation of the cerebellar ataxia syndromes. 99mTc TRODAT-1 SPECT helps in confirmation of degenerative Parkinsonian disorder like MSA-C, from other degenerative ataxia syndromes.
FREQUENCY AND FEATURES OF SPINOCEREBELLAR ATAXIAS IN BRAZILIAN PATIENTS FROM RIO DE JANEIRO

Marina Alvarenga, Luciane Sicilianni, Patricia Penna, Maria Carolina Ganimi
Rede Sarah de hospitais de reabilitação, Neurology, Rio de Janeiro, Brazil

Background and Aims: Previous studies show geographic and ethnic differences in the frequency of hereditary ataxias worldwide. Few data about spinocerebellar ataxias (SCA) are available in Rio de Janeiro (RJ), in the Southeast region, where there is a high proportion of Afro-descendants in the population. The aim of this study is to describe the frequency and features of SCAs in a cohort of patients from RJ.

Results: 147 patients were identified. SCA 3 was the most frequent type (107). Less frequent types were SCA 7 (9), SCA 2 (5), SCA 1, SCA 6 and SCA 8 (2) and SCA 10 (1). The genetic tests were negative in 19 cases. Extra cerebellar symptoms were: dysphagia, pyramidal syndrome, neurogenic bladder, ophthalmoplegias, extra pyramidal syndrome, peripheral neuropathies, epilepsy, and visual impairment. Brain MRI was performed in 106 patients. Cerebellar atrophy was the most frequent finding (88.6%) followed by brain stem atrophy (33%), cross sign (15%), and brain atrophy (10.3%). Normal MRI (9.4%). ENMG performed in 55 SCA3 were abnormal in 74.3%, polyneuropathy (50.9%), motor neuronopathy (40%) and radiculopathy (18.5%). CAG repetitions in SCA3 varied between 50 and 78 (mean = 65).

Conclusions: SCA3 is the most frequent type of spinocerebellar ataxia in Rio de Janeiro, similar to Caucasian populations. Cerebellar atrophy and extra cerebellar neurological manifestations occurred in most cases.
PHENOTYPIC CHARACTERISTICS OF PATIENTS WITH ARSACS FROM SOUTH INDIA

Lakshminarayanapuram Viswanathan, Madhu Nagappa, Doniparthi Seshagiri, Parayil Bindu, Sanjib Sinha, Ab Taly
National Institute of Mental Health and Neurosciences (NIMHANS), Department Of Neurology, Bangalore, India

Background and Aims:: Early onset autosomal recessive ataxias consist of numerous entities with distinctive phenotypes. In 1978, a spastic ataxic syndrome was reported from Quebec, which was acronymized as ARSACS; autosomal recessive spastic ataxia of Charlevoix-Saguenay. We aim to describe a cohort of patients with ARSACS from a South India.

Methods:: We conducted a retrospective review in a single neurology unit of a university teaching hospital. Clinical and electrophysiological details of patients diagnosed with ARSACS based on clinical and characteristic imaging features i.e., linear T2 hypointensities in the pons and anterolateral thalamic hyperintensities were recorded (n=7, M:F=4:3).

Results:: The mean age at onset was 5.8±4.6 years (range: 2-13 years). Four individuals were born to consanguinity. The median time to diagnosis from onset was 18 years (range: 5-26 years). Initial/referral diagnosis was ataxic cerebral palsy (n=2), hereditary motor neuropathy (n=2), spastic ataxia syndrome (n=2) and unexplained gait difficulty (n=1). All patients had motor developmental delay at onset of illness which was subsequently followed by gait difficulty. Though spasticity was observed in only two patients, all the patients except one, had extensor plantar response. Three patients had hyper-myelinated retinal nerve fibers. Nerve conduction studies were abnormal in all the patients. Genetic testing was done in two individuals, both harbored homozygous pathogenic mutations in the SACS gene.

Conclusions:: ARSACS is a slowly progressive autosomal recessive ataxia with pathognomonic imaging findings. Early diagnosis can facilitated by careful characterization of phenotype and review of MRI.
AN UPDATE ON PERIPHERAL BLOOD NEUROFILAMENTS IN THE DIAGNOSIS OF MULTIPLE SCLEROSIS

Agustín Rodríguez Belli¹, Minerva Mañez Sierra¹, Francisco Padilla²
¹University Hospital Virgen de la Victoria, Neurology, Málaga, Spain, ²University Hospital Virgen de la Victoria, Neurology, Malaga, Spain

Background and Aims:: Background: Imagine being able to tell “there is no inflammation or degeneration in your nervous system currently”. Aims: The future of neurofilaments in RRMS and whether they can be included in our routine clinical practice.

Methods:: A total of 440 journal articles were obtained, after 2 screenings 5 studies were extracted, a total of 891 patients studied.

Results:: “Serum neurofilament light chain as a predictive marker in patients after first demyelinating event suggestive of multiple sclerosis”. Concluding that high levels of neurofilaments during the first demyelinating event are suggestive of MS and are associated with greater activity, low levels of neurofilaments are related to NEDA 3, up to 4 years. “Serum neurofilament light chain levels in patients with presymptomatic multiple sclerosis”. Concluding that the levels of neurofilaments can be found elevated up to 6 years before diagnosis, their maximum elevation at the time of clinical debut. “Prognostic value of serum neurofilaments in patients with clinically isolated syndromes”. Concluding that the levels of neurofilaments have a prognostic value in patients with clinically isolated syndrome, the low levels can reduce up to 3 times the risk of developing MS, the increase in the levels represent activity and the levels maintained constant damage. “Serum neurofilament light chain levels are increased in patients with a clinically isolated syndrome”. Concluding that neurofilament levels are elevated in patients with clinically isolated syndrome. “Neurofilament-light chain levels are predictive of ongoing disease activity in radiologically isolated syndrome”. Concluding that neurofilaments are an independent factor to predict disease activity.

Conclusions:: In the previous
BILATERAL OPTIC ATROPHY WITH PITUITARY FAILURE: A RARE DIFFERENTIAL

Shiran Paranavitane, P Manokaran, N. T. Wijesinghe, S Bandusena, A Fernando
National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

Background and Aims: Bilateral optic atrophy together with pituitary failure, likely related to IgG4-related disease is a rare clinical entity.

Methods: A 35-year-old male presented with progressively worsening visual loss of the right eye and was found to have asymmetrical, bilateral optic atrophy, affecting the right eye more than the left. He was noted to have short stature and a lack of secondary sexual characteristics with low testicular volume. He also reported polyuria since 13 years of age. Further assessment showed hypopituitarism and diabetes insipidus. Magnetic resonance imaging of the brain and orbits showed an asymmetrical contrast-enhancing soft tissue lesion in both cavernous sinuses with extension into both orbital apices and involvement of intra-cranial optic nerves and the chiasm with dural thickening and a hypoplastic pituitary gland. Evaluation for tuberculosis and sarcoidosis were negative. Biopsy of the lesion showed lymphocytes, plasma cells and some neutrophils with areas of sclerosis, without necrosis or granuloma formation. IgG4-related disease was considered likely but not confirmed due to the non-availability of the appropriate staining. The serum IgG4 levels were normal. He was treated with hormonal replacement and high dose steroids. Due to inadequate clinical and radiological response, IV rituximab was given. This led to clinical improvement with complete resolution of diabetes insipidus but his vision remains unaltered without a significant radiological improvement at 2 months post-rituximab.

Results:
Conclusions: This case highlights the necessity of entertaining alternate diagnoses such as IgG4-related disease, in patients with enhancing soft tissue lesions involving the CNS negative for tuberculosis and sarcoidosis.
SAFETY OF ECULIZUMAB IN NMOSD AND MG: ANALYSIS OF THE PHASE 3 STUDIES PREVENT AND REGAIN, AND THEIR EXTENSIONS

Renato Mantegazza¹, Todd Levine², Celia Oreja-Guevara³, Cynthia Carrillo-Infante⁴, Eva Laudon-Meyer⁵, Shulian Shang⁶, Sean Pittock⁷, James Howard⁸
¹Fondazione IRCCS, Istituto Neuromologico Carlo Besta, Department Of Neuroimmunology And Neuromuscular Diseases, Milan, Italy, ²Phoenix Neurological Associates, Department Of Neurology, Phoenix, United States of America, ³Hospital Universitario Clínico San Carlos, Department Of Neurology, Madrid, Spain, ⁴Alexion Pharmaceuticals, Inc., Medical Safety, Boston, United States of America, ⁵Alexion Pharmaceuticals, Inc., Global Medical Affairs, Boston, United States of America, ⁶Alexion Pharmaceuticals, Inc., Biostatistics, Boston, United States of America, ⁷Mayo Clinic, Center For Multiple Sclerosis And Autoimmune Neurology, Rochester, United States of America, ⁸University of North Carolina, Department Of Neurology, Chapel Hill, United States of America

Background and Aims:: Eculizumab (a terminal complement inhibitor) demonstrated efficacy in reducing relapse risk and eliciting clinical improvements in the phase 3, randomised, double-blind PREVENT (NCT01892345) and REGAIN (NCT01997229) studies and their open-label extensions (NCT02003144 and NCT02301624, respectively) in aquaporin-4 immunoglobulin G-positive neuromyelitis optica spectrum disorder (AQP4+ NMOSD) and acetylcholine receptor antibody-positive generalised myasthenia gravis (AChR+ gMG), respectively. The aim of this analysis was to compare infection rates for eculizumab vs placebo according to number of concomitant immunosuppressive therapies (ISTs) during these studies. Eculizumab is not reimbursed for neurology indications in Italy as of April 2021.

Methods:: Patients were randomised to eculizumab or placebo. Post hoc analysis examined infection rates overall and by number of baseline ISTs.

Results:: Infection rates/100 patient-years for eculizumab vs placebo in NMOSD and gMG, respectively, were: no IST, 176.1 vs 192.2 and 236.8 vs 305.6; 1 IST, 171.5 vs 154.1 and 228.8 vs 253.1; 2 ISTs, 186.7 vs 238.2 and 170.5 vs 192.5; ≥3 ISTs (gMG only), 97.5 vs 100.1. Serious infection rates/100 patient-years were: no IST, 2.3 vs 8.0 and none observed; 1 IST, 11.2 vs 7.0 and 16.2 vs 34.5; 2 ISTs, 14.8 vs 47.6 and 13.4 vs 24.1; ≥3 ISTs (gMG only), 13.9 vs 0.0. One patient with gMG (2 ISTs) had meningococcal meningitis that resolved with antibiotics and eculizumab was resumed.

Conclusions:: In AQP4+ NMOSD and AChR+ gMG, infection rates were similar in eculizumab and placebo groups, regardless of concomitant IST, and were consistent with eculizumab’s established safety profile. This study was funded by Alexion Pharmaceuticals, Inc.
Background and Aims: Hashimoto’s Encephalopathy (HE), is a rare autoimmune disorder to be considered in patients with neuropsychiatric symptoms accompanied by normal or nonspecific brain MRI, LCR findings and thyroid function or mild hypothyroidism, increased serum levels of thyroid peroxidase antibodies (TPOAb), and response to steroids. We describe the case of a 68-years old caucasian female without previous psychiatric history conducted to Emergency Care in February 2020 for recently debuted confusion, visual hallucinations and cleanliness delusions in response to SARS-COV2 pandemic.

Methods: We found TSH elevation (38.05 μUI/mL) with negative brain CT. EEG presented diffuse 2-4 Hz activity. LCR findings were negative for infections. Brain MRI was inconsistent. We started levothyroxine replacement. At EEG reappeared an alpha activity. TSH began to descend. TPOAb were at a very high titer (>600 U/mL). We started oral prednisone with initial neuropsychiatric improvement. Patient rapidly got again worse in psychiatric aspects and presented also extrapiramidal signs. Antibodies against cell-surface, synaptic and onconeural proteins were absent. CT total body was inconsistent. 18PDG-PET was negative. Levels of beta amyloid, 14-3-3protein, tau and phospho-tau in LCR were normal. Brain PET demonstrated an hypometabolism in frontotemporoparietal bilateral regions. At psychometric tests patient presented a multi-domain disorder. We treated her with high dose intravenous corticosteroids followed by an immunoglobulins cycle.
Results:: At follow-up extrapiramidal and psychiatric disorders got slowly better. At control psychometric tests and cerebral PET patient improved. She is performing 18PDG- PET every 6 months to exclude an underlying paraneoplastic syndrome.

Conclusions:: Hashimoto’s Encephalopathy seems to respond to steroids and immunoglobulins therapy.
Background and Aims:: SARS-CoV-2 infection is now known to be associated with a wide spectrum of neurological autoimmune syndromes, in some cases responding to immunotherapies, arising during or after the infection. Whether molecular mimicry or other immune stimulation may induce an aberrant delayed autoimmune response is still to be established.

Methods:: Case Report

Results:: A 71-year-old man with no previous medical history apart from mild COVID-19 pneumonia 3 month earlier, sought medical attention for a subacute onset of diplopia in left gaze, general malaise and fatigue. MRI was characterized by bilateral FLAIR hyperintensities with punctate, perivascular and confluent post-gadolinium enhancement in the pons, mesencephalon, hypothalamus, internal capsules and right hippocampus. Repeated cerebrospinal fluid analysis were normal (2 cells/µL), with no evidence of oligoclonal bands or atypical cells. Screening panel for autoimmune and infectious aetiologies was negative. Whole-body contrast-enhanced CT was unremarkable. Stereotactic temporal lobe brain biopsy showed aspecific chronic lymphocytic perivascular inflammation. Partial spontaneous remission of symptoms occurred within few weeks. He was then treated with intravenous high-dose methylprednisolone with almost complete enhancement regression on MRI. Collected data were suggestive of CLIPPERS with diffuse bilateral supratentorial involvement. The patient started daily oral steroid tapering and monthly cycles of intravenous cyclophosphamide with persistent clinical and neuroradiological stability.

Conclusions:: CLIPPERS is a rare diagnosis and to the best of our knowledge, this is the first time it was reported after COVID-19 disease. Even though a case report is not enough to suggest a causal link, future reports could support this possibility.
A RARE CAUSE OF DRUG INDUCED MONONEUROPATHY

Jaspreet Kaur¹, Jasmine Singh²
¹Government Medical College and Hospital, Chandigarh, General Medicine, Chandigarh, India, ²Government Medical College and Hospital, Chandigarh, Pediatrics, Chandigarh, India

Background and Aims:: Drug-induced mononeuropathy is a common and painful condition seen with use of chemotherapeutic agents, antimicrobials and anticonvulsants. It takes weeks to months to set in. Churg Strauss Syndrome (CSS) is primarily a disease of middle age and its presentation in childhood is rare. We hereby present a rare case of an adolescent female presenting with mononeuropathy which later turned out to be a part of eosinophilic granulomatosis with polyangiitis or CSS precipitated by prolonged use of leukotriene receptor antagonist.

Methods:: 16 year old female child presented with complaints of rash and swelling over legs and arthralgia for last 7 days. She also had severe pain and numbness in right foot. Child had been diagnosed with bronchial asthma one year back for which she took montelukast. A nerve conduction velocity study was done which showed evidence of sensory neuropathy in right sural nerve. The complete blood counts consistently showed more than 70% eosinophils. Total IgE levels were elevated and HRCT chest showed bronchiectasis. Skin biopsy results revealed leukocytoclastic vasculitis with perivascular eosinophils. With the diagnosis of CSS child was started on oral steroids and montelukast was discontinued. pANCA and cANCA levels were negative.

Results:: After starting corticosteroids, neuropathy improved and eosinophil count was reduced to 8%. She was discharged on oral corticosteroids and is currently on regular follow up.

Conclusions:: With rampant use of LTRAs in asthma, primarily cough variant asthma, among physicians, we should be watchful for such immune mediated phenomenon as there could be life threatening end organ involvement.
PACHYMENINGITIS IN GRANULOMATOSIS WITH POLYANGIITIS: A CASE REPORT

Chiara Gallo¹, Giulia Galli¹, Gionata Strigaro¹, Pier Paolo Sainaghi², Domizia Vecchio¹, Riccardo Fornaro³, Letizia Mazzini¹, Renzo Boldorini⁴, Roberto Cantello¹
¹Department of Translational Medicine, University of Piemonte Orientale, and Azienda Ospedaliero-Universitaria "Maggiore della Carità", Neurology Unit, Novara, Italy, ²Department of Translational Medicine, University of Piemonte Orientale, Internal Medicine Unit, Novara, Italy, ³AOU Maggiore della Carità, Neurosurgery Unit, Novara, Italy, ⁴University of Piemonte Orientale, Department Of Health Science, Novara, Italy

Background and Aims:: Granulomatosis with polyangiitis (GPA; formerly called Wegener's) is a rare small to medium sized necrotizing vasculitis. Neurological manifestations include cranial and peripheral neuropathies whereas meningeal and central nervous system (CNS) involvement is unusual.

Methods:: Case report

Results:: We describe the case of a 51-year-old woman with subacute complete visual loss in her left eye following one month history of progressive visual impairment associated with nausea, vertigo and headache. Her recent past medical history included recurrent otitis, mastoiditis and chronic sinusitis. Neurological examination showed multiple cranial neuropathies: right trigeminal hypoesthesia, left abducens nerve palsy, peripheral facial nerve palsy, right hearing loss. Brain MRI showed contrast-enhanced pathological tissue in the right medium-inner ear involving also the petrous temporal bone and vascular structures, multifocal pachymeningitis (PM) and extensive brain edema. Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were elevated. Lumbar puncture was negative for infection and only showed a mildly elevated CSF protein and cell count. P-ANCA antibodies directed against myeloperoxidase were positive. Finally, a dural biopsy revealed numerous multinucleated giant cells and necrotizing vasculitis. Initially she received standard therapy with corticosteroid with significant improvement, then rituximab was started.

Conclusions:: Pachymeningitis is a rare manifestation of GPA. Our case presented with classical symptoms of otitis, mastoiditis and chronic sinusitis, but was followed by multiple cranial neuropathies and significant meningeal-CNS involvement short after. A dural biopsy was therefore necessary to confirm the clinical diagnosis for a timely therapy.
Background and Aims:: Multiple Sclerosis (MS) and Psoriasis are both autoimmune T cell-mediated diseases, with similarities in genetic risk variants and inflammatory pathways. So far, limited evidence is available on the relationship between the two diseases and on the impact of one disease on the course of the other.

Methods:: We report the case of three cases of MS with psoriasis and correlate our findings with a brief review of literature, to investigate the potential relationship between psoriasis and MS.

Results:: We present the case of three multiple sclerosis patients with psoriasis comorbidity. No family history of psoriasis was found. The median age of onset of MS was 22 years old. Psoriasis preceded MS in only one case, and the duration between the diagnosis of psoriasis and the onset of MS was 15 years. The other two patients developed psoriasis few months after initiation of Interferon-B therapy. Nonetheless, psoriasis lesions were not severe (less than 3% of the body is affected), and did not warrant treatment interruption. All the patients were treated with topical corticosteroids with a favorable outcome. The three patients had slower progression of disease, as manifested by a longer time to second relapse and a longer time to significant neurological disability scores.

Conclusions:: Although psoriasis has been reported as an undesirable effect of interferon-Beta therapy, the common genetic linkages in these two diseases cannot be denied. Further studies are warranted to establish the mechanisms underlying this relationship and its potential clinical and therapeutic consequences.
CLINICAL VARIABILITY AND THE ROLE OF DIAGNOSTIC CRITERIA OF CEREBRAL AMYLOID ANGIOPATHY-RELATED INFLAMMATION (CAA-RI): A CASE SERIES.

Fulvio Pasquin, Valentina Tommasini, Alessandro Dinoto, Francesco Biaduzzini, Laura D'Acunto, Alessio Bratina, Arianna Sartori, Paolo Manganotti
University of Trieste, Neurology Unit, Department Of Medical, Surgical And Health Sciences, Cattinara University Hospital, Asugi, Trieste, Italy

Background and Aims:: Cerebral amyloid angiopathy (CAA) is usually a cause of hemorrhagic stroke. Rarely it could be complicated by an inflammatory brain disease called CAA-related inflammation (CAA-ri) as a consequence of amyloid-β auto-antibodies production. Symptoms and their onset vary widely among patients, from headache to coma, and from chronic to acute onset. In the past, diagnosis was possible only performing a brain biopsy. Recently, in order to avoid procedural risks of a brain biopsy and to accelerate the diagnostic process and consequent treatment, clinicoradiological diagnostic criteria were proposed. Among all proposed therapies, high dose corticosteroids have shown to be the most effective.

Methods:: Three cases of CAA-ri are described. The first case is a 77-year-old woman who presented a subacute cognitive impairment. Her clinical conditions rapidly deteriorated leading to fatal outcome 11 days after admission. Autopsy posed the diagnosis of CAA-ri. The second and the third patients were an 81-year-old man hospitalized for a generalized epileptic seizure and an 80-year-old woman with a recent history of nocturnal headache. After a brain MRI and exclusion of other causes, a diagnosis of probable CAA-ri was made according to the clinicoradiological criteria and a corticosteroid treatment was immediately begun. Both patients fully recovered after
treatment.

**Results:** In the second and third case, application of diagnostic criteria permitted a faster treatment and a better outcome.

**Conclusions:** CAA-ri may present with a wide range of symptoms and severity. The application of clinicoradiological criteria to diagnose CAA-ri has allowed a faster diagnosis and a faster treatment with a consequent improved outcome.
Background and Aims:: Anti-GFAP astocytopathy is a rare and relatively new disease. Neuropathology has been hitherto only described in 4 cases. We report one other case, and discuss the uniqueness of the neuropathology in these cases based on a potential second case.

Methods:: Case report.

Results:: This 64-year-old right-handed gentleman had at presentation a 2 month history of light-headedness, and one month of minor cognitive changes and unsteadiness of gait. An MRI scan revealed left fronto-parietal deep white matter T2 signal abnormality and mild restricted diffusion without mass effect. Numerous serologic and CSF investigations suggested inflammatory etiology but were otherwise unrevealing. The patient continued to have progressive cognitive decline and worsening disequilibrium. A white matter biopsy showed non-neoplastic mononuclear perivascular infiltrates with fairly frequent eosinophils and plasma cells, and diffuse gliosis with non-monoclonal/neoplastic plasma cells diffusely in the white matter. There were some clusters of macrophages surrounding astrocytes, but without demyelination. A concomitant CSF sample tested positive for anti-GFAP antibodies. Patient was given high dose steroids and significantly improved. In 2018 we saw a patient with similar clinical history, MRI scan, and brain biopsy findings. CSF was tested for anti-GFAP antibodies at the time and was negative. This patient passed away and a final diagnosis was never reached.

Conclusions:: White matter parenchymal gliosis with non-neoplastic parenchymal plasma cell infiltrates in the right clinical setting and imaging results may be a strong pointer towards autoimmune GFAP astrocystopathy. However, based on our second patient it may well be that this neuropathological vignette is not entirely specific.
KAPPA INDEX IN PATIENTS WITH AUTOIMMUNE ENCEPHALITIS

Diana Ferraro1, Giulia De Napoli1, Roberta Bedin1, Patrizia Natali2, Matteo Gastaldi3, Diego Franciotta4, Francesca Vitetta5, Valentina Camera1, Giada Giovannini6, Stefano Meletti1, Patrizia Sola5

Background and Aims:: The diagnosis of autoimmune encephalitis (AE) can be complex and is supported by the presence of inflammatory changes in the cerebrospinal fluid (CSF), including intrathecal immunoglobulin synthesis (IS). Aim was to calculate the kappa index (CSF/serum kappa free light chain-KFLC-divided by CSF/serum albumin ratio), as a marker of IS, in patients with a diagnosis of AE or possible AE according to the Graus criteria.

Methods:: CSF/serum KFLC were tested using Freelite kits (The Binding Site Group, UK) on samples stored after the diagnostic spinal tap of patients with AE/possible AE between 2009 and 2019.

Results:: We included 31 patients:22 with AE (7 anti-LGI1, 6 anti-NMDAR, 2 anti-CASPR2, 2 anti-GAD, 2 anti-Ma2, 1 anti-VGKC, 1 anti-GABAbR-positive and one antibody-negative) and nine with possible AE. Eight AE (36%) and one possible AE patient (11%) had CSF-restricted oligoclonal bands (OCB) and three patients each in the AE (14%) and possible AE group (33%) had pleocytosis (>5 cells mm3). Kappa index had a mean value of 9.1(±13.3) in AE and 0.6(±1.2) in possible AE patients. Among AE patients, it was highest in anti-NMDAR (12.6±19.5) and lowest in anti-LGI1 encephalitis (0.87±1.6). Kappa index was ≥3 in 13 (59%) AE and in one (11%) possible AE patient. In two AE patients (9%) an elevated kappa index was the only abnormal CSF inflammatory marker.

Conclusions:: If confirmed in other large series, kappa index might integrate OCB and pleocytosis as a supportive biomarker of neuroinflammation among the Graus criteria.
FULMINANT GUILLAIN-BARRÉ SYNDROME POST-HEMORRHAGIC STROKE: TWO CASE REPORTS.

Sameeh Abdulmana, Naif Al-Zahrani, Shahid Bashir, Adnan Alsarawi, Yahya Sharahely, Talal Al-Harbi
King Fahad Specialist Hospital-Dammam, Neurology, Ad Dammam, Saudi Arabia

Background and Aims:: Guillain-Barré syndrome (GBS) is an acute, immune-mediated inflammatory peripheral polyneuropathy characterized by ascending paralysis. Most of the GBS cases follow gastrointestinal or chest infections. Some patients have been reported either following or concomitant with head trauma, neurosurgical procedures, and rarely Hemorrhagic stroke. The exact pathogenesis is not entirely understood. However, blood-brain barrier damage may play an essential role in triggering the autoimmune activation that leads to post-stroke GBS. Here, we present two cases of fulminant GBS following hemorrhagic stroke to remind the clinicians to be aware of this rare treatable complication if a stroke patient developed unexplainable flaccid paralysis with or without respiratory distress.

Methods:: Case report and literature review.

Results:: Here we report two cases who were diagnosed with GBS following hemorrhagic stroke. The first patient developed GBS after endovascular mechanical thrombectomy for acute ischemic stroke complicated by a hemorrhagic transformation. While the second patient developed GBS after hematoma evacuation.

Conclusions:: These case studies highlighted the importance of considering GBS in the differential diagnosis of patients with flaccid quadripareisis and respiratory failure after a hemorrhagic stroke. It may explain those patients’ clinical progression when early therapy could make a difference in their prognosis and outcome.
Background and Aims:: Primary CNS vasculitis is a rare and poorly understood inflammatory disorder of blood vessels of brain and spinal cord presenting mainly as headaches and recurrent focal neurological deficits. Involvement of cauda equina is rarely reported which makes it even more challenging to diagnose this disease.

Methods:: We present a 15-year-male who presented with history of headache since 8 months and recurrent seizures since 6 months with right hemiparesis since 5 days with clinical examination further showing absent ankle jerks bilaterally. MRI brain had shown miliary perivascular enhancement of brain with multiple hemorrhages and enhancement of cauda equina nerve roots. Patient was further worked up for other secondary causes.

Results:: CSF showed lymphocytic pleocytosis with increased protein with negative workup for secondary causes of vasculitis. Leptomeningeal and cortical biopsy had confirmed diagnosis of primary CNS vasculitis. Patient was further started on immunomulation with partial recovery of symptoms and resolution of imaging findings.

Conclusions:: This report emphasizes the awareness of this varied clinical spectrum of cauda equina involvement in Primary CNS vasculitis and highlights importance of recognition of miliary enhancement on MRI images of brain to suspect and further facilitate diagnostic work-up.
B CELL RELATED PREDICTIVE BIOMARKERS OF TREATMENT RESPONSE IN MYASTHENIA GRAVIS

Valentina Damato¹, Gregorio Spagni¹, Gabriele Monte¹, Alessandra Battaglia², Andrea Fattorossi², Amelia Evoli¹
¹Università Cattolica del Sacro cuore, Neuroscience, ROMA, Italy, ²Fondazione Policlinico Universitario A. Gemelli IRCCS, Woman And Child Health And Public Health, ROMA, Italy

Background and Aims:: Myasthenia Gravis (MG) is a B cell-mediated autoimmune disease characterized by muscle weakness and fatigability, mostly associated to antibodies against the acetylcholine receptor (AChR). MG patients are chronically treated by immunosuppressants and 10-15% are treatment refractory. The purpose of our study is to identify changes in B-cell subsets that could predict treatment response in MG subgroups with different treatment-related status, with the aim of improving MG management, leading to personalized therapy.

Methods:: Peripheral blood mononuclear cells (PBMCs) were isolated from 79 AChR-MG patients for the characterisation of transitional (CD19+CD20+CD24+CD38+), naïve (CD19+CD20+IgD+CD27-), double negative (CD19+CD20+IgD-CD27-), unswitched memory (CD19+CD20+IgD+IgM+CD27+), switched memory (CD19+CD20+IgD-CD27+IgG+), plasmablasts (CD19+CD27+CD38+) by multicolour flow cytometry.

Results:: Thirty/66(46%) patients were women and mean age at onset was 48 years. At sampling, 15/79(19%) patients were immunotherapy- naïve, 38/79(48%) were immunotherapy-responders, 13/79(16%) were refractory to standard immunotherapy and 25/79(36%) were in clinical stable remission (CSR). The frequency of total B-cells did not differ among the clinical subgroups. Naïve B-cells were lower (Fig.1A) in immunotherapy-responders compared to immunotherapy- naïve(p=0.005), refractory and patients in CSR(p=0.009). Transitional B-cells were increased in refractory MG (Fig.1B) compared to immunotherapy- naïve(p=0.01) and responders(p=0.029). Surprisingly, plasmablasts were lower in refractory patients than immunotherapy- naïve patients (Fig.1C)
Conclusions: The persistence of transitional B-cells, rather than antigen experienced B-cells, might predict unresponsiveness to immunotherapy in a subgroup of patients. In these cases, B cell-directed therapies could restore the balance between regulatory and inflammatory B-cells in the pre-germinal compartment.
AUTOIMMUNE ENCEPHALITIS: ANTIBODIES TO NEUROTRANSMITTERS, ION CHANNELS, TUMOR ANTIGENS. WHAT NEXT?

Dmitriy Labunskiy, Svetlana Kiryukhina, Vyacheslav Podsevatkin
Ogarev Mordovia State University, Neurology And Psychiatry, Saransk, Russian Federation

**Background and Aims:** Autoimmune encephalitis (AE) is relatively rare and recently described group of diseases involving autoantibodies (AB) directed against synaptic and neuronal cell surface antigens. AE includes wide range of neurological symptoms. Sensitive and specific diagnostic tests, such as cellular analysis, are of paramount importance for detecting neuronal cell surface AB, in cerebrospinal fluid or serum of patients. Prognosis depends on how quickly the disease is detected, identified, and properly treated.

**Methods:** Under our observation were 54 patients with different CNS autoimmune disorders. Used ELISA and Western blot for evaluation of paraneoplastic, ion (K and Na) channels AB. We studied mice brain slice immunofluorescence by anti-Hu, anti-Ma2, anti-NMDA, anti-voltage gated potassium channel-complex (VGKC-complex) and aquaporin 4. AB, neurological and somatic conditions of patients with autoimmune neurological pathology, brain MRI, EEG and EMG were performed.

**Results:** We found increased levels of Anti-Hu AB in patients with small-cell lung carcinoma. In experimental model in mice with inoculation by this tumor type mice demonstrated lethargic sleep in case of injection by Anti-Ma2 AB. Patients with this pathology demonstrated anxiety, memory loss, headache. Most symptoms were produced by anti-NMDAR AB. They include hyperactivity in open field, tremor, choreic hypekinesis, parasomnia. Immunohistochemistry demonstrated fluorescence of these AB in basal ganglia of affected mice. Animals with anti-aquaporin 4 AB showed early blindness. Neuromiotonia and seizures symptoms appeared in patients suffering from anti-VGKC-complex encephalitis caused by VGKC-complex AB, confirmed by EEG and EMG.

**Conclusions:** Combined autoimmune pathology study in patients and animals allows better understand of pathogenesis and identification of therapeutic strategies.
AN UNDERESTIMATED CAUSE OF BILATERAL VESTIBULOCHOCLEAR DISEASE.

Santosh Sriram Andugulapati, Rushikesh Joshi, Rahil Ansari, Sangeeta Ravat, Neeraj Jain, Mayur Thakkar, Piyush Anshu Seth G.S MEDICAL COLLEGE AND KEM HOSPITAL, Neurology, Mumbai, India

Background and Aims:: Autoimmune inner ear disease (AIED) is an uncommon but potentially treatable cause of progressive sensorineural hearing loss (SNHL). There is a lack of specific autoantibodies and obtaining tissue biopsy is impractical. We describe an uncommon etiology of progressive vestibulochoclear dysfunction.

Methods:: 61 years male presented with 3 months history of acute onset progressive bilateral SNHL with frequent episodic vertigo lasting 6-10 hours, with worsening on postural change. It was associated with vomiting, imbalance while walking. No history of fever, headache, earache/fullness, tinnitus. There were no features of diabetes mellitus or systemic autoimmune disease. Signs of vestibular dysfunction - bilateral horizontal & torsional nystagmus with abnormal dynamic visual acuity, Fukuda and head impulse tests. Otoscopy and ocular examination for keratitis or uveitis were normal.

Results:: Magnetic resonance imaging of brain and inner ear were normal. Computerized tomography of temporal bone with Poschls view was normal. Audiogram was suggestive of bilateral moderately-severe SNHL. Antinuclear antibody was positive (1:100). Systemic autoimmune diseases, Menieres disease, Sarcoidosis and Cogan’s syndrome were ruled out. Diagnosis of AIED was considered based on Garcia-Berrocal et al criteria. Patient was given methylprednisolone pulse therapy followed by oral prednisolone. His symptoms decreased significantly over 4 weeks and hearing threshold improved from 90 to 50. On one-year follow-up patient had no episodes of vertigo and his hearing threshold remained static.

Conclusions:: Due to lack of specific diagnostic tests, AIED should be considered in unexplained sub-acute progressive SNHL and vertigo with a low threshold for treatment with steroids. Response to treatment supports diagnosis and guides further immunotherapy.
Background and Aims:: Guillain-Barré syndrome (GBS) is a rare pathology causing acute flaccid paralysis with hypo- or areflexia. It is thought to mostly have a post-infective immunological-driven pathogenesis, as it is associated with bacterial and viral infections. Post surgical syndromes are described, although rare. Lumbar puncture is rarely complicated by iatrogenic infective myelitic or peripheral involvement, which could mimic GBS.

Methods:: A 55-year-old male in good health underwent spinal anesthesia for right achilles tendon rupture suture. Two weeks after recovery, he developed bilateral ascending radicular pain; at that time no deep tendon reflexes (DTR) abnormalities were noted. Upon inspection, hyperaemia, hyperthermia and swelling were evident at spinal anesthesia site. We performed an electrophysiological study, which turned unremarkable, and lumbar spine MRI, which showed an abscess posteriorly to L3-L4 spinous processes and cauda and leptomeningeal contrast enhancement. The patient remained apyretic during hospitalization and blood tests turned unremarkable. Laségue sign was positive bilaterally but no headache or meningismus were present. Moreover, performing a diagnostic lumbar puncture was deemed at high risk of CSF contamination. Patient’s DTR later disappeared, which prompted the beginning of IVIg therapy. An antibiotic course was also added for the subcutaneous lumbar abscess.

Results:: DTR reappeared and pain ameliorated after therapy; the patient was discharged with only mildly lowered tendon reflexes. On follow-up, MRI and EMG/ENG study turned unremarkable.

Conclusions:: Although not a typical complication, iatrogenic infective radiculitis could explain patient’s symptoms. In our case, anamnestic, clinical and instrumental features helped in excluding such diagnosis in favor of a GBS.
CEREBRAL AMYLOID ANGIOPATHY RELATED INFLAMMATION: STEROID RESPONSIVE OR SPONTANEOUSLY REMISSIVE BRAIN DYSFUNCTION?

Virginia Cancelloni¹, Alessandra Rufa¹, Carla Battisti¹, Ivano Chiarotti², Nicola De Stefano¹, Alfonso Cerase²

¹Azienda ospedaliero-universitaria senese, Unit Of Neurology And Neurometabolic Disorders, Department Of Medicine, Surgery And Neuroscience, Siena, Italy, ²Azienda ospedaliero-universitaria senese, Neuroimaging Unit, Diagnostic And Functional Neuroradiology, Clinical Department Of Neurological And Motor Sciences, Siena, Italy

Background and Aims:: Definite diagnosis of cerebral amyloid angiopathy related inflammation (CAA-ri) requires histopathological features of vascular inflammation and amyloid deposition. However clinico-radiological criteria for CAA-ri have been recently introduced¹ and validated². Clinical syndrome shows dramatic improvement after immunotherapy³. However, spontaneous remission has been described in some patients⁴.

Methods:: We report seven patients with clinico-neuroradiological characteristics of CAA-ri. Clinical features at presentation included seizures, confusion, cognitive impairment and focal neurological signs. Diagnostic studies included infectious diseases and autoimmune work-up and brain MRI, as well as cerebral angiography and CSF analysis in two and one patients, respectively. Three patients were initially diagnosed as PRES or vasogenic edema secondary to vascular malformation.

Results:: Brain MRI showed prominent T2-weighted/FLAIR white matter changes associated with SWI/gradient-echo typical findings of CAA. All patients were diagnosed with CAA-ri. Three patients showed steroid-responsive brain dysfunctions; the remaining patients had a clinical and/or neuroradiological spontaneous remission. Three patients had been lost at follow-up.

A PROOF OF CONCEPT REPORT OF ASL MRI AND 18F-FDG PET IN LIMBIC ENCEPHALITIS

Marta Cheli¹, Alessandro Dinoto¹, Miloš Ajčević¹, Franca Dore², Carmelo Crisafulli², Maja Ukmar³, Arianna Sartori⁴, Paolo Manganotti⁵
¹University of Trieste, Neurology Unit, Department Of Medical, Surgical And Health Sciences, Cattinara University Hospital, Asugi, University Of Trieste, Trieste, Italy, Trieste, Italy, ²Unit of Nuclear Medicine, University Hospital And Health Services Of Trieste, University Of Trieste, Trieste, Italy, ³Radiology Unit, Radiology Unit, Department Of Medicine, Surgery And Health Sciences, University Hospital And Health Services Of Trieste – Asugi, University Of Trieste, Trieste, Italy, ⁴University of Trieste, Neurology Unit, Department Of Medical, Surgical And Health Sciences, Cattinara University Hospital, Asugi, Trieste, Italy

Background and Aims:: Autoimmune limbic encephalitis (LE) is a condition characterized by seizures and cognitive dysfunction. Fluorine-18 Fluorodeoxyglucose (18F-FDG PET) has proved to be an important diagnostic and prognostic tool because it may detect brain metabolism in the earlier phases of the disease. Two main 18F-FDG PET patterns have been reported: a neurodegenerative one and a mixed hypermetabolic/hypometabolic. Arterial Spin Labelling (ASL) MRI reveals brain perfusion, that matches brain metabolism because they are strongly coupled. The aim of the present study was to evaluate patients with LE with both techniques.

Methods:: Two patients with LE underwent to 18F-FDG PET and ASL MRI scans. Areas of altered perfusion and metabolism were analyzed by visual inspection, and findings were compared between the two techniques.

Results:: One patient with LG1 encephalitis during a relapse performed 18F-FDG PET that showed an increased metabolism in the right hippocampus (mixed hypermetabolic/hypometabolic pattern). ASL MRI showed increased perfusion in the same area. One patient with seronegative LE underwent to 18F-FDG PET scan that highlighted left hemispheric hypoperfusion (neurodegenerative pattern). ASL MRI showed similar results.
Conclusions: ASL can detect the two main metabolic patterns described in 18F-FDG PET. This study provides a proof-of-concept that ASL technique could be implemented in the MRI protocols for LE, in order to provide a contrast- and radiation-free method to increase diagnostic performance and to evaluate disease activity even in the first MRI scan.
PARANEOPLASTIC NEUROMYELITIS OPTICA SPECTRUM DISORDER IN A PATIENT WITH BREAST CANCER AND ADIUVANT CHEMOTHERAPY

Maria Margherita Sechi, Antonella Muroni, Mariangela Vacca, Manuela Pintus, Silvia Barca, Giovanni Defazio
Azienda Ospedaliero Universitaria di Cagliari, Institute Of Neurology, Cagliari, Italy

Background and Aims: Neuromyelitis optica spectrum disorder (NMOSD), is an autoimmune inflammatory disorder of the central nervous system mostly associated with antibodies to AQP-4. It is generally idiopathic, but it is frequently associated with systemic autoimmune disorders and in some cases with neoplasm. We propose a case of NMOSD associated with breast cancer and potentially with its treatment.

Methods: A 50 years-old woman with a history of breast cancer and a recent cycle of adjuvant chemotherapy (Paclitaxel and Trastuzumab) was admitted to the Cardiology Department for pulmonary embolism and deep vein thrombosis. Subsequently she developed neurological features typical of a longitudinally extensive transverse myelitis. MRI was suggestive of NMOSD and antibodies against AQP-4 were detected in serum. Treatment with plasmapheresis was started, with a good outcome of the patient.

Results: Paraneoplastic NMOSD syndrome is a rare disease, sometimes associated with cancer. This condition is more typical in female patient aged over 50 years-old at symptoms onset and with breast cancer, and only few cases have already been described. We speculate that in our patient the disorder may have been not only caused by the cancer alone, but possibly by the chemotherapy too, considering the close timing relation with the treatment (few months). However, there are no cases in literature describing the link between NMOSD and Trastuzumab.

Conclusions: This case underlines that NMOSD may be an important complication of breast cancer and its therapies and prompt diagnosis may be imperative to achieve a better prognosis.
Background and Aims:: Background and aims: Autoimmune encephalitis are an upcoming group of immune mediated encephalitis, characterised by subacute onset neurological syndrome with supporting radiological and investigational evidence. The increasing awareness among clinicians, has led to spurt in the number of cases diagnosed. We present a series of autoimmune encephalitis with unusually long clinical history and syndromes.

Methods:: It was a prospective observational study from 2016-2019, it included all patients of antibody proven autoimmune encephalitis who had a prolonged clinical course and atypical clinical features. All of the patients had been misdiagnosed as psychiatric, neurodegenerative or cryptic disorders. The diagnosis was achieved with a combination of presence of serum antibodies, MRI, FDG PET and CSF findings.

Results:: A total of 4 cases of chronic form of autoimmune encephalitis were identified. The duration of symptoms varied between 1 year to 25 years. The corresponding MRIs didn't reveal significant changes of AIE, however FDG-PET of brain showed findings of hyper/hypometabolism and pointed towards the diagnosis of AIE.

Conclusions:: Chronic variants of AIE are difficult to diagnose. FDG PET of brain may help in identifying these cases earlier.
DELAYED SEROPOSITIVITY IN A PATIENT WITH ANTI-LGI1 LIMBIC ENCEPHALITIS

Gianluca Ignazio Cadeddu, Gianluca Floris, Marcello Mario Mascia, Marta Melis, Paola Cimino, Maria Margherita Sechi, Giovanni Defazio
University of Cagliari and AOU Cagliari, Department Of Medical Sciences And Public Health, Institute Of Neurology, Monserrato (CA), Italy

Background and Aims:: Anti Leucine-Rich Glioma Inactivated 1 encephalitis (LGI1) is a rare autoimmune disorder caused by antibodies to synaptic voltage-gated potassium channels. Its typical manifestation includes seizures (mostly tonic-dystonic), hyponatremia, memory disturbances and behavioural changes. Patients may have temporal lobe abnormalities on EEG and brain MRI, instead CSF is often normal. In less than 10% of cases it is associated with cancer (commonly thymoma).

Methods:: A 54 years-old woman without any relevant medical history was admitted to our Neurology Department after subacute onset of moderate deficit on long term verbal memory, spatial disorientation and focal temporal seizures. Brain MRI and EEG showed respectively left hippocampal T2-weighted hyperintensity and left temporal epileptic discharges, both suggestive for limbic encephalitis. Extended laboratory and radiological examinations, including onconeural markers, antibodies against neuronal surface proteins and total body CT scan, were all negative.

Results:: Treatment consisted of glucocorticoids, IVIG and anti-epileptic drugs that brought to moderate improvement of cognitive status and EEG normalization. 20 months later the patient was reassessed and at that point the presence of antibodies anti-LGI1 on both blood and CSF samples was detected. Not any underlying neoplasm has been yet found.

Conclusions:: Although the most known features of anti-LGI1 encephalitis are dystonic seizures, our report suggests that its phenotype could be heterogeneous, including temporal seizures. Our experience suggests that the timing of seroconversion may be delayed, recommending subsequent reassessment of immunological status as well as tight radiological follow-up for possible hidden cancers.
RECURRENT ACUTE MOTOR AXONAL NEUROPATHY WITH COMPLETE RESOLUTION: A CASE REPORT

Pramith Ruwanpathirana, Vithoosan Sahathevan, Asha Kumarasiri, Bimsara Senanayake
National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

**Background and Aims:** Inflammatory polyneuropathies, caused by direct autoimmunne attack on peripheral nerves can be classified as either acute (less than 4 weeks) and chronic (more than 4 weeks) or demyelinating and axonal. The commonest acute variety is demyelinating (AIDP) while the axonal varieties ‘acute motor axonal neuropathy’ (AMAN) or ‘acute motor and sensory axonal neuropathy’ (AMSAN) are responsible only for less than 5%. Acute inflammatory polyneuropathies are usually monophasic illnesses; although inflammatory demyelinating polyneuropathy (AIDP) or Miller-Fisher syndrome can recur. Recurrent AMAN are exceedingly rare. We report a case with two episodes on AMAN with complete resolution, occurring eight years apart.

**Methods:** A 36-year-old male presented with progressive weakness over 3 days involving all 4 limbs without involvement of sensory, autonomic nor cranial nerves. The respiratory muscles were involved requiring intubation and ventilation. He did not have any evidence of rheumatological, endocrine or autoimmune diseases. On examination he had a flaccid quadriparesis (power-0/5 MMRC) with global areflexia. The CSF protein was elevated without a cellular reaction and the nerve conduction studies were suggestive of AMAN. Except the newly diagnosed diabetes the rest of the haematological and biochemical investigations were normal.

**Results:** Eight years ago, he had developed a similar episode with nerve conduction evidence of AMAN which had completely resolved with IVIG (intravenous-immunoglobulins) and intense physiotherapy. He made an uneventful recovery in the current admission with the same treatment, but was not kept on long-term immunosuppressants.

**Conclusions:** Although exceptionally rare, the AMAN type of GBS can recur with prospects to recovery with immunotherapy and rehabilitation.
CENTRAL NEUROGENIC HYPERVENTILATION SECONDARY TO SERONEGATIVE AUTOIMMUNE ENCEPHALITIS

Rajarajan Rajendran\textsuperscript{1}, Ramanathan Suppiah\textsuperscript{2}, Senthilvelmurugan Veeraputhiran\textsuperscript{3}, Saranya Manickavasagam\textsuperscript{3}, Jos Jasper\textsuperscript{4}
\textsuperscript{1}Kauvery Hospital, Neurology, Tiruchirappalli, India, \textsuperscript{2}Kauvery Hospital, Critical Care, Tiruchirappalli, India, \textsuperscript{3}Kauvery Hospital, Radiology, Tiruchirappalli, India, \textsuperscript{4}Kauvery Hospital, Kauvery Brain & Spine Centre, Tiruchirappalli, India

\textbf{Background and Aims::} Central Neurogenic Hyperventilation (CNH) is a rare condition characterised by deep, rapid breathing. Diagnostic criteria for CNH include hyperventilation that persists during sleep, respiratory alkalosis with normal PaO$_2$ in the absence of drug or metabolic causes. Autoimmune encephalitis has varied clinical presentation. It poses a greater diagnostic challenge when there are no detectable antibodies in serum or CSF; these patients are classified as having seronegative autoimmune encephalitis.

\textbf{Methods::} Case Report

\textbf{Results::} A 74-year-old gentleman with a history of hypertension presented with subacute onset of gait unsteadiness which was gradually progressive for 2 months associated with recent-onset breathing discomfort. He also developed dysphagia to liquids>solids and odynophagia. Examination revealed cachexia, tachypnea (30-35/min), left upper and lower limb ataxia with gait unsteadiness, and a mild confusional state. CT Chest, Echo heart, and ECG were normal. MRI brain revealed a focal lesion in the left cerebellum, pons, and midbrain with patchy areas of diffusion restriction and contrast enhancement. Arterial blood gases were pH, 7.60; PaCO$_2$, 15mmHg; and PaO$_2$, 110mmHg. CSF analysis was normal and autoimmune autoantibodies were negative. On D9 of admission, he developed myoclonic jerks associated with worsening tachypnea. Electroencephalogram revealed generalized slowing and amplitude reduction. After ruling out infective and vasculitic etiology, seronegative autoimmune encephalitis was considered and pulse methylprednisolone was given for 5 days. There was a significant improvement in general sensorium and hyperventilation following steroid administration.

\textbf{Conclusions::} This article emphasizes the importance of diagnosing seronegative autoimmune encephalitis, which has a clinical profile and clinical outcome similar to seropositive AE but no diagnostic biomarker.
CHRONIC STEROID-DEPENDENT MYELITIS AND OPTIC NEURITIS: A CASE REPORT

Mario Risi, Federica Matrone, Antonio Gallo, Alessandro D'Ambrosio, Mario Cirillo, Vincenzo Todisco, Gioacchino Tedeschi, Alvino Bisecco
University of Campania Luigi Vanvitelli, Department Of Advanced Medical And Surgical Sciences, Napoli, Italy

Background and Aims: A 34 year-old woman presented a subacute onset of right hemiparesis and right blurred vision. The head and spinal cord MRI revealed a longitudinally extensive transverse C5-D1 myelitis (LETM) and a posterior superior right optic nerve lesion, with peripheral irregular enhancement. No recent infections/systemic symptoms or other diseases were reported. General examination was normal. Neurological exam was characterized by moderate-to-severe ataxo-spastic gait, right weakness, left sensory loss and impaired vision in lower right eye field. Possible differential diagnosis were Neuromyelitis Optica and anti-MOG associated disorders, systemic autoimmune diseases, neurosarcoidosis and atypical paraneoplastic syndromes.

Methods: Diagnostic protocol: blood tests and CSF analysis, including microbiological and autoimmune exams, chest imaging and whole body 18-FDG-PET/CT.

Results: Blood, microbiological and autoimmune exams were normal. Serum was negative for anti-AQP4/MOG and paraneoplastic antibodies, as well as CSF, whose analysis revealed elevated proteins, normal IgG-index, oligoclonal bands type 4 and no cells. Chest imaging and whole body 18-FDG-PET/CT had no abnormalities, while Visual Evoked-Potentials showed right pre-chiasmatic disfunction.

Conclusions: Patient was treated with three cycle of high-dose intravenous corticosteroids but therapy discontinuation rapidly resulted in clinical and MRI disease reactivation, with extension of cervical lesions and persistent gadolinium-enhancement lasting more than three months. Intravenous immunoglobulin was not efficacious. Based-on clinical history and neuroimaging, both NMO and neurosarcoidosis were possible diagnosis, but the radiological characteristics and chronic steroid-dependence, led to possible neurosarcoidosis diagnosis. Full recovery was obtained after two months of continuous steroid treatment. Therefore, patient was shifted to methotrexate, with slow steroid tapering. Since then, no more clinical or radiological disease-activity occurred.
SARCOIDOSIS: CLINICAL AND PARACLINICAL FEATURES: A STUDY OF A TUNISIAN COHORT

Bissene Douma¹, Hajer Derbali², Linda Mrissa³, Mariem Elfekih⁴, Najiba Fekih-Mrissa⁵, Ridha Mrissa², Malek Mansour¹
¹Military Hospital of Instruction of Tunis, Department Of Neurology, sousse, Tunisia, ²Military Hospital of Tunis, Neurology, Monfleury, Tunisia, ³salah azaiz institute, tunis, Department Of Radiotherapy, tunis, Tunisia, ⁴CHU, Neurology, nabeul, Tunisia, ⁵military hospital of instruction of tunis, Department Of Hematology, tunis, Tunisia

Background and Aims:: Sarcoidosis is characterized by its heterogeneous clinical presentation. The aim of this study is to describe clinical and paraclinical characteristics in a cohort of Tunisian patients with sarcoidosis.

Methods:: A retrospective study was conducted at the department of neurology and internal medicine of the Military Hospital of Tunis from 1997 to 2019. We included patients who were diagnosed with sarcoidosis. Clinical and paraclinical features were analyzed.

Results:: We included 65 patients with sarcoidosis. Mean age at presentation was 46.68 years. Neurological symptoms were the first clinical manifestation of sarcoidosis in 14% of cases. The most common manifestations included central nervous involvement and cranial neuropathies. Pulmonary sarcoidosis is observed in 47 patients and ophthalmological involvement is present in 26 patients. Magnetic resonance imaging (MRI) showed a variety of manifestations including diffuse intraparenchymal inflammatory lesions in the brain and spinal cord, leptomeningeal enhancement and optic nerve involvement. Pleiocytosis and elevated CSF protein were found in 14 patient. The genetic study concerned only 50 patients. A high frequency was found for the HLA DRB1 * 1501 , HLA-DRB1 * 0301 and the D allele for the angiotensin-converting enzyme gene. First line therapy with corticosteroids was initiated in 56 cases. Second line therapy consisting of azathioprine and hydroxychloroquine was initiated in 12 cases. Outcome consisted of complete remission in 17 patients.

Conclusions:: Diagnosis of sarcoidosis is difficult due to its clinical polymorphism. Recent advances in the pathophysiology and genetics could have therapeutic implications for early management of these patients.
Background and Aims:: N-methyl-D-aspartate receptor (NMDAR) encephalitis is a potentially treatable condition, although a small proportion of patients remains refractory to immunotherapy. Recently, bortezomib, a proteasome inhibitor used in multiple myeloma, has been used in NMDAR encephalitis and neuromyelitis optica. We performed a systematic review regarding the use of bortezomib in NMDAR encephalitis

Methods:: We performed an independent PubMed search employing “Anti-N-Methyl-d-Aspartate encephalitis AND bortezomib”, including papers published between January 1st, 2007 to June 30th, 2020. Clinical and demographic data were collected. We compared paraneoplastic and non-paraneoplastic encephalitis and patients with favorable (modified Rankin Scale (mRS) ≤2) and unfavorable outcome. Fisher and U-Mann Withney tests were used as appropriate (p-value<0.05).

Results:: Twelve articles were included, with 21 patients. The quality of studies was overall poor. Median age at onset was 26 (8-61) and 7 patients (33.3%) had paraneoplastic encephalitis. Median number of previous treatments was 4 (3-7). 10 patients (47.6%) had a favorable outcome after bortezomib and 9 (42.9%) patients developed side effects. Patients with paraneoplastic encephalitis underwent more frequently to oophorectomy (p=0.010). Patients with favorable outcome were younger (p=0.043) and had lower cerebrospinal fluid NMDAR antibody titer at onset (p=0.006), underwent more frequently to anti-epileptic drug reduction (p=0.035) and had fewer side effects (p=0.044).

Conclusions:: Nearly half of patients with NMDAR encephalitis treated with bortezomib improved, however about half of treated patients developed side effects. The overall quality of published evidence is low and further studies should be performed with systematically defined endpoints and in larger and homogeneous cohorts.
NEUROMYELITIS OPTICA SPECTRUM DISORDERS (NMOSD), SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AND MG RESULTS IN TRANSVERSE MYELITIS

Ivan Ternovykh¹, Maria Topuzova¹, Gennadiy Bisaga¹, Maria Pospelova², Alexandra Chaykovskaya¹, Patimat Isabekova², Anna Mikheeva¹, Dmitrii Fedorov³, Tatiana Pavlova³, Tatiana Alekseeva³
¹Almazov National Medical Research Centre, Neurology And Psychiatry, Saint-Petersburg, Russian Federation, ²Almazov National Medical Research Centre, Neurology, Saint Petersburg, Russian Federation, ³Almazov National Medical Research Centre, Neurology №1, Saint Petersburg, Russian Federation

Background and Aims:: Considering the rarity of such a combination of nosologies, we present this clinical case.

Methods:: A 51-year-old female patient was admitted to the neurology department with complaints of a weakness in the lower limbs; periodic leg pain; feeling of constriction in the ribs area “like a belt”; urinary incontinence. These symptoms bothered her for 1 year, with alternating exacerbations and improvements. A history of MG since 1997. During the study medical history, somatic and neurological status, laboratory, neuroimaging data were evaluated.

Results:: In neurological status: lower spastic paraparesis, superficial sensitivity was impaired in a mosaic pattern, paresthesias in both legs. Pelvic functions - incomplete emptying/incontinence. No ophthalmologic pathology. Laboratory: CRP - 1.02 mg/l (<6.00), RF <20.00 IU/ml (<30.00); antiDNA: 67.30> U/ml (<25), ANZA 1:10 (<1:10), atypical type of fluorescence; positive analysis for ANF, homogeneous (1: 1000) and granular types of fluorescence (1: 320). ANA screening, immunoblot were negative; complement C4 - 0.14 g/l (0.15-0.57). AQP4-IgG titer 1: 320 (<1:10). Thoracic spine MRI with contrast: Th2-Th5 – increased MR-signal in T2 mode; no contrast accumulation. Based on 4 SLICC criteria (ANF, antiDNA, reduced complement fraction, CNS damage) SLE was diagnosed. Considering the anamnesis, clinical, laboratory, MRI data, autoimmune myelitis was diagnosed, stage of exacerbation. Courses of infusion pulse therapy with methylprednisolone, high-volume plasma exchange №5, therapy with cyclophosphamide and rituximab (1000 mg/2 week №2) were completed, with good clinical improvement. Patient monitoring will be continued.

Conclusions:: NMOSD in combination with SLE and MG is a rare situation and causes significant diagnostic difficulties.
ANTI-SMOOTH MUSCLE ANTIBODIES (ASMA) AND VERBAL DYSCALCULIA. A NEW TYPE OF AUTOIMMUNE ENCEPHALITIS.

Wolfgang Trillo Alvarez¹, Claudio Ibañez Escalante², Joaquin Molina Acosta², Juan Valdivia Pino², Adriana Escalante Mercado², Edgar Carrillo Monteagudo², Miguel Manchego Bautista², Joshua Medina Suárez²
¹UNIVERSIDAD CATOLICA DE SANTA MARIA, Human Anatomy, Arequipa, Peru, ²SINAPSIS-UCSM, Neurosciences, Arequipa, Peru

Background and Aims:: F-Actin is ASMA’s molecular target; it forms microfilaments and actin patches. ASMA could lead to dendritic spines retraction causing cortex reduction and cognitive impairment as described in chronic ASMA patients. We have identified a new type of AE due to ASMA, neither reported or classified up to date. The aim is to describe a new type of Autoimmune Encephalitis (AE) due to ASMA, whose core clinical presentation is verbal dyscalculia.

Methods:: We present a series of seven patients diagnosed with encephalitis due to positive ASMA presenting with somnolence, changes in personality and mentation with amnesia, bradypsychia, inattention, dysthymia, asthenia, adynia, and dysesthesia. Physical examination showed verbal dyscalculia as the most common and earliest clinical sign, followed by decreased cognition, Romberg’s, Hoffman’s, Babinski’s, frontal releases signs, altered DTRs, hyperekplexia, dystonia, tremor, aphasia and involuntary movements on extremities. Blood work showed positive ASMA and elevated CRP. Two patients showed mildly elevated LFT. Only one had F-actin measured with positive results. None of the patients showed signs of cirrhosis. Patients had abnormal EEGs with generalized slow waves and MRI had discrete insular and parieto-occipital cortical hyperintensities.

Results:: Patients showed improvement after being treated with Methylprednisolone and Rituximab.

Conclusions:: We propose a new type of AE due to ASMA, with verbal dyscalculia as the most common and earliest clinical sign which is accompanied by personality, neurophysiological and serological changes without hepatic disease manifestations (commonly referred by us as Trillo’s encephalitis). We believe that cortex reduction and cognitive impairment could be explained by ASMA relationship with F-actin.
ANTI-GAD AUTOIMMUNE ENCEPHALITIS RESEMBLING LONG TERM CHRONIC DISOCIATIVE AMNESIA CASE REPORT

Wolfgang Trillo Alvarez, Joshua Medina Suárez, Claudio Ibañez Escalante, Joaquin Molina Acosta, Juan Valdivia Pino, Adriana Escalante Mercado

1UNIVERSIDAD CATOLICA DE SANTA MARIA, Human Anatomy, Arequipa, Peru, 2SINAPSIS-UCSM, Neurosciences, Arequipa, Peru

Background and Aims: GABA plays a major role in the formation of memory in insula, prefrontal cortex, and hippocampus. Neuroinflammation induced by GABA dysregulation and GABAr signaling changes leads to an overall GABA deficit. These cell-mediated inflammatory changes have been associated with motor symptoms, short term anterograde amnesia and neuropsychiatric features such as hallucinations. The aim is to report a case of Anti-GAD AE with organic memory loss resembling long term chronic dissociative amnesic disorder lasting over 15 years.

Methods: A 58 years old Hispanic male with a history of 20 years of disease triggered by a stressful event, followed by 15 years of global amnesia with fugue like symptoms that suddenly ended after a religious delusion. He complained of bilateral periorbital pain, loss of consciousness with drop attacks and involuntary movements while sleeping, nightmares, mood disturbances towards depression, anxiety, religious hallucinations, and fatigue. At examination he was hypertensive, with tangential speech, personality changes, neck stiffness, limb rigidity with positive trigger points and right hemiparesis, Bilateral Hoffman’s, hyperreflexia, involuntary movements, tremor, Romberg’s, and impaired memory with positive frontal release signs. Blood work showed abnormal Anti-GAD, elevated CRP, ESR, creatinine and elevated proteins in CSF 86. MRI found multiple bilateral lacunar infarcts. EEG showed right temporocipital disorganization and generalized slow waves.

Results: The patient was treated with IV methylprednisolone, oral prednisone, paroxetine, baclofen, clonazepam and levetiracetam with clinical improvement.

Conclusions: To our knowledge this is the longest time of organic memory loss symptoms resembling long term chronic dissociative amnesia reported due to Anti-GAD AE.
EPISODIC ATAXIA AS A PRESENTING SYMPTOM OF ANTI-NMDAR ENCEPHALITIS

Jessica Rossi1,2, Laura Giacobazzi1,2, Giada Giovannini1,2,3, Vittorio Rispoli1,2, Annalisa Chiari1,2, Francesca Vitetta1,2, Alessandra Ariatti1,2, Nicola Fini1,2, Stefano Meletti1,2
1University of Modena and Reggio Emilia, Department Of Biomedical Metabolic And Neurosciences, Modena, Italy, 2Ospedale Civile di Baggiovara, Azienda Ospedaliero Universitaria di Modena, Neurology Unit, Modena, Italy, 3University of Modena and Reggio Emilia, Modena, Italy, Phd Program In Clinical And Experimental Medicine, Modena, Italy

Background and Aims:: Anti-NMDA receptor (anti-NMDAR) encephalitis presents commonly with cognitive and psychiatric symptoms, but also movement disorders are reported. Cerebellar ataxia has been described in young children, but it is uncommon in adults. Among paroxysmal movement disorders, dyskinesias are reported. Episodic ataxia is extremely rare and never reported as a presenting symptom.

Methods:: A 61 years-old woman came to our attention for sudden onset of ataxia and confusion while she was at a dinner (she had begun compulsively eating and drinking alcohol). Brain CT, CT angiography, and CT perfusion were negative. The alcohol test was positive and blood examination revealed mild hyponatremia. A diagnosis of pancerebellar syndrome due to alcohol intoxication was made. After hydration, the patient presented a complete regression of symptoms. After one year she returned for an episode of acute confision that occurred on her way to work. The alcohol test was negative, and EEG was unrevealing. The neurologic examination showed confusion, marked bilateral ataxia, and dysarthria, with subsequent complete regression after 12 hours. In the previous 10 months weight loss, depressive symptoms, and working memory deficits were reported, and her husband referred she has become more irritable and talkative than usual.

Results:: MRI scan showed mild cerebellar atrophy. Laboratory tests revealed hyponatremia (Na: 130 mmol/L). CFS examination was within the limits, while blood autoimmune panel revealed a positivity for Ab anti NMDAR, supporting the diagnosis of anti-NMDAR encephalitis.

Conclusions:: Despite the rarity of this phenomenon, episodic ataxia can be a presenting symptom of anti-NMDAR encephalitis.
FETAL OUTCOME IN ANTI-NMDAR ENCEPHALITIS DURING PREGNANCY: A SYSTEMATIC REVIEW.

Giovanna Scorrano1, Fedele Dono2, Giacomo Evangelista2, Stefano Consoli2, Rino Speranza2, Francesca Anzellotti2, Marco Onofri2, Francesco Chiarelli1, Laura Bonanni2
1“G. D’Annunzio” University of Chieti-Pescara, Department Of Pediatrics, Chieti, Italy, 2“G. D’Annunzio” University of Chieti-Pescara, Department Of Neuroscience, Imaging And Clinical Science, Chieti, Italy, 3“SS Annunziata” Hospital, Epilepsy Center, Neurology Clinic, Chieti, Italy

Background and Aims:: Anti-NMDA receptor encephalitis is an autoimmune inflammatory disease which mainly affects young women, causing psychiatric and neurological manifestations. Pathogenic antibodies target extracellular domain GluN1 subunit receptor. An increasing number of reports show that anti-NMDAR encephalitis can occur also during pregnancy leading to maternal and fetal distress. In this systematic review we analyzed fetal outcome after maternal anti-NMDAR antibodies exposure during pregnancy, summarizing the available data.

Methods:: We performed a systematic review according to Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). Epidemiological, clinical, laboratory and neuroimaging data of pregnant women with anti-NMDAR encephalitis and their newborns were collected. Outcomes of the infants were based on clinical features, developmental abnormality, atypical behavior, APGAR score and neuroimaging.

Results:: A total of 20 articles (37 cases) were included. The incidence of anti-NMDAR encephalitis was higher during the first trimester of pregnancy. Ovarian teratoma was found in 2/37 cases. Immunotherapy was used in 20% of cases. Pregnancy outcome was positive in 80% of cases with less than 10% of newborns suffering from transient neurological or respiratory symptoms. Prematurity was found in 40% of cases. At the follow-up, children’s neurocognitive development impairment was found in less than 20% of patients. Data actually showed transplacental antibodies transition. Infants with neuropsychiatric symptoms often had anti-NMDAR antibodies serum positivity.

Conclusions:: Anti-NMDAR encephalitis can be a severe comorbidity during pregnancy. Pregnancy and fetal outcome is usually positive, though children neurocognitive development impairment can occur. Long-term effects of fetus anti-NMDAR antibodies exposure have to be better explored.
OUR CLINICAL EXPERIENCE IN THE TREATMENT OF MYASTHENIA GRAVIS ACUTE EXACERBATIONS WITH A NOVEL NANOMEMBRANE-BASED THERAPEUTIC PLASMA EXCHANGE TECHNOLOGY

Dimitar Tonev¹, Radostina Georgieva¹, Evgeniy Vavrek²
¹Medical University, Sofia, Anaesthesiology And Intensive Care, Sofia, Bulgaria, ²Medical University, Sofia, Neurological Intensive Care Unit, Sofia, Bulgaria

Background and Aims:: The intravenous immunoglobulins (IVIG) and therapeutic plasma exchange (TPE) are equally effective rapid-acting immunotherapies in myasthenia gravis (MG) acute exacerbations. However, according to the American Academy of Neurology 2011 plasmapheresis guideline there is insufficient evidence to support or refute the use of plasmapheresis for MG, which clinical relevance is the aim of our study.

Methods:: 36 adult patients, MGFA 4/4B and 5, with 45 acute MG episodes were entered into a before-after study to compare the standard treatment (before group, n=24) with advanced one using a novel nanomembrane-based TPE (after group, n=12). All patients were treated by a team of neurologists and anestesiologists/intensivists in an academic NeuroICU according to the local guidelines. TPE or IVIG infusions were used in impending and manifest myasthenic crisis (MC), or selectively in patients at high risk for prolonged intubation. The clinical improvement was checked on forms filled in routinely upon admission and on transfer from the ICU using Myasthenia Muscle Score (0-100), with at least 20 points increase for responders. Data regarding immunoglobulin levels, noninvasive ventilation (NIV), invasive mechanical ventilation (IMV), tracheotomy, duration of IMV, ICU and hospital stay, TPE and IVIG consumption, and overall mortality were collected as well.

Results:: There were no between-group changes in survival and IVIG consumption, but a remarkable increase in the use of TPE (71%) and NIV trial (58%), and a reduction of early tracheotomy with 1/2 after the introduction on nanomembrane-based TPE.

Conclusions:: The novel TPE technology shifted our clinical practice towards more preventive rather than protective MC complications treatment.
DIAGNOSTIC DILEMMA IN SUSAC SYNDROME

Dulmini Weerathunga
National Hospital of Sri Lanka, Neurology, Colombo, Sri Lanka

**Background and Aims:** Susac syndrome is an autoimmune endotheliopathy which specifically affect brain, retina and inner ear. The condition is common in young females (20 - 40 years). The diagnosis is made by presence of encephalopathy, branch retinal artery occlusion and sensory neural hearing impairment. Typical reversible “snow ball” appearance in the central corpus callosum favors the diagnosis. Condition could be successfully treated with IV steroids and Immunoglobulin if identified early.

**Methods:** Case She was a 32-year-old diagnosed patient with tension headache and idiopathic epilepsy, for one year. Ten months ago she had been treated with Aspirin for right branch retinal artery occlusion. Six months later she had felt worsening of right vision, leading to the diagnosis of Optic neuritis and was treated with oral Prednisolone, resulting mild improvement. Two months back, she presented with left side visual and Bilateral hearing impairment. There was a peripheral scotoma on visual perimetry and Pure tone audiometry showed sensory neural hearing impairment. At current presentation, her left vision had improved completely following IV Methyl Prednisolone, but there was right optic atrophy and VEP showed delayed P100. MRI done 6 weeks later showed no significant abnormality.

**Results:** The clinical history and response to steroids led to make the diagnosis of Susac syndrome. Previous delay in diagnosis due to incomplete clinical presentation had left some permanent disabilities on the patient.

**Conclusions:** The presentation of Susac syndrome could be nonspecific. Early identification and prompt treatment warrant good recovery. Therefore, the knowledge of this rare condition among health care professionals is important.
AN AMBISPECTIVE COHORT STUDY OF CHRONIC INFLAMMATORY DEMYELINATING NEUROPATHY, AND ITS VARIANTS

Mohit Anand¹, Vishnu V Y², Mv Padma Srivastava³, Rohit Bhatia³, Mamta Singh⁴, Roopa Rajan², Anu Gupta³, Rajesh Singh⁵
¹AIIMS, DELHI, Neurology, Delhi, India, ²All India Institute of Medical Sciences, Neurology, Delhi, India, ³AIIMS, New Delhi, Neurology, Delhi, India, ⁴AIIMS, Neurology, NEW DELHI, India, ⁵All India Institute of Medical Sciences New Delhi, Neurology, New Delhi, India

Background and Aims:: BACKGROUND : The clinical presentation, findings, and outcome may vary between typical chronic inflammatory demyelinating polyradiculopathy (CIDP) and its variants. Aims and Objective: To compare clinical profile and outcome of typical CIDP and its variants.

Methods:: Setting: Tertiary care referral hospital. Materials and Methods: The CIDP patients diagnosed as per EFNS/PNS criteria were included. Hospital records were assessed to note retrospective data of patients included. Prospective patients were subjected to detailed history and examinations. The clinical disability was assessed using ODSS, NIS, IRODS, SCOPA AUT scales. Based on presentation and investigations for underlying diseases, the patients were categorized into typical CIDP and its variants. Treatment prescribed was noted and outcome was assessed at 3 months. The study is ongoing and intends to recruit 100 patients.

Results:: A total of 34 patients have been included till now, ranging from age 20 to 76. 10 (29.4%) had atypical CIDP, POEMS being the commonest variant (7), followed by MADSAM (2) and diabetic amyotrophy (1). Age and sex distribution was similar in both groups, however atypical CIDP had worse scores on ODSS, NIS, IRODS and SCOPA scales, had more relapses (30% vs 0 %) and required polytherapy (90% vs 62.5 %) compared to typical CIDP. The study intends to assess treatment response in both groups after 3 months.

Conclusions:: Of the total patients with CIDP, 29.4% of patients had atypical CIDP which was associated with more severe presentation, more relapses and less response to treatment, requiring the use of polytherapy.
OCRELIZUMAB MODIFIES CIRCULATING IMMUNE ASSET IN RELAPSING-REMITTING MULTIPLE SCLEROSIS SUBJECTS.

Gianmarco Abbadessa¹, Sara Bruzzaniti², Giuseppina Miele¹, Erica Piemonte³, Elisabetta Signoriello¹, Giacomo Lus¹, Giuseppe Matarese², Mario Galgani³, Simona Bonavita¹
¹University of Campania “Luigi Vanvitelli”, II Clinic of Neurology, Department Of Advanced Medical And Surgical Sciences, Napoli, Italy, ²Università di Napoli “Federico II”, Dipartimento Di Biologia, Napoli, Italy, ³Università di Napoli “Federico II”, Dipartimento Di Medicina Molecolare E Biotecnologie Mediche, Napoli, Italy

Background and Aims:: Multiple Sclerosis (MS) is a chronic autoimmune disease of the central nervous system, mediated by autoreactive lymphocytes. Ocrelizumab, a humanized monoclonal anti-CD20 antibody, has shown pronounced effects in reduction of disease activity. Although the clinical response to Ocrelizumab is related to a specific B cell depletion, other circulating lymphocytes may be affected by this treatment.¹ Here, we investigated overtime the possible effects of Ocrelizumab on circulating immune asset in relapsing remitting (RR)-MS subjects.

Methods:: In this prospective longitudinal study, we enrolled n=20 treatment-naïve RRMS patients and n=20 age-sex-BMI-matched healthy controls. RRMS patients were treated with Ocrelizumab and followed up for 6 months. Frequency and phenotype of several circulating immune T cell subset were evaluated by flow cytometry.

Results:: Before initiating treatment, RRMS patients showed lower percentage of lymphocytes compared to healthy subjects. In particular, lower frequency of naïve T cells was observed (i.e., CD4⁺CD45RA⁺ and CD8⁺CD45RA⁺ cells). On the contrary, RRMS patients had higher frequency of both memory T lymphocytes (i.e., CD4⁺CD45RO⁺ and CD8⁺CD45RO⁺ cells) and activated T cells, revealed by HLA-DR expression marker. Six months after the treatment, further reduction of lymphocytes was observed, due to the B cell loss. However, we noticed increased frequency of T cell subset with naïve phenotype. In parallel, a reduction in the activated/memory T cells was observed.

Conclusions:: Together these findings suggest that Ocrelizumab influences also T cell compartment, favoring reduction of activated/memory T cells in RRMS patients.
APPLICATION OF THE APE2 AND RITE2 SCORES IN PATIENTS PRESENTING WITH COGNITIVE DYSFUNCTION

Maria Pia Giannoccaro1,2, Filippo Salvi1, Paolo Tinuper1, Patrizia Avoni1, Rocco Liguori1
1University of Bologna, Dipartimento Di Scienze Biomediche E Neuromotorie, Bologna, Italy, 2IRCCS Istituto delle Scienze Neurologiche di Bologna, Ospedale Bellaria, Bologna, Italy

Background and Aims:: To assess the performance of the Antibody Prevalence in Epilepsy (APE2) and Response to ImmunoTherapy in Epilepsy (RITE2) scores in patients with cognitive dysfunction of unknown etiology.

Methods:: We prospectively collected clinical and paraclinical data of 58 patients referred to our Neurology Unit between January 2020 and December 2020 for altered consciousness level, short term memory loss, or cognitive/neuropsychiatric dysfunction of unknown aetiology. Cell-based assays, tissue-based assays, immunoblot, were performed in serum/cerebrospinal fluid to detect neuronal/glial antibodies. The APE2 and RITE2 scores were calculated and compared with clinical and laboratory data.

Results:: Antibodies were detected in 13/58 patients (22.8%). The APE2 score was significantly higher in patients with antibody positivity (median 6, range 2-11) compared with antibody negative cases (median 4, range 1-9) (P=0.038 Mann-Whitney). An APE2 score>=4 showed a sensitivity of 61.5% and specificity of 40% for the presence of neuronal antibodies and a sensitivity of 78.5% with a specificity of 45.4% for criteria-confirmed diagnosis of autoimmune encephalitis. Using a cut-off of>=5, we increased the sensitivity to 69.2% and the specificity to 68.1% for the presence of neuronal antibodies. Overall, 25 patients received immunotherapy. A RITE2 score>=7 showed a sensitivity of 71.4% and a specificity of 45.4% in predicting a good clinical outcome (improvement in mRS>=1).

Conclusions:: This is the first attempt to independently validate the APE2 and RITE2 score in patients with cognitive impairment. Although useful, both scores performed less well than previously reported. A larger cohort is needed to confirm this result.
EFFICACY AND SAFETY OF RITUXIMAB THERAPY IN PATIENTS WITH AUTOIMMUNE NEUROLOGICAL DISORDERS

Maria Pia Giannoccaro¹,², Vincenzo Donadio²,³, Veria Vacchiano¹,⁴, Patrizia Avoni², Rocco Liguori²,⁵
¹University of Bologna, Dipartimento Di Scienze Biomediche E Neuromotorie, Bologna, Italy, ²IRCCS Institute of Neurological Sciences of Bologna, Uoc Clinica Neurologica, Bologna, Italy, ³IRCCS Istituto delle Scienze Neurologiche di Bologna, Ospedale Bellaria, Bologna, Italy, ⁴IRCCS Istituto delle Scienze Neurologiche di Bologna, Uoc Clinica Neurologica, Bologna, Italy, ⁵Alma Mater Studiorum University of Bologna, Departmenet Of Biomedical And Neuromotor Sciences, Bologna, Italy

Background and Aims:: Our aim was to examine the efficacy and safety of rituximab, an anti CD20 monoclonal antibody targeting B-cells, in patients with autoimmune neurological disorders (AND).

Methods:: We retrospectively assessed the incidence of adverse events (AE) and serious AE (SAE) in AND patients who received one or more continuous cycles of rituximab infusions. An extensive screening for infectious disorders, including hepatitis B (HBV) and C virus (HCV), HIV, tuberculosis, and Strongyloides stercoralis (SS) infection was performed before starting the therapy and every 6-12 months. Patients were clinically evaluated about every 3 months.

Results:: We included 19 patients who received rituximab for AND, including autoimmune encephalitis (n=5), neuromyelitis optica spectrum disorder (n=4), stiff person syndrome (n=2), myasthenia (n=4), inflammatory neuropathy or myopathy (n=3) and vasculitis (n=1). Four patients had a positive infectious screening (2 HBV positive, 1 HCV, 1 quantiferon positive and 1 SS positive). All patients with an infectious disorder received appropriate specific therapy before and over the whole course of rituximab therapy. There were a total of 1 AE and 1 SAE with rituximab treatment, both observed after a single infusion. No disease activity was detected in patients with infectious disorders. Improvement or stabilization of the AND was observed in 13/17 patients who completed at least one cycle.

Conclusions:: This study demonstrates that of peripheral B-cells appears safe and efficacious in treating AND when an accurate infectious screening and appropriate treatment are performed. Longer and larger prospective studies are needed to ascertain risks associated with chronic B-cell depletion.
NEUROLOGIC COMPLICATIONS OF CROHN'S DISEASE

Charfi Rihab¹, Khadija Sonda Moalla², Salma Sakka³, Olfa Hdiji⁴, Nadia Bouattour⁵, Sawsan Daoud⁴, Mariem Damak⁴, Chokri Mhiri⁵
¹CHU Hbib Bouguiba Sfax Tunisie, Of Neurology, Sfax, Tunisia, ²Universal Hospital Habib Bourguiba, Neurology, Sfax, Tunisia, SFAX, Tunisia, ³UNIVERSITY HOSPITAL CENTER HABIB BOURGUIBA, Neurology, SFAX, Tunisia, ⁴CHU habib bourguiba Sfax, Neurology, sfax, Tunisia, ⁵Universal Hospital Habib Bourguiba, Neurology, SFAX, Tunisia

Background and Aims:: Crohn’s disease (CD) is frequently accompanied by systemic complications, but neurologic involvement is uncommon and only few cases are reported in the literature. We report three cases of CD with neurological complications occurring during episodes of increased disease activity.

Methods:: We conducted a search in the medical registry of our department to identify patients with CD and neurological complications. Three medical charts were found and retrospectively reviewed.

Results:: Mean age at neurologic manifestations onset was 45 years. Male to female ratio was 2/1. Neurologic involvement reveals the disease in two cases. The first patient, a 58 years old man, developed an acute motor sensory axonal polyradiculoneuritis while two patients had central nervous system involvement (seizures revealing superior sagittal sinus thrombosis with hemorrhagic infarct in one case and multiple subcortical small infarcts on brain MRI in the other case). The outcome was fatal for two patients; while a progressive improvement was observed in the last case.

Conclusions:: The association of neurological disorders with CD is well established. CD is complicated by an increased frequency of arterial and venous cerebrovascular disease as a consequence of probable hypercoagulability. Mixed sensori-motor axonal neuropathy was also described. Pathogenesis of peripheral involvement seems to be multifactorial including an autoimmune phenomenon affecting the small vessels of peripheral nerves. Folate deficiency has been proposed as an etiological factor in some cases. Gastroenterologist must be aware about neurological complications of CD and its screening should be performed systematically in order to avoid fatal outcome and neurological deficit.
EXPOSURE TO FARM ANIMALS AND MULTIPLE SCLEROSIS: WHAT'S THE RELATIONSHIP?

Sirine Belghuith, Salma Sakka, Nouha Farhat, Nadia Bouattour, Khadija Sonda Moalla, Mariem Damak, Chokri Mhiri
Habib Bourguiba Hospital, Neurological Department, sfax, Tunisia

**Background and Aims::** Multiple Sclerosis (MS) is a complex disease of the central nervous system, and aetiological factors continue to be uncovered. Inconsistent evidence exists regarding the association between exposure to pets and/or other animals and MS risk. We aimed to demonstrate the role of animal exposure's and MS development.

**Methods::** Population based case-control study was conducted in the neurological department of Habib Bourguiba Hospital. Patients with clinically definite MS cases and controls randomly chosen from the community were matched on sex and age. Data was collected from questionnaire detailing pet/animal exposure over the course of participant's lives.

**Results::** 30 patients and 30 controls were included in our study. Animal exposure was noted in 70% of patients with MS versus 37% of healthy controls. Exposure to farming, livestock and specific farm animals showed a significant association with MS risk (p=0.02). Exposure to sheep prior to disease onset was associated with a greater risk of MS (p=0.01) with Odds ratio=0.44 (0.7-0.27). No significant relationship was found between exposure to cats, dogs and rabbits and MS.

**Conclusions::** according to literature data, exposure to farm animals and especially sheep can leads to development of MS. This finding may be explained by the role of Clostridium perfringens epsilon toxin (ETX), wich is bacteria is most commonly linked to a gut infection in sheep, may be a blood-borne trigger for forming MS lesions based on its tropism for blood-brain barrier vasculature and CNS myelin.
COGNITIVE FUNCTION RECOVERY IN PATIENT WITH SEVERE ANTI-N-METHYL-D-ASPARTATE RECEPTOR (ANTI-NMDAR) ENCEPHALITIS

Yusak Siahaan¹², Vinson Hartoyo¹², Pamela Tiffani¹²  
¹Universitas Pelita Harapan, Neurology, Tangerang, Indonesia, ²Siloam Hospital Lippo Village/Universitas Pelita Harapan, Neurology, Tangerang, Indonesia

Background and Aims:: Background Cognitive function impairment is one of the most major symptoms of Anti N-methyl-D-aspartate receptor (anti-NMDAR) encephalitis. This phenomenon can be explained since Anti-NMDAR encephalitis occurs diffusely, affecting NMDA receptors that regulate synaptic transmission. Although improvement may be seen in approximately 80% patients who receive early immunotherapy, about 75% of patients still suffers from cognitive deficits. Aims To report a recovery of cognitive function in a case of severe anti-NMDAR encephalitis.

Methods:: Case A 26-year-old otherwise previously healthy woman was admitted with complaint of localized seizure. Despite initial improvement with medication, her condition deteriorated further with additional symptoms of behavioral changes, cognitive decline, visual hallucinations and new onset refractory status epilepticus (NORSE) that failed to respond with combination of three anti-epileptic agents. She was then transferred to ICU and diagnosed with anti-NMDAR encephalitis after further investigations were conducted. She underwent plasmapheresis and regained consciousness with improvement in her symptoms. However, she still suffered cognitive deficits especially in memory, attention, language, executive function and self-care with MMSE score of 15 and MoCA of 8 one month after discharge (Fig. 1). These deficits impaired her daily function despite no other symptoms.

Results:: Result On one-year follow-up after extensive rehabilitation, she reported significant improvement in self-care, attention, language, and executive function with slight deficit left in short term memory with MMSE score of 30 and MoCA of 26. She had since resume her work and life normally.

Conclusions:: Conclusion Early treatment and rehabilitation play a pivotal role for cognitive function improvement in anti-NMDAR patient.
Background and Aims:: Autoimmune encephalitis (AE) is a complex disorder, whose phenotypic spectrum has not been thoroughly defined. The main features (i.e. memory impairment, psychiatric manifestations, seizures) suggest the prominent involvement of the limbic system. Considering its close anatomo-functional correlations with the central structures subserving smell, we investigated olfaction in a population of AE patients.

Methods:: Adult subjects followed diagnosed with AE and followed for ≥ 6 months were enrolled. The Brief Smell Identification Test (B-SIT), a 12-item, forced-choice, scratch-and-sniff measurement was administered. According to B-SIT score, patients were classified as anosmic (<6), hyposmic (<9) and normal (≥9). All participants underwent anterior rhinoscopy to exclude major nasal conditions. Electro-clinical, laboratory, neuroimaging data were reviewed.

Results:: Nineteen subjects (14 males, median age 64 years) with definite (14/19) or probable/possible (5/19) AE were included. Smell impairment was revealed in 15/19 patients (78.9%), 9 hyposmic and 6 anosmic. Age, gender and smoking habit did not affect B-SIT. Olfactory dysfunction appeared more common among patients with definite AE (p=0.0374), regardless of autoantibody status. Participants with higher modified Rankin Scale (mRS) scores at AE onset more often had hyposmia/anosmia (p=0.027). Subjects with bilateral EEG abnormalities were more likely to present smell impairment (p=0.006).

Conclusions:: We found olfaction to be impaired in a large proportion of AE patients, independent of autoantibody status. Olfactory dysfunction appeared more common in subjects with severe AE (as indicated by both definite diagnosis and higher mRS score), and might represent an additional feature suggesting the immune-mediated etiology of encephalitis.
Background and Aims:: Churg-Strauss syndrome (CSS) is a rare small and medium vessel necrotizing vasculitis. Peripheral nervous system involvement in CSS is extremely common, usually manifesting as mononeuritis multiplex or symmetrical peripheral neuropathy with typically a chronic onset. Central nervous system (CNS) involvement is quite rare, ischemic lesions are the most frequent CNS manifestations while cerebral hemorrhages are extremely uncommon.

Methods:: Herein, we report a case of a 55-year-old woman with atypical clinical presentation of CSS.

Results:: The patient was admitted to the hospital with distal weakness, mild hypoesthesia and pain of the lower limbs. She reported an acute onset of symptoms at about 3 days before admission to the hospital. The patient’s past medical history was significant for allergic rhinitis, sinusitis and one episode of asthmatic attack. The diagnostic examinations showed a severe acute distal axonal polyneuropathy and intracerebral hemorrhage with signs of a previous subcortical microhemorrhage. Laboratory tests revealed new HCV infection, without cryoglobulinemia and normal complement levels. CT scan of the chest showed diffuse pulmonary interstitial thickening with multiple ground glass opacity areas. Basing on the presence of 5/6 of major criteria the patient was diagnosed with CSS. Treatment with intravenous immunoglobulin followed by oral prednisone was started, leading to clinical improvement.

Conclusions:: In conclusion, physicians should be aware that intracerebral hemorrhage can be a rare presenting feature of CSS vasculitis. Furthermore, it would be valuable study if a new HCV infection could predispose to atypical onset with acute polyneuropathy or CNS involvement.
Background and Aims: Chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids (CLIPPERS) – is a recently designated inflammatory central nervous system (CNS) disorder, prominently involving the brain and in particular the pons. Etiology of the disease is unknown. Discussions are underway on whether this is an isolated disease or a syndrome that characterizes a number of other diseases. This pathology was first described by Pittock et al. in 2010. Currently in the world there are about 50 patients with this syndrome. We report the following patient with typical symptoms that are consistent with CLIPPERS syndrome.

Methods: We used the general clinical method, MRI and other additional examinations to determine this disease.

Results: CLIPPERS is a newly diagnosed disease, which was first talked about in 2010. His etiology is still unknown and the pathogenesis of this syndrome is not fully understood. It is not clear whether this is an isolated disease or a group of such illnesses. To determine the criteria for setting this diagnosis, you need more information about this syndrome. Therefore, it's important to publish new cases of CLIPPERS.

Conclusions: Characteristic features of CLIPPERS are mainly the lesion of the bridge, hence the clinical picture, a characteristic MRI picture and a good reaction to glucocorticoids. At this stage, this pathology is an exclusion syndrome. In our case, there are all indications that may indicate the CLIPPERS syndrome, especially since we have excluded a number of diseases that run on similar signs.
GLUR3 ENCEPHALITIS WITH COGNITIVE IMPAIRMENT, ATAXIA AND DYSKENESIA: TWO CASE REPORTS

Lucia Florio, Paolo Emilio Alboini, Maurizio Leone
Fondazione IRCCS Casa Sollievo della Sofferenza, Neurology Unit, San Giovanni Rotondo (fg), Italy

Background and Aims:: GluR3 antibodies are observed in patients with seizure and Rasmussen’s encephalitis. We report GluR3 antibodies positivity in two patients with subacute onset of movement disorders and ataxia.

Methods:: A 67-year-old male patient was referred to our Institution for a generalized weakness associated with hypophonia. Neurological evaluation showed a marked lower limb ataxia, generalized dyskenesias, decomposition of saccades, tongue motor impersistence and psychiatric symptom such as apathy, mental confusion and altered mood. Brain MRI did not reveal any lesion, EEG was normal, CSF assays, including prion protein, were negative. Serum onconeural antibodies were undetectable. Search for associated tumors was negative. A CNS surface antigens assay showed a presence of GluR3 antibodies in serum and CSF samples. Patient was treated with intravenous immunoglobulins (IVIg) and steroids with a complete remission of symptoms. A 56-year-old female patient was referred to our Institution for generalized seizure associated with motor impairment. Neurological evaluation showed a lower limb ataxia, dyskenesia and cognitive impairment. Brain MRI was unspecific. EEG showed epileptic alterations responsive to carbamazepine. Prion protein in CSF and serum onconeural antibodies were undetectable, whereas CNS surface antigens assay showed GluR3 antibodies in serum and in CSF samples. A course of IVIg led to a marked improvement in EEG alterations and ataxia, with movement disorders resolution.

Results:: These cases show that GluR3 antibodies may be not only related to seizure spectrum, but also to cognitive impairment and movement disorders.

Conclusions:: As GluR3 antibodies mechanism of action is still unclear, further studies are required.
ABNORMAL PRESENTATION AND IMAGING FINDING OF ANTI-NMDA RECEPTOR ENCEPHALITIS, A REPORT OF TWO CASES.

Ahmed Elkady¹, Ahmed Anany¹, Ahmed Sharawy¹, Majid Bakheet²
¹Saudi German Hospital Jeddah, Neurology, Jeddah, Saudi Arabia, ²King Abdullah Medical City, Neurology, Mecca, Saudi Arabia

Background and Aims:: Meningitis and myelitis are a very rare atypical presenting feature of anti-NMDA receptor encephalitis. We describe an unusual clinical presentation of anti-NMDA receptor encephalitis, the first case with a typical picture of meningitis followed by encephalitis, the second case with myelitis followed by psychiatric prodroma. We aim to widen the differential diagnosis in two patients presenting with clinical meningitis and myelitis followed by other common clinical symptoms and signs.

Methods:: The first case of a 17-year old woman who initially presented with a lymphocytic meningitis attributed to a viral infection. She subsequently developed fluctuating consciousness, agitation, visual hallucinations, dyskinetic movements. The second case of a 19-year old woman who presented with numbness and paresthesia attributed to cervical myelitis. She subsequently developed anxiety, insomnia, agitation, visual hallucinations, and autonomic instability.

Results:: Investigations in both patients revealed a diagnosis of anti-NMDA receptor encephalitis, with a high titer of antibodies in both serum and CSF. Neuroradiology evaluation of the first case showed typical pachymeningitis with contrast enhancement (Figure 1, A) while the second case showed a posterior cervical cord lesion (Figure 1, B). Both patients made an excellent recovery with immunotherapy, plus removal of an ovarian teratoma in the first case.

Conclusions:: Clinicians should consider autoimmune encephalitis in individuals with meningitis, particularly where extensive investigations fail to identify a causative pathogen and there is a rapid development of an encephalitic phenotype as first case. Moreover, acute myelitis accompanied by severe psychiatric manifestations should expand differential diagnosis to autoimmune encephalitis as a possible cause as the second case.
Background and Aims: Thymectomy plays an important role in producing a durable improvement of symptoms, reduction of medication requirement, and even medication-free remission in most of myasthenia gravis (MG) patients. However, variables potentially affecting remission have not been analyzed. Our aim was to compare the post-thymectomy prognosis in different conditions of MG patients with thymus pathologies.

Methods: We retrospectively analyzed MG patients who was referred to Neurology Department, Sahloul university hospital, Sousse, Tunisia and had undergone a thymectomy between 2015 and 2020. Dividing into different groups was based on gender, age of onset, duration of disease, thymus abnormalities and acetylcholine receptors (AChR) antibodies status to analyze different prognosis in different groups after one year post-thymectomy.

Results: Thirty-five patients were included. Complete stable remission (CSR) was achieved in 18 of 35 patients (51.4%). There is no gender neither antibodies status-related difference in achieving CSR. Patients with early onset of MG (=<50 yearsold) or disease duration less than 12 months had higher CSR rates without significant association (p=0.09 and p=0.25 respectively). While no difference was found in remission rate between thymus pathologies (p=0.56).

Conclusions: Early onset myasthenia gravis patients who had early thymectomy within the first year is proved to possess greater chance of achieving CSR.
ACUTE HAEMORRHAGIC ENCEPHALOMYELITIS MIMICKING CEREBRAL METASTASIS – A DIAGNOSTIC DILEMMA

Dunya Luke¹, Bimsara Senanayake², Sahadevan Vithoosan¹, Mary Muthukumarasami¹
¹National Hospital, Neurology, Borella, Sri Lanka, ²National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

Background and Aims: Acute haemorragic encephalomyelitis (AHEM) is the most severe form of acute disseminated encephalomyelitis (ADEM) and is rare. A comprehensive diagnostic workup including a brain biopsy is needed for a definitive diagnosis as it mimics primary and secondary CNS tumours.

Methods: A previously healthy 35 year old man presented with difficulty in swallowing and dysarthria for five days. He had no limb weakness, preceding infections or vaccination. He had a pseudobulbar palsy. Rest of the neurological examination was normal. Routine bloods were normal. CSF was acellular with mild elevation in protein, normal sugar. MRI brain revealed T2 hyperintensities in bilateral frontal and occipital lobes with ring enhancement, perilesional oedema and hemorrhages. Considerations were hemorrhagic metastasis and AHEM. Extensive search of primary malignancy was negative. Brain biopsy revealed demyelination with perivascular lymphocytic infiltration. A diagnosis of demyelinating ‘pseudotumour’ was made. CSF oligoclonal bands were negative. He was treated with IV methylprednisolone pulses (IVMP) and 5 cycles of total plasma exchange (PLEX) which resulted in significant clinical improvement. Oral steroid maintenance was started.

Results: Tumefactive multiple sclerosis or AHEM can mimic and masquerade brain tumours on MRI. Haemorragic lesions made primary CNS lymphoma less likely but haemorragic metastasis was still possible. A brain biopsy is essential in all doubtful cases.

Conclusions: AHEM is a rare clinical entity with a high mortality. A high degree of clinical suspicion is essential for an early diagnosis and treatment with immunotherapy which would be lifesaving.
BILATERAL SINGLE ISOLATED OPTIC NEURITIS WITH TRANSIENT MOG ANTIBODY POSITIVITY – A CASE REPORT

Gabriela Girafa, Regina Alvarenga, Claudia Vasconcelos, Silvio Neto
UNIVERSIDADE FEDERAL DO ESTADO DO RIO DE JANEIRO, Neurology, Rio de Janeiro, Brazil

Background and Aims:: The antibody against the MYELIN OLIGODENDROCYTE GLYCOPROTEIN (MOG-Ab) has been related to optic neuritis, transverse myelitis and acute disseminated encephalomyelitis. Our aim is to report a case of MOG-Ab associated single isolated optic neuritis (SION) with serological follow-up. This report could contribute with the current question about MOG-Ab persistence or negativation and if it could be used as a marker of recurrence and therapy indication.

Methods:: CASE REPORT.

Results:: We present a 33-years-old female that in 2018 presented with pain on eye movement and blurry vision in the right eye and after 2 weeks also in the left eye and no other neurological symptoms. In the acute phase MOG-Ab was positive, magnetic resonance showed contrast enhancement of the right optic nerve, visual evoked potential had bilateral latency delay (bigger on the right eye) and normal optic coherence tomography. After IV following oral glucocorticoids for 1 month, she had complete remission of the symptoms and total recovery of visual function. After 1 year she remained asymptomatic, MOG-Ab was now negative, OCT showed no reduction of the nervous fiber layers and VEP had little improvement on latency. After 3 years, patient showed no recurrence of the symptoms.

Conclusions:: This is a case of a bilateral optic neuritis with benign course without other neurological symptoms that presented no recurrence after 3 years, with negative MOG-Ab at follow-up. This antibody status and titers behavior during the course of the disease could help enlightening as for risk of recurrence and possible treatment.
RETINAL AND CHORIOCAPILLARY VASCULAR CHANGES IN EARLY STAGES OF MULTIPLE SCLEROSIS: A PROSPECTIVE STUDY

Antonio Luca Spiezia¹, Daniela Montorio¹, Antonio Carotenuto², Maria Petracca³, Marcello Moccia⁴, Chiara Criscuolo⁵, Anna Lamberti⁶, Gilda Cennamo⁶, Roberta Lanzillo¹, Vincenzo Brescia Morra⁷

¹University of Naples Federico II, Department Of Neurosciences, Reproductive And Odontostomatological Sciences, Napoli, Italy, ²IRCSS Ospedale San Raffaele, Neuroimaging Research Unit, Division Of Neuroscience, Milano, Italy, ³Federico II University, Multiple Sclerosis Clinical Care And Research Centre, Department Of Neuroscience, Reproductive Science And Odontostomatology, Naples, Italy, ⁴AOU Federico II, Department Of Neuroscience, Reproductive Sciences And Odontostomatology, Napoli, Italy, ⁵Federico II University, Department Of Neurosciences, Naples, Italy, ⁶University of Naples Federico II, Eye Clinic, Public Health Department, Napoli, Italy, ⁷Federico II University , Naples, Multiple Sclerosis Clinical Care And Research Center, Department Of Neuroscience (nsro), Naples, Italy

Background and Aims:: Optical Coherence Tomography Angiography (OCTA) abnormalities occur in multiple sclerosis (MS) over the disease course. OCTA investigations at early MS stages are lacking. To investigate vessel density (VD) in macular and papillary regions over two-years after an initial demyelinating event (IDE).

Methods:: VD was analyzed in superficial, deep, choriocapillaris and radial peripapillary plexus at baseline and after one and two years. We also evaluated structural OCT parameters [ganglion cell complex (GCC) and retinal nerve fiber layer (RNFL)] changes.

Results:: Thirty eyes from 15 IDE patients (7 females, 8 males, mean age 28.4 ± 9.6 years) were evaluated. GCC and RNFL thicknesses did not change over After 2 years, we reported a reduced VD in superficial capillary plexus, deep capillary plexus and radial peripapillary capillary plexus respect to baseline (coeff. β = -2.779, p= 0.013; coeff. β = -4.055, p= 0.018 and coeff. β = -2.687, p=0.001; respectively). VD reduction was not associated with EDSS change, relapses occurrence and MRI activity.

Conclusions:: Retinal vascular loss occurs in early stages of MS independently from clinical and radiological disease activity and it is not associated with retinal atrophy. OCTA could represent a novel early biomarker to monitor the MS progression.
LONG-TERM MRI CHANGES IN A PATIENT WITH KELCH LIKE PROTEIN 11-ASSOCIATED PARANEOPLASTIC NEUROLOGICAL SYNDROME

Hidehiro Ishikawa, Akihiro Shindo, Atsushi Niwa, Koichi Miyashita, Yuichiro Ii, Akira Taniguchi, Hidekazu Tomimoto
Mie University, Neurology, Tsu, Japan

Background and Aims:: Kelch-like protein 11 (KLHL11) antibodies were first described in 2019, as onconeural antibodies causing autoimmune encephalitis associated with seminoma. Although the clinical features have been reported, long-term observational data is lacking. Our case affords a rare opportunity to study the long term clinical and radiological consequences of Kelch like protein 11-associated paraneoplastic neurological syndrome (PNS).

Methods:: Brain MRI brain was retrospectively assessed. To test for KLHL11 autoantibodies, longitudinal samples from the patient were screened by Phage display Immunoprecipitation and Sequencing (PhIP-Seq). Enrichment for KLHL11 in each sample was generated as a Z-score using the mean KLHL11 RPK generated from 100 Healthy Human plasmas by PhIP-Seq. A threshold of Z-score>3 was considered positive. Immunohistochemistry was performed to identify KLHL11-antigen in seminoma tissue.

Results:: A 49-year-old man presented with 8-year-history of progressive ataxia, sensory hearing loss. Brain MRI revealed progressive brain stem and cerebellar atrophy, and low intensity on susceptibility weighted imaging (SWI) in substantia nigra, red nucleus and dentate nuclei. PhIP-Seq identified positivity for KLHL11 in all samples. Immunohistochemical analysis of seminoma tissue showed anti-KLHL11-antibody positive particles in cytoplasm.

Conclusions:: This study suggests that attention should be paid to the pattern of atrophy and signal changes including SWI considering KLHL11-PNS as differential diagnosis. Investigating the KLHL11 proteins in seminoma tissue may help the diagnosis of KLHL11-PNS if the patient with seminoma has neurological symptoms.
THE USE OF COMBINED THERAPY WITH CFPE AND IVIG IN A PATIENT WITH REFRACTORY STANDARD THERAPY FOR STIFF PERSON SYNDROME

Vasili Tkachenko¹, Julia Makaruk², Daniil Degterev¹, Anna Nikitina¹, Kseniya Smolentseva³, Marianna Ginzberg⁴

¹Moscow clinical scientific center named after Loginov, Neurology, Moscow, Russian Federation, ²First Moscow State Medical University (MSMU, officially I.M. Sechenov First Moscow State Medical University, informally Moscow Medical Academy or Sechenov University, Neurology, Moscow, Russian Federation, ³State Budgetary Institution of Healthcare of the City of Moscow "Moscow City Center for the Rehabilitation of Patients with Spinal Injury and the Consequences of Cerebral Palsy of the Moscow City Health Department", Neurology, Moscow, Russian Federation, ⁴Research Center of Neurology, Neurology, Moscow, Russian Federation

Background and Aims:: Patient, female 56 years old. The disease debuted in 2015, 1 month after radiiodine therapy for thyrotoxicosis, episodes of stiffness and pain in the muscles of the back. Since March 2018, the patient noted an increase in the stiffness of the axial muscles, fear of walking, and began to use a cane. In May 2018, constant muscular activity in EMG in paraspinal muscles, proximal muscles of the thighs, an increase of anti-GAD antibodies to 46 U/ml, diagnosed Stiff-person syndrome.
Methods: Treatment started with IVIG in the initial dose of 2 g/kg, followed by maintenance courses of 1 g/kg with an injection interval of 4-5 weeks, and symptomatic therapy with benzodiazepine at the
maximum tolerated dose. After the first course of IVIG, effect was noted for 3 weeks. Subsequently, the
effect of the introduction persisted for up to 2 weeks, and was accompanied by traumatic falls. The patient
refused glucocorticosteroid therapy.

**Results:** Since August 2019, before each IVIG course, did cascade filtration plasma exchanges, 2-4
sessions in which 2700 ml of plasma were processed, 300-500 ml of plasma were taken. This therapy
significantly reduced the severity of rigidity, but did not affect the frequency of falls. The effect lasted for 4-
5 weeks.

**Conclusions:** In patients who have been unresponsive to first-line therapies IVIG and plasmapheresis
can be used in combination. According to the results of all the courses carried out, during the observation
period, we were able to achieve an increase in the duration of the period of regression of symptoms up to
4 - 5 weeks.
STUDY OF CLINICAL PROFILE OF AUTOIMMUNE ENCEPHALITIS/ IMMUNOTHERAPY RESPONSIVE ENCEPHALOPATHIES AND THEIR CORRELATION WITH WHOLE BODY F-18 FDG POSITRON EMISSION TOMOGRAPHY

Rajeev Ranjan
PGIMER, Neurology, Chandigarh, India

Background and Aims:: Autoimmune Encephalitis (AE) represents a complex category of diseases with diverse immunological markers, varied clinical manifestations and variable therapeutic outcomes. PET may prove to be a useful biomarker to diagnose and prognosticate the patient of AE. We conducted a systematic, hospital based, prospective study to assess the role of F-18 FDG PET in AE/IRE.

Methods:: Its systematic, hospital based, prospective study to assess the role of F-18 FDG PET in AE/IRE. We attempted to elucidate the pattern of F-18 FDG PET in various type of AE. We studied consecutive patients of autoimmune encephalitis (n=50) diagnosed and treated at a tertiary care center in Northern India.

Results:: Mean age in current study (n=50) was 39.5 ± 19.3 years (Range: 14-76 years). Most common autoantibody was NMDA (36%), followed by LGI-1 and GAD (8% each). PET was abnormal in 28 (63.6%) patients. It showed evidence of hypermetabolism in 9 (20.4%) and hypometabolism in 27 (61.4%) patients. In 8 (18.2%) patients showed evidence of both hypometabolism and hypermetabolism.

Conclusions:: Most common form of AE in North India is NMDA-AE. It is possible to prognosticate AE using clinical, laboratory and neuroimaging criteria. With proper treatment, more than 80% of patients show good clinical recovery.
ANTI-NMDAR ENCEPHALITIS PRECEDED BY INFECTION: SYSTEMATIC LITERATURE REVIEW WITH COMPARISON OF NON-HSV AND HSV RELATED ANTI- NMDAR ENCEPHALITIS.

Panda Ashwin Kumar¹, Debashish Chowdhury²
¹GB Pant Institute of postgraduate medical education and research, Neurology, New Delhi, India, ²G B Pant Institute of Post graduate Medical education and Research., Neurology, Delhi, India

Background and Aims:: Antecedent infections are an important trigger for Anti-N-methyl-D-aspartate-receptor (NMDAR) encephalitis (NMDAR-E) with Herpes simplex virus (HSV) being the most recognized. Other infections have also been reported to cause NMDAR-E. We aimed to study the reported cases of non-HSV infections causing NMDAR-E and compare them with HSV-related NMDAR-E.

Methods:: A systemic review of literature was done using key mesh words and newly reported cases (not included in any previous reviews) were included (January 2017 to February 2021). Demography, clinical features, imaging, and treatment details were analyzed.

Results:: We found 51 HSV related and 57 Non-HSV-related NMDAR-E cases described during this period. Viral aetiologies were the commonest infection-related triggers for NMDAR-E (n=92/108, 85%). Non-HSV-related NMDAR-E triggers included bacterial (15.78%), other viral (71.92%), parasitic (3.5%), and mixed (8.77%) infections. Non-HSV-related NMDAR-E cases as compared to HSV-related NMDAR-E had a younger median age of onset (21 vs 33 years), more psychiatric, autonomic, and sleep disturbances (73% vs 35%, 19% vs 7%, 44% vs 22 % respectively), and better outcome (complete recovery in 64% vs 36%). Contrarily, HSV-related NMDAR-E had more cognitive disturbances, headache and hypotonia as symptoms (57% vs 37%, 26% vs 2%, 13 % vs nil), and more disabilities (partial recovery: 61% vs 28%) MRI brain showed normal or diffuse brain involvement in 57% in the former group while temporal lobe involvement was seen in 70% of the latter.

Conclusions:: Non-HSV infections are also important triggers of NMDAR-E. Non-HSV-related NMDAR-E has a slightly different clinical profile and better prognosis as compared to HSV-related NMDAR-E.
Background and Aims:: Bariatric surgery is an efficient treatment to achieve significant weight reduction in patients with morbid obesity. However, neurological complications after bariatric surgery are not uncommon and had been extensively discussed including cases of GBS. We are presenting cases of GBS which occurred after bariatric surgery on different postsurgical stage in our cohort with literature review aiming to stratify GBS development risk after bariatric surgery.

Methods:: Tawam hospital bariatric surgery registry was used to select and review neurological complications with emphasis on GBS development after surgery. We additionally completed a search in PubMed for published GBS cases after bariatric surgery from January 2010 till January 2020 with detailed review of demographics, clinical and electrophysiological presentations, as well as response on treatment and pattern of clinical recovery.

Results:: We were able to identify two cases with rapidly progressive GBS in our cohort and seven GBS published cases developed after bariatric surgery which were found in the Pub Med. All GBS cases after bariatric surgery are going to be presented and discussed in details including a possible risk stratification for GBS development.

Conclusions:: Causative role of bariatric surgery in development of GBS still unclear; however nutritional component after bariatric surgery may play role and most likely can trigger autoimmune and inflammatory mechanisms which may lead to development of acute inflammatory polyneuropathy alone or/and in a combination with malnutritional conditions. Inflammatory component should not be ignored in case of post-bariatric neurological complications and their management.
ADULT PRIMARY CENTRAL NERVOUS SYSTEM VASCULITIS. A CASE-SERIES.

Silvio Piffer¹, Raffaella Tanel¹, Roberto Bortolotti², Umberto Rozzanigo³, Bruno Giometto¹, Sabrina Marangoni¹
¹Presidio Ospedaliero Santa Chiara, U.o. Neurologia, Trento, Italy, ²U.O. Reumatologia, Presidio Ospedaliero Santa Chiara, Area Medica Specialistica, Trento, Italy, ³U.O. Radiologia, Presidio Ospedaliero Santa Chiara, Area Servizi, Trento, Italy

Background and Aims:: Adult primary central nervous system vasculitis (PCNSV) is a rare and challenging disorder of the brain and spinal cord arteries, which can benefit from immunotherapy. The histological demonstration of vasculitis allows a defined diagnosis; however, brain biopsy is sometimes not feasible, and diagnostic suspicion should drive treatment. We report four cases.

Methods:: All cases underwent extensive blood and cerebrospinal fluid (CSF) exams and MRI, angiography was performed in three (#1-3), brain biopsy in one (#4). The follow-up ranged between one and five years.

Results:: Three otherwise healthy women between 43 and 47 years old (#1-3) and a 69 years old man with peripheric atherosclerotic arteriopathy and alcoholic hepatopathy (#4) presented in ER for transient acute neurological deficit associated with headache (#2, #3) or progressive focal motor and sensory deficit (#1, #4). All women had subcortical watershed infarcts and angiographic evidence of cerebral artery stenosis; one presented post-contrast enhancement of the artery wall (#1), another showed extracranial internal carotid dissection and mild subarachnoid haemorrhage (#3). The man had a subcortical tumour-like lesion. CSF exam was normal except for intrathecal synthesis of oligoclonal bands (is-OCBs) in three cases (#2-4). Brain biopsy showed perivascular leucocytes infiltrate. Corticosteroids and cyclophosphamide were started based on radiological (#1), radiological and CSF (#2-3), or CSF and histological data (#4). During follow-up, all patients presented a clinical improvement without relapses.

Conclusions:: After accurate differential diagnosis, a careful imaging evaluation and CSF analysis also for is-OCBs can support the diagnostic suspect of PCNSV and therapeutic decisions.
ISOLATED IMBALANCE DUE TO BILATERAL VESTIBULAR FAILURE FOLLOWING IMMUNE CHECKPOINT INHIBITOR ADMINISTRATION

Surangi Mendis¹, John Ealing², James Larkin³, Samra Turajlic³, Aisling Carr⁴, Diego Kaski⁵, Adolfo Bronstein⁶
¹Royal National Ear Nose and Throat Hospital, Neuro-otology, DG, United Kingdom, ²Salford Royal NHS Foundation Trust, Manchester Centre For Clinical Neurosciences, Manchester, United Kingdom, ³Royal Marsden Hospital, Oncology, London, United Kingdom, ⁴University College London Hospitals, National Hospital For Neurology And Neurosurgery, London, United Kingdom, ⁵University College London, Centre For Vestibular And Behavioural Neuroscience, Department Of Clinical And Movement Neurosciences, Institute Of Neurology, London, United Kingdom, ⁶Imperial College London, Division Of Brain Sciences, London, United Kingdom

Background and Aims: T-cell targeted Immune Checkpoint Inhibitors (ICI) has revolutionised the field of oncology in the last decade and are used to treat a variety of cancers.

Methods: Here, we report two patients who developed acute isolated bilateral vestibular failure following use of ICI therapy and postulate that such presentations where a gait disorder may be the sole presenting feature, may be under-reported.

Results: We show how the vestibular function can be documented using video head impulse testing to objectify change over time.

Conclusions: Whilst the exact means by which ICI administration may lead to cranial mononeuropathy remains unknown, removal of key negative immune regulators is thought to be contributory. It has been suggested that inner ear melanocytes could be a target of an autoimmune process in patients with melanoma treated with ICIs, leading to production of antibodies that cross-react with both the melanoma cells and the labyrinth melanocytes, leading to audiovestibular loss. Neurologists involved in the management of oncology patients receiving ICI should be aware of isolated bilateral vestibular loss as a potential adverse event, with significant functional consequences for a patient’s gait and balance.
NEUROMYELITIS OPTICA SPECTRUM DISORDERS IN THE ELDERLY

Assma Boudanga, Mohamed Chraa, Najib Kissani
Mohammed VI University Hospital Center, Neurology, Marrakech, Morocco

Background and Aims:: Introduction. Neuromyelitis Optica is a severe autoimmune inflammatory demyelinating disease that affects mainly the spinal cord and optic nerves with a young female predilection. It can present with a severe neurological presentation from the beginning with a poor prognosis. However, it is rare to see it in elderly subjects with aggressive and insidious onset of symptoms. Objective. Our cases highlight the varied clinical presentations of NMOSD and we believe that the diagnosis of NMOSD should be considered in elderly patients in the appropriate clinical setting despite the presence of unconventional symptoms.

Methods:: Observation In this work, the authors report late cases of Devic's neuromyelitis Optica in two women aged 66 and 71 years whose neurological examination showed a complete spinal cord syndrome and a tetrapyramidal syndrome respectively. MRI of the spinal cord showed an extensive myelitis appearance. Anti-NMO and anti-MOG IgG antibodies in the blood were positive. Our patients received a high-dose corticosteroid bolus for 5 days with the protocol of Rituximab 1g per course and motor rehabilitation sessions.

Results:: The evolution is marked by a clear clinical improvement.

Conclusions:: Conclusion. Neuromyelitis Optica is an autoimmune pathology that is exceptional in the elderly and has a poor prognosis, hence the interest in evoking it in the presence of a serious and insidious neurological presentation in order to start treatment early.
CD8 T CELL-MEDIATED CEREBELLITIS DIRECTED AGAINST PURKINJE CELL ANTIGEN AFTER IPILIMUMAB FOR SMALL CELL LUNG CANCER

Marc Hardwick¹, Luke Nolan², James Nicoll¹, Sanjay Jogai³, Edurne Arriola⁴, Debora Joseph-Pietras⁵, Christian Ottensmeier², Ian Galea¹
¹University of Southampton, Clinical Neurosciences, Southampton, United Kingdom, ²University Hospital Southampton, Department Of Medical Oncology, Southampton, United Kingdom, ³University Hospital Southampton, Department Of Cellular Pathology, Southampton, United Kingdom, ⁴Hospital del mar, Medical Oncology Department, Barcelona, Spain, ⁵University of Southampton, Cancer Sciences & Nihr And Cruk Experimental Cancer Medicine Centre, Southampton, United Kingdom

Background and Aims:: Immune checkpoint inhibitors are increasingly associated with central nervous system complications, and clinical presentation may resemble that of classical paraneoplastic syndromes. Several immune-mediated cerebellar syndromes have been reported in this context, and histological study is now needed to reveal immunological mechanisms and determine whether these are similar to paraneoplastic cerebellar degeneration.

Methods:: We present a case of cerebellitis in a 63-year-old man who received ipilimumab (cytotoxic T-lymphocyte-associated protein 4 inhibitor) for small cell lung cancer as part of a phase II trial. After death, a post-mortem examination was performed followed by immunohistochemical study of the brain.

Results:: The patient developed a cerebellar syndrome 37 weeks after ipilimumab. Contrast-enhanced magnetic resonance imaging of the brain and spinal cord was normal. Cerebrospinal fluid was acellular with normal glucose but a raised protein and paired oligoclonal bands. Baseline weakly positive anti-Yo antibody titres were unchanged following treatment. He deteriorated despite immunosuppressive treatment and died during week 39. Histology revealed that pathology was limited to the cerebellar cortex, consisting of a patchy CD8 T cell infiltrate spatially corresponding to areas of Purkinje cell loss. There was evidence of CD8 polarisation towards Purkinje cells and Bergmann astrocyte activation. By comparison, CD20-positive B cells were sparse.

Conclusions:: CD8 T cell-mediated cerebellitis after ipilimumab may represent early pathology seen during paraneoplastic cerebellar degeneration. This case highlights the need for continued vigilance with CTLA-4 inhibitors, especially when anti-neuronal antibodies are present at baseline. Treatments which suppress T cell responses merit further study.
IMPACT OF NEUROMYELITIS OPTICA SPECTRUM DISORDER ON QUALITY OF LIFE: ASSESSING THE PATIENTS’ PERSPECTIVE

José Meca-Lallana1, Rocío Gómez-Ballesteros2, Francisco Pérez-Miralles3, Lucía Forero4, María Sepúlveda5, Carmen Calles6, María Luisa Martínez-Ginés7, Inés González-Suárez8, Sabas Boyero9, Lucía Romero-Pinell10, Angel P Sempere11, Virginia Meca-Lallana12, Luis Querol13, Lucienne Costa-Frossard14, Jorge Mauriño2

Background and Aims:: Symptomatology and number of attacks in neuromyelitis optica spectrum disorder (NMOSD) reduce patients’ health-related quality of life (HRQoL). Limited information is available from patients’ perspective in Spain. The aim of this study was to assess the impact of NMOSD on HRQoL from the patients’ perspective.

Methods:: A non-interventional, cross-sectional study was conducted in 13 neuroimmunology clinics in Spain. NMOSD patients (2015 Wingerchuk criteria) were included. Expanded Disability Status Scale (EDSS), SymptoMScreen (SyMS), 29-item Multiple Sclerosis Impact Scale (MSIS-29), 8-item Stigma Scale for Chronic Illness (SSCI-8), Beck Depression Inventory-Fast Screen (BDI-FS), Pain Effects Scale (PES) and Fatigue Impact Scale for Daily Use (D-FIS) were used to assess disability, symptom severity, HRQoL, stigma, mood, pain and fatigue, respectively. Outcome measures associations were analysed using Pearson correlation.

Results:: Seventy-one patients were studied (mean age: 47.4 years ±14.9, 80.3% female, mean disease duration: 9.9 years ±8.1, median EDSS: 3.0 [interquartile range: 1.5-4.5]). Mean physical and psychological MSIS-29 sub-scores were 41.9±16.8 and 20.9±8.3, respectively. SyMS mean scores were highest for fatigue (2.4±1.8) and bodily pain (2.2±1.8). Stigma prevalence was 61.4% (n=43) and 44.3% (n=31) of patients had depressive symptoms. Physical MSIS-29 showed significant correlation with SyMS (rho=0.856, p<0.0001). BDI-FS was correlated with SyMS, psychological MSIS-29, PES, D-FIS and SSCI-8 (rho=0.621, 0.714, 0.664, 0.663, 0.613, respectively, all p<0.0001). Perception of stigma predicted concurrent depression (OR=1.32; 95% CI: 1.13-1.55, p=0.0004).

Conclusions:: NMOSD poses a significant burden on patients’ HRQoL from their perspective. Assessing patient-centered outcomes may be crucial to achieve a holistic approach of disease allowing early interventions.
COMMON PARANEOPLASTIC NEUROLOGICAL SYNDROMES IN PAKISTAN: CLINICAL AND IMMUNOLOGICAL ASPECTS

Fizza Orooj1, Shafain Sheikh1, Arsalan Ahmad2, Tahir Ahmed2
1Shifa International Hospital, Shifa Tameer-e-Millat University, Neurology, Islamabad, Pakistan, 2Shifa International Hospital, Shifa Tameer-e-millat university, Neurology, Islamabad, Pakistan

Background and Aims:: To determine the frequency and clinical features associated with anti-neuronal antibodies in patients suspected of paraneoplastic neurological syndromes and autoimmune encephalitis in a tertiary care hospital in Islamabad, Pakistan.

Methods:: After approval from IRB & ethics committee, we reviewed laboratory records of patients suspected of paraneoplastic syndromes (PNS) and autoimmune encephalitis, from February 2019 to February 2021. Indirect Immunofluorescence technique was used for autoimmune encephalitis and Immunoblot for PNS. The clinical features, response to treatment and associated malignancies were recorded for analysis.

Results:: A total of 46/524 patients (8.7%) had immune encephalitis; mean age 32.07 years; 58.6% were females. Anti-NMDAR antibodies were present in 31/46; Anti-Caspr2: 7/46; Anti-LGI1: 6/46 and Anti-GABA-B receptor antibodies in 2/46. 28/46 with complete clinical data were included for clinical correlation. NMDAR encephalitis was the presentation in 18/28; limbic encephalitis in 9/28 and neuromyotonia in 1/28. 23/28 patients responded to immune-modulatory therapies. Of 357 tested for antibodies for PNS, 25 were positive (7%). Mean age 53.4 years; 52% were female. 7/25 patients had Anti-Amphysin antibodies; Anti-Titin: 5/25; Anti-Yo: 3/25; Anti-SOX1: 2/25; Anti-CV2: 1/25. Multiple antibodies: 5/25 patients. Eleven patients with insufficient clinical data were excluded. Common PNS were myasthenia gravis: 3/14; sub-acute cerebellar degeneration: 3/14; limbic encephalitis: 3/14; encephalomyelitis: 2/14, stiff-person syndrome: 2/14; LEMS in 1/14. Most responded poorly to treatment (9/14); 6/13 patients had malignancies.

Conclusions:: NMDAR antibody encephalitis was the most frequent immune encephalitis and had a favourable response to immunotherapy. Paraneoplastic neurological syndromes were less responsive to treatment, but helped in early tumor detection.
SEVERE ACUTE POLYRADICULONEURITIS REVEALING SYSTEMIC LUPUS ERYTHEMATOSUS

Assma Boudanga, Mohamed Chraa, Najib Kissani
Mohammed VI University Hospital Center, Neurology, Marrakech, Morocco

Background and Aims:: Introduction Systemic lupus erythematosus is a common disease with extremely heterogeneous neurological manifestations in its clinical expression. However, few cases have been reported in the last 50 years where the initial manifestation of SLE is Guillain-Barré syndrome. Our work highlights the importance of SLE as a potential etiology in a patient with acute polyradiculoneuritis.

Methods:: Observation A 41-year-old woman, with a history of three miscarriages and skin photosensitivity, presented with sudden onset symptomatology of synchronous and symmetrical ascending functional impotence of both lower limbs 20 days before admission. Clinical examination revealed a dyspneic patient with a peripheral neurogenic syndrome predominantly distal to the 4 limbs with generalized myxedema associated with alopecia. Electroneuromyography showed an axonal motor polyradiculoneuropathy more marked in the two lower limbs. Biological abnormalities were in favor of SLE. The diagnosis of acute Guillain-Barré type PRN associated with lupus disease was retained. The patient received a bolus of methyl-prednisolone, monthly courses of cyclophosphamide 1 g, and synthetic antimalarials such as hydroxychloroquine (Plaquenil) 400 mg daily.

Results:: The evolution is marked by a clear clinical improvement.

Conclusions:: Conclusion: Neurological manifestations in lupus disease are common; whereas the form of acute polyradiculoneuropathy is very rare with a risk of vital engagement prognosis. Early diagnosis and management are essential.
UNCOMMON ASSOCIATION OF NMDA RECEPTOR ENCEPHALITIS WITH INTRACRANIAL GERM CELL TUMOUR

Seshagiri Doniparthi¹, Madhu Nagappa², Shilpa Rao Rao³, Vani Santosh³, Chandana Nagaraj⁴, Mangalore Sandhya⁴, J Saini⁵, Arimappan Arivazhagan⁷, Sanjib Sinha⁷, Arun Taly²
¹NIMHANS, Dept Of Neurology, Bengaluru, India, ²National Institute of Mental Health and Neurosciences (NIMHANS), Neurology, Bangalore, India, ³National Institute of Mental Health and Neurosciences, Department Of Neuropathology, Bangalore, India, ⁴National Institute of Mental Health and Neurosciences, Department Of Neuro Imaging And Interventional Radiology, Bangalore, India, ⁵National Institute of Mental Health and Neurosciences (NIMHANS), Neuroimaging And Interventional Radiology, Bangalore, India, ⁶National Institute of Mental Health and Neurosciences, Neuroimaging And Interventional Radiology, BENGALURU, India, ⁷National Institute of Mental Health and Neurosciences (NIMHANS), Department Of Neurology, BENGALURU, India

Background and Aims:: N-methyl-d-aspartate receptor encephalitis (NMDARE) has significant association with ovarian teratoma; meticulous search and removal of the same is a key step in the management. We describe challenges in the management odyssey of a 21-year-old lady with NMDARE.

Methods:: Clinical features, brain MRIs, NMDA-antibodies in serum and/or cerebrospinal fluid (CSF) and other investigations during the course of 44 months were reviewed

Results:: This patient presented with seizures, abnormal behaviour and impaired memory of five months duration. Brain MRI showed ill-defined enhancing hyperintensities in cingulate gyri, corpus callosum, and brainstem. NMDA-antibodies were weakly positive in serum. PET-CT showed focally restricted diffusion in right ovary; no lesion was noted on ultrasound and biopsy was denied. She improved with steroids. After five months, she developed apathy and catatonia. Plasmapheresis was given and azathioprine was added. At ninth month, she improved significantly and remained well except for seizure-recurrence at 25th month. Evaluation on four occasions showed that serum NMDA antibodies and brain MRIs were persistently abnormal, but pelvic ultrasound was normal. At 37th month, she discontinued treatment and developed severe relapse in 41st month leading to bedridden state. Brain MRI at 44th month showed remarkable increase in lesion load with diffuse nodular meningeal enhancement (sugar-coating appearance). While serum NMDA antibodies were weakly positive, CSF showed strong positivity for NMDA antibodies. Biopsy from frontal lesion showed features of germ cell tumour.

Conclusions:: While ovarian teratoma is a well-known association with NMDARE, intracranial spread of germ cell tumour is uncommon. Early tissue diagnosis is warranted for diagnosis and appropriate treatment.
PICK YOUR POISON: NEUROBEHÇET OR CENTRAL NERVOUS SYSTEM PARANEOPLASTIC SYNDROME?

Miguel Miranda, Fernando Pita, Cátia Carmona, Sandra Sousa
Hospital de Cascais Dr. José de Almeida, Department Of Neurology, Alcabideche, Portugal

Background and Aims:: The diagnosis of rhomboencephalomyelitis is often challenging, with a wide variety of etiologies to be considered, some potentially fatal in the absence of early diagnosis and treatment, like Neurobehçet and paraneoplastic encephalomyelitis.

Methods:: A case of a 52-year-old patient with a challenging differential diagnosis of rhomboencephalomyelitis is presented.

Results:: A 52-year-old male Portuguese patient, with history of recurrent uveitis, was admitted to the Emergency Department with a subacute progressive left hemiparesis, vertigo and gait instability. On the neurological examination, the patient displayed left hemiparesis and hypoesthesia, scanning speech, appendicular and gait ataxia. Neural axis imaging with MRI was conducted, revealing an asymmetrically bilateral infiltrative lesion, with extension from the diencephalon to the lateral cervical cord. CSF analysis revealed hyperproteinorachia (58mg/dl) and pleocytosis (56.0 leukocytes/uL), with mild mononuclear predominance. Blood and CSF serologies (namely for Listeria monocytogenes) and antineuronal antibodies were negative. A renal carcinoma on the right kidney found on a CT scan and a positive HLA type 51 assay suggested two possible diagnoses: paraneoplastic rhomboencephalomyelitis versus Neurobehçet. A cycle of Methylprednisolone IV was started followed by oral immunosuppressors and the tumor was surgically removed, not requiring adjuvant treatment. At follow-up three months later, marked clinical and imaging improvement was reported. Clinical and paraclinical data suggested Neurobehçet as the most likely diagnosis.

Conclusions:: The broad clinical spectrum, the absence of validated diagnostic criteria and the lack of specificity of ancillary diagnostic testing can dictate the complexity of the diagnosis of a rhomboencephalomyelitis.
OCULAR MYASTHENIA GRAVES IN A PATIENT WITH COVID-19; NEUROLOGICAL OVERVIEW OF AUTOIMMUNE COMPLICATIONS OF COVID-19

Esra Demir¹, Sule Bilen²
¹ANKARA YILDIRIM BEYAZIT UNIVERSITY MEDICAL FACULTY, Department Of Neurology, ANKARA, Turkey, ²ANKARA CITY HOSPITAL, Neurology Clinic, ANKARA, Turkey

Background and Aims:: COVID-19 is a highly contagious pathogen caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). Recent studies have shown that COVID-19 shares similarities with autoimmune diseases in clinical manifestations, immune responses, pathogenic mechanisms and the presence of autoantibodies. Also, some patients have been reported to develop autoimmune diseases such as Guillain–Barre syndrome and Myasthenia Graves (MG) after COVID-19. MG is an autoimmune disease of the neuromuscular junction, affecting ocular, bulbar, respiratory and skeletal muscles. We report an ocular MG developing secondary to COVID-19 infection in a 45-year-old female patient on the 10th-day of COVID-19 infection. She described pain and droopy eyelid in the right eye. Her complaints were increased during the day, especially towards the evening. A neurological examination revealed semi-ptosis in the right eye. There was no blurred or scarcity of vision and no diplopia. Other neurological examination was normal. Her cranial magnetic resonance imaging (MRI), orbital MRI and MRI angiography were evaluated as normal in terms of intracranial pathologies. Serum hemogram, biochemical tests, serological tests, coagulation tests and electrophoresis tests were completed normally. We evaluated the patient in aspects of MG with these clinical findings, and serum and electrophysiological test were performed. Serum acetylcholine receptor antibody (AChR) test resulted positive (5.58 nmol/L). Voluntary single fiber EMG showed increased jitter values that were compatible with motor endplate dysfunction. Thymus gland computed tomography in terms of hyperplasia or thymoma evaluated as normal. The patient was diagnosed with ocular myasthenia and deltacortil (5 mg tb) treatment was started.

Methods:: CASEREPORT
Results:: CASEREPORT
Conclusions:: CASEREPORT
ANTI NMDA ENCEPHALITIS: A RARE CAUSE OF TEMPORAL EPILEPSY

Hakim Si Ahmed, Smail Daoudi
CHU TIZI-OUZOU, Department Of Neurology, Chu Tizi Ouzou, Tizi-Ouzou, Algeria

Background and Aims:: rare, unrecognized and treatable entity.
Methods:: 15-year-old patient, who presented in a rapidly progressive way olfactory hallucinations, paroxysmal, a few days later, appearance of contact breaks with automatisms. Examination: T ° 38.2, profuse sweating and oral dyskinesias. MRI: hyper signal in left temporo-insular. EEG: nonspecific slow waves CSF: high proteinorachia (0.95g / l) normal, cytology: 43 lymphocyte-like elements, presence of oligoclonal bands of IgG. The paraneoplastic assessment is negative NMDA antibody assay were positive in CSF. The patient received corticosteroids by infusion (01g /day for 05 days), then 05 courses of immunoglobulins. The evolution has been towards almost total clinical improvement.
Results:: An infectious origin is quickly eliminated by the negativity of the serologies and the PCR. The diagnosis of dysimmune encephalitis is then suspected, especially anti NMDA (young age, cephalic dyskinesias...), is retained after immunological analysis. Anti-NMDA encephalitis mainly affects women (80%), with an onset between age 18 and 35, first manifests itself in a psychiatric. Then neurological symptoms set in (epileptic seizures, orofacial dyskinesias...). The seizures are most often generalized, tonic-clonic but also complex partial, or secondarily generalized. The study of CSF is often inflammatory, with oligoclonal bands.. Brain MRI finds a hyper signal in the hippocampus, or temporo-insular, or frontal, or extra limbic. EEG can reveal delta brush or rhythmic slow wave anomalies. It is also necessary to know how to look for an ovarian teratoma.
Conclusions:: Focal epilepsy, of recent onset and explosive, of unexplained etiology, especially of the temporal type and drug-resistant, should encourage the search for autoantibodies.
Background and Aims:: We present the case of a male patient with a central nervous system germinoma that simulated three clinical syndromes of NMOSD, so we consider it necessary to screen him in case of therapeutic failure to initial treatment with steroids. A 19 male years old, previously healthy, In May 2019, he presented a sudden decrease in bilateral visual acuity, worsening the right eye. A cranial MRI was negative, and he starts prednisone 25 mg QD, with partial improvement. Despite this therapeutic, he continued with decreased visual acuity. In July 2020, begins with hiccups and cough that later became self-limiting. A quick examination by gastroenterology does not reveal structural alteration.

Methods:: In July 2020, he presented multiple episodes of hiccups and cough that later self-limited. In October, he started with hiccups, nausea, cough, and dysphagia being refractory to symptomatic treatment, in addition to worsening in visual acuity. Serum anti-aquaporin-4 antibodies were negative. In spite of this, he was treated with pulses of methylprednisolone, without response. To December, he developed amaurosis of the right eye and shadow perception in the left eye and multidirectional nystagmus exacerbated by the left gaze version. In funduscopy he presented bilateral optic atrophy.

Results:: In the imaging follow-up with MRI and PET, a lesion persists in the right optic nerve. Neurosurgery decided to approach a lesion biopsy. Histopathology was matched with germinoma. Lumbar puncture showed levels of human chorionic gonadotropin in 69.09 (>2.63 UI/ml).

Conclusions:: CNS germinoma simulated an NMOSD. The patient is under chemotherapy (ifosfamide and etoposide) and radiotherapy.
GRANULOMATOUS ANGIITIS OF THE CENTRAL NERVOUS SYSTEM: CLINICAL AND IMAGING PROFILE AND RESPONSE TO TREATMENT

Nibu Varghese¹, Madhu Nagappa¹, Yasha Chickabasaviah², B N Nandeesh², J Saini³, Rose Bharath⁴, Dhananjay Bhat⁵, Sanjib Sinha¹, Arun Taly⁶
¹National Institute of Mental Health and Neurosciences (NIMHANS), Department Of Neurology, BENGALURU, India, ²National Institute of Mental Health and Neurosciences, Department Of Neuropathology, Bangalore, India, ³National Institute of Mental Health and Neuro Sciences, Neuroimaging And Interventional Radiology, BENGALURU, India, ⁴National Institute of Mental Health and Neurosciences (NIMHANS), Neuroimaging And Interventional Radiology, Bangalore, India, ⁵National Institute of Mental Health and Neurosciences (NIMHANS), Department Of Neurosurgery, BENGALURU, India, ⁶National Institute of Mental Health and Neurosciences (NIMHANS), Neurology, Bangalore, India

Background and Aims:: Granulomatous angitis of central nervous system (GACNS) is a rare idiopathic necrotizing vasculitis. Clinical manifestations are heterogeneous and diagnosis is challenging. We aim to describe the clinical course and outcome in patients of biopsy-proven GACNS.

Methods:: Data on clinical and imaging features, histological findings, and relevant investigations of four patients seen in a single neurology unit were compiled retrospectively.

Results:: All subjects were men. Age at presentation ranged from 19 to 39 years. Duration of symptoms ranged from 0.5 to 60 months. Initial symptom was headache (n=2), facial weakness (n=1), and progressive paraparesis (n=1). Clinical profile included encephalopathy (n=2), cognitive decline (n=2), headache (n=2), seizures (n=1), facial palsy (n=1), paraparesis (n=1), hemiparesis (n=1) and bladder dysfunction (n=2). Brain MRI showed multifocal signal changes in cerebral, cerebellar, and brainstem regions with hemorrhages and variable enhancement in all. Spine MRI showed longitudinally extensive hyperintensity with patchy enhancement in one patient. Cerebrospinal fluid analysis showed pleocytosis in all (10 to 200 cells/cu.mm.) and protein ranged from 40 to 180 mg/dl. Meningocortical biopsy showed perivascular lymphocytic cuffing, epithelioid cell granulomas and multinucleate giant cells with normal intervening parenchyma and hemosiderin foci. All patients received steroid and steroid-sparing agents (cyclophosphamide=three, azathioprine=one). Duration of follow-up ranged from 1 to 40 months. Outcome at last follow-up was: complete improvement in two, partial improvement in one and relapse in one.

Conclusions:: GACNS causes extensive brain involvement and clinical profile is non-specific. Meningocortical biopsy helps in establishing a definitive diagnosis. Outcome is good in appropriately treated patients of GACNS.
Background and Aims:: Muscle-specific kinase (MuSK) myasthenia gravis (MG) is often a more severe form of MG that presents with a rapid onset and prominent bulbar symptoms. Today, the diagnosis of MuSK MG is heavily reliant on the antibody (Ab) status of the patient. In most laboratories worldwide, the Abs are measured by radio immune precipitation assay (RIPA). We have developed another testing platform using surface plasmon resonance (SPR) technology. Our aim was to measure the clinical sensitivity and specificity for two different MuSK Ab assays.

Methods:: To assess clinical utility, we are describing a retrospective clinical evaluation of 987 AchR Ab negative samples that have been measured for MuSK Ab by the two different techniques.

Results:: 132 of the 987 AchR Ab negative samples were either positive or borderline for MuSK Abs by one of the 2 methods. Every final diagnosis of the patients associated with these samples was reviewed in detail. Also, 167 randomly selected patients who tested negative with both tests were assessed for clinical diagnosis. The RIPA assay showed to be 49% to 58% sensitive depending on the criteria of diagnosis used and 89-92% specific. The SPR assay is 68-79% sensitive and 67% specific. When both assays are in congruence the specificity is 100%

Conclusions:: The RIPA assay is the gold standard, but the SPR technique was more sensitive than the RIPA. Unfortunately, the SPR technique is less specific. SPR is helpful to follow antibody titer and evaluate treatment response. A prospective study of its usefulness in these conditions is in planning.
ALTERED IL-33/SST2 AXIS IN GUILAIN BARRE SYNDROME AND ITS FUNCTIONAL ROLE IN DISEASE ACTIVITY

Monojit Debnath¹, Doniparthi Seshagiri², Madhu Nagappa³, Praveen Sharma², Thrinath Mullapudi¹, Nikhitha Sreenivas¹, Saikat Dey¹, Rahul Wahatule³, Vijay Kumawat⁴, Binu S⁵, Sanjib Sinha⁶, Arun Taly⁷

¹National Institute of Mental Health and Neurosciences (NIMHANS), Human Genetics, Bangalore, India, ²National Institute of Mental Health and Neurosciences, Neurology, Bangalore, India, ³National Institute of Mental Health and Neurosciences (NIMHANS), Department Of Neurology, Bengaluru, India, ⁴National Institute of Mental Health and Neurosciences, Transfusion Medicine And Haematology, Bangalore, India, ⁵National Institute of Mental Health and Neurosciences (NIMHANS), Biostatics, Bangalore, India, ⁶National Institute of Mental Health and Neurosciences (NIMHANS), Department Of Neurology, BENGALURU, India, ⁷National Institute of Mental Health and Neurosciences (NIMHANS), Neurology, Bangalore, India

Background and Aims:: Interleukin -33 (IL-33) and its soluble receptor (sST2) regulate Th1/Th2 immune responses; the altered activity of IL-33/sST2 leads to the development and severity of various immune-mediated diseases. This study is aimed to explore the role of IL-33/sST2 axis in Guillain Barre Syndrome (GBS).

Methods:: In this study, 178 patients with GBS and 185 healthy subjects were recruited. Three single nucleotide polymorphisms (SNPs) of Il33 gene (rs16924159; rs7044343; rs1342336) and 3 SNPs of Il1rl1 gene (rs10192157, rs1041973, rs10206753), coding for sST2 were genotyped in all the subjects by TaqMan Allelic Discrimination Assay. Besides, plasma levels of IL-33 and sST2 were measured in a subset of patients (n=80) and healthy subjects (n=80) by ELISA.

Results:: The frequencies of the alleles and the genotypes of the SNPs of Il33 and Il1rl1 genes did not differ significantly between patients with GBS and healthy subjects. Further to this, none of these SNPs correlated with antecedent infections, disability scores or electrophysiological subtypes of GBS. The plasma levels of IL-33 were undetectable in all the studied subjects. However, the plasma levels of sST2 were significantly elevated in patients with GBS compared to healthy subjects (24,934.31 ± 1.81 pg/ml vs 12,518.97 ± 1.51 pg/ml, p<0.001). The levels of sST2 showed a significant correlation with the disability scores at the peak of neurological deficit in patients with GBS.

Conclusions:: The sST2 levels are significantly elevated and correlate with disease disability in GBS. IL-33/sST2 axis may play a pivotal role in the autoimmune origin of GBS.
MEDIATORS OF TOLL-LIKE RECEPTOR (TLR) PATHWAY AS GENETIC DETERMINANTS OF GUILLAIN BARRE SYNDROME

Monojit Debnath1, Debprasad Dutta1, Madhu Nagappa2, Rahul Wahatule2, Sanjib Sinha3, Ab Taly3
1National Institute of Mental Health and Neurosciences (NIMHANS), Human Genetics, Bangalore, India, 2National Institute of Mental Health and Neurosciences (NIMHANS), Neurology, Bangalore, India, 3National Institute of Mental Health and Neurosciences (NIMHANS), Department Of Neurology, BENGALURU, India

Background and Aims:: Toll-like receptor (TLR) pathway is crucially involved in initiating innate immune response against microbes. Dysregulation of TLRs can exacerbate immune-inflammatory responses and genetic variations within tlr genes contributes to differential risk to infection. This study is aimed to examine the role of genetic variations within tlr2, tlr3, and tlr4 genes as well as genes coding for intracellular signalling molecules such as myd88, nf-kb1, ikbα, traf3, traf6, trf, and irf3 of TLR pathway.

Methods:: In this prospective study, 150 patients with GBS and 150 healthy subjects were recruited. Fourteen polymorphisms, two from each of tlr2 (rs3804099; rs111200466), tlr3 (rs3775290; rs3775291), tlr4 (rs1927911, rs11536891), myd88 (rs7744, rs4988453), and one from each of nf-kb1 (rs28362491), ikbα (rs696), traf3 (rs12147254), traf6 (rs4755453), trf (rs8120) and irf3 (rs2304204) were genotyped in all the subjects either by PCR-RFLP or TaqMan Allelic Discrimination Assay.

Results:: Statistically significant differences of genotype frequencies of rs111200466 and rs3804099 of tlr2, rs3775290 of tlr3 and rs11536891 of tlr4 were observed between GBS patients and healthy controls. The Del/Del genotype rs111200466 (p<0.001) and CT genotype of rs3804099 (p=0.002) of tlr2 gene were significantly associated with the risk of GBS. The TT genotype of rs3775790 of tlr3 (P<0.001) and CT genotype of rs11536891 of tlr4 (P<0.001) genes were also found to confer increased risk to GBS. Gene-gene interaction analysis by Multifactor Dimensionality Reduction (MDR) analysis suggest a significant combined effect of tlr2, tlr4 and ikbα genes on the risk of GBS.

Conclusions:: The genes of the TLR pathway could serve as important genetic determinants of GBS.
PROBABLE AUTOIMMUNE ENCEPHALITIS PRESENTING WITH EPILEPSY, FEVER AND AGEUSIA: A POSSIBLE COVID-19-RELATED EVENT?

Davide Fasolato¹, Valentina Carlucci¹, Stefano Mozzetta¹, Annachiara Cagnin²
¹Neurology Clinic, Department Of Neuroscience, Padova, Italy, ²University of Padova, Padova Neuroscience Center, Padova, Italy

Background and Aims:: Encephalitis is an acute inflammation of brain parenchyma, clinically characterized by confusional state and cognitive decline, fever, headache, and an altered level of consciousness. Encephalitis is typically viral or autoimmune. Aim of the study is to discuss a case of autoimmune encephalitis with anosmia and epileptic seizures at clinical presentation.

Methods:: Blood and CSF analysis, electroencephalography and brain 18 FDG PET-MRI were done. Cognitive status was tested by Mini Mental State Examination.

Results:: We report on a 60-year-old man with an episode of incongruos speech and behaviour, spatial disorientation, diarrhea, ageusia and hyperpyrexia occurred in December 2019. Blood examination was normal for infective and inflammatory diseases. At admission EEG showed irritative anomalies in the left frontal-central regions. CSF analysis showed 12 WBC and no evidence of infection; brain MRI was normal. The patient was treated with acyclovir with partial benefit. In the following months he had apathy, deflected mood and drowsiness. In November 2020 a new episode of confusion occurred, with transitory visual field impairment and headache. This time he was tested with MMSE, with a score of 25/30. A new brain MRI and EEG, in February 2021, were unchanged. Brain FDG-PET/MRI revealed slight hypermetabolism of the left amygdala. Anti AMPAR, GABA R, GAD, VGKC and antineuronal antibodies were negative. CSF was normal a part from presence of oligoclonal bands. CSF anti COVID-19 spike protein antibodies assay was negative.

Conclusions:: A diagnosis of autoimmune encephalitis with unknown antibodies was made and possible association with COVID-19 infection was deemed unlikely.
Background and Aims:: Rheumatoid arthritis is a chronic systemic autoimmune disorder, leading to joints` inflammation and their destruction. Extra articular manifestations are described in about 20% of patients with rheumatoid arthritis. Rheumatoid meningitis (RM) is a very rare severe complication with CNS involvement. The severity and lethality of rheumatoid meningitis is determined by its challenging diagnosing due to multiplicity of clinical symptoms and takes 60% by Mélanie Trabelsi et al, in spite of treatment. The purpose of this case study is to spread the social awareness about rheumatoid meningitis.

Methods:: Contrast enhancing brain MRI, blood tests.

Results::
A young woman of 22 years old admitted to the outpatient clinic complaining of a 2-day history of the unilateral neck and occipital area headache on the right. The pain was associated with photophobia, subfebrile temperature and arthralgia. Physical examination: mildly positive meningeal signs, brisk tendon reflexes. Head magnetic resonance imaging (MRI) and computed tomography scans were normal. Blood tests: red blood cells 4.07 x 10^12/l, ESR 58 mm per hour, thrombocytes of 504x10^9/l, white blood cells 11.29, CRP 23.73 mg/l, ASO 265 IU/ml, rheumatoid factor 14.73 mg/l, other blood tests were
unremarkable. Gadolinium-enhanced head MRI showed right hemisphere pachymeningeal and leptomeningeal enhancement. The patient was diagnosed with: Aseptic rheumatoid meningitis. The treatment included prednisolone with complete improvement.

**Conclusions:** We present a case of unilateral RM, an extremely rare neurological complication of first diagnosed rheumatoid arthritis. The improvement was noted after two week of per os treatment with 8 mg/day prednisolone.
PARANEOPLASTIC AUTOIMMUNE AUTONOMIC GANGLIONOPATHY AS A DEBUT OF A BLADDER UROTHELIAL CARCINOMA: A CASE REPORT

Carmen De Rojas Leal¹, Olmo Leon Plaza¹, Jose Maria Lage Sanchez², Omar Hamad-Cueto³, Javier Pinel Rios⁴
¹Hospital Universitario Virgen de la Victoria, Neurology, Málaga, Spain, ²Hospital Universitario Virgen de la Victoria, Urology, Málaga, Spain, ³HOSPITAL CLÍNICO UNIVERSITARIO VIRGEN VICTORIA, Neurología, MÁLAGA, Spain, ⁴Hospital Virgen de la Victoria, Neurology, Malaga, Spain

Background and Aims:: Autoimmune autonomic ganglionopathy (AAG) is a rare immune-mediated disorder associated with anti-α3 subunit of the ganglionic-type nicotinic acetylcholine receptor (anti-gAChRα3) antibodies, which bind to the acetylcholine-receptor in autonomic ganglia (parasympathetic and sympathetic), leading to autonomic failure. This disorder is mostly associated with viral infections, but it can also be associated with systemic malignancies. Here, we report the first case of a paraneoplastic autonomic ganglionopathy as a debut of a bladder urothelial carcinoma.

Methods:: Case report.

Results:: A 44-year-old man, without medical history of interest, went to the emergency department because of blurry vision, eye and mouth dryness, constipation and orthostatic hypotension, for the last 2 weeks. A drop in blood pressure (BP) upon standing was documented [100/60 mmHg (decubitus) vs. 80/50 mmHg (sitting)]. Blood tests, chest x-ray, brain-MRI, cerebrospinal fluid and electroneuronography were unremarkable. Electrochemical skin conductances were decreased in the feet. Serological examinations were positive for anti-gAChRα3 antibodies. A full-body computed tomography showed a bladder tumor, which was surgical treated by transurethral bladder resection. The pathology showed a low grade non muscle invasive bladder urothelial papillary carcinoma. After tumor resection and treatment with intravenous immunoglobulins and corticosteroids, the patient gradually improved.

Conclusions:: Subacute panautonomic failure can be the debut of systemic malignancies. As far as we know, this is the first case report showing a paraneoplastic autonomic ganglionopathy as debut of bladder urothelial carcinoma. This case highlights the importance of a systemic study to rule out the presence of cancer when AAG is present.
INFECTIOUS LESIONS OF THE INSULA ASSOCIATED WITH EXTREME SINUS BRADYCARDIA: REPORT OF THREE CASES

Carmen De Rojas Leal1, Ignacio Del Pino De Laguno2, Pablo González Redondo3, Omar Hamad-Cueto4, Lina Carazo Barrios5, Virginia Delgado Gil6
1Hospital universitario Virgen de la Victoria, Neurology, Málaga, Spain, 2Hospital Universitario Virgen de la Victoria, Neurology, Málaga, Spain, 3Hospital Virgen de la Victoria de Málaga, Internal Medicine, Málaga, Spain, 4HOSPITAL CLINICO UNIVERSITARIO VIRGEN VICTORIA, Neurología, MÁLAGA, Spain, 5University Hospital Virgen de la Victoria, Neurology, Málaga, Spain, 6HOSPITAL VIRGEN DE LA VICTORIA, Neurología, Málaga, Spain

Background and Aims:: The relationship between ischemic lesions in the insula and alterations of the heart rhythm due to autonomic nervous system dysfunction is known. However, the association with infectious (viral or bacterial) lesions has been poorly reported in the literature. Here, we described 3 cases of sinus bradycardia associated with infectious lesion of the insula.

Methods:: Case series.

Results:: Case 1: A 36-year-old man went to the emergency department because of 6 repetitive transient-losses-of-consciousness on the same day along with headache. During a new syncope, a sinus bradycardia at 35 bpm with asystole (> 5 seconds) was documented, and a transitional pacemaker was implanted. Due to fever, a lumbar puncture was performed, showing herpes-simplex-virus-DNA. MRI showed linear uptake in the right insula. After acyclovir treatment, the electrocardiographic alterations disappeared. Case 2: A 54 year-old man went to the emergency department because of headache and fever and a sinus bradycardia of 40 bpm was documented. A lumbar puncture showed herpes-simplex-virus-DNA. MRI showed linear uptake in the right insula. After acyclovir and foscarnet treatment, the heart rate returned to normal. Case 3: A 54 year-old woman, diagnosed with acute pneumococcal meningitis caused by bilateral otitis media, developed a bradycardia of 33 bpm, without any other alteration in ECG. Echocardiogram was normal. A brain MRI showed purulent material in the context of cerebritis at right insular level. After antibiotic treatment, the bradycardia disappeared.

Conclusions:: Clinicians should be aware that viral or bacterial lesions in the insula could lead to cardiac arrhythmia due to central autonomic nervous system dysfunction.
RELATIONSHIPS BETWEEN RESTING AND REFLEXIVE MEASURES OF HEART RATE VARIABILITY (HRV)

Patrick Kwon¹, Steven Lawrence², Bridget Mueller³, Jessica Robinson-Papp³
¹New York University, Neurology, Brooklyn, United States of America, ²Columbia University, Mailman School Of Public Health, New York, United States of America, ³Mount Sinai School of Medicine, Neurology, New York, United States of America

Background and Aims:: Resting HRV is an important diagnostic and prognostic tool in the evaluation of autonomic dysfunction. Resting and reflexive HRV are markers of the autonomic nervous system, however, their relationship has largely been described only in healthy and diabetic patients. This relationship has not been explored in patients with neurologic disease or in medically complex patients. This study aims to investigate the demographic, medical, neurologic, and autonomic correlates of resting HRV in order to further understand factors that may be considered potential confounders in studies of resting HRV.

Methods:: In this retrospective study of a diverse, urban population (50.2% female, 45% HIV+, median age 50 (IQR 41,57)), results from autonomic function testing (AFT) of 209 patients were analyzed.

Results:: Moderate correlation was found between both root-mean square of differences of successive RR intervals (rMSSD) and percent of differences of adjacent RR intervals >50ms (pNN50) and heart rate during deep breathing (HRDB) (r=.53, p<0.0005), Valsalva ratio (VR) (r=.45, p<0.0005), and age (r=-.25, p<0.0005). No correlation was found between pNN50/rMSSD and the motor portion of the Unified Parkinson’s Disease Rating Scale (m-UPDRS). pNN50 was significantly different in patients with and without diabetes mellitus (DM), hypertension (HTN), distal sensory polyneuropathy (DSP), chronic obstructive pulmonary disease (COPD), and kidney disease (p<0.05).

Conclusions:: Resting HRV is positively correlated with reflexive HRV and negatively correlated with age; DM, HTN, DSP, COPD and kidney disease are associated with less heart rate variability and are potential confounders in studies of resting HRV.
Background and Aims:: Objective: To describe a case of Harlequin syndrome in a Movement Disorder Clinic in El Salvador. Background: Harlequin syndrome is a rare dysautonomic disorder characterized by asymmetric facial sweating and flushing in response to heat and exercise.

Methods:: We performed a clinical evaluation and open application of OnabotulinumtoxinA with scheme for the treatment of Harlequin syndrome by a Movement Disorders specialist.

Results:: A 47-year-old female with a 3-year history of episodes of profuse sweating and flushing on the right side of the face triggered by heat, sun exposure and exercise and episodic migraine since childhood (5 episodes per month), with chronic use of over-the-counter medications. Brain MRI was normal. Four cycles of 100 units of OnabotulinumtoxinA were applied to the right hemi face, presenting an 80% improvement in hyperhidrosis and a 90% improvement in migraine episodes and significant reduction in pain medication use. Onset of therapeutic effect was at 7 days, and duration of the maximum therapeutic effect was at 5 months.

Conclusions:: In our patient, OnabotulinumtoxinA was effective in improving unilateral flushing and facial hyperhidrosis and showed a preventive therapeutic effect in episodic migraine.
HIGH THROUGHPUT METHOD TO CLEAN, AND ITERATIVELY FILTER RAW ECG DATA USING OPEN SOURCE SOFTWARE

Steven Lawrence¹, Jessica Robinson-Papp², Patrick Kwon³
¹Columbia University Mailman School of Public Health, Biostatistics, New York, United States of America, ²Mount Sinai School of Medicine, Neurology, New York, United States of America, ³New York University, Neurology, Brooklyn, United States of America

Methods:: Using window filters, an iterative process was used to filter each heart rate (HR). Likely artifactual HRs are removed (40 > HR > 180 & HR > 10% mean previous 50 beats). The Hampel filter removes HRs > 4 median absolute deviations (MAD) in a 5-beat window. Smoothing splines were used to interpolation for time analysis measures. We developed and tested the package using patient HRV data (n= 334).

Results:: Following processing with the package <3% of the HR data warranted any manual edits. RMSSD was reduced by ~38% on average and pNN50 by ~9% after filtering. Efficient use of iterative filtering was approximately 6 iterations.

Conclusions:: The open-source “tidyrhrv” package helps to automate the calculation of HRV markers from raw ECG, a process which is otherwise expensive and/or time consuming for large datasets.
Background and Aims:: Patients with primary neurogenic disorders such as pure autonomic failure or multiple system atrophy may present first with cardiocirculatory symptoms such as orthostatic intolerance or fluctuations in heart rate with symptomatic tachycardia. It is therefore clinically important to identify such patients since circulatory manifestations are only one of a series of symptoms resulting from autonomic dysfunction in various organ systems. These patients need a multimodal diagnostic and therapeutic approach and should undergo extensive evaluation in a specialized autonomic nervous system (ANS) outpatient unit.

Methods:: Based on a clinical case presentation, the present review summarizes the diagnostic and therapeutic approach to key cardiovascular symptoms of primary autonomic disorders, and their neurologic work-up in a specialized autonomic function lab.

Results:: The combined neuro and cardio workup in the presented case revealed the diagnosis of PAF with baroreflex failure including OH and supine arterial hypertension, a diminished heart rate variability; quantitative sensibility testing revealed evidence of small fibre neuropathy; and norepinephrine plasma levels were very low. Surprisingly, sudomotor nerve function was normal, despite of clinically severe impairment of sweating.

Conclusions:: Thanks to an increased awareness for symptoms and complaints of autonomic nervous failure and a careful diagnostic workup, even rare neurogenic causes of OI as pure autonomic failure can be detected. The early consideration of specialized neurological and autonomic diagnostics may accelerate the otherwise prolonged and sometimes hopeless search for the origin of OI in patients with multifaced complaints of the ANS.
COMPOSITE AUTONOMIC SYMPTOM SCORE 31: LINGUISTIC VALIDATION FOR RUSSIAN-SPEAKING POPULATION

Dmitry Zhuravlev¹, Anna Gersamiya², Marina Lebedeva¹,³, Dmitry Tumurov¹, Alexander Yakovlev¹,⁴, Mikhail Zinchuk², Alla Guekht⁵,⁶
¹Moscow Research and Clinical Center for Neuropsychiatry, Neurology, Moscow, Russian Federation, ²Moscow Research and Clinical Center for Neuropsychiatry, Suicide Research And Prevention, Moscow, Russian Federation, ³Institute of General Pathology and Pathophysiology, Pathophysiology, Moscow, Russian Federation, ⁴Institute of Higher Nervous Activity and Neurophysiology of RAS (IHNA&NPh RAS), Laboratory Of Functional Biochemistry Of The Nervous System, Moscow, Russian Federation, ⁵Moscow Research and Clinical Center for Neuropsychiatry, Neuropsychiatry, Moscow, Russian Federation, ⁶Pirogov Russian National Research Medical University, Neurology, Moscow, Russian Federation

Background and Aims:: Reliable assessment of the autonomic symptoms severity is crucial for clinical and academic neurology. Composite autonomic symptom score 31 (COMPASS-31) (Sletten et al. Mayo Clin Proc 2012;87:1196-1201) was translated in many languages. Still, it did not have a validated translation into the Russian language. We aimed to provide linguistic validation of the Russian translation of COMPASS-31.

Methods:: After receiving permission from Dr. Wolfgang Singer and approval from the local ethics committee, we provided appropriate procedure of translation and back translation of COMPASS-31 into Russian. Five hundred thirteen healthy volunteers (166 males, median age 34 years with range 18-69 years) completed COMPASS-31 online. To identify domains of questions and assess their internal consistency, we used exploratory factor analysis with orthogonal rotation and calculated Cronbach alpha-coefficient.

Results:: Factor analysis revealed 9 domains of questions (with the factor loading range 0.477-0.948) that could be combined in originally proposed 6 domains with good internal consistency (Cronbach alpha-coefficient range 0.737-0.931) except for secretomotor domain (Cronbach alpha-coefficient 0.545). Secretomotor domain contained the question regarding sudomotor dysfunction that did not fit any domain but was kept due to its clinical significance as in the original version.

Conclusions:: Our study validated consistency of translated COMPASS-31 for Russian-speaking population that was similar to the original English version of the score. We provided Russian version of COMPASS-31 for clinical and scientific use. Acknowledgement: We are sincerely grateful to Professor Max Hilz (Erlangen, Germany) for the guidance regarding this work.
THE SYSTOLIC TO DIASTOLIC PRESSURE RATIO IN NON-DIPPING ESSENTIAL HYPERTENSION PATIENTS

Andrea Bassi¹, Marco Iosa², Francesco Ruggiero³, Laura Serra⁴, Giulia Bechi Gabrielli⁴, Marco Bozzali⁵,⁶
¹Santa Lucia Foundation IRCCS, Department Of Clinical And Behavioural Neurology, Rome, Italy, ²Sapienza University of Rome, Department Of Psychology, Rome, Italy, ³University of Rome "Foro Italico", Contract Professor, Rome, Italy, ⁴IRCCS Fondazione Santa Lucia, Neuroimaging Laboratory, Rome, Italy, ⁵University of Torino, Department Of Neuroscience “rita Levi Montalcini”, Turin, Italy, ⁶University of Sussex, Department Of Neuroscience, Brighton & Sussex Medical School, Brighton, United Kingdom

Background and Aims:: Nocturnal blood-pressure (BP) decline or dipping is a physiological response in healthy BP-regulation; the lack of this adaptation is frequently observed in patients with essential hypertension (EH) [Chesebro,2020]. Involvement of autonomic dysregulation in EH may result in adrenergic overdrive [Mancia and Grassi,2014; Carthy, 2014]. Heart morphology [Henein, 2011] and systolic to diastolic pressure ratio (SDPR) were previously related to the harmony of the so-called golden ratio (GR=1.618) [Yetkin, 2015]. We aimed here to identify patterns of circadian dysfunction in newly diagnosed patients with EH compared to individuals with normotensive individuals (NIs) by monitoring them with a non-invasive ambulatory blood pressure monitoring (ABPM) system and evaluating their SDPR.

Methods:: Systolic and diastolic BP were monitored for 24 hours (BP lab®, Petr-Telegin) in 14 EH patients and 10 matched NIs, dividing data in awake (day) and sleeping (night) by the actigraph.

Results::

As shown in figure, systolic (p<0.001) and diastolic (p<0.014) pressures were significantly higher in EH patients than NIs in both day and night assessments. In the patient group, SDPR was not significantly different from GR during night and day (p=0.209 and p=0.952). Conversely, in controls, SDPR was significantly lower than GR in day-time (1.52±0.08, p=0.014) but not during night (p=0.695).

Conclusions:: The circadian trend of comparative arterial pressure assessed by SDPR is close to GR in all subjects. However, differently from NIs, patients with EH show a reduced ability to modify their SDPR in day-time (during activities). These findings suggest the importance of monitoring SDPR as a biomarker of autonomic dysfunction.
ZIC-4 ANTIBODIES IN LIMBIC ENCEPHALITIS: A CASE REPORT

Fabiana Colucci1, Filippo De Mattei2, Marinella Clerico1, Giuseppa Jolanda Rosa3, Roberto Ferri4, Marco Ludicello5

1University of Torino, Clinical And Biological Sciences Department, Torino, Italy, 2University of Turin, Als Center, “rita Levi Montalcini” Department Of Neuroscience, Torino, Italy, 3Hospital of Fidenza, Neurology Clinic, University Of Parma, Fidenza, Italy, 4Patologie Neurologiche Specialistiche, AOU San Luigi Gonzaga, Clinical And Neurological Sciences Department, Orbassano, Italy, 5S.S.D. Patologie Neurologiche Specialistiche, AOU San Luigi Gonzaga, Clinical And Neurological Sciences Department, University Of Torino, Orbassano, Italy

Background and Aims:: Limbic encephalitis (LE) is an inflammatory disease involving the brain’s limbic structures. Typical symptoms include memory deficits, behavioral changes, psychosis, and seizures. Frequently, it is associated with antibodies against the central nervous system (CNS). Serum and cerebrospinal fluid tests for anti-LGI1, GABABR, AMPAR, CASPR2, Hu, Ma2, and GAD must be performed, as positive results might underlie a specific tumor. Zic-4 antibodies are more likely linked to cerebellar dysfunction as paraneoplastic form related to small-cell lung cancer (SCLC). We report a case of LE with isolated Zic-4 antibodies positivity. The latter should be included in the ALE antibodies list.

Methods:: A 66-year-old gentleman is admitted with confusion and acute psychosis. Although his past medical history was unremarkable, his sister reported a 2-months history of behavioral disturbances (spending money and anxiety). Over the following weeks, his condition rapidly declined: short-memory deficits, disorientation, hallucination, aggression, and confabulation occurred. Cerebral spinal fluid analysis showed normal 14-3-3 protein levels, and PCR results were negative for the neurotropic viruses. Cerebral MRI and PET were normal. EEG showed diffuse slow activity without epileptic discharge. HIV, syphilis, borreliosis were negative.

Results:: Zic4 antibodies were found in serum; endovenous immunoglobulin therapy ensued with mild clinical improvement. Unlikely, he got a SarCov2 infection needing CPAP treatment. Cytologic pleural spillage exam (shown on chest CT scan) to investigate malignant cells related to SCLC has not yet been performed.

Conclusions:: Zic-4 antibodies have been mainly associated with cerebellar dysfunction. Our findings suggest that LE symptoms should prompt extensive onconeural antibodies screening among with Zic-4.
CERVICAL DISC HERNIATION OR CERVICAL SPONDYLOSIS MAY CAUSE UNILATERAL OR SEGMENTAL ANHIDROSIS: THE DISTRIBUTION OF ANHIDROSIS DEPENDS ON THE SITE OF SPINAL CORD COMPRESSION

Yoko Inukai¹, Satoshi Iwase²
¹Aichi Medical University, Department Of Physiology, Nagakute, Japan, ²Aichi Medical University, Department Of Neurology And Physiology, Nagakute, Japan

Background and Aims:: Some patients with unilateral or segmental anhidrosis have cervical disc herniation or cervical spondylosis. We investigated whether cervical myelopathies by these pathemas were involved in those sweating disorders.

Methods:: We analyzed 14 patients aged 37–74 years with unilateral or segmental anhidrosis in the absence of causative abnormalities other than cervical disc herniation or cervical spondylosis. The patients were exposed to 40°C ambient temperature and examined the total sweat distribution (Minor’s method) and distribution of the total skin temperature by infrared thermography, and performed MRI to confirm the lesion.

Results:: MRI revealed the largest protrusion of the intervertebral disc toward the almost anhidrotic side at the midline (paramedian herniation) significantly (89%) in the patients with unilateral anhidrosis, and area 3 mm lateral to the midline (lateral herniation) to segmental anhidrotic side significantly (100%) in the patients with segmental hemianhidrosis. In 80% of the latter patients, disc protrusion was ipsilateral and corresponded to the segment of
Conclusions: Paramedian herniation of the intervertebral disc might induce unilateral anhidrosis, while lateral herniation might induce segmental anhidrosis. The protruded disc near the midline may compress the sulcal artery and cause hemilateral insufficient peripheral perfusion for the sudomotor pathway. Disc protrusion at the lateral site may compress the sympathetic premotor neuron in the dorsolateral funiculus and spare the upper segments synapsing with spinal segmental interneurons and propriospinal neurons.
projecting to the intermediolateral nucleus. It is necessary to identify the difference in the site of spinal cord compression from patients with motor and sensory disturbances as well.
HAS THE TIME COME FOR GASTROINTESTINAL FUNCTIONAL TESTING TO BE INCLUDED AS PART OF AUTONOMIC NERVOUS SYSTEM TESTING?

Laura Pace¹, James Hemp², Melissa Cortez³, Brent Goodman⁴
¹University of Utah, Center For Genomic Medicine, Salt Lake City, United States of America, ²Metrodora Institute, Research And Development, Salt Lake City, United States of America, ³University of Utah, Neurology, Salt Lake City, United States of America, ⁴Mayo Clinic, Neurology, Scottsdale, United States of America

Background and Aims:: Individuals with autonomic nervous system (ANS) disorders have a high burden of gastrointestinal symptoms. Unfortunately, many of these individuals are diagnosed with functional gastrointestinal disorders without a comprehensive clinical evaluation or an understanding of the underlying pathophysiological mechanism. The ANS regulates all body systems and is responsible for maintaining homeostasis by coordinating responses to physiological processes and perturbations and is integral in controlling functions of the gastrointestinal system.

Methods:: We performed a retrospective analysis of 85 patients that had undergone both quantitative autonomic testing (HUT, Valsalva, HRV to deep breathing, and quantitative sensory testing) along with gastrointestinal motility testing via wireless motility capsule.

Results:: In this cohort 85.6% had a confirmed ANS disorder diagnosed. Of those with an ANS disorder, 82.2% had dysmotility, 78.1% had a mast cell disorder, and 60.3% had all three. 60.3% had dysmotility involving the stomach (44.5% rapid, 54.5% delayed), 35.6% the small intestine (3.8% rapid, 92.6% delayed), 38.4% the colon (25% rapid, 75% delayed), and 38.4% the whole gut (17.9% rapid, 82.1% delayed). While 28.1% had only one region affected, 53.5% had two or more regions affected.

Conclusions:: Given the critical role of the ANS in controlling gastrointestinal functions, it is not surprising that individuals with ANS disorders have high rates of gastrointestinal dysmotility. Additionally, their symptoms often suggest abnormalities beyond alterations in motility and therefore we propose that comprehensive gastrointestinal function testing should be performed as part of an evaluation for ANS disorders when gastrointestinal symptoms are present.
SYMPTOMATIC GASTROINTESTINAL DYSMOTILITY IN AUTONOMIC NEUROPATHY

Jordan Langford¹, Leah Millsap¹, Laura Pace², James Hemp³, Melissa Cortez¹
¹University of Utah, Neurology, Salt Lake City, United States of America, ²University of Utah, Center For Genomic Medicine, Salt Lake City, United States of America, ³University of Utah, Internal Medicine, Salt Lake City, United States of America

Background and Aims:: Autonomic neuropathy (AN) patients frequently experience multi-systemic symptoms, ranging from cardiovascular, urinary, secretory, and gastrointestinal (GI). Further, there is marked heterogeneity among patients, often limiting the yield of conventional diagnostic evaluations. The aim of this study was to describe our single-institution experience with wireless motility capsule (WMC) testing to quantitatively evaluate segmental dysfunction in AN patients with GI symptoms.

Methods:: We utilized an institutional database to identify cases that presented to the University of Utah with undiagnosed GI and autonomic symptoms (2015-2019; n=102). Inclusion criteria: AN diagnosis based on autonomic testing. Of the initial cohort, 27 subjects met inclusion criteria. WMC results were analyzed to identify abnormalities in gastric emptying and small bowel/colonic/global transit times.

Results:: Subjects were predominately female (25/29); aged 17-62 years (median 29). Mean COMPASS-31 score was 54.4, with a mean GI domain score of 15.6. Overall, 25/29 subjects had dysmotility in at least one segment of the GI tract, with a mean of 2.0 segments affected. Of the 14/27 with one or more slow segments on WMC, 13 reported symptoms of constipation, while all of those with one or more rapid segments (8/8) reported symptoms of diarrhea. Of subjects with abnormal sudomotor function, 11/20 showed corresponding anatomical segmental dysfunction in the GI tract on WMC testing.

Conclusions:: In this cohort of AN patients with prominent undiagnosed GI symptoms, 86% had abnormal WMC testing. These findings establish GI dysmotility as a quantifiable feature of AN with GI symptoms, and merit future studies to evaluate underlying pathophysiology.
SEASONAL VARIATION OF BLOOD PRESSURE AND ORTHOSTATIC INTOLERANCE IN PARKINSON'S DISEASE

Yuki Niimi¹, Yasuhiro Hasegawa², Tomoko Yamana¹, Takao Yagi¹, Tetsuro Yanagisawa¹, Kazuo Mano³, Yasuo Koike²
¹Tsushima City Hospital, Neurology, Tsushima, Japan, ²Chubu University, College Of Life And Health Science, Kasugai, Japan, ³Japanese Red Cross Nagoya Daiichi Hospital, Neurology, Nagoya, Japan

Background and Aims:: Patients with Parkinson’s disease (PD) have autonomic dysfunction, for example, orthostatic hypotension (OH). In general, resting blood pressure has seasonal variation and OH may become worsen in summer and ameliorated in winter. It has not yet been studied whether orthostatic intolerance has seasonal changes and it influences on seasonal variation of resting blood pressure in PD. The purpose of this study is to elucidate how orthostatic intolerance in PD is influenced by climatic differences.

Methods:: Subjects were 54 (29 men and 25 women) PD patients with age of 76 ± 6 yrs, disease duration of 4.3 ± 2.6 yrs, and Hoehn-Yahr’s stage of 3.0 ± 0.6 (mean ± SD). Once at a season (spring: Mar.-May, summer: June-Aug., autumn: Sept.-Nov., winter: Dec.-Feb.) in a year, they were asked to visit the outpatient clinic, where they were required to sit on chair for 5 min, and then to stand-up actively within 5 s. The intermittent systolic blood pressure (SBP), diastolic blood pressure (DBP) were measured.

Results:: The resting SBP and DBP were higher in winter than in summer. The SBP decreased by standing in all seasons. The DBP decreased by standing only in summer and the ΔDBP was larger in summer than in other seasons. The ΔSBP and ΔDBP were not correlated the maximum-minimum difference (MMD) of SBP and DBP.

Conclusions:: Seasonal changes in sympathetic outflow to the periphery could be responsible for this orthostatic intolerance in summer, but it could not influence seasonal variation of resting blood pressure in PD.
SENSORY CHANGES IN POSTURAL TACHYCARDIA SYNDROME COMPARED TO CHRONIC MIGRAINE

Leah Millsap¹, Kevin Brennan², Melissa Cortez³
¹University of Utah, Department Of Neurology, Salt Lake City, United States of America, ²University of Utah Neurology, Neurology, Salt Lake City, United States of America, ³University of Utah, Neurology, Salt Lake City, United States of America

Background and Aims:: Postural tachycardia syndrome (PoTS) and migraine frequently present together in clinical practice. Up to 90% of PoTS patients report headaches of some kind, with migrainous headaches as the most widely recognized primary headache in this cohort. Given this comorbidity, pathophysiological interaction is possible, which could identify key features of disease pathophysiology and targeted treatment interventions. We hypothesized that migrainous and non-migrainous PoTS subjects would show features of central sensitization, including allodynia and photophobia.

Methods:: Eighty patients (30 PoTS, 30 chronic migraine [CM], and 20 non-headache healthy controls [NH]) were evaluated via tilt table testing, sensory sensitivity thresholds, and questionnaire to evaluate headache burden and associated symptoms. Sensory thresholds and clinical characteristics were compared across groups, including PoTS sub-group analysis based on headache phenotype.

Results:: Sensory sensitivity thresholds were significantly lower and symptom scores were higher in PoTS and CM groups compared to controls. Interestingly, however, the expression patterns differed between PoTS and CM, with reduced pain thresholds in the forearm expressed most prominently in PoTS subjects, compared to both periorbital and forearm lower thresholds in CM. Light sensitivity thresholds were significantly lower in PoTS than either CM or NH.

Conclusions:: These distinguishing aspects of PoTS disease burden reveal an underappreciated aspect of this syndrome, and suggest network sensitization similar to, but separable from, that of migraine. The finding of non-trigeminally-mediated sensitization in PoTS supports prior reports of central sensitization, while providing further evidence that PoTS might be considered a multisensory gain disorder, with distinct physiological manifestations.
Background and Aims:: Meningitis is the inflammation of tissues which covers brain & spinal cord. Thus lactyl stearate coupled liposomes bearing rifampicin (highly lipophilic) is used for effective management of meningitis. Brain drug targeting brings a healthy skepticism to the study of the BBB, which is the most frustrating obstacle for pharmacologists wishing to find treatments for brain disorders.

Methods:: Synthesized Lactyl stearate was used to prepare liposomes bearing rifampicin by Lipid cast film method. Formulations were characterized for vesicle shape by Transmission Electron Microscopy(TEM), vesicle size, drug entrapment efficiency, in-vitro drug release. The in-vivo studies the drug distribution in various organs and blood of albino rats was assessed after I.V. administration. The quantitative uptake of the formulations by the brain in albino rats was assessed by fluorescent microscopy.

Results:: The % encapsulation efficiency was 41% & 34% in uncoupled & coupled liposomes. Brain uptake was increased about 2-3 times in case of uncoupled liposomes and plain drug. Accumulation was increased about 6-8 times with coupled liposomes in comparison to uncoupled and about 10-12 times higher compared to drug solution.

Conclusions:: Fluorescence study indicates that the preparation is crossing basal carotid system & accessing the nervous system. This delivery system not only increased the brain uptake of the drug but it also reduces the administered dose and toxic effect of the drug. Thus, Lactyl stearate coupled liposomes effectively delivers the drug to the brain and has great potential for brain targeting.
PUPIL INVOLVEMENT IN PATIENTS WITH DIABETES-ASSOCIATED OCULOMOTOR NERVE PALSY

Emna Smaoui, Khadija Sonda Moalla, Nouha Farhat, Salma Sakka, Nadia Bouattour, Sawsan Daoud, Olfa Hdiji, Mariem Damak, Chokri Mhiri

1 CHU habib bourguiba Sfax, Neurology, sfax, Tunisia, 2 Universal Hospital Habib Bourguiba, Neurology, SFAX, Tunisia, 3 Universal Hospital Habib Bourguiba, Neurology, sfax, Tunisia, 4 Habib Bourguiba university hospital, Neurology, Sfax, Tunisia

Background and Aims:: Introduction: Diabetics are predisposed to acute mononeuropathies, including oculomotor nerves. It was noted that pupil involvement in diabetes occurs more often than has been previously recognized.

Methods:: A 55-year-old man with a medical history of poorly controlled diabetes and hypertension presented with a non-fluctuating droopy eyelid with diplopia. Ophthalmo logical exam revealed palsy of the right oculomotor nerve with bilateral mydriasis and an abolished light reflex. Dilated fundus exam showed non-proliferative diabetic retinopathy. Neurological exam revealed an associated proprioceptive dysfunction. Cerebral MRI and MRA showed no pathological findings, no aneurysmal compression of the oculomotor nerve was found. The examination of cerebrospinal fluid was normal. Laboratory tests including thyroid hormones, immunologic and infectious testing were normal. ENMG showed length dependent neuropathy. One week later, mydriasis and ptosis regressed. Light reflex became normal.

Results:: Pupillary involvement in diabetes-associated oculomotor nerve palsy occurs in about 1/4th of all cases. Dysfunction of the parasympathetic nervous system causes relative mydriasis and diminished constriction to light. This condition can explain the pupillary involvement in diabetes. Certain pupil characteristics like an incomplete pupillary involvement and anisocoria < 2 mm may help to distinguish diabetic from aneurysmal (compressive) injury of the oculomotor nerve. Imaging should be considered when patients present with additional cranial nerve palsy or neurological abnormalities or where pupil shows characteristics of a compressive lesion.

Conclusions:: Abnormal pupillary dynamics in diabetes is suggestive of an autonomic neuropathy. It progresses with the severity of retinopathy. Mydriasis is quite rare but imaging should be considered in order to rule out other differential diagnosis.
Background and Aims:: Paediatric acquired demyelinating syndromes (ADS) represent a group of clinical conditions caused by inflammatory processes in the central nervous system (CNS). An early differential diagnosis between a monophasic and a chronic or relapsing form is crucial. Main treatments available for acute attacks are steroids and intravenous immunoglobulins (IVIg), while more recently there is increasing evidence of efficacy of disease-modifying therapies (DMTs) for chronic forms, including periodic cycle of IVIg, showing that an early treatment is fundamental to avoid disability accrual.

Methods:: We describe the case of a 10-year-old girl with a diagnosis of autism spectrum disorder presenting with three attacks of encephalopathy, seizures and focal neurological signs. Brain MRI, performed at different times, showed bilateral, cortical-subcortical, supra-infratentorial demyelinating lesions, compatible with multiphasic acute disseminated encephalomyelitis (ADEM). Anti-MOG antibodies were found in the serum, while anti-AQP4 were negative. The patient was treated with steroids and monthly cycles of IVIg with good clinical and radiological response and no more relapses; however, serum anti-MOG antibodies positivity persisted for more than 6 months.

Results:: The features of disease onset, the clinical and radiological progression of the patient, and the response to steroids and IVIg cycles suggest a form of ADS of multiphasic ADEM-like presentation with persistent anti-MOG antibodies positivity, compatible with a MOG Antibody Disease (MOGAD).

Conclusions:: The unusual case suggests the need of a multidisciplinary approach (neurologists, neuropediatricians, neuro-radiologists) and a strict clinical and radiological follow up of these patients. We here provide a flow-chart of clinical management by reviewing existing literature on ADS in pediatric
DYGGVE-MELCHIOR-CLAUSEN SYNDROME: A MUCOPOLYSACCHARIDOSIS MIMIC

Bharath Patil1, Jasmine Singh2
1Government Medical College and Hospital Chandigarh, Orthopaedics, CHANDIGARH, India, 2Government Medical College and Hospital, Chandigarh, Pediatrics, Chandigarh, India

Background and Aims:: Dyggve–Melchior–Clausen (DMC) syndrome is a rare, autosomal recessive, progressive Spondylo-epi-metaphyseal dysplasia caused by mutations in Dym gene mapped on chromosome 18q12-12. Due to significant differences in prognosis and treatment, it is important to ascertain the diagnosis in such cases.

Methods:: We present a 9-year old child who was brought with complaints of intellectual disability and severe bony deformities. Child was born out of consanguineous marriage at full term. On examination, child had short stature and microcephaly along with coarse facies, short forehead, prominent ears, thick lips and macrognathia. A short-neck and deformed chest was present with pectus carinatum and flaring of costal margins. Rhizomelic shortening of upper limbs was noted. Genu valgum; with fixed flexion deformity in both lower limbs. Neurological assessment revealed profound mental retardation with a social age of 11.3 months according to VSMS (Vineland Social Maturity Scale). MRI brain showed thinning of corpus callosum. Considering a possibility of Mucopolysaccharodosis, urinary glycosaminoglycan screen was done which was negative. Radiography revealed widening of anterior ends of ribs, dorsolumbar spine showed evidence of platyspondyly with double hump deformity, hypoplastic ilium with widened acetabulum and lacy iliac crest were spotted on radiographs of pelvis. Femoral epiphyseal flattening and compression with metaphyseal splaying were noted.(Figure 1-3)

Results:: Hence, in view of mental retardation with radiological features and absence of urinary glycosaminoglycans with a history of consanguinity consistent with autosomal recessive nature of the disease, a diagnosis of DMC syndrome was established for this child. Gene studies could not be done due to non-affordability

Conclusions:: Rates of survival with DMC syndrome are better however the quality of life is limited by bony significant bony deformities.
ADRENOCORTICOTROPIC HORMONE INDUCED STATUS DYSTONICUS: CAUTION ADVISED

Jasmine Singh¹, Roosy Aulakh², Jaspreet Kaur³
¹Government Medical College and Hospital, Chandigarh, Pediatrics, Chandigarh, India, ²Government Medical College and Hospital, Chandigarh, Pediatrics, Chandigarh, India, ³Government Medical College and Hospital, Chandigarh, General Medicine, Chandigarh, India

Background and Aims:: Dystonia is a movement disorder characterized by involuntary sustained or intermittent muscle contraction causing repetitive twisting movements and abnormal postures. The localization of dystonia is dysfunctional interactions of basal ganglia, cerebellum, thalamus, cerebral cortex and brainstem. Status dystonicus, or dystonic storm, is a life threatening emergency marked by development of increasingly frequent or continuous severe episodes of generalized dystonic spasms. The etiology of status dystonicus has not been clearly. We hereby present a case report of a child with WS who went on to develop status dystonicus following intramuscular ACTH injection.

Methods:: Eleven month old male child presented with complaints of flexor spasms for 2 months. There was history of birth asphyxia followed by mechanical ventilation for a period of 5 days. Child had global developmental delay with MRI brain showing sequelae of perinatal hypoxic insult. The diagnosis of WS was confirmed by EEG which showed hypsarrhythmias. Intramuscular ACTH was added and oral trihexyphenidyl was started for dystonia. On day 7 of ACTH, child developed frequent ophisthotonic posturing.

Results:: Management protocol for grade 4 status dystonicus was initiated and child was shifted to Pediatric Intensive Care Unit. The dystonias gradually responded over the next week and child was slowly weaned off sedatives.

Conclusions:: Administration of N terminal of ACTH in rat locus coeruleus has been shown to produce human dystonia like movement and abnormal posturing. Effectiveness of anticholinergics against dystonia has been attributed to suppression of ACTH released caused by them.
INVESTIGATION OF THE OCCUPATIONAL PERFORMANCE OF THE CHILDREN WITH NEURODEVELOPMENTAL DISABILITIES DURING THE COVID-19 PANDEMIC

Gokcen Akyurek, Yasemin Turgut
Hacettepe University Faculty of Health Sciences, Occupational Therapy, Ankara, Turkey

Background and Aims:: All individuals, including children, had difficulties in fulfilling their roles, and children with neurodevelopmental disorders faced many difficulties in attending therapies since the pandemic began. This study was aimed to investigate the change in the occupational performance of the children with neurodevelopmental disabilities during the Covid-19 pandemic.

Methods:: Children aged 6-12 years with neurodevelopmental disorders and their caregivers (n=40) were included in the study from Hacettepe University Faculty of Health Sciences, Department of Occupational Therapy, pediatric unit. After the pandemic, the children with neurodevelopmental disabilities who came to the clinic for occupational therapy were diluted and some of them continued face-to-face therapies, while others continued their therapy with the telerehabilitation method. The Canadian Occupational Performance Measure (COPM) was applied to caregivers twice, in March 2020 and March 2021. Wilcoxon test was used for analysis.

Results:: Even though the change in occupational performance was clinically significant in children who received therapy face-to-face, but there was no statistically significant change in occupational performances with either method (p>0.05).

Conclusions:: According to the results of the study, there was no significant change found in the occupational performance (performance and satisfaction) scores during the pandemic. The reason may have been participants’ desires and situations to continue the therapies were affected negatively and the level of anxiety of families was increased.
THE EFFECT OF OCCUPATIONAL THERAPY HOME INTERVENTION ON ORAL SENSORY PROCESSING AND NUTRITION PROBLEMS IN CHILDREN WITH ORAL HYPERSENSITIVE DOWN SYNDROME

Gulsah Zengin, Gokcen Akyurek
Hacettepe University Faculty of Health Sciences, Occupational Therapy, Ankara, Turkey

Background and Aims:: This study aimed to investigate the effect of home program on oral sensory processing and nutritional difficulties in children with oral hypersensitive Down Syndrome.

Methods:: The study included a total of 36 children; 18 oral hypersensitive Down Syndrome between the age 3-8 and 18 healthy children. Oral sensory processing of these children were determined by Dunn Sensory Profile (DSP), nutritional difficulties were determined by Screening Tool of Feeding Problems (STEP). All of the children underwent routine occupational therapy (sensory integration) and 10 of them were provided an extra home program on oral sensory processing. The home program was controlled with a schedule. Children were evaluated twice before and after the intervention.

Results:: When the participants were examined, oral sensory processing and nutritional difficulties were observed. Significant improvements were found in the DSP’s oral sensory process subtest and STEP scores after occupational therapy and home program group (p <0.05).

Conclusions:: The benefits of sensory integration-based occupational therapy interventions in children with Down syndrome are known. In addition, these children may have oral sensory processing and nutritional difficulties. It was observed that occupational therapy and home programs for this purpose reduced significantly oral sensory processing and nutrition problems. Therefore, it is important to support occupational therapy intervention programs with home programs in children with down syndrome who affected by oral sensory processing.
THE EFFECT OF BIMANUEL TRAINING ON OCCUPATIONAL PERFORMANCES IN A CHILD WITH ISOLATED MIRROR MOVEMENT DISORDER: A CASE STUDY

Gokcen Akyurek, Gulsah Zengin
Hacettepe University Faculty of Health Sciences, Occupational Therapy, Ankara, Turkey

Background and Aims:: Mirror movements disorders (MMD) are defined as involuntary movements of the contralateral homologous extremities during voluntary movements of one side. Mirror movements were reported with many developmental defects, diseases, or autosomal dominant and autosomal recessive inherited and no certain reason displayed types. The aim of this study was to investigate the effect of occupational therapy on occupational performance in a child with MMD.

Methods:: A child aged 15 years with MMD was admitted to the study. To evaluate occupational performance, the Canadian Occupational Performance Measure (COPM) was applied. Occupations that are considered to be important for the child are determined as written work, manipulation movement, eating and drinking, and functional communication respectively. Activities to improve bimanual and social skills for the occupational therapy program seemed appropriate. During the intervention, selected activities were conducted for 12 weeks a day per week for 55 minutes each day.

Results:: As a result of the intervention, the COPM performance score increased from 2 to 6 and the COPM satisfaction score of these activities increased from 1,75 to 5,75. It was seen that occupational therapy including bimanual and social skill activities was effective in increasing the occupational performance of the child.

Conclusions:: The research evidence supports that occupational therapy improves occupational performance and satisfaction in everyday life for children with MMD. Because the knowledge of the clinical aspects of these disorders is insufficient. It is therefore important to understand the impact of occupational therapy and to ensure its quality and accessibility.
ATYPICAL AURAS IN PEDIATRIC MIGRAINE: CLINICAL SERIES AND PATHOPHYSIOLOGICAL CORRELATIONS.

Giovanna Martina Nocera¹, Vincenzo Raielli²
¹University of Palermo, Italy, Child Neuropsychiatry Unit Department Pro.m.i.s.e. “g D’alessandro”, PALERMO, Italy, ²ARNAS Civico Palermo, P.o. Di Cristina - Child Neuropsychiatry Dept, Palermo, Italy

Background and Aims:: Aura is one of the most important symptoms of migraine and “Cortical Spreading Depression (CSD)” has been suggested as the most plausible underlying pathophysiological mechanism. However, recent reports raised doubt against the concept that CSD could account for all presentations of migraine aura. Here, we show a series of atypical paediatric aura hardly explainable by the CSD principles, suggesting partly different pathophysiological mechanisms.

Methods:: We selected retrospectively all clinical records that presented migraines aura that can be considered as atypical on the basis of the following criteria: 1)the spreading wave appears to be not related to the CSD model; 2)the chronological sequence and homunculus are not respected by the sequence and characters of aura symptoms; 3)time intervals between symptoms onset not justified by CSD theory; 4)atypical clinical symptoms not accountable by CSD; 5)atypical correlation with pain onset and pain side.

Results:: We collected 15 cases (5 M/10 F, range age 9-16ys). All subjects underwent EEG and BrainMRI. The subjects were subdivided according to the criteria(see above) why their aura were found to be atypical: Four subjects satisfied the criterion 1; Five the second; Five the third; Five the fourth; one the criterion 5; some children satisfied more than one criterion.

Conclusions:: Our series shows that the current CSD theory cannot fully explain the modalities of the aura presentation in some subjects. Therefore, some aspects need further investigation and reassessment, on the basis of clinical practice. Furthermore, we underline how accurate exploration of the migrainous aura can provide useful insight on pathophysiological aspects.
NODDI DISCLOSES EARLY CHANGES IN THE NORMAL APPEARING WHITE MATTER IN PAEDIATRIC MULTIPLE SCLEROSIS.

Monica Margoni¹, Umberto Villani², Silvia Franciotta¹, Martina Rubin¹, Margherita Nosadini³, Stefano Sartori², Mariaghiulia Anglani², Francesco Causin⁴, Paola Perini¹, Francesca Rinaldi¹, Alessandra Bertoldo², Paolo Gallo¹

¹University of Padua, Department Of Neuroscience, Padova, Italy, ²University of Padua, Department Of Information Engineering, Padova, Italy, ³University of Padua, Department Of Women's And Children's Health, Paediatric Neurology And Neurophysiology Unit, Padova, Italy, ⁴University of Padua, Neuroradiology Unit, Padova, Italy

Background and Aims:: Paediatric-onset multiple sclerosis (PedMS) is characterized by high degree of brain inflammation and rapid accumulation of white and grey matter damage. Abnormalities in the normal appearing white matter (NAWM) and their clinical relevance in PedMS were investigated by Neurite Orientation Dispersion and Density Imaging (NODDI).

Methods:: Eighteen PedMS and 10 age- and sex-matched healthy controls (HC) underwent a 3T brain MRI; clinical disability was assessed through the Expanded Disability Status Scale (EDSS). Individual maps of intracellular volume fraction (ICVF), extracellular volume fraction (ECVF) and orientation dispersion index (ODI) were obtained. Between-group differences in diffusion tensor/NODDI measures were investigated in the corpus callosum (CC), cortico-spinal tract (CST) and posterior thalamic radiation (PTR). Their association with clinical scores were also evaluated.

Results:: Compared to HC, pedMS showed significantly lower ICVF and higher ECVF values in all the WM tracts investigated (p≤0.038). In the PTR, patients showed lower FA (p=0.006) and higher MD (p=0.029). Lower FA and ICVF values in the CC NAWM were associated with a higher CC LV (r=-0.592, p=0.006; r=-0.582, p=0.007, respectively), whereas higher CC NAWM MD and ECVF were associated with higher CC LV (r=0.575, p=0.008; r=0.657, p=0.002). EDSS score positively associated with CC and PTR LV (r=0.471, p=0.049 and r=0.556, p=0.017, respectively), CC NAWM MD (r=0.580, p=0.012) and ODI (r=0.613, p=0.007) and PTR NAWM ODI (r=0.574, p=0.013)

Conclusions:: NODDI disclosed significant microstructural changes in the NAWM of pedMS. Our findings further provide in vivo evidence supporting the hypothesis that inflammatory-triggered neurodegeneration affects MS brain since the biological onset of the disease.
SURVEY OF BRAZILIAN CHILDREN WITH CEREBRAL PALSY: A RETROSPECTIVE STUDY

Matheus Klettenberg¹, Victor Rodrigues², Isadora Cavalcante², Melina Marques², Paulo Correia³, Lisiane Ferreira⁴, Kennea Ayupe⁵

¹Universidade de Brasília, Department Of Pediatrics, BRASÍLIA, Brazil, ²Universidade de Brasília, Department Of Pediatrics, Brasília, Brazil, ³Universidade de Brasília, Faculty Of Medicine, Brasília, Brazil, ⁴Universidade de Brasília, Associate Professor Of The Faculty Of Medicine, Brasilia, Brazil, ⁵Universidade de Brasília, Associate Professor Of The Faculty Of Health Sciences, Brasília, Brazil

Background and Aims:: Cerebral palsy (CP) is known worldwide as the most prevalent cause of motor disability during childhood. In Brazil, there are no epidemiological studies of this population. Thus, with this study we aim to verify the epidemiological data of children and adolescents with CP, followed up at the neuropediatrics outpatient clinic of Brasília University Hospital.

Methods:: This research was approved by the Ethics Research Committee (34383220.9.0000.5558). All medical records of patients attended in the neuropediatrics clinic between 2000 and 2020 were analyzed retrospectively to verify: number of children with CP; clinical type; etiology; associated comorbidities; use of medications. Analysis of the data was attained by descriptive statistics.

Results:: Were analyzed 1199 medical records, of which 119 (9.9%) were of children with CP. The clinical types identified were: 115 (96.6%) spastic, 2 (1.6%) ataxic, 2 (1.6%) dyskinetic. Malformations of the central nervous system (28.6%), hypoxic-ischemic encephalopathy (26.8%), neurogenetic syndromes (10.9%), prematurity (7.5%) represented the main etiologies. Among children with CP, 59.6% had epilepsy, 26.8% showed neurodevelopmental disorders and 12.6% presented endocrinopathies. Regarding medications, approximately 40% of children used antiepileptic, 8.4% psychostimulants and 8.4% baclofen.

Conclusions:: The prevalence data obtained on clinical types and etiologies do not correspond to those observed in the world literature. This discordance may be justified due to subdiagnosis of CP in Brazil and the lack of data in the medical records. More studies are needed to identify the profile of Brazilian children with CP in order to adapt the therapeutic planning to this population.
SPEECH DYSORDERS IN CHILDREN WITH COGNITIVE EPILEPTIFORM DISINTEGRATION AGED 2-10

Rimma Gamirova¹, Elena Gorobets², Ruzalina Shaykhutdinova², Tatyana Bolshakova², Layla Mardieva⁴, Liliya Safiullina⁴
¹Kazan Federal University, Laboratory Of Clinical Linguistics, Department Of Fundamental Basis Of Clinical Medicine, Kazan, Russian Federation, ²Kazan Federal University, Laboratory Of Clinical Linguistics, Kazan, Russian Federation, ³A.Yu.Ratner’s Pediatric City Hospital №8, Department Of Pediatric Neurology, Kazan, Russian Federation, ⁴Kazan Federal University, Department Of Applied And Experimental Linguistics, Kazan, Russian Federation

Background and Aims:: Cognitive epileptiform disintegration (CED) is a symptomatic complex of acquired cognitive disorders in children associated with severe epileptiform activity on the EEG in the absence of epileptic seizures. It is one of the reasons for developmental dysphasia, the cases of which rapidly increase. The aim of the study is to reveal the structure of speech disorders in children with CED.

Methods:: From 2016 till March 2021 we observed 112 children aged 2-10 with CED (76 preschoolers, 36 from primary school). All children passed through neurological examination and video-EEG-monitoring with sleep deprivation. Speech was assessed with reliance on the principles worked out by T.V.Akhutina et al., by 25 specific subtests created at the Laboratory of Clinical linguistics (Kazan Federal University).

Results:: In 97 children (97: 86.6%) we registered speech disorders: total absence of expressive and impressive speech (19: 16.9%); impressive speech disorders (28: 25%); general speech retardation (43: 26.7%); echolalia (31: 27.7%); logorrhea (42: 37.5%); non-communicative speech (23: 20.5%); delayed answers to the questions (16: 14.2%); dyslexia, dysgraphia (28 from 36 schoolchildren/77.7%). 84.5% of children with speech impairment had autism spectrum disorders (ASD) (non-stable response to the name, stereotype behavior, emotional deficit, etc.). In 63.5% there were attention deficit and hyperactivity disorders (ADHD).

Conclusions:: The analysis of speech development in children with CED shows that impressive speech disorders are primary in relation to other types. They are closely connected with ASD and ADHD. This work was supported by the Program of Strategic Academic Leadership of Kazan Federal University.
EPIDEMIOLOGICAL, CLINICAL AND PARA CLINICAL CHARACTERISTICS OF NEURODEGENERATION WITH BRAIN IRON ACCUMULATION IN CHILDHOOD

Khaoula Jemai, Hanene Ben Rhouma, Ichraf Kraoua, Aida Rouissi, Thouraya Ben Youness, Hedia Klaa, Ilhem Ben Youssef Turki
Child and Adolescent Neurology in National Institute Mongi Ben Hmida of Neurology of Tunis, Child And Adolescent Neurology In National Institute Mongi Ben Hmida Of Neurology Of Tunis, tunis, Tunisia

Background and Aims:: Neurodegeneration with brain iron accumulation (NBIA) represents a clinically and genetically heterogeneous group of disorders. The aim of our study is to describe epidemiological, clinical, and paraclinical characteristics of NBIA in children.

Methods:: We conducted a descriptive, retrospective study over 14 years, including patients followed up for NBIA in the department of Child and Adolescent Neurology in National Institute Mongi Ben Hmida of Neurology of Tunis.

Results:: Thirty-nine patients were followed up for NBIA. The sex-ratio M/F was 1.29. Six patients were followed for genetically confirmed Pantothenate-kinase-associated neurodegeneration. The mean age of onset was 4.4 years. Main initial clinical feature was dystonia. MRI revealed the eye of the tiger sign in all cases. Thirty-three patients were diagnosed infantile-neuroaxonal-dystrophy (INAD). The mean age of onset was 14 months. All patients had psychomotor regression, hypotonia, and spastic tetraparesis. MRI showed cerebellar atrophy in all cases. PLA2G6 mutations were found in 17 patients. Two siblings (girl: 16 years, boy: 7 years) were followed for a genetically confirmed Mitochondrial-membrane-protein-associated neurodegeneration (MPAN). They presented with spastic paraparesis and cognitive impairments. MRI showed hypointense signal in the globi pallidi with a T2 hypointense signal in the sub thalamic nuclei in the girl’s case. A 7-year-old boy had a Neuroferritinopathy. He presented with parkinsonism. MRI showed T2 hyperintense signal in the pallidi and the dentates.

Conclusions:: The main characteristics of our study is the predominance of INAD among other NBIA and the possible involvm ent of the subthalamic nuclei MPAN. Larger studies could provide more information about this disease.
NEUROLOGICAL AND NEUROPSYCHOLOGICAL EXAMINATION OF CHILDREN WITH ALALI

Rimma Gamirova¹, Elena Gorobets², Oleg Esin², Ilshat Khayrullin¹, Victor Gorobets², Natalia Budarina², Tatyana Shchuklina³
¹Kazan Federal University, Laboratory Of Clinical Linguistics, Department Of Fundamental Basis Of Clinical Medicine, Kazan, Russian Federation, ²Kazan Federal University, Laboratory Of Clinical Linguistics, Kazan, Russian Federation, ³Kazan Federal University, Department Of Applied And Experimental Linguistics, Kazan, Russian Federation

Background and Aims:: Sensorimotor alalia (SMA) is a disorder of impressive and expressive speech development without the previous period of normal speech according to ICD-10. Neurological/neuropsychological examination of children with SMA helps conduct speech habilitation. The aim of the study is to determine the neurological and neuropsychological specificity in children with SMA.

Methods:: The research included 94 patients aged 3.1–8.0 with SMA, 72 boys (76.6%) and 22 girls (23.4%). Inclusion criterion: SMA. Exclusion criteria: traumatic brain injury, epilepsy, epileptiform cognitive disintegration, neuroinfection, aphasia, hearing impairment, mental retardation, autism spectrum disorders. All children passed neurological examination, neuropsychological (methodology of T.V. Akhutina et al.) and speech assessment (tests worked out at the Laboratory of clinical linguistics (KFU).

Results:: 83(88.2%) patients had microfocal neurological symptoms: diffuse muscle hypotension in 69/94(73.4%), motor problems – 42/94(44.6%), coordination – 36/94(38.3%), pyramidal symptomatology in the lower limbs – 22/94(23.4%), gait with internal rotation of stop socks – 12/94(12.8%), non-progressive moderate hydrocephalic syndrome – 9/94(9.5%), apraxia elements – 8/94(8.5%), unstable convergent strabismus – 3/94(3.1%), hypersalivation 3/94(3.1%), pseudobulbar syndrome – 2/94(2.1%), eye slits asymmetry – 1/94(1%). 83(88.2%) patients had neuropsychological specificity: deficiency of executive functions – 44/94 (46.8%), attention deficit – 43/94(45.7%), echolalia – 36/94(38.3%), kinesthetic processing deficiency – 22/94(23%), visual-spatial gnosis deficiency – 18/94(19.1%), lack of energy supply to the brain –13/94 (13.9%).

Conclusions:: The majority of children with SMA had deficiency of executive functions, attention deficit and a tendency to echolalia, diffuse neurological micro-focal symptoms, and frontal-cerebellar symptoms. This work was supported by the Program of Strategic Academic Leadership of Kazan Federal University.
Background and Aims:: Deficiency of adenosine deaminase type 2 (DADA2) is a rare monogenic vasculitis syndrome caused by mutations in the ADA2 gene that encodes the adenosine deaminase 2 (ADA2) protein. It is an autosomal recessive disease characterised by a large phenotypic variability due to the many organs that can be affected. Ischemic and/or hemorrhagic stroke could be a manifestation of the disease. We described a case of ischemic stroke as presentation of DADA2.

Methods:: Case report and literature review.

Results:: A nine-year-old girl experienced wake-up diplopia. Headache or other symptoms were not complained. History of recent minor head trauma was reported. No fever or recent infections were present. Family history was negative. Neurological examination showed oculomotor deficit in left eye with diplopia, no other deficits were observed. General examination was normal, and no other signs of vasculopathy were detected. Brain RM showed small acute left paramedian mesencephalic and right thalamic ischemic lesions; moreover, a chronic right posterior thalamic ischemic lesion was observed. MR angiography documented a thin vertebro-basilar artery system without occlusions. Conventional cerebral angiography was normal. Laboratory investigations showed a slight CRP increase. Viral screening, and cerebrospinal fluid examination were normal. Prothrombotic disorders were excluded. Cardiological investigations showed small patent foramen ovale. Genetic workup showed mutations in the ADA2 gene. We concluded for ischemic lacunar stroke as first manifestation of DADA 2.

Conclusions:: Early etiological diagnosis of ischemic stroke in pediatric population is difficult. It should always include a complete diagnostic workup to identify rare disease as DADA 2, and provide appropriate therapy.
EFFICACY AND SECURITY OF ONASEMNogene ABEPARVOVEC-XIOI IN SPINAL MUSCULAR ATROPHY: A SYSTEMATIC REVIEW AND META-ANALYSIS

Background and Aims:: Onasemnogene abeparvovec-xioi is a gene therapy approved by FDA in 2019; however, the drug profile is not fully known. We aimed to evaluate efficacy and security of Onasemnogene abeparvovec-xioi in patients with type 1 spinal muscular atrophy (SMA).

Methods:: We conducted a literature search in databases PubMed, SCOPUS and the Cochrane library, until January 2020. We performed a meta-analysis using the univariate model of random effects, and heterogeneity was evaluated using I2. Funnel plots, and Egger’s test were used to evaluate publication bias. The certainty of evidence was assessed with the GRADE system.

Results:: We selected 3 studies with a total of 137 patients. We found that 87.82% (95%CI 72.92-102.71) achieved the ability of swallowing and 83.11% (95%CI 68.67-97.58) attained the ability of sitting with very low certainty of evidence. The motor function, measured by the CHOP INTEND score at three months, showed an increase of 7 points ± 8.72 SD in one study and an increase of 15.4 points in another study with low certainty of evidence. Adverse effects reported were elevated transaminases with a frequency of 67.44% (95%CI 35.56-99.31), fever/pyrexia with 45.42%(95%CI 28.47-62.37) and serious adverse effects (transaminase elevation> 10 times normal, vomiting) with 11.83% (95%CI 5.88-17.77), all of them with very low certainty of evidence.

Conclusions:: With very low certainty, Onasemnogene abeparvovec-xioi improves the achievement of sitting and swallowing abilities with few serious gastrointestinal and systemic adverse effects in patients with type 1 SMA.
SCREENING FOR NEURODEVELOPMENTAL DISORDERS AMONG CHILDREN WITH UNTREATED EPILEPSY IN NORTHERN NIGERIA

Edwin Trevathan¹, Aminu Taura², Hafsat Ahmad³, Folorunsho Nuhu⁴, Umar Sabo⁵, Halima Adamu⁵, Auwal Salihu², Angela Paolucci¹, Lizet Tirres¹, Donna Ingles¹, Juanita Prieto-Garcia¹, Gregory Ayers¹, Zubairu Iliyasu⁶
¹Vanderbilt University Medical Center, Vanderbilt Institute For Global Health, Nashville, United States of America, ²Aminu Kano Teaching Hospital, Psychiatry, Kano, Nigeria, ³Ahmadu Bello University, Paediatrics, Zaria, Nigeria, ⁴Federal Neuropsychiatric Hospital, Psychiatry, Kaduna, Nigeria, ⁵Aminu Kano Teaching Hospital, Paediatrics, Kano, Nigeria, ⁶Bayero University Kano, Community Health, Kano, Nigeria

Background and Aims:: Little is known of the frequency of neurodevelopmental disorders among children with untreated epilepsy in sub-Saharan Africa. The "Bridging the Childhood Epilepsy Treatment Gap in Africa (BRIDGE)" project identified children with untreated epilepsy for a cluster non-inferiority randomized clinical trial of task-shifted care, and screened these children for neurodevelopmental disorders.

Methods:: A previously validated Hausa language version of a 23-question screening questionnaire (23Q) for autism spectrum disorder (ASD), cerebral palsy (CP), intellectual disability (ID), and hearing impairment (HI) was administered to parents of children with previously untreated epilepsy enrolled in the BRIDGE project. The 23Q was administered by epilepsy-trained CHWs, trained in the 23Q as part of their preparation for the BRIDGE project. Data were entered directly into REDCap® and uploaded to the BRIDGE Data Coordinating Center for analysis.

Results:: Among children who were eligible for screening, 31% (459 of 1482) screened positive for possible CP, 16.7% (248 of 1489) screened positive for possible HI. 48% (707 of 1474) screened positive for possible ID, and 28.5% (403 of 1412) screened positive for possible ASD.

Conclusions:: The percentage of children with epilepsy who screened positive for ID, ASD, HI and CP was significantly higher among children with untreated epilepsy in northern Nigeria than expected based upon studies of neurodevelopmental disabilities among children with epilepsy from the US and Europe. Detailed neurodevelopmental assessments are underway among children who screened positive for these disabilities in the BRIDGE project. More research on neurodevelopmental co-morbidities among untreated children with epilepsy in sub-Saharan Africa is needed.
CORRELATION OF COGNITIVE IMPAIRMENTS WITH SCHOOL PERFORMANCE DEPENDING ON THE FORM OF CEREBRAL PALSY.

Yasmina Ganikhujayeva
Tashkent Pediatric Medical Institute, Pediatric Neurology, Tashkent, Uzbekistan

Background and Aims:: Purpose of the study: determination of the severity of cognitive impairments depending on the form of the cerebral palsy in order to determine their further education.

Methods:: 25 children with various forms of cerebral palsy of preschool age were examined. Analysis of cognitive functions using special scales (Wechsler's scale of cognitive function adapted for children from 4.5 to 6.5 years old).

Results:: A study of cognitive functions according to the Wechsler scale adapted for childhood was carried out in 25 patients with cerebral palsy of the non-dominant hemisphere (6 patients with spastic diplegia, 5 with double hemiplegia, 5 with a hemiparetic form, 5 with hyperkinetic, 4 - with atonic-astatic) at the age of 4.5 to 7 years on the basis of the Cerebral Palsy Center and the Children's Clinical Hospital #4. It was found that intellectual development close to normal was observed in 60% of patients with hemiparetic form, in 33% with spastic diplegia, 40% with hyperkinetic form, 25% with atonic-astatic form and in 20% of patients with double hemiplegia. Mental retardation was observed in 50% of children with atonic-astatic form, 40% with hemiparetic, 16.7% with spastic diplegia, 20% with hyperkinetic form of the cerebral palsy, 20% with double hemiplegia.

Conclusions:: • Children with spastic diplegia and hemiparetic form of the disease with lesions of the non-dominant hemisphere were recommended to study in general education schools. • Children with atonic-astatic and hyperkinetic form of the disease - in specialized schools. • Children with double hemiplegia – home education.
CLINICAL AND PARA CLINICAL FEATURES AND THE NATURE OF THE COURSE OF EPILEPTIC ENCEPHALOPATHY IN PRESCHOOL CHILDREN

Gulchiroykhon Vafoeva¹, Yakuthon Madjidova², Gulchehra Sodikova¹, Saida Saidkhodjaeva³
¹Tashkent Pediatric Medical Institute, Neurology, Child Neurology And Medical Genetics, -, Uzbekistan, ²Tashkent Pediatric Medical Institute, Neurology, Tashkent, Uzbekistan, ³Tashkent pediatric medical institute, Neurology, Tashkent, Uzbekistan

Background and Aims:: Currently, some researchers consider interictal epileptic psychoses as a manifestation of epileptic encephalopathy (EE).

Methods:: This study was based on the data of examination of 30 children with a diagnosis of EE at the age of 3 to 7 years. In this work, we used general clinical, neurological and instrumental research methods (EEG).

Results:: According to the data obtained, we found that 8 children (26.6%) with EE were diagnosed with Lennox-Gastaut syndrome, Landau-Kleffner syndrome - in 3 (10%) and in 2 (6.7%) West syndrome. All these children were classified as type I EE. Tonic seizures were observed in 11 children (36.67%), among them short-term seizures were recorded in 8 children, which lasted for several seconds. Atypical absence seizures were observed in 5 patients (16.7%), had a relatively gradual onset and end, in contrast to the sudden nature of typical absences. Atonic seizures were observed in 7 children (23.3%) and were characterized by a sudden and significant loss of postural tone with the involvement of the whole body or only the head muscles. Myoclonic seizures were recorded in 4 patients (13.3%) (nodding, pecking, flinching). Polymorphism of epileptic seizures was observed among 23.3% (7 children) of patients. When analyzing the neurological status, it was found that children with type 1 EE are characterized by micro-focal neurological symptoms in the form of: disorders of the cranial nerves, pyramidal insufficiency, transient coordination disorders.

Conclusions:: Thus, type I EE is characterized by micro-focal neurological disorders with progressive disorders of the cognitive sphere, intelligence, speech and other cerebral functions.
NEUROCOGNITIVE DEFICITS IN SICKLE CELL DISEASE

Gisele Kandosi¹, Desire Tshala-Katumbay², Daniel Okitundu¹
¹University of Kinshasa, Neurology, Kinshasa, Congo, ²Oregon Health & Science University, Neurology, Portland, United States of America

Background and Aims:: The neurological burden of sickle cell disease remains poorly documented. The current study was aimed at assessing neurocognitive functions in Congolese children with sickle cell disease.

Methods:: Neurocognitive assessments using the Kaufman Assessment Battery for Children, 2nd edition (KABC-II) for cognition testing and the Bruininks/Oseretsky Test, 2nd Edition (BOT-2) for motor proficiency were performed in 189 children (102 boys vs. 87 girls, 9.8 ± 2.5 years of age, overall; 129 homozygous (SS), 38 heterozygous (AS), and 22 non-carriers (AA). Predictors of neurocognitive performance were determined using general linear models at the significance level p˂0.05 (STATA, version 12.1.)

Results:: Overall, sickle cell disease was associated with poor motor performance (p = 0.001). Mental processing and motor proficiency were negatively with advanced age [beta (CI): -0.093 (-0.150; -0.037), p = 0.001] and [beta (CI): -0.131 (-0.174; -0.088), p <0.001], respectively. Mental processing was also positively associated with socioeconomic status (SES) [beta (CI) = 0.228 (0.139; 0.317), p<0.001]. Children on hydroxyurea had higher performance scores at motor and cognitive testing at simultaneous and sequential processing, learning, planning, and delayed recognition (p <0.05).

Conclusions:: Scaling up treatment with hydroxyurea and SES- and gender-focused rehabilitation strategies may improve neurocognitive outcomes in children with sickle cell disease.
CASE REPORT: HEREDITARY SPASTIC PARAPLEGIA WITH THIN CORPUS CALLOSUM

Malbora Xhelili¹, Altin Kuqo¹, Eni Reka¹, Eti Muharremi¹, Arben Rroji², Jera Kruja¹
¹Neurology service, Neurology, Tirana, Albania, ²Neurology service, Neuroimaging, Tirana, Albania

Background and Aims:: Hereditary spastic paraplegias (HSPs) are a group of inherited neurodegenerative disorders with clinical varieties depending on the genetic profile. Since 1981 it was established the clinical tableau into a pure and a complicated type which among other conditions encompasses mental retardation/cognitive impairments. The genetic profile is as heterogeneous as the clinical one including autosomal dominant, x-linked, and autosomal recessive mode of inheritance. HSP with thin corpus callosum(TCC) is an autosomal recessive form of the disease with a few reported cases in Japan and a limited number of Caucasian patients. According to the literature SPG11 is the most frequent of HSP with TCC, followed by SPG15 in fewer cases. Both forms share similar clinical and imaging presentations with very few distinctions.

Methods:: We present the case of a 32-year-old caucasian male, with a history of dysarthria, gait disturbance and frequent falls progressively developing into a spastic deficit of lower limbs accentuated in the second decade. The diagnostic criteria of HSP with TCC were carefully reviewed and all the clinical and radiological criteria were met. Magnetic Resonance Imaging(MRI) evidenced the thin corpus callosum with frontoparietal cortical atrophy.

Results:: To our knowledge there are very few cases of autosomal recessive HSP with TCC in Albania as elsewhere in the world.

Conclusions:: The clinical profile of HSP-TCC accompanied with a thin corpus callosum and other characteristics in MRI should be evocative to genetically investigate our patients in order to correctly address genetic counseling.
Background and Aims:: Idiopathic intracranial hypertension (IIH) is a rare neurological disorder in children. It is characterized by raised intracranial pressure in the presence of normal cerebrospinal fluid chemistry, normal neuroimaging, and no localizing signs on neurological exam (with the exception of cranial nerve VI palsy). We review clinical presentation, diagnosis and management of IIH in children.

Methods:: Retrospective review of six children with the diagnosis of IIH. All patients underwent neurological, ophthalmological and radiological exams.

Results:: Our study included six girls. The average age was 8.5 years. Three patients were in the peripubertal period. All patients complained of headache, blurred vision, often associated with vomiting. Two patients had binocular diplopia. The neurological examination was normal in all patients. Visual acuity was decreased in two patients. Bilateral papilloedema was found in all cases and two patients presented limitation in abduction. Goldmann visual field was performed in three patients and found an enlarged blind spot. Brain MRI showed partial empty sella in one patient and was normal in five patient. Lumbar puncture was done in all patients and showed a high cerebrospinal fluid opening pressure (25-51 cmH2O). The body mass index and the endocrine balance were correct. All patients received acetazolamide. The evolution was favorable in all cases.

Conclusions:: Children with suspected IIH should have careful ophthalmological and full neurological examination. IIH could be associated to hormonal changes occurring on peripubertal period. If not treated properly, IIH may lead to severe visual dysfunction.
OUTCOMES OF SELF-REGULATION IN 24-MONTH-OLD CHILDREN AFTER PEDIATRIC ARTERIAL ISCHEMIC STROKE

Vadim Gusev¹, Maria Lavrova², Ekaterina Suleymanova³, Olga Lvova¹
¹Ural Federal University, Lab Neurotechnology, Yekaterinburg, Russian Federation, ²Ural Federal University, Department Of Clinical Psychology And Psychophysiology, Yekaterinburg, Russian Federation, ³Ural Federal University, Yekaterinburg, Laboratory For Brain And Neurocognitive Development, Yekaterinburg, Russian Federation

Background and Aims:: The ability to self-regulation (initiation, organization and control of own activity) is one of the most important qualities of the human. Pediatric arterial ischemic stroke (PAIS) in infancy usually entails dysfunction, which can also manifest itself in difficulties of self-regulation. Objective was to assess the level of self-regulation in children with PAIS in comparison with the control group.

Methods:: Level of self-regulation was assessed using a parent questionnaire Scale "Adaptive behavior" (Bayley-III). The study involved 65 children aged 5 months and 41 children 24 months old. The control group included children without organic lesions and chronic diseases, full-term: 52 children (34 boys) 5 months (6,0±0,7 month) and 27 children (15 boys) at 24 months (25±0,8). The experimental group included children survived PAIS before 5 months of life: 13 children (8 boys) 5 months (5,9±1) and 14 children (10 boys) at the age of 24 months (25.1±1.6)

Results:: At the age of 5 months there were no significant differences between the level of self-regulation in the groups; at 24 months the differences were revealed: raw scores were 41±11 in the experimental group and 48.5±10 in the control group (t=2.4, p=0.02).

Conclusions:: Self-regulation is a systemic, integrative phenomenon, with cognitive, emotional and behavioral components (Vilenskaya 2016). Taking into account the importance of self-regulation as an integrative function, providing the child adaptation, it is important to pay attention to the recovery and rehabilitation of children with PAIS not only for the motor skills or speech development, but also for self-regulation development.
A CHILDHOOD CASE OF BAG-3 MYOFIBRILLAR MYOPATHY HEART TRANSPLANTED PRESENTING PANCREATIC TUMOR.

Corrado Angelini
Azienda Ospedaliera di Padova, Neurosciences, Padova, Italy

Background and Aims:: A child affected by myofibrillar myopathy caused by a mutation in BAG3, a co-chaperon, presented cardiomyopathy, peripheral neuropathy, respiratory insufficiency, pancreatic tumor.

Methods:: A girl has been studied for BAG3-related cardiomyopathy by cardiac ECHO, catheterism, muscle biopsy, MRI.

Results:: This girl suffered from age 3 of exercise intolerance, was found to have restrictive cardiomyopathy by cardiac Echo, bilateral atrial dilatation, telediastolic reflow. At 11 years of age, she was diagnosed with genetic myopathy due to a mutation of the BAG3 gene, for a heterozygous variant (p.Pro290Leu.) She presented hypertrophic cardiomyopathy, peripheral neuropathy. At the neurological exam, she had a waddling gait, bilateral winging scapulae, was able to raise with Gowers' manoeuvre, showed distal weakness and wasting, erythromelalgia. Because of dyspnea, her cardiomyopathy was treated with 2.5 mg/day bisoprolol, aldactazide, she was able to sleep with one cushion, during cardiac catheterization she had systolic ventricular hypertension, elevated pulmonary pressure. Cardiac biopsy was done, that showed fibrosis, focal lymphocytic infiltrates: cardiac transplant was planned. At age 12 a muscle biopsy showed cytoplasmic bodies, rimmed vacuoles, splitting fibers, internal nuclei. At age 14 she underwent a cardiac transplant, was in ICU, and presented OSAS. Her scoliosis deteriorated. In the following months, she was immunosuppressed. Motor functions improved. A muscle MRI showed fibro-fatty substitution of the right scapular girdle, bilaterally in thigh muscles and distal leg muscles. At age 16 she presented pancreatic tumor.

Conclusions:: This BAG-3 patient was successfully heart transplanted in the follow-up she needed psychological support, subsequently a pancreatic tumor was found, possibly related to her BAG3 variant and immunosuppressive therapy.
PROGNOSIS OF SURGICAL TREATMENT OF THE TETHERED CORD SYNDROME IN CHILDREN

Kirill Sysoev
Almazov National Medical Research Centre, Pediatric Neurosurgery, St. Petersburg, Russian Federation

Background and Aims: Purpose. The aim of this study was to identify the factors relevant to the prognosis of the outcome of the surgical treatment of the tethered cord syndrome (TCS).

Methods: Methods. The results of surgical treatment performed on 58 children with TCS were analyzed, with follow-up periods ranging from 6 months to 5 years. The data of preoperative clinical and instrumental examinations, as well as those of intraoperative electrophysiological diagnostics and morphometry, were compared with the dynamics of the TCS clinical presentation.

Results: Results. The recovery rate was significantly higher in children with filum terminale abnormality (p=0.014), as well as Grade I tethering (p=0.0037), and when the spinal cord tracts at the level of intervention were intact (p=0.018). Complete untethering (p=0.04) and a low threshold value of amperage in direct stimulation (<1 mA) (p=0.016) were identified as factors for a favourable outcome. Worsening of neurological symptoms was more frequent in children operated over the age of 10 (p=0.03), when the TCS was manifested exclusively through the pelvic dysfunction (p=0.00004), if the F-wave block is less than 30% (p=0.0045) and the stimulation threshold during root mapping ranged from 1 to 5 mA (p=0.01).

Conclusions: Conclusion. The operation is recommended when structural changes are minimal. In case of severe structural changes, if the spinal cord tracts are intact, the indications for operation are determined by the risk of irreversible structural changes due to the natural course of the disease, although the risks are substantially higher.
**BILATERAL VISUAL IMPAIRMENT AS A RARE MANIFESTATION OF ARNOLD CHIARI MALFORMATION TYPE 1**

Pramod Dhonde  
Dhonde Hospital, Neurology, Nanded, India

**Background and Aims::** This is to report a rare presesntation of bilateral diminution of vision in a case of Arnold Chiari Malformation type 1 in an young boy.

**Methods::** Four year old boy presented with bilateral progressive diminution of vision (DOV) with episodes of occipital headache with vomittings more after crying. Episodes of headache were short lasting with recurrent falls. He had history of sleep apnea also. On examination patient has scaphocephaly, bilateral optic atrophy with bilateral gaze evoked nystagmus. On neuroimaging MRI Brain revealed Arnold Chiari Malformation type 1 (ACM 1) with prominent subarachnoid space around bilateral optic nerves.

**Results::** The hypothesis for DOV was repeated episodes of raised intracranial tension during crying leading to increased pressure on both optic nerves with axonal degeneration over years. As patient was posted for posterior fossa decompression, it was postulated that further progression in optic nerve damage will be diminished.

**Conclusions::** To bring out this case is not to miss in early stage of DOV, ACM 1 as one of the etiology as early treatment can halt the progression of optic nerve axonal degeneration. Prominent subarachnoid space around optic nerves and ACM 1 are correlating radiological pearls in this particular case.
A CASE OF INFANTILE BOTULISM AND CMV COINFECTION: RED FLAGS OF AN INSIDIOUS DIAGNOSIS AND THE ROLE INTESTINAL DYSBIOSIS AND HYPOGAMMAGLOBULINEMIA AS RISK FACTORS

Mattia Pozzato¹, Robertino Dilena², Lucia Baselli³, Giovanna Chidini⁴, Cristina Bana², Sergio Barbieri², Alberto Cappellari²
¹Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Neurology Unit & MS Centre, Dino Ferrari Centre, Neuroscience Section, Department Of Pathophysiology And Transplantation, University Of Milan, Milan, Italy, ²Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Neuropathophysiology Unit, Milan, Italy, ³Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Pediatric Unit, Milan, Italy, ⁴Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Pediatric Intensive Care Unit, Milan, Italy

Background and Aims:: Botulism is a rare pathology caused by a neurotoxin produced by bacteria of the genus Clostridium, responsible of a clinical condition characterized by flaccid paralysis and autonomic dysfunctions. Some forms, called infantile botulism, are secondary to the colonization of Clostridium botulinum spores in the gut of children and the subsequent production of the toxin. The reason why only some children develop the disease after ingesting the spores present in the environment and others not is not entirely clear, but it is probably linked to host factors. In particular, alterations of the gut microbiota, latent subclinical viral infections and alteration of immune response could be at the basis of this phenomenon, with important implications in the treatment of dysbiosis as a preventive weapon for numerous diseases, including infantile botulism.

Methods:: Herein we described the first case of infantile botulism and CMV coinfection in a 6-month-old boy.

Results:: The mechanisms by which some children develop the disease after ingesting the spores present in the environment and others not is not entirely clear, but it is probably linked to host factors. In particular, alterations of the gut microbiota, latent subclinical viral infections and alteration of immune response could be at the basis of this phenomenon, with important implications in the treatment of dysbiosis as a preventive weapon for numerous diseases, including infantile botulism.

Conclusions:: We discuss the possible role of gut microbiota alterations and immunological changes associated with CMV infection (with minor or no clinical symptoms) as risk factor for the growth of C. botulinum spores. In addition as the most probable mimicker is Guillain-Barré Syndrome (GBS), we highlight that every acute floppy infant under one year of age with clinical features of GBS with autonomic involvement, but absence of confirmatory GBS instrumental features (CSF albumin-cytological dissociation, MRI enhancement, sensory and motor involvement) should receive fast laboratory investigations also for C. botulinum in first days of admission.
ASSOCIATION BETWEEN HLA GENE POLYMORPHISM AND CUTANEOUS ADVERSE REACTIONS CAUSED BY ANTIEPILEPTIC DRUGS

Xinrui Li, Yunhua Hao
Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China, Department Of Neurology, Shanghai, China

Background and Aims:: There are approximately 10 million patients with epilepsy currently in China, seriously affecting the lives of patients. Adverse drug reactions of antiepileptic drugs often occur easily, the most common of which is the cutaneous adverse drug reaction (cADR). In recent years, it has been shown that human leukocyte antigen (HLA) polymorphism has a significant correlation with the incidence of cADRs.

Methods:: Through the case-control study, 30 child patients with AED-induced cADRs (cADRs group), 60 AED-tolerant child patients (AED-tolerant group) and 60 normal children not taking AEDs (normal group) were collected. The HLA-B*15:02 and HLA-A*31:01 genotypes were detected using the polymerase chain reaction-sequence-specific oligonucleotide (PCR-SSO) probe method, and the correlation of HLA-B*15:02 and HLA-A*31:01 genes with the incidence of cADRs was analyzed.

Results:: The positive rate of HLA-A-B*15:02 gene was 83.33% in the cADRs group, which was significantly increased compared with that in the AED-tolerant and normal groups (P<0.01). The positive rate of HLA-A*31:01 gene was 63.33% in the cADRs group, which was obviously increased compared with that in the AED-tolerant and normal groups (P<0.01). There were no significant differences in HLA-B*15:02 and HLA-A*31:01 genotypes between the AED-tolerant and normal groups (P>0.05).

Conclusions:: The results showed that HLA-B*15:02 and HLA-A*31:01 are significantly associated with cADRs in a Chinese Han population in Shanghai, suggesting that HLA-B*15:02 and HLA-A*31:01 genotypes should be detected in the application of AEDs.
EFFECT OF AGE OF ONSET AND TREATMENT ON CONTROL OF EPILEPTIC SPASMS: FINDINGS FROM THE SRI LANKA INFANTILE SPASMS REGISTRY

Jithangi Wanigasinghe1, Gemunu Hewawitharana2, Saraji Wijesekera3, Pyara Ratnayake4, Chathurika Weeraratne5, Udana Mahika6, Ashan Jayawickrama7, Udana Dassanayake8

1University of Colombo, Paediatrics, Colombo, Sri Lanka, 2Teaching Hospital Karapitiya, Neurology, Galle, Sri Lanka, 3University of Sri Jayawardena Pura, Paediatrics, Nugegoda, Sri Lanka, 4Lady Ridgeway Hospital, Neurology, Colombo, Sri Lanka, 5Teaching Hospital Anuradhapura, Neurology, Anuradhapura, Sri Lanka, 6University of Colombo, Paediatrics, Colombo, Sri Lanka, 7University of Colombo, Paediatrics, Dehiwela, Sri Lanka

Background and Aims:: Objective To describe the effect of age of onset and treatment lag on response to therapy among children diagnosed with West syndrome in Sri Lanka
Methods:: Method Data was extracted from the Sri Lanka Infantile Spasm registry. Onset of spasms was considered early if onset occurred at <3 months and late if > 12 months. Treatment-lag was categorized as <14 days, 14-28 days and > 28 days. Spasm control was ascertained at 14 days and other time points.
Results:: Results There are 261 Children entered in the registry as at January 2021. Mean age of onset was 5.44 months (SD. 3.93); early in 58 (24.4%) and late in 14 (5.9%). Electroencephalography showed hypsarrhythmia in 89%, normal in 7.5%, unavailable/ not done in the balance. Most commonly known aetiologies included low birth weight (36%), neonatal seizures (31%), Birth asphyxia (15.1%). Of the three categories, largest treatment lag of >28 days reported in 44%. Majority (87%) received standard first-line therapies. Mean duration for spasm freedom was 13.2 days for first-line versus 40.5 days for non-standard therapies. First line therapies were oral prednisolone in 151(73%) and ACTH in 49(24%). Spasm control was significantly better if received prednisolone (p=0.04) Early onset of spasms (p=0.4), delayed treatment lag of >28 days (p=0.198). or male sex (p=0.37) were not associated with day 14 poor spasm control.
Conclusions:: Conclusions Data from this large cohort suggest faster control of spasms occurs with standard first-line therapies. Poor control was not associated with early onset or delayed treatment of >28 days.
SPECTRUM OF NEUROLOGICAL DISORDERS IN HIV POSITIVE PATIENTS ATTENDING A TERTIARY CARE CENTRE OF EASTERN INDIA

Arpan Dutta¹, Alak Pandit¹, Biman Ray¹, Shantasil Pain², Goutam Gangopadhyay¹
¹Institute of Post Graduate Medical Education and Research, Neurology, Kolkata, India, ²Institute of Post Graduate Medical Education and Research, Internal Medicine, Kolkata, India

Background and Aims:: Neurological complications are common in HIV and can affect any part of the neuraxis. This study was conducted to describe the different neurological disorders occurring in HIV and analyse their pattern according to the CD4 count, WHO clinical stage, duration of HIV infection, treatment status, and treatment duration.

Methods:: 61 HIV-positive patients who had neurological involvement were included. Demographic parameters, clinical findings, investigations, duration of HIV, CD4 count, WHO stage, ART regimen, and its duration were recorded. Written consent was obtained.

Results:: 39 patients were male and the median age was 36 years. 36 patients were taking ART, TLE being the most common regimen (80.55%). Neurological disorder was the presenting manifestation of HIV in 23% of patients. The most common diagnosis was CNS tuberculosis (27.8%), followed by distal symmetric polyneuropathy (13%), and progressive multifocal leukoencephalopathy (11.5%). The median CD4 count was 172 cells/mm³. 59% of the disorders occurred below CD4 count of 200 cells/mm³. 64% of patients were in WHO stage 4. The median duration of HIV was 3 months and 52.5% of cases occurred within 3 months. 37.5% of disorders were direct HIV-related, while 54.7% were due to opportunistic infections. Opportunistic infections occurred significantly more compared to direct complications in WHO stage 4 (p<0.0001), CD4 count <200 cells/mm³ (p=0.004), within 6 months of HIV diagnosis (p=0.002), in patients not on ART (p= 0.004), and within 6 months of ART initiation (p=0.03).

Conclusions:: Various neurological disorders can occur in HIV. Despite widespread ART use, opportunistic infections are still prevalent.
Background and Aims:: Neurosyphilis can present with wide variability of central nervous system manifestations making difficult reaching a correct diagnosis. In addition, features of neurosyphilis that mimic herpetic or autoimmune encephalitis have been described. We present two patients whose clinical manifestations were suggestive of encephalitis.

Methods:: Patient 1. A 54-year-old man presented with a language disturbance, mainly consisting in speech arrest, started 6 months prior and later associated to ideomotor slowing, cognitive impairment and ataxic gait. A brain MRI was normal. EEG arose the hypothesis of non-convulsive status epilepticus and treatment with levetiracetam was started. The patient’s seizures disappeared, while the cognitive difficulties persisted. Patient 2. A 45-year-old man was brought to the emergency room because of a generalized tonic-clonic epileptic seizure. For some days he had been complaining of headache and dizziness. His EEG showed an electrographic seizure and interictal epileptiform discharges in the right hemisphere. Brain MRI revealed high signal in bilateral mesial temporal lobes.

Results:: Cerebrospinal fluid (CSF) analysis demonstrated in both patients elevated proteins and pleocytosis leading to consider an infectious or autoimmune/paraneoplastic etiology for their subacute encephalopathy. However, the screening for all these conditions was found to be negative, while serologic and CSF tests for syphilis were positive. Both patients were successfully treated with a 14-day course of Cetriaxone.

Conclusions:: The presented cases outline that neurosyphilis may mimic herpetic and autoimmune encephalitis. This possibility should be considered because its early recognition and treatment are crucial to prevent further progression of the disease and allow the recovery.
A RARE CASE OF LISTERIA RHOMBENCEPHALITIS WITH A SUDDEN CLINICAL ONSET AND UNUSUAL MRI FEATURES

Federica Garrì, Silvia Miante, Alessandro Miscioscia, Davide Simonato, Francesca Rinaldi, Paolo Gallo

1PARKINSON AND MOVEMENT DISORDERS UNIT - CENTER FOR RARE NEUROLOGICAL DISEASE (ERN-RND), Department Of Neuroscience, PADOVA, Italy, 2Padova University Hospital, Department Of Neuroscience, Padova, Italy, 3Multiple Sclerosis Center, Department of Neurosciences DNS, Neurology, Padua, Italy

Background and Aims:: Listeria rhombencephalitis is a very rare and fatal CNS infections. Here we describe a peculiar case of listeria rhombencephalitis with a sudden clinical onset and uncharacteristic radiological findings.

Methods:: Case Report

Results:: A 66 years-old female presented with a sudden onset of unsteadiness, dysarthria, left arm weakness, acute fever up to 39 °C and recurrent vomiting. Her medical history was significant for pancreas carcinoma (stage III) on neoadjuvant chemotherapy. Laboratory tests revealed leucocytes 33.50 x10.9/L, neutrophils 31,5 x10.9/L, deranged LFTs, CRP 16.60 mg/L and negative procalcitonin. Brain-CT scan was unremarkable. GCS was 15. Within few hours of admission, a rapid neurological deterioration was observed, with fluctuating consciousness and muticism, dropping to a GCS of 11. Neurological examination revealed inconstant execution of simple motor task, deviation of head and eyes to the left side, pinpoint pupils slightly reactive to light, absent corneal reflex, left side paresis, along with mild meningeus. Soon after, she developed an acute respiratory distress, so orotracheal intubation was performed. CSF examination revealed a leukocyte count of 372/mm³ (90% neutrophils), a protein concentration of 247 mg/dl and a glucose concentration of 4.2 mmol/L. CSF-PCR was positive for L. monocytogenes, while CSF culture was unrevealing. A 3T Brain-MRI showed gross brainstem involvement with associated hemorrhage, suggestive of rhombencephalitis.

Conclusions:: Our case is worth of consideration for the MRI findings, showings an extensive hindbrain involvement, instead of more typical abscesses with ring enhancement. Moreover, the sudden onset, not preceded by a prodromal phase is an atypical presentation preluding a devasting clinical course.
Background and Aims:: Introduction Neurocysticercosis(NCC) is a rare neurological disorder caused by the larval stage of the pork tapeworm Taenia solium (TS). Even though cysticercosis is endemic in India it has not been reported from Sri Lanka in an adult

Methods:: Case Report A 29 year old man presented with chronic headache and adult onset epilepsy. He was well before headache set in 18 months ago. Neurological examination including fundi was normal.

Results:: His haematological and biochemical evaluation was normal. His CSF too was normal .MRI brain revealed multiple focal lesions in bilateral cerebral hemispheres. On T2 MRI images these lesions had a target appearance due to multiple alternating signal intensities. All lesions enhanced with gadolinium. The MRI appearance was characteristic of parasitic infection due to NCC with lesions of different stages. TS antibodies were negative in both serum and CSF. Repeat MRI brain imaging showed new lesions appearing whilst some old lesions disappearing. With the clinical history and neuroimaging findings suggesting NCC, the patient was started on Albendazole 15mg/kg daily dose with steroids, dexamethasone 0.1 mg/kg/day. The treatment was continued for 14 days. Within 2-3 days of initiation of treatment, there was significant improvement in headache. Post treatment MRI showed near complete resolution of the previous lesions without any new lesions.

Conclusions:: Even though serological diagnosis of cysticercosis may be difficult, a proper clinical evaluation together with imaging findings will lead to the diagnosis of NCC. It is interesting as to why an infectious disease endemic in neighbouring India is so uncommon in Sri Lanka.
Background and Aims:: Central nervous system (CNS) infection is associated with high rates of morbidity and mortality, and despite advancements in molecular testing, aseptic meningitis remains challenging to diagnose. Aseptic meningitis cases are often underreported worldwide, which impacts the quality of patient care. Therefore, we aimed to assess the results of BioFire® FilmArray® meningitis/encephalitis (ME) PCR panel, clinical characteristics, and etiologies of aseptic meningitis patients.

Methods:: From January 2018 to January 2020, all pediatric and adult patients in a large tertiary medical center who underwent lumbar puncture and cerebrospinal fluid (CSF) testing by a ME multiplex PCR panel and who fit the aseptic meningitis definition were retrospectively reviewed.

Results:: Data were reviewed from 1,607 patients; 240 met the inclusion criteria (54.6% males; 68.8% <4 years of age). The rate of detected viral causes of aseptic meningitis was 40.4%; therefore, 59.6% of the patients remained with unidentified etiology. Among the identified viral meningitis, enterovirus and human herpesvirus 6 (HHV-6) were the most common (25 and 7.9%, respectively). The median length of hospital stay was 6 days, and it was longer in patients with unidentifiable aseptic meningitis (p < 0.0001).

Conclusions:: Aseptic meningitis is common among suspected meningitis patients, but most cases remained of unknown etiology. The most common identified viruses were enterovirus followed by HHV-6, and there is predominance in males and the pediatric age group. These results highlight that further research is needed to identify other etiologies and possible additional viral pathogens for aseptic meningitis in the current diagnostic methods.
LONG SEGMENT MYELITIS SECONDARY TO NEURO MELIOIDOSIS

Vithoosan Sahathevan, Gayathri Perera, Asha Kumarasiri, Nadun Vithanage, Bimsara Senanayake
National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

Background and Aims:: Neuro melioidosis, comprising approximately 4% of all cases of melioidosis carries a high mortality and morbidity. Long segment myelitis due to melioidosis is very rarely reported. We describe a Sri Lankan male who presented with long segment myelitis secondary to melioidosis.

Methods:: 47 year old previously healthy male presented with progressively worsening quadriplegia with bladder and bowel involvement. He also had intractable hiccups. Neuro exam revealed flaccid quadriparesis.

Results:: Initial hematological investigations and inflammatory markers were normal. CSF protein was elevated (76mg/dl) with a significant sugar drop (72mg/dl (RBS 159 mg/dl)) without a cellular reaction. CSF TB gene X pert testing was negative. Initial MRI spine revealed long segment myelitis with post contrast enhancement extending from lower medulla up to D10 level. Rest of the MRI brain was normal. The patient was started on IV MPP followed by TPEs without significant improvement. His repeat MRI revealed abnormal high signal in brain stem and whole spinal cord with contrast enhancement. A repeat CSF study revealed protein 1187 mg/dl, sugar 78 mg/dl (RBS 198) with lymphocytes 1600/mm3 and neutrophils 10200/ mm3. CSF culture become positive for Burkholderia pseudomallei. Serum melioidosis antibody titre was 1:160. The patient was started on IV meropenem with oral cotrimoxazole.

Conclusions:: Even though various neurological manifestations have been described due to melioidosis, long segment myelitis with positive CSF culture has not been described. This case highlights the importance of considering melioidosis as a differential diagnosis in patients with long segment myelitis in the endemic areas in addition to other known causes.
MENINGOVASCULAR SYPHILIS IN RECURRENT STROKE: A CASE REPORT

Ignacio Del Pino De Laguno¹, Carmen De Rojas Leal², Lina Carazo Barrios³, Carlos De La Cruz¹
¹Hospital Universitario Virgen de la Victoria, Neurology, Málaga, Spain, ²Hospital universitario Virgen de la Victoria, Neurology, Málaga, Spain, ³University Hospital Virgen de la Victoria, Neurology, Málaga, Spain

Background and Aims:: Syphilis is a known cause of tardive vasculitis which has preference over aortic and intracranial vessels. It may lead to vascular deficit and subsequent stroke.

Methods:: We present a case report whose diagnosis, treatment and ultimate follow-up was carried out by our Neurology and Infectious Diseases Departments.

Results:: A 38-year old man with known HIV infection presented to the Emergency Room with mild right hemiparesis. Complementary tests showed acute left pontine stroke along with parietal thickening and narrowing of the basilar artery, suggestive of inflammatory process. Serum VRDL and cerebrospinal fluid VRDL both tested positive. The patient received intravenous penicillin G for 21 days and was discharged with residual paresis. Five months later the patient returned with a new left pontine stroke and critical stenosis of the middle segment of the basilar artery, and was discharged under dual-antiplatelet therapy, given the fact that endovascular approach was unfeasible. This could not prevent the patient from having a new right medullary stroke one month later, which left the patient with severe left hemiparesis.

Conclusions:: Considering the recent rise in the incidence of syphilis in the West, the diagnosis must be considered in strokes of initially undetermined causes. Meningovascular syphilis and the subsequent obliterative endarteritis is the most common clinical variety of neurosyphilis. The present case illustrates the clinical presentation of meningovascular syphilis and depicts how difficult to control and treat the disease can be even using standard antibiotherapy.
SKULL BASE OSTEOMYELITIS: CLINICAL PREDICTORS AND OUTCOMES

Alisha Saxena¹, Birinder Paul¹, Gagandeep Singh¹, Archana Ahluwalia², Gunchan Paul³
¹Dayanand Medical College and Hospital, Neurology, Ludhiana, India, ²Dayanand Medical College and Hospital, Radiodiagnosis, Ludhiana, India, ³Dayanand Medical College and Hospital, Critical Care, Ludhiana, India

Background and Aims:: Background: Skull base osteomyelitis (SBO) is an enigmatic clinical diagnosis which is difficult to decipher and is associated with poor outcomes. Aim: The study aims to examine the demographic and clinical characteristics of patients with SBO and its outcomes.

Methods:: Material and Methods: Medical records of thirty patients with diagnosis of SBO over last five years were assessed for demographic and clinical characteristics, type of SBO, radiological parameters, treatment received, diagnostic or therapeutic procedure performed, microbiological profile, comorbidities and complications including cranial nerve palsies. These factors were analysed for prediction of outcome (death or survival).

Results:: We found SBO was the disease of elderly population (64.07±6.13 years) with male predominance (83.3%) highly associated with uncontrolled diabetes status (93.3%). Headache (100%) and cranial nerve palsy (80%) were the most common neurological presenting complaints followed by stroke (17%) and encephalopathy (10%). Pathological and radiological correlation showed that fungal infection (aspergillus) was associated with anterior SBO (10%) while bacteria (pseudomonas) was cultured from posterior SBO (30%). Fifty percent patients were alive after one year out of which 33% had good functional outcome. The mortality rate was 33.3% in our cohort and multiple lower cranial nerve palsies (P=0.04), sub-optimal duration of medical treatment (P=0.03), surgical intervention during clinical course (P=0.02) and development of intracranial or extracranial complications (P=0.03) were the predictors of mortality.

Conclusions:: Discussion: Early recognition of this condition including identification of pathogenic organisms and optimal duration of treatment are crucial for improved
outcomes.
Background and Aims:: Introduction: Parotid gland involvement as a form of extra pulmonary tuberculosis is a very rare manifestation. Extension of tuberculosis to skull base with multiple cranial nerve involvement is even rarer. We report a case of atypical presentation of tuberculosis with multiple cranial nerve palsies.

Methods:: Case: A previously healthy 40-year-old woman presented with progressive dysphagia and deviation of mouth to left for one-week without a history of fever, chronic cough, or headache. On examination she had bilateral nontender asymmetrical parotid enlargement without cervical lymphadenopathy. Nervous system examination revealed right sided lower motor type of facial nerve palsy, right palatal palsy and weakness of left sternocleidomastoid and trapezius with wasting.

Results:: ESR was 40mm/1st hour. Cerebrospinal fluid analysis showed elevated protein of 143mg/dl with lymphocyte count of 10/cu mm. Sputum for AFB, Mantoux test and tuberculosis PCR were negative. Serum ACE level was normal. MRI brain showed enhancing thickened right cranial nerve (CN) VII and left CN XII. Excision biopsy of left parotid gland showed caseating granulomatous inflammation. Retroviral antibodies were negative. She was empirically started on anti-tuberculosis treatment for one year without corticosteroid. During the first three months of treatment, parotid swelling had regressed, and dysphagia and facial nerve palsy had improved remarkably.
Conclusions:: Even though the caseating granulomatous inflammation is characteristic of tuberculosis, sarcoidosis also can rarely give rise to it. Our patient responded well to anti tuberculosis treatment without corticosteroids clearly supported the diagnosis of tuberculosis. Diagnosis of tuberculosis with atypical presentation needs a high degree of clinical suspicion.
BRAIN VOLUMETRIC CHANGES AND ITS ASSOCIATION WITH COGNITIVE OUTCOME IN TUBERCULOSIS MENINGITIS PATIENTS – A LONGITUDINAL STUDY

V H Ganaraja¹, J Saini², Sujas Bhardwaj³, Jamuna Rajeswaran⁴, S Nagarathna⁵, M Netravathi¹
¹National Institute of Mental Health and Neuro Sciences, Neurology, BENGALURU, India, ²National Institute of Mental Health and Neuro Sciences, Neuroimaging And Interventional Radiology, BENGALURU, India, ³National Institute of Mental Health and Neuro Sciences, Neurology, Bengaluru, India, ⁴National Institute of Mental Health and Neuro Sciences, Clinical Psychology, Bengaluru, India, ⁵National Institute of Mental Health and Neuro Sciences, Neuromicrobiology, BENGALURU, India

Background and Aims:: Studies on brain volumetric analysis and neuropsychiatric impairment in patients with Tubercular Meningitis (TBM) are limited and none with long term follow up.

Methods:: This prospective study was conducted between 2017 to 2019. Total of 29 adults with TBM (definite-8, probable-21) were included. Volumetric changes on Brain MRI and cognitive profile by eight neuropsychological tests were analyzed and compared at baseline and at 1 year.

Results:: Mean Total Intracranial Volume(TIV), Grey Matter(GM) and White Matter(WM) volume at baseline were 1298.43 ±126.68cm³, 598.67± 58.11 cm³, 414.00 ± 48.13 cm³ respectively. Mean cortical thickness was 2.70±0.09mm. At 1 year of follow up, mean TIV, GM and WM volume were1321.97±126.06 cm³, 615.34±55.36 cm³, 413.62± 43.04 cm³, 2.76± 0.08mm. There was no significant difference between gray matter, white matter volume, however cortical thickness was more at the end of 1 year of follow up, mainly in definite TBM (p=0.005). On comparing GM volumes of different areas at baseline and follow up, by Montreal Neurological Institute (MNI) coordinates, significant volume differences were noticed in temporal and frontal areas mainly hippocampus, superior frontal gyrus, and occipital gyrus, all on the left side. Neuropsychological tests done at baseline were suggestive of frontal and temporal region involvement, predominantly involving areas as observed with MNI coordinates with better recovery of frontal lobe functions during follow up.

Conclusions:: On morphometric analysis, cortical thickness was high suggesting persistence of inflammation with grey matter involvement and eventual development of cognitive disturbances. This was confirmed by neuropsychological tests as evidence by impaired left fronto-temporal lobar functions.
PARTIAL OCULOMOTOR NERVE PALSY AS THE SOLE SYMPTOM OF NEUROBORRELIOSIS

Bissene Douma, Ines Bedoui, Mariem Elfekih, Ridha Mrissa, Malek Mansour
Military Hospital of Instruction of Tunis, Department Of Neurology, sousse, Tunisia

Background and Aims:: neuroborreliosis is a tick-transmitted multisystem inflammatory disease. Neurological complications have been reported, including meningitis, facial nerve palsy, and peripheral neuropathy. Isolated oculomotor nerve palsy is rarely seen.

Methods:: We report a case of neuroborreliosis manifesting with isolated oculomotor nerve palsy and we describe outcome after instauration of antibiotic therapy.

Results:: A 58 year old man, without past medical history, was presenting at our department of neurology with a newly acquired partial ptosis and deviation of the left eye. The past 2 weeks he had suffered from intermittent headache. No tick bite exposure has been reported. Neurologic examination revealed a palsy of the third cranial nerve. There was no pupillary dysfunction and no further cranial nerve palsy was observed. The rest of his physical and neurological examinations were normal. Magnetic resonance imaging (MRI) with angiography (MRA) did not show any abnormalities. Routine blood examination was normal. Cerebrospinal fluid (CSF) analysis did not reveal pleocytosis with normal proteins. The oligoclonal bands were not detected in the CSF. Auto immune antibodies and infectious tests were negative. Serum anti-Borrelia burgdorferi IgG- and IgM were positive. The diagnosis of Lyme Borreliosis was established. The patient was treated with oral doxycycline 200 mg per day for 21 days. Two months after antibiotic and orthoptic treatment, the ocular movement improved and ptosis definitively disappeared.

Conclusions:: This case is an example of unusual presentation of neuroborreliosis. Clinicians should consider Lyme disease for any idiopathic oculomotor nerve palsy.
PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY IN AN EVER-TREATED PULMONARY SARCOIDOSIS

Giulia Carolina Primicerio¹, Antonella Muroni², Paola Cimino³, Giovanni Defazio⁴
¹Università degli Studi di Cagliari, Neurology, Cagliari, Italy, ²Azienda Ospedaliero Universitaria di Cagliari, Institute Of Neurology, Cagliari, Italy, ³University of Cagliari and AOU Cagliari, Department Of Medical Sciences And Public Health, Institute Of Neurology, Monserrato (CA), Italy, ⁴University of Cagliari, Department Of Medical Sciences And Public Health, Monserrato, Italy

Background and Aims:: PML has been described in various immunological diseases, usually in patients receiving immunosuppressive therapies. We describe a case of PML in an ever-treated pulmonary sarcoidosis.

Methods:: A 60-year-old Italian male patient, affected by pulmonary sarcoidosis under no treatment, was referred to us because, one month earlier, started noticing loss of memory, aphasia nominum and cognitive slowing. Neurological examination revealed cognitive-motor slowing, mild right hemiparesis, right-sided hyperreflexia and mild coordination ataxia. Routine laboratory exams were unremarkable; TPHA and HIV tests were negative. CSF cell count, protein and glucose levels were normal. PCR testing for CMV, EBV, HSV 1-2, VZV replication was negative; no oligo-clonal bands nor paraneoplastic antibodies were detected.

Cranial
MRI revealed large hyperintense areas on T2-weighted images in the subcortical white matter of both frontal lobes, with no contrast enhancement. Thinking of an atypical neurosarcoidosis, corticosteroids were initiated. During the hospitalization clinical conditions worsened, a CSF exam was repeated and JCV-specific DNA detected, without JCV replication in blood. Corticosteroids were immediately suspended and empirical therapy with Mirtazapine was initiated. Unfortunately, the progression was very rapid, with the early development of right spastic hemiparesis, sphincter incompetence and severe dysphagia quickly
leading the patient to death.

**Results:** The clinical, virological and imaging findings were consistent with PML, even though at first misdiagnosed due to the concurrent sarcoidosis and the absence of immunosuppressive therapy.

**Conclusions:** Even if it's rare, PML should always be investigated because its physiopathological pattern is not well-established, not knowing if the cause is primarily the immunosuppressive therapy or the disease itself.
Background and Aims:: SSPE is a chronic progressive encephalitis due to persistent measles viral infection. Clinical features, neuroimaging, EEG, CSF and serum measles antibody levels assist in the diagnosis. We report a case of SSPE confirmed by CSF measles antibodies and MRI abnormalities but without myoclonus or characteristic EEG changes.

Methods:: 35-year-old female presented with acute blindness worsening over two weeks. Rest of the neurological exam was normal with no evidence of optic neuritis or papillitis. Brain MRIs (Figure 1) showed progressive involvement of white matter extending from occipital region to frontal cortex. Patient gradually lost cognitive and motor skills. Measles antibodies were suggestive of SSPE (Table 1), Serial EEGs persistently showed only non-specific mild patchy background slowing which remained same. Brain biopsy was consistent with panencephalitis. A diagnosis of SSPE was made. No known classical EEG changes appeared over a one year follow up period. Vaccination history was uncertain. She was treated with alpha Interferon, Ribavirin and intrathecal
Isoprinosine.

Figure 1: A, B, C, D, E, F: T1 flare images showing rapid occipital to frontal progression of hyperintensity.
Results: The diagnosis of SSPE is mainly based on Dyken’s criteria (Table 2). EEG can be normal or generally slow in the early stages of SSPE but with time EEG evolves showing the characteristic ‘myoclonic’ pattern and later increasingly disorganized with high amplitudes and random dysrhythmic slowing.

<table>
<thead>
<tr>

<tr>
<td>Serum antibody titer</td>
<td>&gt; 1/256</td>
</tr>
<tr>
<td>CSF to serum antibody ratio</td>
<td>1/25 (more than 1/100)</td>
</tr>
</tbody>
</table>

Table 1

Conclusions: To best of our knowledge, there are no reported cases of SSPE with normal or near normal EEGs occurring throughout the course of the illness over one year. This finding made the diagnosis difficult in this case.

Table 2: Dyken’s criteria
Definitive: criteria 5 and three more criteria
Probable: three of the five criteria
1) Clinical – Progressive, subacute mental deterioration with typical signs like myoclonus
2) EEG - periodic, generalized, bilaterally synchronous and symmetrical high-amplitude (300–1500 μV) slow waves 0.5- to 2-seconds that recur at regular intervals of 5–15 s called Radermecker complexes
3) Cerebrospinal fluid – Raised globulin (greater than 20% of the total CSF protein) or oligoclonal bands
4) Measles antibodies – Raised titer in serum (>1/256) and/or CSF (>1/4)
5) Brain biopsy – Suggestive of panencephalitis
Background and Aims:: Tuberculosis (TB) is a common infection worldwide. Approximately one third of the entire world population is infected with TB. Involvement of spinal cord and spinal nerve root is one of the leading causes of disability in these patients and it has a significant impact on morbidity and mortality. Through this study we aim to study the incidence, prognosis and impact of different types of spinal cord involvement in patients of CNS TB.

Methods:: Prospective observational study.

Results:: Current study included 99 patients of TBM. The commonest clinical features were fever(100%), headache(94.9%) and vomiting(70.7%), loss of weight/appetite(71.7%) and seizures(26.3%). Clinically, meningeal signs(94.9%), altered sensorium(62.6%), and focal deficits were most common. Clinical evidence of spinal cord involvement was found in 22 patients. MRI spine was abnormal in 61.6% of patients, including arachnoiditis(47.5%), isolated root enhancement(8.1%) and Pott's spine(6.1%) patients. All the patients were treated with standard antitubercular therapy as per guidelines. Presence of hydrocephalus, infarcts, exudates, and tuberculomas, and spine involvement correlated highly significantly with final outcomes. Positive influence of clinical and radiological evidence of cord/ root involvement on poor outcome as defined by mRS(p=0.01)

Conclusions:: Spinal disease in form or cord/ root or bone involvement is common in patients with CNS TB being seen in approximately 61.6% of all patients. Most common abnormality is in form of arachnoiditis. Clinical and radiological evidence of spinal disease is associated with poor functional recovery in CNS TB.
COMPARISON OF DEXAMETHASONE REGIMENS IN TUBERCULAR MENINGITIS (TBM): A RANDOMIZED OPEN LABEL CLINICAL TRIAL

Deepti Vibha1, Alvee Saluja1, Awadh Pandit1, Marjari Tripathi1, Achal Kumar Srivastava2, Kameshwar Prasad2, Sada Dwivedi2, Rajesh Singh2, Mv Padma Srivastava1
1AIIMS, New Delhi, Neurology, New Delhi, India, 2All India Institute of Medical Sciences New Delhi, Neurology, New Delhi, India

Background and Aims:: Corticosteroids are used as adjunctive treatment in tuberculous meningitis (TBM). There is no universally accepted regimen of steroid administration. It is also not known about the optimum duration and route of steroid administration. Overlapping intravenous with oral dexamethasone versus directly switching intravenous to oral dexamethasone has not been compared in TBM. We aimed to study two regimens of dexamethasone: overlap oral steroid (OOS) arm and a direct oral steroid (DOS) arm, via a randomized controlled trial.

Methods:: In a randomized open labelled study, patients with TBM were divided into overlap oral steroid (OOS) arm and a direct oral steroid (DOS) arm. The primary outcome was the proportion of patients with symptomatic resolution at one month. The secondary outcomes were mortality and modified Rankin Scale (mRS) at three and six months.

Results:: Fifty-three (53) TBM patients were randomized. The symptomatic resolution at one-month in OOS (71.4% (15/21)) versus DOS ((85.0% (17/20) arm) was similar (p value: 0.45). Median mRS was 2.5 (IQR:1.0;6.0) in the OOS arm versus 1.0 (IQR: (0.0;4.0) in the DOS arm (p value: 0.31) at six months. The mortality at six months was 31.8% (7/22) in the OOS arm versus 20.0% (4/20) in the DOS arm (p value: 0.49).

Conclusions:: The outcomes were similar with both regimens in terms of achieving symptomatic resolution at one, three and six months in patients of TBM. Furthermore, there was no difference in morbidity and mortality at three and six months. These results are applicable to stage I, II and III TBM.
PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY AFTER DARATUMUMAB IN MULTIPLE MYELOMA: A CASE REPORT.

Nicoletta Giuseppa Caracciolo\textsuperscript{1,2}, Laura Di Clemente\textsuperscript{2}, Pierluigi Galizia\textsuperscript{2}, Silvia La Cesa\textsuperscript{2}, Luca Prosperini\textsuperscript{2}, Valeria Cozzolino\textsuperscript{2}, Claudio Gasperini\textsuperscript{2}, Carla Tortorella\textsuperscript{2}
\textsuperscript{1}Sapienza University of Rome, Department Of Neurosciences, Rome, Italy, \textsuperscript{2}San Camillo-Forlanini Hospital, Department Of Neurosciences, Rome, Italy

Background and Aims:: Progressive multifocal leukoencephalopathy (PML) is a rare severe central nervous system (CNS) opportunistic infection usually occurring in immunocompromised patients. Iatrogenic PML has been described in patients assuming treatment suppressing immune surveillance in CNS. Daratumumab is an anti-CD38 monoclonal antibody, used to treat Multiple Myeloma (MM), causing the destruction of suppressive cells and the increase of CD4+ helper and CD8+ cytotoxic T cells. Only two cases of PML on daratumumab has been reported in literature.

Methods:: We report a case of PML in a patient affected by MM who started daratumumab treatment two months before our observation.

Results:: The patient was a 69 years old woman who experienced subacute onset of left hemiparesis and dysarthria followed by status epilepticus. A diagnosis of right frontal ischemic lesion was suggested on the emergency CT scan. The clinical course was rapidly progressing. Daratumumab was suspended. Cerebrospinal fluid (CSF) PCR demonstrated JCV DNA in the CSF. Brain MRI showed a large edematous frontal T2-hyperintense, T1-hypointense lesion with peripheral and patchy Gd-enhancement. PML-immune reconstitution inflammatory syndrome (IRIS) was diagnosed. Intravenous methylprednisolone was started, but the patients died within one month.

Conclusions:: PML is a life threatening condition often complicated by PML-IRIS in patients ongoing immunosuppressive treatment. PML cases under Daratumumab has been rarely reported. Since no specific PML treatment are available the unique treatment approach for such a condition is the restoration of the host's adaptive immune response. A close proactive surveillance aimed to an early diagnosis allowing early treatment discontinuation is challenging for hematologists and neurologists.
**Background and Aims::** Tuberculosis (TB) is an infectious disease caused by Mycobacterium tuberculosis, which adds considerably to global morbidity and mortality. Intracranial tuberculoma remains a significant cause of intracranial mass lesion. It can occur anywhere in the brain with diverse clinical symptoms. Disseminated tuberculosis resulting from the lymphohematogenous spread of Mycobacterium tuberculosis in two or more contiguous sites is a debilitating disease. Although frequently reported in immunocompromised patients, we encountered a case of disseminated tuberculosis with pulmonary and renal involvement and multiple intracranial tuberculoma in an immunocompetent patient.

**Methods::** Case Report

**Results::** A 48-year-old gentleman, hypertensive for five years, presented with acute onset gait unsteadiness which was slowly progressive for the past 10 days. He was getting tired of doing his everyday routine tasks, and he had the tendency to sway to the side while walking. CNS examination revealed bilateral cerebellar signs with brisk deep tendon reflexes. MRI brain with contrast showed multiple ring-enhancing lesions of varying size in the bilateral cerebellar, cerebral hemisphere, and in the brainstem with perilesional edema. CT chest showed non-homogeneous density in the left upper lobe with small cavities and reticulonodular densities in bilateral lung fields with adjacent pleural thickening. Based on the clinical history, examination, and imaging findings, anti-tuberculous drugs and steroids were initiated. His MRI was repeated after 3 months which showed resolution of lesions along with clinical improvement.

**Conclusions::** Our case report highlights the extensive involvement of CNS tuberculosis in an immunocompetent individual and prompt resolution of clinical symptoms and recovery with appropriate treatment.
ACUTE LYME NEUROBORRELIOSIS FOLLOWING COVID-19 VACCINATION: JUST AN UNLUCKY TEMPORAL CORRELATION?

Davide Cardellini, Maria Rigoni, Federico Giopato, Alberto Terrin, Alessandra Vidali, Domenico Bonifati
Ca’ Foncello Hospital, Neurocardiovascular, Treviso, Italy

Background and Aims:: Diagnosis of Neuroborreliosis is often challenging and requires an extensive investigation, especially in atypical cases. Herein we report a case of rhombencephalitis developed eight days after Vaxzeria vaccine. Criteria of possible acute Neuroborreliosis were fulfill and other causes ruled out.

Methods:: A 38 years-old healthy woman was admitted to emergency room for fever, drowsiness and mental confusion. The day after her symptoms worsened and neurological examination revealed mild deficit of right VII cranial nerve, ataxia, dysphagia and slurred speech. A diagnosis of rhombencephalitis was made. Lumbar puncture showed lymphocytes pleocytosis (119 white cells/mm³) and mild increase of proteins (53 mg/dL, range 15-45), while cerebral MRI was negative. Impairment of bilateral R2 response at blink reflex confirmed a brain steam involvement. A broad microbiological and immunological search performed on serum and CSF was unremarkable, except IgM for Borrelia (both enzyme immunoassay and immunoblot) and Coxiella Burnetii. Borrelia specific intrathecal antibody and polymerase chain reaction on CSF resulted negative, CXCL13 was not performed. Acyclovir and ampicillin treatment were started and when microbiological result was available we switched treatment to parenteral ceftriaxone.

Results:: Symptoms drastically improved in the following three weeks and patient was thereafter discharged with only mild cerebellar signs.

Conclusions:: Clinical course and response to antibiotic treatment support diagnosis of acute Lyme Neuroborreliosis, in addition IgM positivity for Coxiella Burnetii is a further clue for previous exposure to tick borne. The covid-19 vaccination doesn’t seem to have a casual correlation, but immune system engagement may have had a role.
PRIMARY WHIPPLE DISEASE OF THE BRAIN: CASE REPORT WITH LONG-TERM CLINICAL FOLLOW-UP

Rim Smaoui, Nouha Farhat, Salma Sakka, Olfa Hdiji, Khadija Sonda Moalla, Sawsan Daoud, Mariem Damak, Chokri Mhiri
Universal Hospital Habib Bourguiba, Neurology, SFAX, Tunisia

Background and Aims:: Whipple disease (WD) is a rare multisystem disorder caused by infection with Tropheryma whippelii. Central nervous system involvement is a quite common feature observed in 20–40% of cases, whereas only 4% of patients has an exclusively neurological presentation.

Methods:: We linked the information about our patient with a literature review of patients with WD with neurological manifestations to elucidate the clinical features and diagnosis of neuro-whipple disease.

Results:: We report the case of a 53-year-old man with no medical history who consulted with a 2-month history of eye movement disorder, progressive mild cognitive decline and sleep disturbances. The patient also reported a loss of appetite and gradual weight loss. The examination showed oculo-masticatory myoryhythmias, bilateral vertical gaze palsy, skin hyperpigmentation and brittle nails. Brain MRI was normal. He also underwent a total-body CT scan which detected retroperitoneal and mesenteric lymphadenopathy and right sacroiliac ankylosis. Laboratory serological tests showed a biological inflammatory syndrome. Blood smear and routine CSF analysis were normal. Neuro-Whipple disease was then suspected and it was confirmed by the duodenum biopsy. Our patient was treated with IV ceftriaxone for 4 weeks, followed by oral doxycycline and hydroxychloroquine with a marked improvement.

Conclusions:: This case emphasizes the need to consider WD within the differential diagnosis of patients with movement disorders, cognitive impairment or sleep disturbance of unclear origin or with normal brain MRI because it is a potentially treatable disease.
CHARACTERISING A COHORT OF ENCEPHALITIS PATIENTS: AN EXPERIENCE FROM A SOUTH EAST LONDON TRUST

Wenona Barnieh¹², Bazo Raheem², Flavia Niccolini¹², Eli Silber¹², George Dervenoulas¹
¹Queen Elizabeth Hospital, Woolwich, Lewisham & Greenwich NHS Trust, Department Of Neurosciences, London, United Kingdom, ²King’s College Hospital NHS Foundation Trust, Department Of Neurosciences, London, United Kingdom

Background and Aims:: Encephalitis is inflammation of the brain parenchyma; the aetiology is commonly infectious, autoimmune or unknown. The estimated incidence rate in England is 2-8 cases/100,000/year. Patients present with symptoms of reduced consciousness, seizures, psychiatric symptoms or cognitive impairment. To aid the diagnostic process neuroimaging, lumbar puncture, EEG and antibodies targeting surface or intranuclear antigens are commonly used. Prompt treatment within 48 hours reduces the mortality and chronic physical and neuropsychological sequelae. The aim of the study was to explore clinical characteristics in a cohort of encephalitis patients. Our cohort included patients admitted in a district general hospital at south east London.

Methods:: A retrospective cohort study of patients who were diagnosed with encephalitis across two district general hospitals in South East London were enrolled in the study. 94 patients which met the encephalitis criteria were included in the study.

Results:: More than 90% received intravenous acyclovir. Cases of autoimmune encephalitis (n=8) were treated with either intravenous immunoglobulins or plasmapheresis. The average number of days of admission was 26 days. 27 patients were admitted to the intensive care unit and 11 patients died. On discharge the majority of cases had some disability (modified rankin scale 2). 40% received at least 1 follow up appointment.

Conclusions:: The adherence to encephalitis guidelines need to be improved to aid prompt diagnosis and appropriate management of the patient. These patients have significant morbidity and require close follow up after the admission.
DIAGNOSTIC GRID FOR PREDICTION OF INFARCTION IN PATIENTS WITH TUBERCULOUS MENINGITIS

Neha Kuthiala, Ashu Bhasin, Sakshi Sharma, Mv Padma Srivastava
ALL INDIA INSTITUTE OF MEDICAL SCIENCE, Neurology, NEW DELHI, India

Background and Aims:: TBM is commonest CNS-infection and poses significant diagnostic-management challenges in the developing countries-India.

Methods:: A total of 300 patients diagnosed with TBM were screened and out of which n=129 were recruited in the study and n= 171 patients were excluded (n=55 refused for CSF examination, n=65 had disseminated TBM and n=51 did not match inclusion criteria). Inclusion Criteria: Early TBM: Diagnosed within a month of onset IA). Not on ATT. IB). On ATT for one week Late TBM: Diagnosed after a month of onset IIA). Not diagnosed till presentation IIB). Diagnosed-not started on ATT

Conclusions:: Patients with TBM having low Glasgow coma scale score on presentation and presence of exudates have a significantly high risk for development of infarction.
Background and Aims:: TBM has the highest morbidity and mortality, chiefly in the initial few days to weeks and therefore it is important to modify the principles of the treatment to prevent this. AIMS To observe if administration of Linezolid along with four drug standard weight ATT based regimen in intensive phase of treatment in TBM will be safe and help reduce mortality and morbidity at 1 and 3 months among patients with TBM when compared to standard ATT alone.

Methods:: Patients with TBM were screened and recruited after obtaining a written and informed consent, if they fulfilled the criteria. Patients were randomized in a 1:1 ratio into two treatment groups either to receive standard ATT alone (control group); or add on 600 mg BD linezolid daily for 4 weeks along with conventional four drug weight based ATT[ HRZE/S]. A total of 26 patients were randomized, (14 in intervention and 12 in the control arm).

Results:: There was no difference in the two groups in the baseline characteristics . There was no significant difference between two groups in terms of mortality at one and three months and morbidity at three months . However there was significant shift towards a favourable mRS at one month and a statistically significant improvement in mean GCS score at day 14 and 30 post randomization in the linezolid arm.

Conclusions:: There was no difference between mortality and morbidity between linezolid and control arms at one and three months . Study with a larger sample size is required.
MENINGITIS AND INFECTION DISSEMINATED BY MYCOBACTERIUM BOVIS ASSOCIATED WITH CONSUMPTION OF NON-PASTEURIZED DAIRY, AN INCREASINGLY FREQUENT DISEASE IN MEXICO.

Minerva Lopez Ruiz¹, Laura Escobedo Jaimes², Omar Muñoz Miranda¹, Martha Ramírez Guerra², Luis Narváez Díaz³, Mario Hernández Aldama⁴
¹Hospital General de México, Neurología, Ciudad de México, Mexico, ²Hospital General de México, Neumología, ciudad de México, Mexico, ³Instituto Nacional de Enfermedades Respiratorio, Laboratorio De Micobacterias, ciudad de México, Mexico, ⁴Hospital General de México, Radiología, México, Mexico

Background and Aims:: Tuberculosis is a public health problem, with high morbidity and mortality; M. bovis causes tuberculosis in humans, livestock, and primates. Primary infection can occur through ingestion of unpasteurized dairy products and inhalation of aerosols.

Methods:: We studied the characteristics of neuroinfection and dissemination of mycobacterium bovis in 12 patients.

Results:: Twelve patients were studied, with a mean age of 30 years. Among the risk factors it was found that they had consumption of unpasteurized dairy products in 7, HIV in 6, diabetes 3, lupus 1, pregnancy 1. In ten patients the chest X-ray was observed without alterations; however, when performing a washing liquid study bronchial, a positive Lowestein culture was found. The neurological manifestations presented were headache, seizures, hallucinations, cognitive, sensory and motor deficits. Six patients required management in intensive therapy. The isolation of M. bovis was performed in CSF in 10/11; lung 9/10, urine 8/11; and in ascites, bone marrow, skin, ganglion and brain abscess. In all cases, M bovis showed intrinsic resistance to pyrazinamide, in four patients resistance to two or more drugs was demonstrated, for which a second-line drug treatment was administered. Eight patients showed resolution of the disease.

Conclusions:: Tuberculosis by M bovis in people with immunocompromised there is a greater risk of dissemination of the disease, an exhaustive study should be carried out to isolate and identify the bacillus and perform drug sensitivity tests. The appropriateness of the treatment depends on all this and the survival of patients with minimal neurological sequelae depends on it.
PERI-IMPLANT POTT'S SPINE IN AN OPERATED CASE OF BURST FRACTURE: A RARE CASE REPORT

Bharath Patil1, Rohit Jindal2
1Government Medical College and Hospital Chandigarh, Orthopaedics, CHANDIGARH, India, 2Government Medical College and Hospital, Chandigarh, Orthopaedics, Chandigarh, India

Background and Aims:: Short segment pedicle screw fixation is a standard of treatment for Lumbar burst fractures. Isolated case reports have been published on tubercular infection of bone and joints following fracture fixation surgery, but no report is available on tubercular infection of the adjacent vertebra following pedicle screw fixation.

Methods:: 27-year-old female was diagnosed with L1 burst fracture without any neurological deficits following a road traffic accident and was operated with posterior pedicle screw fixation from D12 to L2. Post-operatively patient was asymptomatic for 5.5 years after which she started complaining of lower back ache which was insidious in onset, non-radiating and gradually progressive. There were no constitutional symptoms or deficits. On radiographic evaluation there was collapse at L2-L3 level with T1 hypointense and T2 hyperintense marrow, edema and collection. Diagnosis of late infection was made with the possibilities being pyogenic or tubercular infection. Percutaneous pedicle biopsy was taken from L3 vertebrae and was sent for histopathology, Culture sensitivity and Cartridge based nucleic acid amplification test (CBNAAT) for tubercular infection. Histology revealed tubercular epitheloid granulomas and CBNAAT was positive for mycobacterium tuberculosis.

Results:: Patient was put on Anti-tubercular therapy (ATT) with two months of Isoniazid, rifampicin, ethambutol and pyrazinamide (HRZE) and 16 months of HRE with regular follow-up. Pain settled within two months after onset of therapy. At the end of ATT course patient was planned for implant removal surgery and did not need any stabilisation and healed with a kyphosis of <20 degrees.

Conclusions:: The distinct possibility of tubercular infection should always be kept in spondylodiscitis infections and conservative management with ATT yields good results when residual kyphosis is not significant.
COMPARISON OF PATTERN OF INFACTIONS IN TUBERCULOUS AND CRYPTOCOCCAL MENINGITIS

Nikita Dhar, Mritunajai Kumar, Ashutosh Tiwari
All India Institute of Medical Science, Neurology, Rishikesh, India

Background and Aims:: To compare the frequency and pattern of stroke, the specificity of tubercular zone (TBZ) infarction and its effect on outcome in tuberculous (TBM) and cryptococcal meningitis (CM).

Methods:: This retrospective study was conducted at two tertiary centres in India during May 2018 to Jul 2020. Sixty-one patients with TBM and 22 with CM were included. The primary outcome was proportion of patients of TBM and CM with infarction. Secondary outcomes included anatomical locations of infarction and in-hospital mortality.

Results:: Infarctions were noted in 52.5% of patients with TBM and 54.5% in CM (P = 0.87) with caudate head infarcts in 9.4% vs 41.7% (P=0.01), cerebellar in 9.4% vs 33.3% (P=0.05), thalamic in 25% vs 0 and lobar in 28.1% vs 0 respectively. In TBM, the infarcts were located in TBZ in 3 (9.4%), ischemic zone (IZ) in 23 (71.9%), with six (18.8%) patients showed infarcts in both, while in CM group, it was in 0 (0%), 6 (50%) and 6 (50%) patients respectively. Infarcts were not associated with in-hospital mortality neither in TBM nor CM.

Conclusions:: Caudate head and cerebellar infarctions were more common in CM, while, thalamic, and lobar infarcts were frequent in TBM. TBZ infarcts were not specific to TBM.
EP0154 / #2409

VANISHING CEREBRAL RING ENHANCING LESIONS; A THREE YEAR MYSTERY

Devasmitha Wijesundara, Bimsara Senanayake
National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

Background and Aims:: Vanishing tumor is a rare phenomenon where the tumor spontaneously disappears or reduces to less than 70% of the initial volume without definitive treatment. We revisit the diagnosis of a patient initially diagnosed with cerebral metastases of unknown primary whose lesions vanished after three years.

Methods:: Case report A 44 year old woman presented with subacute onset hemiparesis, confusion and focal seizures. The presence of multiple haemorrhagic ring enhancing lesions (figure 1) prompted a diagnosis of cerebral metastases. Extensive workup failed to reveal a primary neoplasm and unfortunately she did not receive specific treatment and defaulted follow up. Three years later during evaluation for uveitis (figure 2) the cerebral lesions were found to have disappeared (figure 3). Cerebrospinal fluid analysis was normal. Investigations excluded sarcoidosis and tuberculosis. Further questioning uncovered a history of parotitis and contact with cats. Toxoplasma IgG was positive in serum and a diagnosis of toxoplasmosis was made. She was non-diabetic and immunodeficiency screening including HIV was negative.
Results:: Discussion Vanishing cerebral lesions pose a diagnostic dilemma. Differential diagnosis includes primary CNS lymphoma, inflammation, demyelination, neurosarcoidosis, and infection. As biopsy is often deferred due to operative risks, a careful history and patient follow up is paramount. Eccentric target sign (figure 1) is characteristically seen in cerebral toxoplasmosis with a specificity of 95%. Although there have been reports of cerebral toxoplasmosis in immunocompetant patients, an underlying immunodeficiency state should always be considered.

Conclusions:: Cerebral toxoplasmosis can lead to vanishing brain lesions. This diagnosis is supported by pathognomonic neuroradiological findings and serology.
Background and Aims:: Neurocysticercosis (NC) is one of the main parasitological diseases affecting the central nervous system. It is a disease linked to poverty and is considered endemic in most countries in Asia, Sub-Saharan Africa, and Latin-America. The evaluation of its frequency in endemic countries is difficult to carry out since there are no systematic records. In this context, the evaluation of the frequency of hospitalization represents information of interest. The objective of this work was to evaluate the evolution of the frequency of hospitalization of patients with NC between 1995 and 2019, at the Manuel Velasco Suarez National Institute of Neurology and Neurosurgery (INNN).

Methods:: The data were obtained from the hospital epidemiology service, using ICD-10 coding B.69. We complement this information with the hospital discharge data from the different public care institutions between 2004 and 2019. The index of NC hospitalizations/total hospitalizations was obtained for each service. The public care institution's information was obtained from national records and an official health secretary website.

Results:: In the INNN, the frequency of hospitalization decreased significantly in neurosurgery (R = -0.69; p <0.001) and in neurology (R = -0.68; p = 0.001).

The analysis of hospital discharges from the public institutions in the country showed the same trend. (R = -0.978; P<0.0001).
The average age of the patients increased significantly during the period of study ($R = 0.77; p < 0.001$).

**Conclusions:** These results are very encouraging, probably related to the improvement of hygienic-sanitary conditions in rural areas. However, although less frequent, the disease persists. Efforts to achieve eradication must continue.
PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY AFTER IMMUNOCHEMOTHERAPY WITH DRD PROTOCOL FOR MULTIPLE MYELOMA: A CASE REPORT

Riccardo Maria Borgio¹, Salvatore Palmieri², Mario Cirillo³, Mario Risi⁴, Paola Maria Cinque⁵,⁶, Elena Grimaldi⁷, Gioacchino Tedeschi⁸, Antonio Gallo⁹
¹University of Campania Luigi Vanvitelli, Department Of Advanced Medical And Surgical Sciences, Naples, Italy, ²Hematology Cardarelli Hospital, Hematology, Naples, Italy, ³University of Campania Luigi Vanvitelli, I Division Of Neurology, Department Of Advanced Medical And Surgical Sciences, Naples, Italy, ⁴AOU University of Campania, Department Of Advanced Medical And Surgical Sciences, Naples, Italy, ⁵San Raffaele Scientific Institute, Infectious Diseases, Milano, Italy, ⁶University of Campania Luigi Vanvitelli, Department Of Experimental Medicine, Napoli, Italy, ⁷University of Campania Luigi Vanvitelli, Department Of Advanced Medical And Surgical Sciences, Napoli, Italy, ⁸University of Campania "Luigi Vanvitelli", Department Of Advanced Medical And Surgical Sciences, Napoli, Italy

Background and Aims:: A 65-years-old woman with a refractory Multiple Myeloma (MM) treated with Daratumumab in combination with Lenalidomide and Dexamethasone (DRd) was admitted to our Neurology Unit for the subacute onset of left upper limb weakness, ataxia, and dysarthria.

Methods:: As differential diagnosis, we considered: infective CNS diseases, cerebrovascular disease, chemotherapy- related encephalopathy and autoimmune or paraneoplastic syndromes. In order to make the correct diagnosis we performed a diagnostic procedure, including brain and spinal cord MRI, blood tests and CSF analysis.

Results:: MRI findings showed multiple diffuse white matter (WM) T2/FLAIR hyperintensities localized in the central pons and bilateral cerebellar peduncles and white matter, with diffusion restriction at the edges of the lesions. CSF analysis was positive for the presence of JC virus DNA (942 copies/mL), whereas all other microbiological investigations were negative. Blood laboratory tests showed the presence of JCV DNA on plasma (1020 copies/mL). Taken together these findings supported the diagnosis of progressive multifocal leukoencephalopathy (PML) secondary to a profound and combined immunodeficiency attributable to both the MM and the immunochemotherapy.

Conclusions:: PML is a life-threatening demyelinating CNS disorder caused by JC virus reactivation. To the best of our knowledge, there are only few other reports on PML occurring in association with Daratumumab therapy. Moreover, MRI findings of this case were relatively uncommon since demyelinated areas were exclusively and extensively located in the brainstem and cerebellar areas. Further studies are required to assess a causal relationship between Daratumumab and PML.
THE UNAVERTED COEXISTENCE OF MENINGEAL AND SPINAL TUBERCULOSIS, A SERIES OF CASES

Minerva Lopez Ruiz¹, Laura Escobedo Jaimes², Omar Muñoz Miranda², Martha Ramírez Guerra², Luis Narváez Díaz³, Mario Hernández Aldama⁴, Diana Orejuela Cabrera⁵, Héctor Mayoral Reyes⁵, Valentín Chávez López⁶, Alejandro Méndez Viveros⁷

¹Hospital General de México, Neurología, Ciudad de México, Mexico, ²Hospital General de México, Neumología, ciudad de México, Mexico, ³Instituto Nacional de Enfermedades Respiratorias, Laboratorio De Micobacterias, ciudad de México, Mexico, ⁴Hospital General de México, Radiología, Mexico, Mexico, ⁵Hospital General de México, Medicina Interna, Ciudad de México, Mexico, ⁶Hospital General de México, Neurología, México, Mexico, ⁷Hospital General de México, Neurocirugía, México, Mexico

Background and Aims:: Tuberculosis is a public health problem with high mortality. Central nervous system affection represents 2% of all cases, it can affect intracranial or spinal structures. The association of meningeal and spinal infection is infrequent, being associated with a poor prognosis.

Methods:: A retrospective study was carried out in a cohort of patients with meningitis tuberculosis associated with spinal tuberculosis treated from January 2013 to February 2021.

Results:: There were 22 patients with both, meningeal and vertebral tuberculosis, the risk factors were HIV infection 27.27% and diabetes mellitus 22.72%; and 45.45% remained without risk factors. The initial symptoms were fever in 77.27%; headache 72.72%; weight loss 63.63%; 27.27% presented paraplegia and 18.18% paraparesis. The results obtained from the CSF study and the MRI established the final diagnosis. The CSF study showed pleocytosis 40.90%, hyperproteinorachia 50%, with a mean of ADA of the 19.07 U / L, 31.81% showed a positive Lowestein Jensen culture, 27.23% GeneXpert +. The MRI of the skull and spinal showed leptomeningitis 28.6%, tuberculomas 28.6%, and arachnoiditis 28.6%; hydrocephalus and vasculitis in 21.4%, spondylodiscitis 57.1%, vertebral collapse 35.7%, paravertebral abscess 35.7%, and spinal tuberculomas 21.4% of the patients.

Conclusions:: The association of meningeal and vertebral tuberculosis should be suspected in every patient who presents fever, weight loss and gait alteration associated with comorbidity such as HIV and diabetes. Some cases require drainage of the paravertebral abscess and spinal cord decompression. If a rapid diagnosis and treatment is not accomplished, the risk of complications, disability and death increases.
GEOPHAGY AS RISK BEHAVIOUR FOR NEUROCYSTICERCOSIS AMONG CONGOLESE WOMEN

Marcellin Bugeme¹, Olivier Mukuku², Kegnide Affognon³, Emmanuel Muyumba¹
¹University of Lubumbashi, Internal Medicine, Lubumbashi, Congo, Republic of, ²Institut Supérieur des Techniques Médicales de Lubumbashi, Research, Lubumbashi, Congo, Republic of, ³Centre hospitalier national universitaire de Fann, Clinique De Neurologie, Dakar, Senegal

Background and Aims:: Neurocysticercosis (NCC) is a common helminthic infection of the nervous system that occurs when humans become intermediate hosts in the life cycle of the pork tapeworm, Taenia solium, after ingesting its eggs. The disease is most often transmitted by tapeworms to healthy individuals through unhygienic handling or direct contact with human excreta. Clay (Pemba) consumption soiled by Taenia solium eggs can cause NCC. This study aims to describe socio-demographic, clinical, and neuroimaging features of patients with NCC related to geophagy or consumption of clay in our environment.

Methods:: This is a cross-sectional descriptive study, carried out in Lubumbashi in the Democratic Republic of Congo, from January 2019 to June 2020. For each patient examined, we collected socio-demographic, clinical and neuroimaging features, and therapeutic modalities.

Results:: We examined 6 patients, all of whom were female, with a mean age of 27.5 years (range: 23-37 years). Contact with pork was noted in 5 patients (83.3%), all patients regularly consumed clay (100%). Generalized epilepsy was observed in 66.6%. In neuroimaging, first stage lesions were found in 3 patients, third stage lesions in 2 patients, and fourth stage lesions in 5 patients. In 2 patients, 2nd, 3rd and 4th stage lesions were noted simultaneously. Frontal location of lesions was the most found (100%), followed by parietal location (66.6%). Three patients (50%) had more than 10 lesions. All patients evolved well under antiepileptic drugs alone or associated with antiparasitic treatment.

Conclusions:: This study shows that geophagy is also a risk behavior of neurocysticercosis found in our environment.
CRYPTOCOCCAL MENINGITIS: DIAGNOSTIC AND THERAPEUTIC CHALLENGE IN PLACES WITH SCARCE RESOURCES.

Helena Buque, Elder Lorenzo
Hospital Central de Maputo, Medicina- Neurologia, Maputo, Mozambique

**Background and Aims:** A 34 years old male, HIV positive diagnosed 2 months ago during hospitalization due to bifrontal hemorrhage contusion after cranioencefalic trauma, in antiretroviral treatment with TDF-3TC-DTG, hospitalized with generalized clonic tonic convulsions, severe headache and behavior change characterized by incoherent speech. Neurological examination: with slower speech, depressed mood, facial acymetry with deviation of the right lip commissure; gait unevaluable, patient prostrate and not sitting without support, muscular strength 3/5 in the left hemibody, right lower limb with 4/5. with stiff neck and positive Kernig signal. General physical examination: fever temp: 38,5 celsius, extreme cachexia, with decubitus bedsores in the buttocks and calcaneus. skin with several insignia of traditional treatment.

**Methods:** case report

**Results:** CBC: WBC: 4,45; HB: 10.9; linf: 15,3%; Neutrof: 73.8% VHS: 52mm/H Biochemistry: normal CSF cytochemistry: Yeasts are observed, glucose- 0.22 Anti-toxoplasmosis antibody: non-reactive IgG / IgM

**Conclusions:** Definitive diagnosis: Cryptococcal meningitis; AIDS AIDS IV Specific Treatment instituted: Amphotericin B 50mg / day ev; Fluconazole 1200mg / d Antiretroviral Treatment Others treatments: Cotrimoxazol 960mg/d, Ceftriaxone 2g 12/12h; hidratation, analgesics. With current difficulties due to the absence of imaging exams like TAC and NMR, and ideal treatments options, the diagnosis of CNS infections has been a huge challenge, but we strive for the best for patients.
NEUROCOGNITIVE IMPAIRMENT AND EPILEPSY IN SCHOOL-AGED CHILDREN AFTER SEVERE MALARIA IN A MALARIA ENDEMIC AREA.

Alfred Njamnshi¹, Constance Ayuk Agbor², Evelyn Mah³, Leonard Ngarka⁴, Samuel Angwafor¹, Wepnyu Yembe Njamnshi⁵, Leonard Nfor⁶, Earnest Tabah⁵, Prosper Sayong², Nicolas Ruffieux⁷, Jean-Marie Annoni⁷

¹Brain Research Africa Initiative (BRAIN), Yaoundé, Cameroon/Geneva, Switzerland, Administration, Bamenda, Cameroon, ²Central Hospital Yaoundé, Cameroon;, Neurology Department, Yaounde, Cameroon, ³Faculty of Medicine and Biomedical Sciences, University of Yaounde 1, Department Of Pediatrics, Yaounde, Cameroon, ⁴Brain Research Africa Initiative Administration, Yaounde, Cameroon, ⁵Brain Research Africa Initiative Neuroscience Research, Yaounde, Cameroon, ⁶Brain Research Africa Initiative Research, Yaounde, Cameroon, ⁷University of Fribourg, Neurosciences, Fribourg, Switzerland

Background and Aims: Severe malaria is a contributor to neurocognitive impairment and epilepsy in children living in sub-Saharan Africa but there is no published data on this subject in Cameroon. We thus sought to understand the possible neurological long term effects of severe malaria in school-aged children in Yaoundé.

Methods: In this retrospective cohort study of 50 eligible children who survived severe malaria in Yaoundé, demographic, clinical, neuropsychological and electroencephalographic evaluations were done using standard clinical procedures.

Results: The mean age was 9.38±3.06 years. The prevalence of neurocognitive impairment and epilepsy were 38% and 20% respectively. The risk of developing epilepsy evaluated by EEG epileptic activity was 34.4%. The incidence of neurocognitive impairment was 226 cases per 1000 person years. The incidence of epilepsy and epileptic activity on the electroencephalogram were 140 and 154 cases per 1000 person years respectively. The most affected cognitive domains were: fine motor skills, sustained attention, mental flexibility and verbal memory. There was no association between coma and neurocognitive impairment (p=0.54) but there was an association between high daily seizure frequency during malaria and subsequent epilepsy (p=0.013 respectively) and between disease duration and epileptic activity (p=0.043).

Conclusions: The prevalence and incidence rates of neurocognitive impairment and epileptic activity are significantly high in children who suffered from severe malaria in Yaoundé. High seizure frequency during severe malaria appears to be a predictor of epilepsy while coma is not a predictor of neurocognitive impairment in these children.
CHRONIC PAIN AMONGST HIV-INFECTED ADULTS FOLLOWED-UP AT THE BAMENDA REGIONAL HOSPITAL, CAMEROON

Angwafor Anye¹, Ngwanui Tasha¹, Alfred Njamnshi²,³, Dora Mbanya⁴
¹Faculty of Health Sciences, University of Bamenda, Clinical Sciences, Bamenda, Cameroon, ²Brain Research Africa Initiative, Neuroscience Research, Yaounde, Cameroon, ³Neurology Department, Central Hospital Yaoundé/Faculty of Medicine and Biomedical Sciences (FMBS), The University of Yaoundé I, Neurology, Yaounde, Cameroon, ⁴Faculty of Medicine and Biomedical Sciences, Microbiology,parasitology, Hematology And Infectious Diseases, Yaounde, Cameroon

Background and Aims:: Pain has been recognised as a common symptom people living with HIV. The prevalence ranges from 24% amongst ambulatory patients, 50%-60% in hospitalised patients and 60%-70% in hospice settings. Severe pain can potentially impact in quality of life and functional ability. Little is known on the prevalence of pain and associated factors in Cameroonian population of people living with HIV, hence the study.

Methods:: This was an observational cross-sectional study involving HIV-infected adults followed-up at the Bamenda Regional Hospital. Data were collected on demographics, baseline HIV information and on pain. Research tools included the Brief pain inventory short form, the patient health questionnaire-2 and the self-administered Leeds assessment for neuropathic symptoms and signs.

Results:: A total of 290 participants completed the questionnaire of which 71.0% were female. The mean age was 47.47 (SD11.047). Almost 90% were adherent to combined antiretroviral therapy and 37.2% had been on treatment for 11 – 15 years. The prevalence of chronic pain was 27.6% with musculoskeletal (22.5%) and neuropathic (65%) pain being the most common. Pain most severely interfered with walking ability. None of the factors analysed including, age, gender or adherence to combined antiretroviral therapy, were significantly associated with chronic pain (p=0.224 95% CI 0.151 – 0.242 for non-adherence to p=0.847 95% CI 0.990 – 1.000 for gender).

Conclusions:: Pain is common in this population with HIV with musculoskeletal pain being the most prevalent. None of the factors analysed including age, gender or adherence to combined antiretroviral therapy were significantly associated with chronic pain.
NEUROLOGICAL OPPORTUNISTIC INFECTIONS AND WHY WE SHOULD NOT RELY ON CD4+ THRESHOLDS - A REPORT OF TWO CASES OF HIV-INFECTED PATIENTS WITH CNS DISEASE.

Melina Da Silva Bernardes¹, André Bertola Vanzan Filho¹, Carolina Souza Bandeira², Regina Alvarenga³, Marcos Gomes De Sousa²
¹Hospital Universitário Gaffrée e Guinle, Neurology, Rio de Janeiro, Brazil, ²Hospital Universitário Gaffrée e Guinle, Infectology, Rio de Janeiro, Brazil, ³Universidade Federal do Estado do Rio de Janeiro, Neurology, Rio de Janeiro, Brazil

Background and Aims:: CD4+ T-cell count (CD4+) has guided the diagnostic assumptions on HIV-infected patients with neurological disease. However, evidence has revealed the incidence of neurological opportunistic infections despite CD4+ > 200 cells/mm³. Aim: to describe two cases of CNS opportunistic infections in patients with CD4+ over the risk ranges.

Methods:: Case study.

Results:: Patient 1: A 46-year-old man with HIV infection presented with cognitive impairment, tremor, and fecal incontinence over the past few months. His CD4+ was 464 cells/mm³ and he was under treatment with ART. He had been treated for cerebral toxoplasmosis one year prior - his CD4+ was 18 cells/mm³ then. Neurological examination disclosed parkinsonian symptoms and slowed thought processes. A brain MRI showed bilateral T1 gadolinium-enhanced lesions in the basal ganglia. He was diagnosed with cerebral toxoplasmosis and had a marked improvement after pyrimethamine, sulfadiazine, and leucovorin therapy.
Patient 2: A 31-year-old man with HIV/AIDS poorly adherent to the treatment with ART presented with recurrent seizures and acute left hemiplegia. His CD4$^+$ was 258 cells/mm$^3$. Seven months before, he had been treated for cryptococcal meningitis - with a CD4$^+$ nadir of 64 cells/mm$^3$. Head CT showed large hypodense areas in the right frontal and parietal regions. CSF was positive for JC virus on polymerase chain reaction. He was diagnosed with progressive multifocal leukoencephalopathy. The ART was adjusted then and the clinical condition remained stable.
Conclusions: CNS opportunistic infections should be suspected in patients with HIV/AIDS and medical history of severe immunosuppression, even if they have partially recovered the CD4+.
INCIDENCE OF TICK-BORNE ENCEPHALITIS IN THE REPUBLIC OF BASHKORTOSTAN (RUSSIA) IN XXI CENTURY

Robert Ibatullin, Mansur Kutlubaev, Rim Magjanov
BGMU, Neurology, Ufa, Russian Federation

Background and Aims:: Tick-borne encephalitis (TBE) is transmissive zoonotic disease often severely affecting nervous system. A number of studies conducted in different geographical areas demonstrated evolution of TBE. Official registration of the cases of TBE in the Republic of Bashkortostan started approximately 70 years ago. Aim. To assess the main clinical and epidemiological features of TBE in XXI century and compare them with the data registered in XX century.

Methods:: We analyzed clinical and epidemiological features of 736 cases of TBE in the Republic of Bashkortostan starting from 2000. The comparative analysis with the data registered in XX century was performed (data in brackets).

Results:: The overall incidence of TBE in 2000-s was 0,91±0,45 cases per 100 000. In comparison to 1970-90-s this parameter decreased 3 times (3,05±1,12).Mean incidence mostly decreased in the Cis-Urals region while the majority of cases of TBE with clinical manifestation occurred in South Urals region of the Republic of Bashkortostan. The proportion of people who contracted TBE during outdoor recreational activities increased (р<0,05) and reached 40,46±12,60% (28,22±8,36%).

Conclusions:: 1) The incidence of TBE in the Republic of Bashkortostan in XXI century in comparison to 1970-90-s (р<0,05) decreased down to 0,91±0,45 cases per 100 000 people. 2) The frequency of the cases of TBE contracted during the outdoors recreational activities increased (р<0,05) up to 40,46±12,60% in XXI century, in comparison to XX century.
PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY RELATED TO HIV1 INFECTION WITHOUT CELLULAR IMMUNODEFICIENCY: CASE REPORT

Claudia Giliberto1, Elona Brahimi2, Enri Nako2, Flora Govone2, Gabriella Turano2, Vincenzo Marotta2, Alessia Di Sapi2
1Regina Montis Regalis Hospital, Neurology, CN, Italy, 2ASLCN1, Neurology, CN, Italy

Background and Aims:: Progressive Multifocal Leukoencephalopathy (PML) is a rare and debilitating disease of Central Nervous System (CNS) caused by JC virus (JCV), a poliomavirus generally located in CNS as asymptomatic infection in general population. In immunosuppressed patients, JCV can induce progressive damage of oligodendrocytes. We describe a patient with HIV1–related PML that occurred despite undetectable impairment of cellular immunity.

Methods:: Case report:A 42-years-old male came to our attention with a ten-months history of progressive vision loss and limbs tremor. His past medical history included HIV1 infection since 28-years old, treated with antiretroviral therapy. At admission, neurological examination showed bilateral ipovision, dysarthria, dysmetria, ataxia, mixed tremor at four limbs. Serum HIV load was 20700 copies/ml with normal CD4+ cell count. Brain MRI showed bilateral T2–weighted hypertintense lesions in cortical and subcortical parieto-occipital lobes; post-gadolinium T1-weighted images showed punctate foci of enhancement (milky way sign) in cerebellar hemispheres, basal ganglia and ribbon-like enhancement of U-fibers in fronto-parietal lobes. CSF PCR detected JVC and confirmed the diagnosis of PML. Empiric treatment with mirtazapine and short course of high dose steroids was started, but despite these treatments the patient’s neurological condition worsened and he died 5 months after diagnosis.

Results:: In the present case, PML was related to HIV1 infection with absence of any serological sign of immunosuppression.

Conclusions:: Very rarely PML was reported in apparently immunocompetent patients assuming these clinical cases may have undetectable immunodeficiency at the stage of diagnosis.
COMPLEX THERAPY OF NEUROLOGICAL SYNDROMES IN HIV INFECTED PATIENTS

Doston Sultonov, Satima Kuranbaeva, Sevara Kalandarova, Gulnora Rakhimbaeva, Sardorbek Khakimov

1Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan, 2Tashkent Medical Academy, Neurology, Farabi str., Tashkent, Uzbekistan

Background and Aims:: The aim of the study was to optimization of pathogenetically based approach to complex therapy of major neurological syndromes in HIV patients.

Methods:: The study is based on the survey data of 73 patients with HIV infection (54.4% women and 45.6% men), aged from 20 to 45 years old. For neuropsychological studies used Wechsler Memory Scale (WMS), "Schulte tables" and "Incomplete contours of objects" (AR Luria). The citicoline (1000 mg/day) added to the basic HIV therapy, was studied in 38 patients. The comparison group consisted of 35 HIV patients who did not receive neuroprotective therapy. The effectiveness of treatment was assessed using the clinical scale CGI (Clinical Global Impression).

Results:: In the main group, despite the therapy, deterioration was not noted. After treatment, there was significant increase in the mean equivalent memory indices (EMI) (96.8 ± 2.5 versus 112.6 ± 3.8; P <0.05). In the comparison group, there is also a tendency to an increase in the average EMI values, before treatment was 8 (22.8%) of cases, then after treatment it is increased by 5.7% (P> 0.05), while in the main group consisted of 12 (31.5%) patients. In 18 (47.3%) patients of main group showed expressed improvement, and in 20 (52.7%) had a moderate improvement. In comparison group of patients were expressed, moderate, improvement and without improvement observed in 11 (31.4%), 17 (48.5%), 4 (11.4%) and 3 (8.7%), respectively.

Conclusions:: The present study has demonstrated the effectiveness of citicoline ("ceraxone") in the treatment of neurological disorders in patients with HIV.
Background and Aims:: Neuromeningeal cryptococcosis (NMC) is a most common opportunistic fungal disease in people living with HIV/AIDS (PLWHA). This infection is caused by Cryptococcus neoformans, a yeast-fungus, encapsulated, cosmopolitan and living in several ecological niches very frequent in Africa because of climatic and ecological conditions. This study aims to describe the sociodemographic, clinical, and outcome features of NMC among PLWHA in Lubumbashi in the Democratic Republic of Congo.

Methods:: This is a retrospective study of 108 cases of NMC diagnosed in PLWHA. Data are collected for 3 years (from January 2015 to December 2017) at HIV / AIDS Center of Excellence in Lubumbashi. Variables studied were age, gender, clinical, biological, therapeutic, and outcome features.

Results:: The overall prevalence of NMC was 2.5%. The mean age was 41.5 ± 13.1 years old, with 72.2% of patients aged less than 50 years. The main clinical symptomatology was headache (100%) and fever (100%). The main cytochemical abnormalities of cerebrospinal fluid analysis were hyperproteinorachy (91.9%), hypoglycorachy (94%) and lymphocytosis (98.2%). The mean CD4 cell count was 168.7/mm$^3$. Patients were initially treated with fluconazole. The overall mortality was 43.5%.

Conclusions:: NMC is a serious opportunistic infection in PLWHA, and the mortality rate remains unacceptable. Fighting NMC in PLWHA requires early diagnosis, increased access to antiretrovirals, rapid introduction of appropriate treatment.
TOCILIZUMAB AS STEROID-SPARING AGENT FOR POST-INFECTIOUS INFLAMMATORY RESPONSE SYNDROME IN TWO NON-HIV CRYPTOCOCCAL MENINGITIS PATIENTS

Bridgette Jeanne Billioux¹, Peter Williamson², Seher Anjum²
¹National Institutes of Health, National Institute Of Neurologic Disorders And Stroke, Bethesda, United States of America, ²National Institutes of Health, National Institute Of Allergy And Infectious Diseases, Bethesda, United States of America

Background and Aims:: Non-HIV Cryptococcal Meningitis (CM) is often complicated by a post-infectious inflammatory response syndrome (PIIRS), characterized by neurologic deterioration in previously-healthy patients with CM after appropriate antifungal therapy and conversion of CSF fungal cultures to negative. PIIRS is due to an appropriate inflammatory response to fungal antigen released during therapy, mediated by IFN-gamma and IL-6 stimulating T-helper cells, leading to immune-mediated host damage. At the National Institutes of Health (NIH), patients with non-HIV CM-related PIIRS have been successfully treated with methylprednisolone burst and slow prednisone taper. However, occasional patients will be refractory to steroid therapy, unable to be weaned from high-dose steroid, or require prolonged periods of high-dose corticosteroids that may have problematic side-effects. Hence, appropriate steroid-sparing agents are needed in the treatment of refractory PIIRS. Due to the role of IL-6 in its pathogenesis, IL-6 receptor blockade by tocilizumab is of interest in the treatment of PIIRS.

Methods:: Two previously healthy patients with non-HIV CM-related PIIRS who were steroid-refractory were seen at the NIH. Due to intractable symptoms (Patient A with refractory headaches and elevated intracranial pressures despite VP-shunt, and Patient B with persistent altered mental status), and ongoing evidence of CSF inflammation, both patients were treated with monthly tocilizumab infusions.

Results:: Both patients exhibited rapid symptomatic improvement, permitting steroid taper. Patient A had near resolution of headaches. Patient B showed mental status improvement as evidenced by improved MOCA score. Both had improved CSF parameters, and no significant side-effects.

Conclusions:: Tocilizumab may be a safe and effective treatment for steroid-refractory non-HIV CM-related PIIRS.
Background and Aims:: Neurosyphilis is a great imitator and has varied presentations. We report a case presenting as corticobasal syndrome and its atypical MRI findings are described.

Methods:: Descriptive Case report of rare clinical presentation and MRI findings of Neurosyphilis

Results:: A 65 year old male presented with progressive cognitive decline of 2 years duration. There was associated slowness and posturing of left hand. He worsened over time and became partially dependent for activities of daily life. On examination he had nonfluent aphasia, executive dysfunction, ideomotor, dressing and constructional apraxia, visuospatial deficits, asymmetric parkinsonism (left more), left hand dystonia and cortical sensory deficits. MRI Brain showed right parietal T2 FLAIR hyperintensity with curvilinear blooming artifacts. Curvilinear cortical blooming artifacts were also seen over bilateral temporal, frontal, occipital and left parietal areas. There was parenchymal atrophy as well as small vessel ischemic changes. Serum VDRL and TPHA were positive and HIV was negative. EEG showed mild theta slowing. CSF evaluation showed lymphocytic pleocytosis (20/mm3), mild protein elevation (55mg/dL) and positive CSF VDRL. Serum paraneoplastic antibody panel, anti thyroperoxidase antibody and CSF autoimmune antibody panel were negative. A diagnosis of Neurosyphilis was made and he was treated with benzylpenicillin 4 MU fourth hourly for 2 weeks. Symptomatic treatment was given with levodopa-carbidopa, memantine and donepezil.

Conclusions:: Neurosyphilis is a great imitator. Corticobasal syndrome is a rare presentation of Neurosyphilis. Susceptibility weighted images showing cortical blooming may point towards neurosyphilis. High index of suspicion is needed to diagnose neurosyphilis and CSF VDRL examination should be part of dementia workup.
Background and Aims:: In Tuberculosis/COVID 19 co-infection, successive inflammatory stimuli lead to depletion of T cells. The resulting lymphopenia affects the immune response against pathogens. This co-infection can have secondary effects such as a greater expression of the ACE2 receptor on the cell surface stimulated by IFN, IL4, IL13, with greater immunopathological damage. Both entities are transmitted by air and mainly affect the lungs, they can also affect other organs and have similar symptoms, which makes the diagnosis of this co-infection difficult.

Methods:: presented two cases

Results:: We present 2 clinical cases: the first is a 17 year old male, without risk factors, admitted for fever, headache, nausea, vomiting, weight loss, cough, and disabling bone pain in the lumbar and cervical spine. Chest X-ray with bilateral nodules, pneumonia and mediastinal widening, positive PCR test for SARS-CoV2. Due to bleeding from the lower digestive tract, he was taken to surgery, finding intestinal and peritoneal tuberculosis. MRI of the neuroaxis revealed meningeal tuberculosis and paravertebral abscesses in the cervical and lumbar spine. The second case is a 24 year old male, HIV +, with a history of splenectomy due to thrombocytopenic purpura, and consumption of unpasteurized dairy products. Both men had cough, dyspnea, and hypoxemia, and required intubation. Their neurological manifestations were headache; seizures; hallucinations; cognitive, sensory and motor deficits; and sphincter disorders. M. bovis was isolated in the CSF, gastric juice, expectoration and urine, the first patient had tuberculosis in 7 organs.

Conclusions:: Both of them survived the SARS-CoV2 infection and continued to be treated for tuberculosis.
HEPATITIS E INDUCED BRACHIAL PLEXITIS

Muhammed Noushad
University Hospitals Plymouth, Neurology, Plymouth, United Kingdom

Background and Aims:: A 57 years old heavy vehicle driver had sudden onset shooting pain in the left upper limb that spread to the other side. He also noticed anaesthesia of both his upper limbs. He had difficulties in lifting his arms above the shoulder. He also had exertional breathlessness. He had significant motor weakness of his upper limbs. Reflexes were absent in the upper limbs. He had no clear sensory abnormality or cerebellar signs. He was tachypnoeic. Hepatitis E IgM came back as positive. His hepatitis E RNA showed 1810 RNA units. The nerve conduction and EMG help us get the diagnosis as bilateral brachial neuritis associated with an acute HEV infection. Six weeks later, he returned with worsening orthopnea. He had paradoxical abdominal movements while lying flat. He developed bilateral diaphragmatic paresis during the sniff test. The chest X ray revealed that the domes of diaphragm were at the same level. He was discharged with non-Invasive ventilation.

Methods:: Retrospective analysis of a rare case
Results:: Hep E is an important cause of Brachial neuritis
Conclusions:: The brachial neuritis associated with an acute HEV infection is often bilateral and severe. Such plexopathy usually affects middle-aged men, like our patient. Bilateral phrenic paralysis was reported in less than 1% patients with idiopathic brachial neuritis. [4] The involvement of the phrenic nerve with diaphragmatic weakness is more common than brachial neuritis with HEV infection. [2] The prognosis of brachial neuritis associated with HEV infection is often unfavourable because of severe bilateral involvement of the brachial plexus and diaphragm. Recovery is often incomplete.
A CORRELATIVE STUDY OF THE INCIDENCES OF ACUTE GUILAIN-BARRÉ SYNDROME AND VIRAL MENINGOENCEPHALITIS IN ADULT PATIENTS AT BENGHAZI MEDICAL CENTER DURING 2019 (PRE COVID 19)

Heba El-Zawawi
Benghazi Medical Center, Neurology, Benghazi, Libya

Background and Aims:: Viral diseases cause meningoencephalitis VME. Associated GBS is recognised. We aimed to study the correlation between the incidences of GBS and VME, in adult patients admitted to Benghazi Medical Center BMC, from 1st January 2019 to 31st December 2019.

Methods:: A retrospective study reviewing the files of patients admitted to BMC diagnosed with acute GBS and or VME.

Results:: From a total of 226 neurological admissions, 28 Libyan patients had the conditions: GBS 26 cases, VME 3 cases, GBS and VME 1 case. Males: 13, Females 15. The GBS age range was: 17-86 years. VME occurred at ages 24-45 years. The incidence of GBS in 2019 was 2.6/100,000. Acute inflammatory demyelinating polyneuropathy AIDP frequency was 63.2%, and axonal types 21.1%. 57.1% received IVIG, 39% plasma exchange, and 17.9% both. The incidence of VME in 2019 was 0.3/100,000 population. No mortalities were recorded.

Conclusions:: For a population of one million we found an annual incidence of GBS of 2.6/100,000, similar to other countries pre COVID 19. We found a wide age range for GBS. The most frequent GBS types were AIDP, followed by the axonal type, similar to other countries. VME was less frequent but correlated with the first half of the year rises in GBS. A peak of GBS in May, a case appearing to have both conditions, correlated with the recognised aetiology of GBS. GBS also peaked in winter. Both conditions increased in August, consistent with others, increasing in the hotter months. We found similar peaks recorded for COVID 19 during 2020.
DIAGNOSTIC ACCURACY OF THE FILMARRAY™ MENINGITIS/ENCEPHALITIS PANEL IN ADULT PATIENTS WITH SUSPECTED BACTERIAL MENINGITIS IN A TERTIARY CARE HOSPITAL IN THE PHILIPPINES

Ferron Ocampo, Lina Laxamana
St. Luke's Medical Center, Institute For Neurosciences, Quezon City, Philippines

Background and Aims:: Bacterial meningitis is associated with significant morbidity and mortality if not diagnosed and treated early. Isolation of the causative agent from cerebrospinal fluid culture is the gold standard for the diagnosis of this condition; however, it takes several days for results to be available. The FilmArray™ Meningitis/Encephalitis (ME) panel is a nucleic acid-based test that allows simultaneous detection of 14 bacterial, viral, and fungal pathogens in the cerebrospinal fluid with a rapid turnaround time. Our aim was to evaluate the diagnostic performance of the ME panel in detecting bacterial pathogens in the cerebrospinal fluid of adult patients with suspected bacterial meningitis.

Methods:: We performed a retrospective review of hospital records of adult patients with suspected bacterial meningitis who were admitted at a tertiary care hospital in the Philippines and underwent diagnostic testing with the FilmArray™ Meningitis/Encephalitis (ME) panel from January 1, 2018 to July 31, 2019. Overall percent agreement, sensitivity, and specificity for individual bacterial pathogens included in the panel were determined.

Results:: A total of 98 patients were included in the analysis. The ME panel demonstrated 98% overall agreement, 50% sensitivity, and 99% specificity in comparison with CSF culture in detecting bacterial pathogens in the cerebrospinal fluid.

Conclusions:: The results show that the FilmArray™ Meningitis/Encephalitis panel has high diagnostic accuracy and can be utilized in the rapid diagnosis and targeted treatment of patients with bacterial meningitis, aid antimicrobial stewardship, and improved patient outcomes.
HUMAN HERPES VIRUS 6 ENCEPHALITIS PRESENTING AS FATAL REFRACTORY STATUS EPILEPTICUS: A CASE REPORT AND SYSTEMATIC REVIEW

Ferron Ocampo, Roland Dominic Jamora
St. Luke's Medical Center, Institute For Neurosciences, Quezon City, Philippines

Background and Aims:: Encephalitis secondary to human herpesvirus 6 (HHV-6) infection is frequently detected in immunocompromised patients; in contrast, HHV-6 encephalitis in immunocompetent patients is rare. We report a case of a previously healthy 46-year-old female with HHV-6 encephalitis who presented with status epilepticus unresponsive to multiple antiepileptic medications.

Methods:: Case Report

Results:: Our patient is a 46-year-old female who presented with a one-week history of back pain, fever and generalized tonic-clonic seizures that progressed to status epilepticus. The video electroencephalography showed epileptiform discharges on both frontotemporal regions. Neuroimaging showed hyperintensities on the bilateral insula and temporal lobes. Lumbar puncture was performed and the cerebrospinal fluid showed elevated pressure. The CSF was tested using the FilmArray Meningitis/Encephalitis panel and was positive for HHV-6. She was given ganciclovir and a total of eleven antiepileptic drugs. Despite these medications, she developed refractory status epilepticus and eventually succumbed due to multiple medical complications.

Conclusions:: Our case highlights HHV-6 encephalitis as an important diagnostic consideration in patients with refractory status epilepticus, regardless of immune status.
Background and Aims:: Introduction: Intracranial tuberculous abscess is a less common form of tuberculosis, accounting 0.15 to 4 percent of extrapulmonary tuberculosis. Furthermore, involvement of the sellar area is one of the rarest location, with only few cases documented in the literature. This case reported a 38-year-old male who presented with chronic headache. He was clinically diagnosed and treated as a case of tuberculous meningitis (TBM), however, a cranial magnetic resonance imaging with contrast showed a sellar mass which was initially diagnosed as pituitary macroadenoma and not a sequela of TBM; with the expansile mass effect, he had new-onset bilateral hemianopia and pituitary function panel revealed central hypothyroidism and secondary adrenal insufficiency. Objective: This case report aims to identify the clinical implication of considering tuberculous abscess as differential diagnosis in the setting of a cystic sellar mass.

Methods:: An endoscopic endonasal trans-sphenoidal surgery with complete drainage of caseous material in the pituitary fossa was performed. The finding was consistent with pituitary tuberculous abscess.

Results:: The symptoms significantly resolved after drainage and antibiotic therapy, with resolution of hypothyroidism and adrenal insufficiency.

Conclusions:: Pituitary tuberculous abscess is rare. A high index of suspicion for a prompt combination of medical and surgical treatment of this condition is important to prevent the development of life-threatening complications.
SUBAIGUE SCLEROSANTE PANENCEPHALITIS: MRI BENEFITS STUDY OF 8 CASES OBSERVED IN A TROPICAL ENVIRONMENT

Cisse Amara, Guelngar Carlos Othon, Djibo Hamani Abdoul Bachir
Academic Hospital, University of Conakry (Guinea), Neurology, Sélectionner, Guinea

Background and Aims:: the goal of a reassessment of this pathology from a clinical and evolutionary point of view. The interest of this work lies in the fact that these observations are a good illustration of subacute sclerosing panencephalitis and the difficulty of differential diagnosis that it entails with neurodegenerative disorders with myoclonic and epileptic connotations in tropical settings.

Methods:: eight (8) patients were evaluated retrospectively over a period of January 1, 2012 to December 31, 2019. The diagnostic approach was based on clinical data: progressive mental deterioration myoclonus, ophthalmologic abnormalities, specific electroencephalographs and cerebrospinal fluid abnormalities and neuroradiological aspects. The differential diagnosis of subacute sclerosing panencephalitis can arise with other conditions, in particular the myoclonic syndromes observed in neurodegenerative conditions and the various encephalic infections common in tropical settings.

Results:: an infectious clinical picture without vaccination was identified in 14 patients and only 4 patients had a record notifying vaccination with measles. The clinical signs were summarized as the existence of a clinical headache with severe cognitive deterioration due to the under-medicalization and ophthalmologic abnormalities observed in patients. The disease virus IgG and IgM laboratory tests were instrumental in the diagnosis.

Conclusions:: this study shows the presence of Subacute sclerosing panencephalitis and requires increased prevention by vaccination.
VARICELLA ZOSTER ENCEPHALITIS: SPREAD SPECTRUM

María Dolores Calabria Gallego
Complejo Asistencial Universitario de Salamanca, Neurology, Salamanca, Spain

Background and Aims:: Varicella Zoster Virus (VZV) is a human neurotropic virus. The primary infection causes varicela (chickenpox), and then, the virus remains latent in the sensory cranial neurons or dorsal root ganglia. VVZ can be reactivated in elderly (age older than 50 years) or immunodepressed patients, causing herpes zoster, vasculopathy, meningoencephalitis, meningoradiculitis, cerebellitis, myelopathy and ocular disease.

Methods:: We present two case reports with diagnosis of VZV meningo-encephalitis.

Results::

CASE A. 87-years-old woman, without relevant medical history, who presented jerks in left extremities and language alteration. In the emergency room, we activated stroke code, with normal neuroimaging studies. After this, she presented comatose state and ocular robbing, and some hours later she started to present psicomotor agitation. We performed a lumbar puncture, with leucorrhachia (mononuclear prevalence). MRI was normal. There were no fever, rash, increased CRP, or leukocytosis.

CASE B. 66-years-old woman, without relevant medical history, who presented fever and myalgias for four days. After this, she also presented skin lesions with dysesthesia. Later, she also presented severe headache. The neurological examination was normal, except for stiff neck. The CT was normal, and the lumbar puncture showed leucorrhachia (mononuclear prevalence).
In both cases, PCR test of the cerebrospinal fluid for VZV was positive, and after a few days with acyclovir treatment the symptoms disappeared.

**Conclusions:** We can appreciate how VZV meningo-encephalitis can vary in its clinical presentation. It is important to have a high degree of suspicion to avoid subsequent complications due to delays in the administration of treatment.
ASSESSMENT OF DIAGNOSTIC APPROACH AND MANAGEMENT OF SUSPECTED ENCEPHALITIC PATIENTS AT OMDURMAN TEACHING HOSPITAL

Mohammed Eltahier Omer¹, Mohamed Alebeed², Khalid Mohammed³
¹Gadarif University Faculty of Medicine and Health Sciences - Sudan, Medicine, Omdurman, Sudan, ²Khartoum University, Medicine, Omdurman, Sudan, ³Gadarif University/ Faculty of Medicine, Internal Medicine, Khartoum, Sudan

Background and Aims:: The objectives of this study were to assess the approach and management of suspected encephalitis cases in Omdurman Teaching Hospital.

Methods:: This study was a descriptive cross-sectional study over 6 months (May to October 2019). The study included 84 patients with suspected encephalitis, selected by convenience sampling. A standardised questionnaire was used to interview patients and the collected data was analysed by SPSS version 27.0.

Results:: The most common presenting symptoms among the study participants were fever and headache (100%), seizures (36.9%) and agitation (28.6%). Neurological examinations showed hemiparesis in 13.1% of patients. Complete blood counts showed lymphocyte predominance in all patients. 65.5% of patients made a full recovery, whereas 26.2% of cases culminated in motor deficit.

Conclusions:: The patients’ outcome was poor as below two-thirds of suspected encephalitis cases recovered fully. The NICE criteria for diagnosis had not been adequately followed, as only a minority of patients had undergone CSF and MRI investigations. Recommendations: Greater adherence to NICE diagnostic criteria must be observed. Documentation of specific reasons is also necessary if neurological imaging is not used. The exact etiology must be identified and targeted antimicrobial treatment must be initiated. If CSF results cannot be obtained in cases of suspected encephalitis, rapid administration of intravenous acyclovir should be included as part of empirical antimicrobial therapy.
ACUTE MEMORY AFFECTION DUE TO VIRAL ENCEPHALITIS WITH HYPOCELLULAR CEREBROSPINAL FLUID (CSF) IN SPITE OF MRI FINDINGS: A CASE REPORT

Mostafa Meshref¹, Eshak I. Bahbah¹, Ahmed Said Ali²
¹Al-Azhar university - Egypt, Neurology, Cairo, Egypt, ²Al-azhar university - Egypt, Undergradute, cairo, Egypt

Background and Aims:: Herpes simplex virus encephalitis (HSVE) is one of the most potentially fatal infectious central nervous system (CNS) disorders. Thus, early detection is very critical in determining the fate of the case. Clinical history and examination, brain computed tomography, dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI), and lumbar puncture have been used to establish a diagnosis.

Methods:: This case report showed a case of HSVE with hypocellular cerebrospinal fluid (CSF) and rare presentation of memory affection. However, typical MRI findings consistent with HSVE and CSF polymerase chain reaction (PCR) positive for HSV1 DNA, which responded to treatment.

Results:: CT brain showed a normal brain with no mass, lesions, or vascular event. Lumbar puncture for CSF sampling results: shows evidence of hypocellular csf (5cells) with pcr +ve test for HSV 1 MRI brain with contrast result showed left mesial temporal, insular areas of abnormal signal with mass effect in the form of obliteration of the temporal horn and effacement of the cortical sulci with corresponding restricted diffusion. However, no abnormal contrast enhancement was observed.
Conclusions:: HSVE is considered a fatal neurological illness, which can be represented by any symptoms and unusual CSF results. Thus, early intervention and start specific antiviral treatment once a case is suspected to prevent complications and improve outcomes.
OPISTHOTONOS WITH PRESERVED CONSCIOUSNESS IN A PATIENT WITH COINFECTION BY MYCOBACTERIUM TUBERCULOSIS AND MYCOBACTERIUM ABSCESSUS

Ritu Shree\textsuperscript{1}, Abeer Goel\textsuperscript{2}, Manish Modi\textsuperscript{2}, Manoj Goyal\textsuperscript{3}, Kusum Sharma\textsuperscript{4}, Vikas Lakhanpal\textsuperscript{5}, Neeraj Balaini\textsuperscript{6}, Karthik Mahesh\textsuperscript{1}, Vivek Lal\textsuperscript{1}

\textsuperscript{1}Postgraduate Institute of Medical Education and Research, Chandigarh, Neurology, Chandigarh, India, \textsuperscript{2}PGIMER, Neurology, Chandigarh, India, \textsuperscript{3}Postgraduate Institute of Medical Education and Research, Neurology, Chandigarh, India, \textsuperscript{4}PGIMER, Chandigarh, Microbiology, Chandigarh, India, \textsuperscript{5}PGIMER, Chandigarh, Neurology, Chandigarh, India

Background and Aims:: Tubercular meningitis (TBM) represents 1\% infection caused by Mycobacterium tuberculosis (MTB). Opisthotonos has been reported mainly from data from children with hydrocephalous. Consciousness is depressed in patients developing opisthotonos with further deterioration to coma. CNS infections by Mycobacterium abscessus (MABS) complex are rarely reported and carries a high mortality rate (35-70\%).

Methods:: We present a 16-year-male who was diagnosed as TBM based on clinical, radiological, and microbiological evidence, started on antitubercular treatment (ATT), underwent ventriculoperitoneal shunt for increasing hydrocephalous and initially improved in his symptoms for 2-3 weeks. He worsened and presented with opisthotonos, however the consciousness was preserved.

Results:: CSF examination revealed positive Genexpert for MTB resistant to rifampicin, culture showed MABS. Gadolinium enhanced magnetic resonance imaging showed increasing hydrocephalous, gross cerebral edema with obliteration of cisterns and exudates.

Conclusions:: Opisthotonos in adults with TBM who is already on ATT is an ominous sign. Nontuberculous mycobacteria are ubiquitous with the potential to cause pathological presentations which are indistinguishable from MTB. They are very reported for neurological manifestations and difficult to culture in CSF which is responsible for delay in diagnosis and treatment apart from multidrug resistant MTB.
MALARIA AMONG ADULT SUDANESE COVID PATIENTS BETWEEN THE 4TH OF APRIL 2020 TO THE 15TH OF JANUARY 2021

Radi Tofaha Alhusseini¹, Abdalaziz Salh², Khabab Mohamed Ahmed³, Amira Abdelgalil⁴, Mohamed Ahmed⁵, Mohamed Mohamed Ahmed⁶, Hussien Abbashar⁷, Abdallah Mustafa², Radi Alhusseini⁸, Albokhary Abkar⁹, Muhanad Hamed¹⁰, Hamda Abd Elrahman¹¹, Abbasher Hussien³
¹Alzaiem alazhari university, Anatomy Department, Khartoum, Sudan, ²Daoud research group, Neurology, Khartoum, Sudan, ³University of Khartoum, Faculty Of Medicine, Khartoum, Sudan, ⁴Alneelen university, Community Medicine, Khartoum, Sudan, ⁵Omdurman Teaching Hospital, Medicine, Khartoum, Sudan, ⁶Alneelen university, Medicine, Khartoum, Sudan, ⁷Yarmouk college, Medicine, Amman, Sudan, ⁸Alzaiem Alazhari University, Medicine, Khartoum, Sudan, ⁹Nahda college, Medicine, Khartoum, Sudan, ¹⁰Fedail Hospital, Medicine, Khartoum, Sudan, ¹¹Ahfad university, Medicine, Khartoum, Sudan

Background and Aims:: Malaria can occur on the top of covid19. Aims: To assess the possible link between malaria and covid 19.

Methods:: This is a retrospective cohort study conducted among adult Sudanese COVID-19 patients between the 4th of April 2020 to the 15th of January 2021. 87 of the patients were included.

Results:: Among the 87 patients 64.9 % were males while 35.6 were females. 27.6 % had a positive blood film. 64.7% of the malaria patients had p.falciprum while 35.3% had p.vivax. 52.9% of the patients showed positive RT-PCR for covid 19 with 52.9 % showed positive CT findings. Generalized fatigability was observed in 52.9 % of the patients with malaria followed by headache, nausea, fever with chills, fever with shivering, vomiting and diarrhea in 42.5%,36.8%,20.7%,12.6%,9.2%,9.2% respectively. In covid 19 patients 85.1% had fever and generalized fatigability, Followed by cough, headache, SOB, Sore throat ,myalgia, chest pain, and diarrhea In 73.6 %,59.8, 52.9, 20.7 ,20.7,10.3,5.7 respectively. 13.79 % had malarial pneumonitis, followed by pulmonary edema , choleric malaria, thrombocytopenia and malaria induced hepatitis in 10.39 %,9.2 %, 9.19 %, 6.9% respectively. 8.4% had cerebral malaria while 1.1% had cerebellar syndromes. 44.8 % had ARDS, 17.2% had heart failure, 8% had pulmonary embolism, 8% had stroke, 3.9% had encephalitis and 1.1% had convulsions.

Conclusions:: Malaria and covid 19 have a possible link that they both share similar presentations and complications.
CEREBELLAR HYPERMETABOLISM AND CORTICAL HYPOMETABOLISM IN OPSOCLONUS-MYOCCLUS SYNDROME: TWO CASE REPORTS

Pierpaolo Santurelli¹, Stefano Mozzetta¹, Matteo Villa¹, Diego Cecchin², Annachiara Cagnin³
¹University of Padua, Neurosciences, Padua, Italy, ²University of Padua, Nuclear Medicine, Via Giustiniani, Italy, ³University of Padua, Department Of Neurosciences, Padova, Italy

Background and Aims: Opsoclonus-myoclonus syndrome (OMS) is a rare syndrome characterized by opsoclonus, myoclonus, ataxia, behavioral and sleep disturbance. We describe two cases of OMS due to parainfectious condition and with similar brain functional imaging findings.

Methods: Both patients performed brain FGD-PET/MRI at the onset and after 3 months from clinical recovery.

Results: Case one: 54-year-old man presented with one-month history of jerky limbs movements, gait unsteadiness, blurred vision, delusional thoughts. Neurological examination revealed opsoclonus and generalized myoclonus. Blood tests revealed decreased CD4+ and positive HIV viral load. Onconeural anti-neuronal antibodies were negative. CSF showed increased protein level, 14 lymphocytes, oligoclonal bands and HIV viral load higher than on blood. The patient was started on antiviral, high dose steroid and Ig. Brain FDG-PET/MRI before and after three months of treatment showed high cerebellar metabolism associated with widespread cortical hypometabolism reverted in the follow-up scan. Case two: 46-year-old woman with one-week history of fever was admitted for gait unsteadiness and limbs tremor. Neurological examination revealed opsoclonus, cerebellar ataxia and intentional and postural tremor with overlapping myoclonus. Anti-CMV IgM antibodies were positive on blood. CSF examination showed 100 lymphocytes, increased proteins with blood-brain barrier dysfunction. Brain FDG-PET/MRI revealed increased metabolism of cerebellar nuclei and cortex and occipital hypometabolism. The patient was treated with high dose steroids and Ig, with complete recovery. Control brain FDG-PET/MRI after three months was normal.

Conclusions: These results may suggest that cerebellar over-activation is involved in developing OMS. Increased cerebellar metabolism and posterior cortical hypometabolism may be the functional correlates of OMS due to parainfectious encephalitis.
EPILEPTIC PARTIALIS CONTINUA (EPC) AS CAN BE AN INITIAL PRESENTATION OF HIV - A RARE CASE SCENARIO

Balakrishnan Arivalagan
Command Hospital Airforce, Internal Medicine, Bangalore, India

Background and Aims:: BACKGROUND EPC as initial presentation of HIV is very rare AIM To disseminate that EPC could be initial presentation of HIV

Methods:: 21 yr male presented with witnessed seizure(seminology characterized by jerky movements of left angle of mouth and left upper limb with up rolling eyeball and tongue bite followed by postictal confusion). Managed conservatively by antiepileptic, a day later he developed repetitive involuntary clonic-myoclonic movement of left arm with facial deviation to right ,no loss of consciousness. He was then managed by sequential antiepileptics showing no significant reduction in seizure. EXAMINATION Hypotonic and scanning dysarthria, EPCs present in Left upper (UL) & lower limbs(LL) ,Power – UL (Rt & Lt) - 4/5 & LL (Rt & Lt) - 3/5, DTR – Lt Biceps and knee 3+ others 2+, B/L Plantar Extensor response , Dysmetria,titubations note HIV 1 positive(ELISA ) confirmed by Western Blot ,HIV RNA – 163771 IU/L ,CD4 – 95 cells/c.mm, HIV 2 - negative, CSF Sugar - 82 mg% ,Protein : 40.8gm%,Gram / ZN/ Fungal/JC Virus- Negative , RBC -03 & WBC -02cells/c.mm, no malignant cells , ADA – 1.0 IU/L , ANA,Auto Immune Encephalitis panel - negative He was diagnosed as a case of HIV Encephalopathy – EPC ,Managed with TLE regime (ART) and appropriate prophylaxis for opportunistic infections .EPC controlled with 04 anti epileptics (Oxcarbazepine,Levitracetam,Lacosamide and Perampanel). He responded well.

Results::
Conclusions:: EPC in HIV infected person is rare and same could be a rarest initial presentation. Anti-epileptics – ART interactions needs to be kept in mind.
INVASIVE RHINO-ORBITO-CEREBRAL ASPERGILLOSIS PRESENTING AS MULTIPLE CRANIAL NEUROPATHIES – A CASE REPORT

Miguel Miranda, Vera Montes, Sandra Sousa, Fernando Pita, Cátia Carmona
Hospital de Cascais Dr. José de Almeida, Department Of Neurology, Alcabideche, Portugal

Background and Aims:: Presenting as a complication of paranasal fungal sinusitis, due to continuous spread of an invasive agent to adjacent tissues, the rhino-orbito-cerebral syndrome is frequently associated with Aspergillus or Mucor infections.

Methods:: A case of a 66-year-old patient with rapidly progressive cranial neuropathies in the context of an invasive Aspergillosis is presented.

Results:: A 66-year-old male patient, with a myelodysplastic syndrome and history of recent severe COVID19 infection, was admitted to the Emergency Department due to periorbital pain and fever. On physical examination, the patient displayed III, IV and VI left cranial neuropathies, decreased visual acuity and left hearing loss. A septic thrombosis of the cavernous sinuses was initially admitted and antibiotic therapy started. However, on the following day, peripheral facial diplegia, V2 paresthesia and dysarthria were identified. An MRI was conducted, revealing bilateral ethmoiditis and post-septal left orbital cellulitis, and PAS staining of a nasal biopsy identified spores and hyphae. After admission to an Infectious Diseases unit, the patient clinically deteriorated, with pre- and post-septal cellulitis and progression of periorbital edema to the contralateral eye. A positive PCR test for Aspergillus spp was detected in the CSF and nasal mucosa. Thirty-one days later, after antifungal therapy (anfotericin B, isavuconazole), clinical improvement was registered.

Conclusions:: Patients with severe COVID-19, subjected to corticosteroids, are particularly prone to develop fungal infections due to immune system dysfunction. This clinical case highlights the relevance of fungal etiology in the differential diagnosis of ophthalmoplegia in immunosuppressed patients, whose early diagnosis and treatment is essential, excluding potentially fatal infections.
WHEN HERPES LINGERS ON: A RARE COMPLICATION OF ACUTE HERPES SIMPLEX
ENCEPHALITIS

Lakshminarayanapuram Viswanath¹, Madhu Nagappa¹, Doniparthi Seshagiri², Arimappan
Arivazhagan³, Anita Mahadevan¹, Tc Yasha⁴, Parayil Bindu¹, J Saini⁵, Rose Bharath⁵, Sanjib Sinha¹, Ab
Taly¹
¹National Institute of Mental Health and Neurosciences (NIMHANS), Department Of Neurology,
BENGALURU, India, ²National Institute of Mental Health and Neurosciences (NIMHANS), Department Of
Neurology, Bengaluru, India, ³National Institute of Mental Health and Neurosciences, Department Of
Neurosurgery, Bangalore, India, ⁴National Institute of Mental Health and Neurosciences, Department Of
Neuropathology, Bangalore, India, ⁵National Institute of Mental Health and Neurosciences, Department Of
Neuroimaging And Interventional Radiology, Bangalore, India

Background and Aims:: Herpes simplex encephalitis (HSE) is the most common viral encephalitis.
Rarely chronic granulomatous inflammation in response to persisting herpes virus antigens in the brain
may occur. We aim to describe the clinical course of a patient with chronic granulomatous HSE (CGHSE)
which was proven by brain biopsy.

Methods:: Clinical course and serial brain MRIs were reviewed. Biopsy of the right temporal lobe was
performed.

Results:: A 16-year-old boy presented with acute febrile encephalopathy. Brain MRI showed T2
hyperintensities in the right medial temporal lobe. He was treated on lines of HSE and he recovered with
acyclovir. He had recurrent seizures and mild cognitive decline 1.5 months after the acute illness. Serial
MRIs at 2, 6, and 8 months post-HSE showed progressive increase in signal changes involving the entire
right temporal lobe and left mesial temporal region with gyriform enhancement. Work up for immune-
mediated causes (autoimmune encephalitis, sarcoid and vasculitis) were negative. CSF PCR for HSV
was negative but antibody titers were elevated. Brain biopsy revealed granulomatous angiitis.
Immunohistochemistry for HSV antigen was negative, but PCR on the brain tissue was positive for HSV
DNA. The patient was diagnosed to have CGHSE and treated with valacyclovir. There was good clinical
and radiological response at 24 months follow up.

Conclusions:: CGHSE occurs in a small number of patients post-acute HSE. Diagnosis may be aided by
brain biopsy that demonstrates granulomatous inflammation with evidence of persistent HSV
antigens/DNA. This peculiar entity is treatable and has a reasonably good outcome.
BILATERAL OPTIC TRACT ENHANCEMENT: AN UNUSUAL IMAGING FINDING IN NEUROSYPHILIS

Lakshminarayanapuram Viswanathan¹, Madhu Nagappa², Doniparthi Seshagiri¹, S Nagarathna³, Karthik Kulanthaivelu⁴, Sanjib Sinha¹
¹National Institute of Mental Health and Neurosciences (NIMHANS), Department Of Neurology, BENGALURU, India, ²National Institute of Mental Health and Neurosciences (NIMHANS), Department Of Neurology, Bengaluru, India, ³National Institute of Mental Health and Neuro Sciences, Neuromicrobiology, BENGALURU, India, ⁴National Institute of Mental Health and Neurosciences, Department Of Neuroimaging And Interventional Radiology, Bangalore, India

Background and Aims:: The differential diagnosis of lesions affecting the optic tract commonly include infectious, inflammatory, and neoplastic conditions. We aim to describe a rare but treatable cause of optic tract enhancement.

Methods:: Brain MRI, visual evoked potentials (VEP) and cerebrospinal fluid analysis (CSF) were carried out.

Results:: A 44-year-old gentleman presented with 2 months history of intermittent blurred vision, transient headaches and unsteadiness while walking. Six months prior to onset of these symptoms; he had hematuria which was treated with oral antibiotics. After 8 weeks he developed a diffuse maculopapular rash over the trunk and involving the palms and soles. General physical and neurological examination was normal. Visual acuity, perimetry and VEP were normal. MRI revealed slight enlargement of the right optic tract with central T2 hypointensity and enhancement within the both optic tracts (right>left). In addition, subtle leptomeningeal enhancement was seen in the upper cervical cord. CSF analysis revealed lymphocytic pleocytosis (42 lymphocytes/mm³) with elevated protein (66.2 mg/dL). CSF and serum Venereal Disease Research Laboratory (VDRL) and Treponema pallidum hemagglutination test (TPHA) were positive (1:2560). Patient was treated with Penicillin and had clinical and serological improvement at 3-months follow up.

Conclusions:: Syphilis affects the nervous system in 5-30% of infected individuals. The manifestations are varied and temporally related to the time of acquisition of the infection. Perivascular lymphocyte aggregation results in ‘gumma’ formation. Neurosyphilis should be considered as a differential diagnosis in patients with enhancing lesions in the optic tract in the setting of CSF pleocytosis.
INTRATHECAL HYALURONIDASE FOR IMPENDING AND SYMPTOMATIC ARACHNOIDITIS IN TUBERCULAR MENINGITIS.

Vaibhav Mathur, Parth Patel
SMS Medical College and Hospital, Dept Of Neurology, Jaipur, India

Background and Aims:: CNS Tuberculosis, the most rampant infection of the developing world, clinicopathologically can occur alone or combined as Tubercular Meningitis, Tuberculomas (intracranial and/or spinal), Arachnoiditis (basal, optocochiasmatic, spinal) or Myelitis. The viscous exudates in basal cisterns cause Optocochiasmatic arachnoiditis[1], and nodular, thickened, clumped nerve roots called Lumbosacral arachnoiditis.[2] We herein propose use of intrathecal hyaluronidase, as adjuvant for symptomatic as well as impending arachnoiditis.

Methods:: •A prospective cohort study including 48 patients of TB Meningitis (15-65 yrs) with 4 treatment groups (Group A-D) was designed. •Group A (n=11) and B (n=14) had patients of Symptomatic Arachnoiditis (SA) defined as those with new diminished visual acuity & prolonged P100 latency (Visual Evoked Potential), deranged Barthel index and/or hydrocephalus in neuroimaging (without obstructive tuberculomas). •Group C(n=10) and Group D(n=13) were Impending Arachnoiditis (IA)- Those having CSF Protein >250mg/dl[1] and/or MRI evidence of arachnoiditis without yet manifested symptoms. Standard treatment (ATT + Steroids) for Group A & C, adjuvant Intrathecal Hylase (1500 IU biweekly for first 2 weeks, thereafter weekly for 4 weeks) for Group B & D.
Patients having residual/worsening deficits at completion of intensive phase at 2 months - 54.5% (6) from Group A, 21.4% (3) from Group B, 50% (5) patients from Group C and 15.3% (2) from Group D.

Only 1 patient had skin reaction on sensitivity testing, was excluded from study.

Conclusions:
1. Optochiasmatic & Spinal arachnoiditis was common in TBM patients with initial CSF protein >250mg/dl.
2. Incorporating early administration of intrathecal hyaluronidase in TBM treatment protocol can benefit impending as well as symptomatic arachnoiditis (p value < 0.01).
ATYPICAL SPINAL TUBERCULOSIS WITH ISOLATED SOLITARY VERTEBRAL BODY INVOLVEMENT

Shubham Dubey¹, Ayush Dubey², R G Dhawale³
¹MMCH & RI, Department Of Neurology, Kanchipuram, India, ²Gandhi Medical College, Department Of Medicine, Bhopal, India, ³RDGMC, Department Of Medicine, Ujjain, India

Background and Aims:: Typical spinal tuberculosis affects the continuous vertebral levels and causes narrowing of the adjacent disc space and bone destruction. However, atypical form of spinal tuberculosis is difficult to distinguish from malignancy, leading to misdiagnosis and inadequate treatment.

Methods:: A 40 year old male patient, farmer by occupation and having no prior comorbidities, was admitted with gradually progressive low back pain for 3 months and weakness of both lower limbs since 2 months.

Results:: On examination, there was wasting and hypotonia in both lower limbs and grade 1 power in both lower limbs, absent knee and ankle reflexes, mute plantars and spinal tenderness at lumbosacral region at L2-L3, with no gibbus deformity. X-ray lumbosacral spine showed anterior vertebral scalloping of L2 with sparing of the disc. MRI spine revealed altered signal intensity lesion in L2 vertebral body which was hypointense on T1W, hyperintense on T2W and STIR images, with normal appearing adjacent intervertebral disc along with large right paravertebral and epidural soft tissue component resulting in compression of traversing nerve roots at same level. Histopathology of L2 vertebral body revealed epithelioid cell granulomas suggestive of TB spine.
Conclusions: Spinal tuberculosis involving only one vertebral body without disc involvement is a rare presentation. Imaging studies are an important tool for characterizing the lesion, performing biopsy, evaluating the success of treatment and detecting any complications in the follow-up.
PROGRESSION IN COGNITIVELY IMPAIRED PATIENTS WITH ATRIAL FIBRILLATION: AN OBSERVATIONAL STUDY

Benedetta Storti, Francesco Brovelli, Federico Emanuele Pozzi, Alessandro Zuffi, Marco Piatti, Ildebrando Appollonio, Lucio Tremolizzo, Carlo Ferrarese
Università Milano Bicocca, Neurology, Monza, Italy

Background and Aims:: Data about progression in patient with AF and concomitant cognitive impairment are not known. Moreover, there is no agreement in the scientific literature about anticoagulants use in these patients.

Methods:: We analyzed cognitive impairment progression in n=90 outpatients with any grade of cognitive deficit regularly seen from January 2015 to February 2021. Forty-five patients (50%) were affected by AF (AF+). AF+ and AF- patients were matched 1:1 for sex, age, years of education and MMSE at presentation. Mean MMSE (± SD) at entry study was 23.6 ± 3.8 and 23.4 ± 3.9 for AF+ and AF- patients, respectively. Mean follow up was 22 months and was not significantly different between the two groups. Cognitive decline was inferred using Mini-Mental State Examination (MMSE) score collected in subsequent visits, calculating a Disease Progression Index (DPI) as raw MMSE decline over time.

Results:: DPI in AF+ was 3 times faster than in AF- patients (-0.18 ± 0.25 vs. -0.06 ± 0.24, AF+ vs. AF-, respectively) (figure 1). Among the FA+ patients, those using anticoagulants (AC+) did not show any significant between-group difference in cognitive decline compared to those not using them (AC-); however, the sample size of this latter group was small (figure 2).
Conclusions:: Our results confirm the worse outcome in global cognitive function for cognitively impaired AF+ subjects compared to those without AF. Albeit preliminary, our results also suggest that the use of anticoagulants seems not to significantly affect cognitive decline; an increase in sample size is necessary to confirm this latter result.
Background and Aims:: Nursing homes for people with Dementia are a fundamental resource for disease management; non pharmacological approaches are used in these structures. An emerging reality in this field is “museum-therapy” (MT), an experience born at the Museum of Modern Art of New York City and recently arrived in Italy. In this study we investigated the efficacy of MT in a group of patients with dementia.

Methods:: 30 patients affected by various typologies of Dementia underwent a standard rehabilitation program in our Institute (~ 80 days). Patients were randomized in two groups: one group of 15 patients participated to three structured visits at the National Gallery of Modern Art of Rome; the other group in the same time was occupied by other open air extra activities. One week before and one week and one month after the end of the visits patients were double-blind evaluated with an extensive neuropsychological battery. ANOVA and Student's t paired groups were conducted to analyze data.

Results:: The two groups of patients did not differ for clinical/socio-demographical variables. As expected both the group of patients improved their performances in tests of memory, attention and executive functions and reduced behavioural disturbances (p<0.01). Patients who partecipated to MT significantly improved their performances in the tests of cognitive estimation and pragmatic abilities (p<0.001), this did not happen for the other group.

Conclusions:: MT demonstrated to have positive effects on cognition of demented patients, different from those ones usually involved by other more conventional techniques. MT could become a precious resource for dementia’s management.
OLIVE POLYPHENOLS AND BIOAVAILABLE GLUTATHIONE: PROMISING RESULTS IN PATIENTS DIAGNOSED WITH MILD ALZHEIMER’S DISEASE

Massimo Marianetti¹, Silvia Pinna¹, Angelo Venuti¹, Gianfranco Liguri²
¹Roman Province Fatebenefratelli, Experimental Alzheimer Centre, Rome, Italy, ²University of Florence, Department Of Biochemistry And Molecular Biology, Florence, Italy

Background and Aims:: Recent studies highlighted a potential efficacy of olive polyphenols and of a derivatized form of glutathione to counteract neuropathology affecting specific brain regions at early AD stages. We performed a cross-over clinical trial to evaluate their potential benefits in mild AD.

Methods:: 40 patients diagnosed with mild AD according to IWG-2 criteria were enrolled in a twelve month trial and randomly assigned to two groups of equal sizes: Group 1, receiving treatment in the first six months and no treatment for the second six months, and Group 2, receiving no treatment for the first six months, and treatment for the second six months. Treatment consisted in a nutraceutical formulation comprising 50 mg/cps S-acetyl glutathione and 80 mg/cps oleuropein administered bid. Patients should have undergone a complete set of neuropsychological tests at the moment of the enrollment (T0), after six months (T1) and after twelve months (T2). Due to the difficulties related to COVID-19 emergency, only 10 patients in Group 1 and 8 in Group 2 could be enrolled. They could be evaluated only at T0 and T1.

Results:: All cognitive functions resulted stabilized or improved following the treatment, while behavioural disturbances significantly diminished.

Conclusions:: If further research will confirm these data the described treatment could be proficiently adopted for patients with mild AD as well as a preventive tool for those at risk of developing dementia.

ACKNOWLEDGMENTS: Enrico Calvanese and Luca Giani for statistical analysis; Innbiotec Pharma s.r.l. for developing the formulation; Igea Pharma NV for supplying the product.
MRI AND COGNITIVE TESTS-BASED SCREENING TOOL FOR DEMENTIA

Tetiana Habuza¹, Nazar Zaki¹, Yauhen Statsenko², Sanaa Elyassami³
¹College of Information Technologies, United Arab Emirates University, Computer Science And Software Engineering, Al Ain, United Arab Emirates, ²College of Medicine and Health Sciences, United Arab Emirates University, Radiology, Al Ain, United Arab Emirates, ³Abu Dhabi Politechnic, Information Security Engineering Technology, Abu Dhabi, United Arab Emirates

Background and Aims:: Establishing an association between cognitive status and either disease- or age-related neuronal loss reflected by MRI may have a diagnostic value. Deep Learning (DL) is an AI technique that allows for the discovery of such an association by building models that can predict cognitive performance from the brain structure. The relationship between the brain structure and its functioning may have patterns specific for preserved versus impaired cognition. The models trained on healthy populations will not predict cognitive status accurately in cognitively impaired individuals. We aimed to work out a screening tool for MCI and dementia.

Methods:: We tested if a gap between the actual cognitive performance and the one predicted from MRI is informative as a marker of cognitive deterioration. To calculate the gap we designed a DL regression model and trained it on T1W MRI images of 422 normal controls (NC). An outcome of a model was the result of a cognitive assessment with MMSE, ADAS-cog, RAVLT, DSST, and TMT tests. This allowed us to build five models and compare their performance in NC with 377 patients with Alzheimer’s disease (AD).

Results:: In AD cognitive gap values differed significantly from NC. For MMSE they were 6.23±3.08 in AD versus 1.09±0.73 in NC; p<0.0001. The distinction of AD and NC had 0.9951 sensitivity, 0.9919 specificity, and 0.9935 accuracy.

Conclusions:: The application of DL to a combination of MRI and cognitive assessment may provide computer-aided diagnostics of AD.
EFFECTS OF BUTYLPHTHALIDE ON COGNITIVE FUNCTION AND INFLAMMATORY STATUS IN PATIENTS WITH ACUTE CEREBRAL INFARCTION COMPLICATED WITH COGNITIVE DYSFUNCTION

D.H. Wang¹, L.B. Zhang¹, W. Zhang¹, Y.Q. Dong¹, R.S. Chen¹, J.Z. Yu², Y.S. Sun³
¹The NO.1 Affiliated hospital of Shanxi Datong University, Neurology, Datong, China, ²Shanxi Datong University, Institute Of Brain Science- Shanxi Key Laboratory Of Inflammatory Neurodegenerative Diseases, Datong, China, ³School of Medicine, Datong University, Neurology, Datong, China

Background and Aims:: Acute cerebral infarction not only leads to physical functional impairment, but also leads to non-physical dysfunction. Butylphthalide can reduce the poor prognosis of non-physical dysfunction after acute cerebral infarction, and effectively improve the cognitive function of patients. Aims: To investigate the effects of butylphthalide on cognitive function and inflammatory status in patients with acute cerebral infarction complicated with cognitive dysfunction.

Methods:: 100 patients with acute cerebral infarction complicated with cognitive dysfunction were divided into observation group and control group. Control group was treated with aspirin and atorvastatin. Observation group was additively treated with butylphthalide for 3 months. Compared two groups with simple mental state check table (MMSE), Montreal cognitive assessment scale (MOCA), serum High sensitivity C-Reactive Protein (hs-CRP), pentraxin3(PTX-3), interleukin-6 (IL-6) levels, the incidence of the poststroke dementia (PSD) and adverse reactions.

Results:: After treatment, MMSE and MOCA scores in observation group were more higher than control group compared with them in before, while serum hs-CRP, PTX-3 and IL-6 levels were more lower than those in control group (P<0.05). The incidence of PSD and the adverse reactions in the observation group were lower than those in the control group, but the differences were not statistically significant (P>0.05).

Conclusions:: Butylphthalide in the treatment of patients with acute cerebral infarction complicated with cognitive dysfunction can effectively improve their cognitive function, inhibit inflammatory response.
KNOWLEDGE OF ALZHEIMER’S DISEASE AMONG MEDICAL STUDENTS AND HEALTHCARE PROVIDERS IN SUDAN

Ismat Babiker\textsuperscript{1}, Awab Elnaeim\textsuperscript{1}, Mohamed Elnaeim\textsuperscript{2}, Awab Saad\textsuperscript{1}  
\textsuperscript{1}University of Medical Sciences and Technology, Medicine, Khartoum, Sudan, \textsuperscript{2}Alzaiem Alazhari University, Medicine, Khartoum, Sudan

\textbf{Background and Aims::} The objective of this study was to assess knowledge of Alzheimer's disease among medical students and healthcare providers in Sudan.

\textbf{Methods::} In this cross-sectional study, that was conducted in Sudan during the period from July to December 2020, we used Google forms to collect data from 217 medical students and healthcare providers using Alzheimer’s Disease Knowledge Scale (ADKS). ADKS is a widely used validated instrument that measures what people know about Alzheimer disease using 30-item true/false questionnaire across seven critical knowledge domains: risk factors, symptoms, assessment and diagnosis, disease trajectory, life impact, treatment and management, and caregiving.

\textbf{Results::} Our studied population consisted of doctors (n = 108), medical students (n=25), dentists and pharmacists (n=40) and other healthcare providers (n=44). 77.4 % were females. The mean age was 29 years (SD = 6.5), and When rating their knowledge from 0-10, Our participants' mean value was 5.3 ± 2.1. Regarding ADKS the mean knowledge score (out of 30) is 20.6 ± 2.8. The best average score was treatment and management 86.8%, followed by life impact 78.3%, assessment and diagnosis 72.4%, disease trajectory 71.5%, symptoms 62.7%, caregiving 59.2%, and risk factors 59%. We did not detect any significant association between the average overall score and gender, occupation, source of information, or having a relative with Alzheimer’s disease.

\textbf{Conclusions::} Specific knowledge deficits were observed in domains focusing on risk factors, symptoms and caregiving for Alzheimer’s disease.
POST-STROKE COGNITIVE IMPAIRMENT AND THE BALANCE OF COAGULATION AND FIBRINOLYSIS

Ivan Koltsov¹, Mikhail Martynov¹, Ekaterina Kovalenko¹-², Anna Bogolepova¹-², Albina Yasamanova¹, Oleg Brusow³, Ivan Shchukin¹, Mikhail Fidler¹
¹Pirogov Russian National Research Medical University, Neurology, Neurosurgery, And Medical Genetics Department, Moscow, Russian Federation, ²Federal Center of Brain Research and Neurotechnologies, Cognitive Impairment Deartment, Moscow, Russian Federation, ³Mental Health Research Center, Biochemistry Laboratory, Moscow, Russian Federation

Background and Aims:: Post-stroke cognitive impairment (PCI) contributes greatly to the global stroke burden. In recent years, the role of hemostasis in PCI is acknowledged more and more. This study aimed to evaluate the connection between PCI and coagulation/fibrinolysis balance.

Methods:: Thirty-two ischemic stroke patients with no aphasia were included in the study. At admission, the NIHSS scores were recorded, and blood plasma samples were obtained. Using a Thrombodynamics analyzer, two tests were done to assess the coagulation/fibrinolysis balance. The first test was performed according to the standard Thrombodynamics protocol; the second test was performed with the addition of a recombinant tissue plasminogen activator (rTPA). Using Karmin software, hemostasis potential (HP) and fibrinolysis potential (FP) were calculated. PCI was assessed using Montreal Cognitive Assessment (MoCA) scale 10 to 14 days after admission. Local ethical committee approved the study.

Results:: In univariate and multivariate analyses that included age and NIHSS at admission as covariates, hypercoagulation and higher HP at admission were found to be associated with lower MoCA scores (by -1.062 in univariate model [95% CI from -1.884 to -0.240, p=0.013] and -0.872 in multivariate model [95% CI from -1.592 to -0.152, p=0.019] for every ten points of HP). Moreover, better response to rTPA and higher FP were associated with higher MoCA scores (by 1.206 in univariate model [95% CI from 0.183 to 2.228, p=0.022] and 1.017 in multivariate model [95% CI from 0.138 to 1.895, p=0.025] for every ten points of FP).

Conclusions:: Hypercoagulation/hypofibrinolysis are associated with lower early MoCA performance and PCI in ischemic stroke.
THE CORRELATION BETWEEN SERUM CRP, NSE, CCL2 AND COGNITIVE IMPAIRMENT AFTER ACUTE ISCHEMIC STROKE

R.S. Chen¹, Y.S. Sun², D.H. Wang¹, L.B. Zhang¹, Y.L. Hou³
¹The NO.1 Affiliated hospital of Shanxi Datong University, Neurology, Datong, China, ²School of Medicine, Datong University, Neurology, Datong, China, ³The first hospital of Shanxi medical university, Neurology, Taiyuan, China

Background and Aims:: Early detection of cognitive dysfunction after stroke, and early intervention to reduce the patient and family great mental and economic burden is particularly important. Aims: To explore that Neuron Specific Enolase (NSE), C-Reactive Protein (CRP) and Chemokine CC motif 2 (CCL2) can become the screening and early warning organism of cognitive dysfunction after acute ischemic stroke, which is convenient, quick and does not significantly increase the cost of diagnosis and treatment the possibility of scientific indicators.

Methods:: 200 patients with acute ischemic stroke and 100 healthy people were selected, and divided into normal cognitive function group (93 cases), cognitive dysfunction group (107 cases) and control group (100 cases). To study the relationship between serum NSE, CRP and CCL2.

Results:: 1. The serum concentrations of NSE, CRP and CCL2 in patients with acute ischemic stroke were higher than those in normal control group (P<0.05). 2. The levels of NSE, CRP and CCL2 in patients with cognitive impairment after acute ischemic stroke were higher than those in patients without cognitive impairment after stroke (P<0.05). 3. The cognitive scores were positively correlated with serum NSE, CRP and CCL2 (r=0.21, P<0.05).

Conclusions:: The serum NSE, CRP and CCL2 can be used as biological detection indicators of cognitive dysfunction after acute ischemic stroke. It can be used as an effective index for clinical diagnosis, disease condition and prognosis evaluation of cognitive dysfunction after acute ischemic stroke.
THE BEHAVIORAL VARIANT OF FRONTOTEMPORAL DEMENTIA: LINKING CEREBELLAR MRI ALTERATIONS TO BEHAVIORAL AND AFFECTIVE SYMPTOMS

Giusy Olivito1,2, Davide Quaranta3, Libera Siciliano4, Marco Bozzali5,6, Naike Caraglia3, Camillo Marra2, Maria Leggio1,2, Maria Caterina Silveri8,9
1Sapienza University of Rome, Department Of Psychology, Rome, Italy, 2IRCCS Santa Lucia, Ataxia Research Lab, Rome, Italy, 3IRCCS Policlinico Universitario “A. Gemelli”, Institute Of Neurology, Rome, Italy, 4Sapienza University of Rome, Phd Program In Behavioral Neuroscience, Rome, Italy, 5University of Torino, 7 Department Of Neuroscience, Torino, Italy, 6Brighton and Sussex Medical School, 7) department Of Neuroscience, Falmer, United Kingdom, 7Università Cattolica del Sacro Cuore, Department Of Neuroscience, Rome, Italy, 8Università Cattolica del Sacro Cuore, Department Of Psychology, Milan, Italy, 9Fondazione Policlinico Universitario A. Gemelli, 10) centre For The Medicine Of Aging, Rome, Italy

Background and Aims:: Frontotemporal dementias (FTDs) are progressive neurodegenerative disorders associated with grey matter (GM) loss in frontal and temporal brain regions (Rascovksy et al., 2011) and presenting with marked behavioral symptoms and/or language deficits. The Behavioral variant of FTD (bvFTD) is clinically characterized by insidious changes in personality, interpersonal conduct and emotion processing (Piguet, et al 2017). Considering its role in higher-level functions (Schmahmann & Sherman, 1998) the cerebellum was recently proposed to be implicated in FTD pathophysiology (Yu Chen et al., 2019) although its specific contribution to bvFTD symptoms still needs to be clarified. Aim of the present study was to assess cerebellar GM changes in patients with bvFTD and their potential association with affective symptoms.

Methods:: Patients with bvFTD and healthy subjects (HS) underwent MRI scanning at 3.0T with acquisition of T1-weighted volumes. Voxel-based morphometry (VBM) was performed to compare cerebellar GM volumes between patients and HS. Patients' behavioral measures were also acquired to be correlated with MRI data.

Results:: Compared to HS, bvFTD patients showed regional GM loss in the right Crus I, the left lobule VI, the left Crus I and Crus II of the cerebellum.

Conclusions:: These findings indicate a specific pattern of cerebellar GM atrophy that involves regions primarily connected to the prefrontal cortex (Kelly & Strick, 2003). We argue that an association exists between cerebellar GM changes and damage to corresponding prefrontal regions mediated by cerebro-cerebellar loops which may account for the behavioral and affective symptoms observed in bvFTD.
Background and Aims: Subjective Cognitive Decline (SCD), defined as a subjective decline in cognitive function without an objective impairment on tests, has been demonstrated to be an at-risk stage for dementia, which already costs around a trillion dollars per year. This research aimed to ascertain what has been published around the world on that subject.

Methods: Authors searched MEDLINE, EMBASE, PubMed, among others for complete articles from 2014 to 2020, in English and Spanish, using the keyword “Subjective Cognitive Decline” and “Deterioro Cognitivo Subjetivo”

Results: Of 3470 results, 487 were eligible articles. The largest publishers were the USA, China, Netherlands, and Germany, each with approximately 10% or more of the total publications. In 2014 8 articles were published, contrasting with 167 in 2020 (an increase of almost 2000%) with 87% of the total published in high-income countries. Unexpectedly in the USA, 24% of the articles used biomarkers, contrasting with China, with 68%. The mechanisms of SCD was the most studied subject (33,14%), followed by Clinical manifestations (20,98%) and prognostics (14,51%), and there were 3 articles relating the condition to COVID-19.

Conclusions: This review demonstrates an increasing number of publications and relevance of the topic, with a concentration of articles in some countries, especially in high-income. Among middle-income countries, China stands out with a growing number of publications. The main interest of the articles were the mechanisms, especially biomarkers, the presentation, and the relation of the condition with dementias. The association to COVID-19 studies demonstrates new concerns regarding the topic of cognition and highlights its importance.
Background and Aims:: Mild Cognitive Impairment (MCI) is a dynamic state which has evolved into a highly defined condition due to its association with dementia syndromes. There are no published data on the demographic and clinical characteristics of MCI in the Philippines. These data will help in defining the population at risk for the condition and in modifying the factors for its prevention.

Methods:: From 2010 to 2019, 446 subjects were diagnosed with MCI based on the criteria published by the International Working Group on MCI. The demographic profile, vascular risk factors, and Vitamin B12, Vitamin D, and homocysteine levels were reviewed. Results of neuropsychological tests, such as Alzheimer's Disease Assessment Scale-Cognitive Subscale (ADAS-Cog), Mini-Mental State Exam (MMSE), and locally-adapted Montreal Cognitive Assessment-Philippines (MoCA-P), were collected. Neuroradiologists reviewed the MRIs to determine the Fazekas score.

Results:: The median age was 72 years [34 – 99] with 58.3% females. The median years of education was 14 [4 – 28]. Median ADAS-Cog, MMSE, and MoCA-P scores were 11.3 [0 – 37.7], 27 [13 – 30], and 21 [4 – 30], respectively. Hypertension and dyslipidemia were present in 67.0% and 38.3%, respectively. Normal homocysteine, Vitamin B12, and Vitamin D levels were found in 62.8%, 60.2%, and 48.2%, respectively. The median Fazekas was 1 (58.8%).

Conclusions:: This is the first study to document the demographic and clinical profile of Filipinos with MCI in a clinical setting. This review serves as a foundation for increased understanding of MCI with the long-term goal of controlling the factors which may impact its prevention.
NEUROLOGICAL SOFT SIGNS IN NEURODEGENERATIVE DEMENTIAS: A PILOT STUDY

Federico Emanuele Pozzi¹, Lucio Tremolizzo², Giuseppe Fiamingo¹, Ildebrando Appollonio³, Carlo Ferrarese²,4,5
¹Ospedale San Gerardo, Neurology, Monza, Italy, ²University of Milano-Bicocca, School Of Medicine And Surgery, Monza, Italy, ³“San Gerardo” Hospital and University of Milano-Bicocca, Neurology Unit, Milan, Italy, ⁴University of Milano Bicocca, Department Of Medicine And Surgery, Monza, Italy, ⁵University of Milano-Bicocca, Neurology, Ospedale San Gerardo, Monza, Italy

Background and Aims:: Neurological Soft Signs (NSS) are sensory-motor abnormalities linked with cerebellar and microstructural subcortical white matter alterations, which are not systematically evaluated during standard neurological examination. Although historically observed in psychiatric conditions, NSS have been recently associated with migraine, mild cognitive impairment and Alzheimer’s disease (AD), and correlated with age and apoE polymorphisms. However, no study to date has evaluated the burden of NSS in other types of dementia. Our research aims to confirm the increase of NSS in AD patients, and extend their assessment to fronto-temporal dementia (FTD), cortico-basal syndrome (CBS) and Lewy-body dementia (LBD), correlating them with the severity of cognitive impairment.

Methods:: Mini-Mental State Examination (MMSE), Frontal Assessment Battery (FAB) and a modified version of the Heidelberg NSS Scale have been administered to 75 patients with mild and moderate dementias and 30 healthy matched controls.

Results:: Demented patients showed almost 3-times higher NSS values compared to controls (p<0.05), with CBS/LBD patients bearing the highest burden, followed by AD and FTD patients, with significant between-groups differences (p=0.003). Statistically significant differences in single NSS scale items across different types of dementia were observed. NSS inversely correlated with MMSE and FAB, and positively correlated with disease duration only in AD subjects.

Conclusions:: Our work suggests that NSS are significantly more expressed in neurodegenerative dementias compared to healthy controls, especially in subcortical types. The modified version of the Heidelberg NSS Scale could represent a helpful instrument in the differential diagnosis of cognitive decline, with a potential role in the follow-up.
Background and Aims:: It is well known that persons with Alzheimer’s disease often present with word finding difficulties since the early phases of the disease. Although speech therapy might be indicated for treating this disorder costs, mobility and recently pandemic issues often hinder access to the cure. Here we provide experimental evidence supporting the feasibility and efficacy of a telemedicine approach based on word repetition for treating anomia in AD.

Methods:: Inclusion criteria were diagnosis of AD, pathological picture naming performance and spared word repetition. The treatment protocol lasted 1 month and was entirely administered at the distance by means of a tablet. The protocol comprised the following phases: item selection (3 words sets with equal subjective difficulty were selected, as control and experimental sets); baseline (the words set were named 3 times each to define a baseline level); training (the two experimental sets were assigned each to a training condition. Both conditions consisted in repeating the target word coupled with the corresponding picture but the presentation order of the picture and the to-be-repeated word varied across condition. outcome (the 3 word sets were named 3 times after training). A Logistic mixed model was carried over to analyse the effect of training on the control and experimental sets.

Results:: Naming significantly improved on the trained words with only minor hints of generalisation to the untreated items.

Conclusions:: Our results confirmed the feasibility and efficacy of telemedicine to improve access to speech therapy in AD.
CONNECTED SPEECH DEFICIT AS AN EARLY HALLMARK OF CSF-DEFINED ALZHEIMER'S DISEASE AND CORRELATION WITH CEREBRAL HYPOPERFUSION PATTERN

Giulia Mazzon¹, Miloš Ajčević¹, Tatiana Cattaruzza¹, Francesco Biaduzzini¹, Alina Menichelli², Michele Guerriero², Selene Capitania², Valentina Pesavento², Franca Dore³, Sandro Sorbi⁴, Andrea Marini⁵, Paolo Manganotti¹

¹Neurology Unit, Department Of Medical, Surgical And Health Sciences, Cattinara University Hospital, Asugi, University Of Trieste, Trieste, Italy, ²Rehabilitation Medicine, Department Of Rehabilitation Medicine, Neuropsychology Unit, University Hospital And Health Services Of Trieste, University Of Trieste, Trieste, Italy, ³Unit of Nuclear Medicine, University Hospital And Health Services Of Trieste, University Of Trieste, Trieste, Italy, ⁴University of Florence, Department Of Neuroscience, Psychology, Drug Research And Child Health, Firenze, Italy, ⁵University of Udine, Department Of Language And Literatures, Communication, Education And Society, Udine, Italy

Background and Aims:: There is still a growing interest for the detection of early and non-invasive biomarkers for diagnosis of prodromal Alzheimer's disease (AD). Although progressive episodic memory impairment is the typical predominant feature of AD, communicative difficulties can be already present at the early stages of the disease and could represent an early non-invasive AD biomarker. This study investigate narrative discourse production deficit as a hallmark of cerebrospinal fluid (CSF) defined prodromal AD and its correlation with cerebral hypoperfusion pattern.

Methods:: Narrative assessment with a multilevel procedure for discourse analysis was conducted on 28 subjects with Mild Cognitive impairment (15 MCI due to AD; 13 non-AD MCI) and 28 healthy controls. Diagnostic workup included CSF AD biomarkers. Cerebral hypoperfusion pattern was identified by SPECT image processing.

Results:: Discourse analysis of global coherence and lexical informativeness indexes allowed to identify AD-MCI from non-AD-MCI and healthy subjects. These findings could suggest loss of narrative efficacy as a possible early clinical hallmark of Alzheimer's disease. Furthermore, a significant correlation of global coherence and lexical informativeness reduction with SPECT hypoperfusion was found in the dorsal aspect of the anterior part of the left inferior frontal gyrus, supporting the hypothesis that this area plays an important role in communicative efficacy and, in particular, in semantic selection executive control.

Conclusions:: This study contributes to the understanding of the neural networks for language processing and their involvement in prodromal Alzheimer's Disease. It also suggests an easy and sensitive tool for clinical practice that can help identifying individuals with prodromal Alzheimer's Disease.
DEMENTIA IN PAKISTAN: RESULTS FROM OUR REGISTRY AT A TERTIARY CARE PRIVATE UNIVERSITY HOSPITAL

Ramsha Siddiqui, Arsalan Ahmad, Maimoona Siddiqui
Shifa International Hospital, Shifa Tameer-e-millat university, Neurology, Islamabad, Pakistan

Background and Aims:: To analyze data of our dementia patients enrolled from 2010 to 2015 from our dementia registry and to report their epidemiology, frequency, investigations and management.

Methods:: All patients with dementia coming for neurology consultation who gave their consent were enrolled in the registry from October, 2010 to June, 2015. The registry was approved by our Institutional Review Board and Ethics Committee. Demographic and clinical data was recorded on a predesigned dementia registry form and included clinical features, pertinent investigations and cognitive assessment: Mini Mental State Examination, Neuro Psychological Inventory, Beck Depression Inventory and Beck Anxiety Inventory. Forms with incomplete data were excluded and data was entered in SPSSv23 for analysis. A total of 267 patients were included for final analysis.

Results:: Out of 267 patients, 55.9% were male. The mean age was 69.3 ± 10.96 years. 26.20% were smokers. 32.96% had Alzheimer’s disease, mixed Alzheimer’s/vascular dementia comprised 23.22%; Parkinson’s disease dementia: 18.35%; Lewy body dementia: 4.87%, Mild Cognitive Impairment: 3.37%, Frontal lobe dementia: 4.12%, Huntington’s disease dementia: 1.49%, Primary progressive aphasia: 1.12%; Creutzfeldt-Jakob disease: 1.50%; others: 5.99%. MRI was done in 36.70% and CT scan in 23.60%. Medications used were Rivastigmine in 15.70%, Donepezil in 6.40%, Galantamine in 5.20% and Memantine in 9.00%.

Conclusions:: Alzheimer’s disease was the most common type of dementia in our patients followed by Mixed Alzheimer’s/vascular dementia and Parkinson’s disease dementia. MRI and CT scan were the main radiological investigations. Only 36.3% opted for symptomatic treatment with cholinesterase inhibitors or memantine.
DONEPEZIL MODULATION OF BETA-AMYLOID Oligomer Phagocytosis IN PERIPHERAL MONOCYTES. BED TO BENCH OBSERVATIONS FROM ALZHEIMER'S DISEASE PATIENTS.

Aristotelis Karantzoulis¹,², Elisa Conti¹,², Federica Angiulli¹, Martina Slango¹, Virginia Rodriguez Menendez², Mario Mauri¹, Fulvio Da Re¹,², Angelo Aliprandi⁴, Paola Basilico⁴, Andrea Salmaggi⁴, Ildebrando Apollonio¹,², Lucio Tremolizzo¹,², Carlo Ferrarese¹,²

¹Università degli Studi di Milano - Bicocca, Medicine And Surgery, MONZA, Italy, ²Università degli Studi di Milano - Bicocca, Milan Center For Neuroscience, MONZA, Italy, ³Experimental Neurology Unit, School Of Medicine And Surgery, MOnza, Italy, ⁴Manzoni Hospital, Neurology Unit, Lecco, Italy

Background and Aims:: Beta-Amyloid (Abeta) aggregates are reputed to play a central role in AD pathogenesis, partly by triggering neuroinflammation. Peripheral monocytes can shift into the CNS, hence participating in Abeta oligomer clearance. Donepezil's anti-AD mechanism remains largely elusive; however, it can interact with monocyte a7nAChR that is involved in Abeta phagocytosis. We believe that by binding to a7nAChR, Donepezil can modulate Abeta internalization driven by both a7nAChR and TREM2.

Methods:: Differentiated monocytic cell line U937 or differentiated monocytes from AD patients were treated for 24 h with 125 pM Abeta42 oligomers or methyllycaconitine (MLA, a7nAChR inhibitor) and/or pre-treated with Donepezil. Western blot and Real Time-PCR were performed. Phagocytosis was assessed by confocal microscopy analyses with fluorescent Abeta. 20 AD patients (n=10 treated with Donepezil and n=10 naive) and n=10 controls were recruited from our Neurology unit for TREM2 assessment.

Results:: In U937 cells, Abeta was able to significantly reduce TREM2 levels, while co-administration of Donepezil significantly restored them; neatly, this action was blocked by adding MLA. A rise in Abeta internalization after treatment with Donepezil was demonstrated by confocal microscopy studies and this tendency was reverted by MLA. The study in treated and untreated AD patients showed a decrease of TREM2 mRNA levels in AD with respect to controls. Conversely, amongst AD patients, those taking Donepezil presented higher TREM2.

Conclusions:: Our data indicate that on peripheral monocytes Donepezil, by interacting with a7nAChR, might contribute to Abeta clearance, by decreasing neuroinflammation thus favouring TREM2's action.
CARDIOVASCULAR RISK FACTORS AMONG ELDERLY WITH COGNITIVE IMPAIRMENT IN URBAN PRIMARY CARE

Vikas Dhikav
ICMR-NIIRNCD, Mental Health & Neurological Research, JODHPUR, India

Background and Aims:: Background Cardiovascular (CV) risk factors are common in elderly but their frequency in those with cognitive impairment is not known. Also, the relationship that they have with cognitive impairment is complex and under investigation. It has been stressed that controlling CV risk factors can reduce risk of cognitive decline. Majority of the data in this regard has come from the tertiary care institutions and ours is first such study assessing frequency of vascular risks and their relationship with cognitive impairment in primary care setting. Aim A cross sectional study was conducted to assess the frequency of CV risk factors among elderly in primary care in Western India, screen them using mini-mental state examination (MMSE) and see if there was any relationship of the same with cognitive impairment.

Methods:: Material & Methods A total of 204 elderly (Mean age=66.61±6.63; M:F=131:73) coming to primary care centre were examined using MMSE for cognitive impairment. Written records were examined for the presence of CV risks e.g. diabetes, hypertension/ & diabetes together, stroke and coronary artery disease.

Results:: Results Frequency of CV risk factors in those with cognitive impairment was 84/204 (41.2%) and in those without cognitive impairment was 31/204 (26.9%). A Chi Squared test of proportion showed values to be statistically significantly different (p-value=<0.001. Odds Ratio was calculated to be 6.5 (p-value=<0.0001).

Conclusions:: A higher frequency of common cardiovascular risk factors were observed among those with cognitive impairment compared to those who were cognitively normal elderly.
DIFFERENTIATION OF MILD COGNITIVE IMPAIRMENT (MCI) PROGRESSION TO ALZHEIMER DISEASE (AD) VS DEMENTIA WITH LEWY BODIES (DLB): IS THIS POSSIBLE NEUROPSYCHOLOGICALLY?

Panagiota Voskou
University of Athens, 1st Department Of Neurology, Athens, Greece

Background and Aims:: Aim of the present review was to describe and compare the neurocognitive features of MCI which could predict its progression to DLB vs AD.

Methods:: A literature review in the Pubmed database has been made, after the year 2005, using the key-words neuropsychological assessment; MCI; AD; DLB. Seventeen relevant articles have been found.

Results:: Data from most studies supports that, in MCI, impairment in executive, attentional and visuospatial functions, as well as letter fluency and fluctuating concentration are mainly related to progression to DLB. In contrast, prominent episodic and recognition memory deficits are mostly found in MCI which progresses in AD. Furthermore, non-amnestic MCI has been related mainly to progression in DLB, whereas the amnestic type to AD, although memory loss may not necessarily predict the development of AD. Nevertheless, fewer studies suggest that MCI-DLB is related to cognitive profile similar to that of MCI-AD, while cognitive scoring alone does not accurately predict MCI-DLB vs MCI-AD. Interestingly, quantitative electroencephalogram may help predicting the progression of MCI to DLB, while preservation of hippocampal volume is associated with increased risk of DLB vs AD, especially in non-amnestic MCI.

Conclusions:: Predicting the progression of MCI to AD or DLB based on neuropsychological profiles is challenging and useful for early therapeutic interventions. More studies are needed, since there are some conflicting findings, while the combination of clinical symptoms with neurocognitive assessment and neuroimaging remains the ideal method for the prediction of MCI progression to various types of dementia.
THERAPEUTIC MODULATION OF NEUROINFLAMMATION IN ALZHEIMER'S DISEASE

Bradlee Heckmann
USF Health Neuroscience Institute, Byrd Alzheimer's Center, Tampa, United States of America

Background and Aims:: Neuroinflammation contributes to the establishment and progression of neurodegenerative diseases including Alzheimer’s Disease (AD). LC3-associated endocytosis (LANDO) protects the brain from aberrant neuroinflammation and is downregulated in AD. Abrogation of LANDO decreases neuroinflammation and AD pathology. Therapeutic intervention targeting neuroinflammation reverses pathology downstream of amyloid deposition, including amelioration of tau-phosphorylation and restoration of memory. Herein, we detail new approaches for targeting neuroinflammation and applicability to human AD therapy.

Methods:: We have utilized two murine models of AD lacking LANDO, one replicating early-onset AD and the second spontaneous age-associated AD. We have utilized two approaches to targeting both NFkB pathway activation and NLRP3-inflammasome activation and have found that NLRP3 inflammasome inhibition alone is therapeutically efficacious using either an established or novel brain-penetrant inhibitor.

Results:: Mice with established disease treated with either of our NLRP3 inflammasome inhibitors displayed robust responsiveness to therapeutic intervention. IL-1b production was suppressed as were decreases in all other inflammatory markers. Tau-hyperphosphorylation was reduced as was activate neurodegeneration. All mice receiving therapeutic intervention had improved memory across multiple analyses.

Conclusions:: The loss of LANDO drives spontaneous AD in mice, and inhibition of neuroinflammation is a potential therapeutic approach for treating neurodegeneration and memory loss. A decline in expression of LANDO regulatory genes in the brains of human AD patients suggests the possibility that a similar mechanism may contribute to disease in human AD and is a viable therapeutic modality in treating AD pathology.
MULTIMODAL EVALUATION OF THE MELANOPSIN RETINAL GANGLION CELLS SYSTEM IN RELATION TO CIRCADIAN RHYTHMS IN ALZHEIMER’S DISEASE AND AGING.

Chiara La Morgia¹, Micaela Mitolo², Aurelia Santoro³, Martina Romagnoli¹, Michelangelo Stanzani Maserati¹, Stefanià Evangelisti², Maddalena De Matteis¹, Flavia Palombo⁴, Maria Giulia Bacalini⁴, Sabina Capellari⁵, Piero Parchi¹, Michele Carbonelli¹, Rocco Liguori¹, Caterina Tonon², Raffaele Lodi², Valerio Carelli⁴

¹IRCCS Istituto delle Scienze Neurologiche di Bologna, Neurology Unit, Bellaria Hospital, Bologna, Italy, ²IRCCS Istituto delle Scienze Neurologiche di Bologna, Functional And Molecular Neuroimaging Unit, Bologna, Italy, ³University of Bologna, Department Of Experimental, Diagnostic And Specialty Medicine, Bologna, Italy, ⁴IRCCS Istituto delle Scienze Neurologiche di Bologna, Neurogenetic Unit, Bologna, Italy, ⁵IRCCS Istituto delle Scienze Neurologiche di Bologna, Department Of Biomedical And Neuromotor Sciences, Bologna, Italy

Background and Aims:: Melanopsin retinal ganglion cells (mRGCs) are deputed to circadian photoentrainment and pupillary light reflex (PLR) regulations. Circadian dysfunction is reported in Alzheimer’s disease (AD) and contributes to dementia. Single-Nucleotide-Polymorphisms (SNPs) in clock genes have been associated to AD.

Methods:: We included 29 mild-moderate AD and 26 matched controls performing neuroophthalmological evaluation including optical coherence tomography (OCT), actigraphic recordings of rest-activity rhythms, chromatic pupillometry and brain functional MRI (fMRI) with light stimulation. 84 clock genes were also analyzed by NGS and relevant single nucleotide polymorphisms (SNPs) validated in a larger cohort of AD (n=449) and controls (n=326).

Results:: In AD disease duration was 3.9±2.8 years and MMSEc score 20.2±4.2. OCT showed a significant reduction of the infero-temporal GCL thickness (p=0.036) in AD. Actigraphy did not disclose significant differences for circadian parameters (IS, IV, RA). However, a subgroup of “circadian-impaired” AD was evident, and most of circadian parameters declined with aging. Pupillometry revealed a significant reduction of PLR peak amplitude in the rod protocol (p=0.006) significantly correlating with aging in AD. Brain fMRI documented the absence of significant responses in AD with sustained blue light stimulation at difference with controls. Genetic analysis in extended AD and control cohorts showed a significant association of the rs30127178 SNP in PER1 gene with AD.

Conclusions:: These results demonstrate, by innovative multi-modal approach, that mRGC system in AD is affected by neurodegeneration. This can be envisaged as a possible biomarker also for conversion from MCI to AD with potential implication for light therapy as a counteracting measure for dementia.
SEX HORMONES AND ALZHEIMER'S DISEASE: A MENDELIAN RANDOMIZATION APPROACH

Cynthia Kusters¹, Steve Horvath², Janet Sinsheimer³, Beate Ritz⁴
¹University of California, Los Angeles, Department Of Human Genetics, Los Angeles, United States of America, ²University of California, Los Angeles, Human Genetics And Biostatistics, Los Angeles, United States of America, ³University of California, Los Angeles, Human Genetics, Biostatistics, And Computational Medicine, Los Angeles, United States of America, ⁴University of California, Los Angeles, Epidemiology, Neurology And Environmental Health, Los Angeles, United States of America

Background and Aims:: Sex hormones have been hypothesized to influence AD risk. However, studies of AD based on reproductive characteristics have been inconclusive. Here, we used a Mendelian randomization approach to assess the association between sex steroid hormones (SHBG, Testosterone, Estradiol, and DHEAS) with Alzheimer's disease (AD).

Methods:: We performed MR-egger Mendelian Randomization (MR analysis) using external GWAS summary data to estimate the effects of genetic variants on measured sex hormone levels, stratified by sex. We included independent variants (linkage disequilibrium R²<0.1) and a P-value of 5x10⁻⁸ in the GWAS for sex hormones. Sensitivity analyses included using alternate MR techniques and varying the P-value thresholds.

Results:: Our preliminary findings indicate an association between sex hormone concentrations and AD risk. Specifically, an increased testosterone concentration (per 1 nmol/l) appears to be associated with a decrease in AD risk among women (OR:0.86;95%CI:0.75 – 0.98;P-value 0.03), and possibly among men (OR:0.99;95%CI:0.98 – 1.00;P-value:0.08); and an increase in DHEAS (per 1 umol/l) was associated with a decreased AD risk among the total population (men and women; OR:0.57;95%CI:0.33 – 0.99;P-value 0.05). No associations were found for estradiol and AD, and a possible effect between SHBG and AD among (OR:0.99;95%CI:0.98 – 1.00;P-value 0.09).

Conclusions:: We found an indication that testosterone and DHEAS might have a protective effect on AD. Our findings are limited due to weak instrument bias, especially for estradiol. These preliminary findings indicate sex hormones may influence AD risk, further supporting the hypothesis that sex hormones may be neuroprotective.
ELIGIBILITY FOR DISEASE-MODIFYING TREATMENT IN ALZHEIMER’S DISEASE: EVIDENCE FROM AN OBSERVATIONAL STUDY OVER 4 YEARS

Salvatore Caratozzolo¹, Luca Rozzini¹, Maura Cosseddu¹, Rosanna Turrone¹, Silvia Compostella¹, Alberto Benussi², Andrea Scalvini¹, Nicola Zoppi², Marcello Giunta¹, Paghera Barbara², Alessandro Padovani¹

¹ASST Spedali Civili di Brescia, Neurology Unit, Dept. Clinical And Experimental Sciences, University Of Brescia, Brescia, Italy, ²ASST Spedali Civili di Brescia, Nuclear Medicine, Brescia, Italy

Background and Aims:: AD diagnosis rarely relies on a pathophysiological marker in memory centers requiring procedure standardisation for real world diagnostic work up. To study the epidemiology of prodromal and mild stages of AD patients who are eligible for clinical trials with disease modifying therapies.

Methods:: We retrospectively analysed data collected at Centre of Dementia and Cognitive Decline, to study the incidence and characteristics of this population eligible for a disease modifying treatment from March 2014 to March 2018. The sample underwent a standardised operational procedure in order to select patients for participation in DMT clinical trials.

Results:: 1143 patients entered the study. Among them, 622 were diagnosed with overt dementia whereas 98 were diagnosed as subjective cognitive impairment and 423 as MCI. Of these, 121/423 (28,6%) were affected by significant somatic comorbidities, 57/301 (18,9%) had a MRI positive for significant cerebrovascular abnormalities, 68/244 (27,8%) patients were lost because of refusals. Among those who were eligible for amyloid biomarker testing 39/177 (22,2%) were negative. A diagnosis of prodromal AD, certified by the use of amyloid-related biomarkers, could be established in 138 (12,1%) out of 1143 patients. By a logistic regression, age, CIRS severity, MTLA, and amnesic MCI were associated with eligibility (p.<001).

Conclusions:: Most patient referred to a Memory Center were not diagnosed at a prodromal stage. Among prodromal AD, most did not fulfil eligibility criteria for entering a disease modifying treatment arguing for the need of more stringent patient journey in the perspective of disease-modifying treatment.
Background and Aims:: Objective: To compare the predictive accuracy of Medial Temporal Lobe Atrophy (MTLA) measurements, for cognitive decline at two-years follow up in subjects subjective memory impairment (SMI).

Methods:: We selected 98 SMI subjects from a memory clinic-based cohort. We clinically assessed all subjects and measured MTLA according to the Scheltens’ visual rating scale. Follow-up was performed annually up to 24 months. Outcome measures were cognitive progression to MCI or dementia. Patients converted to MCI and dementia were assessed by Amyloid PET (Florbetapir).

Results:: Out of 98, 34 SMI subjects progressed to MCI (n= 24) or dementia (n=10) after a 24 months follow-up. Of these, 28 (82%) were positive at Amyloid PET. MTLA measure and APOE genotype but not demographic, clinical and cardiovascular and other somatic risk factors was significantly associated to progression at 12 and 24 months (p<.000), controlling for age.

Conclusions:: according to this study amyloid burden is a common cause of SCI. MTLA and Apoe genotype are useful to predict cognitive decline and amyloid burden in subjects with subjective memory impairment. This may have implications for clinical implementation and screening in the real world.
FTI: A NEUROPSYCHOLOGICAL MARKER TO DISCRIMINATE DIFFERENT CORTICAL FORMS OF DEMENTIA

Alessandro Cocuzza¹,², Claudia Gendarini¹,², Alessandra Romandini¹,², Silvio Mauri¹,², Matteo Mercurio³,⁴, Andrea Arighi³,⁴, Elio Scarpi³,⁴, Giacomo Pietro Comi¹,⁵, Maria Cristina Saetti¹,²
¹Dino Ferrari Centre, Neuroscience Section, Department Of Pathophysiology And Transplantation, University Of Milan, Milan, Italy, ²Fondazione Ca’ Granda, IRCCS Ospedale Maggiore Policlinico, Neurology Unit, Milan, Italy, ³Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Neurodegenerative Disease Unit, Milan, Italy, ⁴Dino Ferrari Centre, Neuroscience Section, Department Of Biomedical, Surgical And Dental Sciences, University Of Milan, Milan, Italy, ⁵Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Neuromuscular And Rare Disease Unit, Milan, Italy

Background and Aims: Verbal fluency depends on the linguistic ability to retrieve lexical information (mainly ascribable to the temporal cortex) and on the attentive-executive ability to select several appropriate words (mainly ascribable to the prefrontal cortex). The former ability is especially crucial for semantic fluency, while the latter for phonemic fluency. Therefore, a deficit in phonemic fluency points towards a prefrontal dysfunction, while a deficit in semantic fluency points towards a temporal one. We evaluated whether FTI (Fluency Type Index), a quantitative comparison of performance in the two fluency tasks, functions as a viable parameter to discriminate FTD (Fronto-Temporal Dementia) from AD (Alzheimer’s Disease). Since Tau/Aβ is used with the same purpose, we expected a correlation between FTI and Tau/Aβ in demented patients.

\[
FTI = \frac{aCF - aLF}{aCF + aLF}
\]

\(aCF =\) adjusted Categorial Fluency
\(aLF =\) adjusted Letter Fluency

Methods: We tested the performance in phonemic and semantic fluency tasks of NC (Normal Controls; n=117) and of patients examined at the UVA of Policlinico Maggiore Hospital, already diagnosed with AD (n=85), bvFTD (behavioral variant FTD; n=48), or aMCI (amnestic Mild Cognitive Impairment; n=97).

Results: The rate of FTI>0 (suggesting a prefrontal impairment) is higher in FTD, while the rate of FTI<0 (suggesting a temporal impairment) is higher in AD \(\left(\chi^2=22.6; df=1; p<0.001\right)\). FTI significantly correlates with Tau/Aβ \(F=3.76; df=1.156; p<0.05\).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Normality range</th>
</tr>
</thead>
</table>

FTI: from -0.22 to +0.50 (calibrated on the NC group)

\( \text{Tau/Ab} \leq 0.52 \)

**Conclusions:** Similarly to Tau/Ab, FTI functions as a (neuropsychological) marker of dementia, capable of distinguishing AD from other neurodegenerative causes of dementia.
PUPILLARY CONSTRICTION VELOCITY AS A BIOMARKER OF BEHAVIOURAL AND PSYCHOLOGICAL SYMPTOMS OF DEMENTIA IN A COHORT OF PATIENTS WITH ALZHEIMER DISEASE

Valentina Francioni¹, Francesca Beretta¹, Caterina Salito², Dario Bovio², Ildebrando Appollonio¹, Lucio Tremolizzo¹, Carlo Ferrarese¹
¹"San Gerardo" Hospital and University of Milano-Bicocca, Neurology Unit, Milan, Italy, ²Biocubica srl, Innovative Solutions & Support, Milan, Italy

Background and Aims:: Behavioural and Psychological Symptoms of Dementia (BPSD) represent a huge challenge in Alzheimer’s Disease (AD); commonly, they are assessed through scales administered to the caregiver with a potential subjective bias. The aim of our study was to evaluate the correlation between autonomic parameters and NPI-10 results, in order to find an objective, rapid, and non-invasive biomarker of BPSD

Methods:: N=93 AD patients were recruited (age 78.2 ± 6.1 y.o.; MMSE score 19.5 ± 5.4). Neuropsychiatric Inventory 10-item version (NPI-10) and Caregiver Burden Inventory (CBI) scales were administered to the caregiver; separate symptoms and clusters of NPI-10 were further analyzed. Cohen-Mansfield Agitation Inventory (CMAI) was administered for n=21 patients. Patients and n=28 caregivers underwent assessment of autonomic parameters using Osver ® (Biocubica, Milan, Italy), a polygraphic system able to rapidly measure: pupillary constriction velocity (PCV), frontal temperature (FT), heart rate (HR), perspiration (PER).

Results:: As expected, PCV was lower in AD sample compared to cognitively-spared caregivers (p<0.005 two-tailed Student’s t-test); no differences were observed for FT, HR, PER. Interestingly, PCV decreased to the increase of the NPI-10 score (r=-0.26, p<0.02), and of the CBI (r=-0.28, p<0.01). PCV negatively correlated with the affective cluster (r=-0.38, p<0.002) including anxiety and depression, and with CMAI (r=-0.55, p<0.01), marking agitation. Finally, the anticholinergic burden correlated to PCV (r=-0.25, p<0.02) and HR (r=0.22, p<0.05).

Conclusions:: PCV could represent a potential biomarker of BPSD in general, and of anxiety, depression and agitation symptoms more specifically. Objective measurement of BPSD is necessary in order to guide future therapeutic strategies.
NEUROINFLAMMATION AND BEHAVIORAL DYSFUNCTION: EXPLORING THE ROLE OF DIAZEPAM BINDING INHIBITOR

Vittoria Aprea1, Elisa Conti2, Gessica Sala2, Chiara Zoia2, Benedetta Storti1, Fulvio Da Re1, Ildebrando Appollonio1,2, Lucio Tremolizzo1,2, Carlo Ferrarese1,2
1“San Gerardo” Hospital and University of Milano-Bicocca, Neurology Unit, Monza, Italy, 2Laboratory of Neurobiology Università degli Studi di Milano - Bicocca, Milan Center For Neuroscience, MONZA, Italy

Background and Aims:: Alzheimer’s disease (AD) and delirium share common pathogenic mechanisms and neuroinflammation, in particular, represents one plausible candidate link. Diazepam Binding Inhibitor (DBI) is an endogenous ligand of the TSPO receptor, which is expressed by both activated microglia and peripheral monocytes. For this reason, DBI may play a major role in transversely modulating the neuroinflammatory process between the CNS and the periphery. Aim of this preliminary work consisted in assessing DBI serum levels in delirium and AD patients with respect to healthy controls, analyzing particularly behavioral correlates.

Methods:: n=20 not demented patients with delirium were screened by the 4AT scale and recruited from the Neurology ward, together with n=20 matched healthy controls (CTRL) and n=110 AD outpatients without delirium. Serum DBI was assessed by commercial ELISA (AB Frontier).

Results:: DBI serum levels were more than four-fold higher in delirium patients and two-fold higher in AD patients with respect to CTRL (p<0.001). Interestingly, DBI serum levels in AD patients correlated with the Neuropsychiatric Inventory (NPI) total score (r=0.21 p<0.05) and with the Agitation/Aggression NPI subscore (r=0.29 p<0.01). Finally, cognate CSF samples were available from n=23 AD patients: their DBI CSF levels correlated with the serum ones (r=0.50 p<0.05) and with the total-Tau CSF levels (r=0.57 p<0.01).

Conclusions:: Increased DBI serum levels in delirium and AD mark the shared neuroinflammatory landscape both in periphery and the CNS. Notably, DBI levels seem to be increased particularly in agitated patients. Further studies may disclose if serum DBI may be useful as agitation marker in dementia, offering new perspectives for treatments.
ACCELERATED LONG-TERM FORGETTING AS A COGNITIVE MARKER OF SUBJECTIVE MEMORY DECLINE

Massimiliano Ruggeri, Monica Ricci, Carmela Gerace, Carlo Blundo
San Camillo Forlanini Hospital, Unit Of Cognitive Disorders And Dementia, Rome, Italy

Background and Aims:: Subjective memory decline (SMD) is defined as a self-perceived memory decline not detected by standard cognitive testing. SMD may represent the preclinical stage of Alzheimer’s disease (AD) and may underpin initial AD neuropathology. Memory complaints in SMD patients resemble the inter-critical memory failures reported by subjects with epileptic amnesia. In these patients it has been found the Accelerated Long-Term Forgetting (ALF), a defect of the consolidation of memory traces in the post-retention phase, which is usually associated with dysfunctions of the hippocampal regions. The aim of this study is to investigate the presence of ALF in SMD patients.

Methods:: 18 patients with SMD underwent neuropsychological assessment. ALF was evaluated by means of one-week delay trials of Recall and Recognition of the Rey Auditory Verbal Learning Test (RAVLT), Recall of the Rey Complex Figure, and Memory Efficiency Index (a combined score of the RAVLT Recall, Recognition hits and false responses). Results were compared to a matched control group. Mood disorders and memory failures in everyday life were measured respectively by the Depression Anxiety Stress Scale (DASS-21), and the Everyday Memory Questionnaire (EMQ).

Results:: The SMD group performed significantly worse than healthy subjects on verbal memory measures in the one-week delay condition. No correlations were found instead between memory measures and EMQ and DASS-21 scores.

Conclusions:: The SMD patients showed ALF, a defect of the consolidation of memory traces in the post-retention phase. Therefore, ALF might be a useful cognitive marker of SMD and an early sign in the preclinical stage of AD conditions.
CORTICAL NETWORK MODULARITY CHANGES ALONG THE COURSE OF FRONTOTEMPORAL AND ALZHEIMER’S DEMENTING DISEASES

Ersipamer”,, Roma, Italy, ⁹University of Brescia, Neurology Unit, Department Of Clinical And Experimental Sciences, Brescia, Italy, ¹⁰University of Brescia, Dept. Clinical And Experimental Sciences, Brescia, Italy

Background and Aims:: Cortical brain network modularity underpins cognitive functions. We hypothesized its progressive derangement along the course of two neurodegenerative conditions: frontotemporal (FTD) and Alzheimer’s (AD) dementing diseases.

Methods:: EEG was recorded in 18 FTD, 18 AD, and 20 healthy control (HC) matched for age, gender and education. In the FTD and AD patients, the EEG recordings were performed at the prodromal stage of dementia, at the onset of dementia, and three years after the onset of dementia. HC underwent three EEG recordings at 2 to 3-year time interval. Information flows underlying EEG activity recorded at electrode pairs were estimated by means of Mutual Information (MI) analysis. The functional organization of the cortical network was modelled by means of the Graph theory analysis on MI adjacency matrices.

Results:: Graph theory analysis showed that the main hub of HC (left parietal area) was lost in FTD patients at onset of dementia, substituted by provincial hubs in frontal leads. No changes in global network organization were found in AD.

Conclusions:: Despite a progressive cognitive impairment during the FTD and AD progression, only the FTD patients showed a derangement in the cortical network modularity, possibly due to dysfunctions in frontal functional connectivity.
A NEUROPSYCHOLOGICAL STUDY OF AGRAPHIA IN ARABIC IN PATIENTS WITH ALZHEIMER’S DISEASE

Mohamed Taiebine1, Mustapha El Alaoui Faris2, Maria Benabdellil3, Khadija Al Zemmouri4
1Mohammed V University. Faculty of Medicine and Pharmacy, Alzheimer’s Center, RABAT, Morocco, 2Mohammed V University. Faculty of Medicine and Pharmacy-Rabat, Morocco, Neurology And Neuropsychology, Alzheimer’s Center, RABAT, Morocco, 3Mohammed V University. Faculty of Medicine and Pharmacy-Rabat, Alzheimer’s Center-department Of Neurology A And Neuropsychology, Hôpital Des Spécialités, RABAT, Morocco, 4Alzheimer’s center, Neurology And Neuropsychology, Rabat, Morocco

Background and Aims:: Agraphia in Alzheimer’s disease has been widely studied in various occidental languages, but to our knowledge no study has been reported in Arabic language. Methods:: We studied the handwriting’s sample of nine patients with moderate to severe Alzheimer’s disease from the Alzheimer’s Center of Rabat. The average age is 69.2 years (SD: 5.76; 61-77) and of education 12.1 years (SD: 3.3; 6-15), duration of the disease is 4.3 years (SD 2.1; 1-8). Writing samples have been analyzed from MMSE sentence writing. The paragraphias have been analyzed according to the methodology of Caramazza et al, (1987).

Results:: The most frequent paragraphias found are graphomotor patterns (42%), followed by literal substitution (27%), then simple omissions of diacritics (11%). The number of paragraphias was influenced by the level of education, the severity of the diseaes, while age and gender did not have effect. The allographic errors are mainly graphemic simplifications that shared a visuo-spatial similarity with the target letters.

Conclusions:: The graphemic disorders in our patients’ writing are due to an impairment of the peripheral writing processes at probably both graphemic and allographic buffers’ levels (El Alaoui-Faris et al, 2004; McCloskey et al 2018). Furthermore, the missing of diacritics is a typical visuo-spatial feature of the Arabic script.
MUTATIONS IN MME GENE CAUSING DISTAL HEREDITARY MOTOR NEUROPATHY AND MCI-AD

Adriana Barquín Toca¹, Amaia Martínez Arroyo¹, Aida Rodríguez Sainz¹, Javier Arranz Martínez¹, Irene Sustatxa Zárraga¹, Itxaso Azkune Calle¹, Jone Bocos Portillo¹, Silvia Vázquez Picon², Claudio Catalli³, María Ángeles Gómez-Beldarrain¹
¹Galdakao-Usansolo University Hospital, Neurology, Galdakao, Spain, ²Galdakao-Usansolo University Hospital, Neuropsychology, Galdakao, Spain, ³Cruces University Hospital, Genetics, Barakaldo, Spain

Background and Aims:: MME gene encodes neprilysin protein(NEP). It is expressed in a wide variety of tissues and it is known to cleave and degrade beta-amyloid. It may have a role in Alzheimer Disease (AD), but it is not yet well understood. Distal hereditary motor neuropathy(dHMN) is a rare cause of neuropathy. MME homozygous mutations cause dHMN. To our knowledge, there are not previous reports of MME dHMN and AD. AIM:Report a patient with dHMN caused by MME homozygous mutation and MCI-AD.

Methods:: 67-year-old healthy woman. At the age of 58, she started with subjective memory loss. On examination MMSE 30/30(GDS2), pes cavus, distal lower limb weakness and atrophy. Her mother suffered from late onset AD. Her brother had axonal motor neuropathy.

Results:: MRI showed an extensive leukoencephalopathy with microangiopathy. EMG: distal axonal motor neuropathy. Toxic-metabolic, infectious, oncologic and immune causes were ruled out. Genetic panel testing of leukoencephalopathy and early-onset dementia was negative. Genetic panel testing for neuropathy showed a pathogenic MME homozygous mutation c.1342C>T(p.Arg448Ter). Her cognitive decline progressed and at 67-years-old, a complete neuropsychological study showed executive dysfunction (GDS3). Biomarkers in CSF were compatible with AD.

Conclusions:: Some studies have investigated relationship between NEP and 1-42 beta-amyloid in AD; it has not been well elucidated, though. There are few cases reported of dHMN caused by MME mutations, but this is, to the best of our knowledge, the first case associated with MCI-AD and CSF-biomarkers. We consider the MME mutations could be the underlying cause of both entities, dHMN and the cognitive decline.
IMPACT OF C9ORF72 AND TARDBP-43 MUTATIONS IN A SARDINIAN COHORT OF FRONTOTEMPORAL DEMENTIA PATIENTS

Giuseppe Piga, Gianluca Floris, Giuseppe Borghero, Giulia Primicerio, Claudia Molinu, Laura Fadda, Giovanni Defazio

1University of Cagliari, Azienda Ospedaliero Universitaria di Cagliari, Emergency Department, Institute Of Neurology, Cagliari, Italy, 2Azienda Ospedaliero Universitaria di Cagliari, Emergency Department, Institute Of Neurology, Cagliari, Italy, 3University of Cagliari, Department Of Medical Sciences And Public Health, Cagliari, Italy

Background and Aims:: Sardinians have distinctive genetic characteristics from other Europeans, including mainland Italians. We aim to determine the frequency and the impact of C9orf72 and TARDBP mutations in a Sardinian cohort of FTD patients.

Methods:: Eighty-four patients with frontotemporal dementia (77 unrelated subjects and 7 siblings belonging to three families) were consecutively seen at our Department over a ten-year period (2008 to 2018). FTD diagnosis was made according with the Rascovksy criteria for the bvFTD and the Gorno-Tempini criteria for the PPA. All patients were Sardinian by at least three generations. The following assessments were performed: neurological, neuropsychological, and neuroimaging evaluation, genetic analysis for C9orf72 and TARDBP gene mutations, and family history of FTD and/or ALS.

Results:: Genetic mutations were found in 25 out of 84 patients (30%): 19 carried the GGGGCC hexanucleotide repeat expansion of C9orf72, 5 the p.A382T mutation of TARDBP and 1 carried both mutations. As compared with patients who did not carry any of the investigated mutations, genetic cases were characterized by a lower age at onset (especially in the TDP-43 genotype), and a higher frequency of positive family history (74% of C9orf72 and 100% of TDP-43 mutations). The main clinical phenotype was the bvFTD (69% overall, 100% of C9orf72 and 80% of TDP-43). Compared to non-mutated patients, the C9orf72 showed a higher frequency of parkinsonism (60%) and the TDP-43 of motor-neuron disease (40%).

Conclusions:: Information from our sample confirmed the high frequency of these mutations among Sardinian patients with FTD an their role in clinical presentation and evolution of frontotemporal dementia.
USE OF THE MOROCCAN ARABIC VERSION OF MINI-LINGUISTIC STATE EXAMINATION (MLSE) TO STUDY LANGUAGE DISORDERS IN PATIENTS WITH ALZHEIMER’S DISEASE

Mohamed Taiebine, Samir Diouny, Mustapha El Alaoui Faris, Maria Benabdellil, Khadija Al Zemmouri

1Mohammed V University. Faculty of Medicine and Pharmacy, Alzheimer’s Center, RABAT, Morocco, 2Chouaib Doukkali University, Faculty Of Letters And Human Sciences, EL JADIDA, Morocco, 3Mohammed V University. Faculty of Medicine and Pharmacy-Rabat, Morocco, Neurology And Neuropsychology, Alzheimer’s Center, RABAT, Morocco, 4Mohammed V University. Faculty of Medicine and Pharmacy-Rabat, Alzheimer’s Center-department Of Neurology And Neuropsychology, Hôpital Des Spécialités, RABAT, Morocco, 5Alzheimer’s center, Neurology And Neuropsychology, Rabat, Morocco

Background and Aims:: The MLSE is a multilingual battery specifically designed to assess language disorders in neurodegenerative diseases. It has been initially developed in English and Italian (Catricalà et al, 2017; Patel et al, 2020). It included eleven tests exploring different language’s domains: motor speech, phonology, semantics, syntax and working memory. We used the Moroccan Arabic version of the MLSE to study language’s disorders in patients with Alzheimer’s disease (AD)(Taiebine, 2021).

Methods:: We study fourteen patients from the Alzheimer Center of Rabat: 4 women and 10 men; 4 with moderate AD and 10 with severe AD. The average age is 68.2 years (SD 6; 57-77), and for education is 13 years (SD 2.9; 6-16). The mean duration of disease is 4.2 years (SD 1.97; 1-8)

Results:: Statistical analysis showed that MLSE scores were mainly influenced by the gender and the severity of the disease, while education level and age had no effect. We found that women performed better than men in semantics, phonology and syntax. There are no difference on motor speech. The marked syntactic deterioration in our patients are probably due to the linguistic structure of Arabic.

Conclusions:: The MLSE opens a new perspective to study language disorders in AD and other neurodegenerative diseases from a cross-linguistic perspective.
FASUDIL PROTECTS NEURONS THROUGH INHIBITING OXIDATIVE STRESS RESPONSE AND RESTORING MITOCHONDRIAL FISSION-FUSION IMBALANCE

Wen-Yue Wei¹,²,³, Yu-Yin Wang¹,³, Min-Fang Guo³, Su-Yao Li¹,³, Jing Zhang¹,³, Qing-Fang Gu², Li-Juan Song¹,², Zhi Chai¹, Jian-Jun Huang⁴, Dong Ma⁴, Jie-Zhong Yu³, Cun-Gen Ma¹,²,³

¹Shanxi University of Chinese Medicine, Research Center Of Neurobiology / The Key Research Laboratory Of Benefiting Qi For Acting Blood Circulation Method To Treat Multiple Sclerosis Of State Administration Of Traditional Chinese Medicine, Jinzhong, China, ²Shanxi Medical University, Physiology/neurology, Taiyuan, China, ³Shanxi Datong University, Institute Of Brain Science / Shanxi Key Laboratory Of Inflammatory Neurodegenerative Diseases, Datong, China, ⁴General Hospital of National Medicine and Datong Coalmine, Neurosurgery, Datong, China

Background and Aims:: The pathogenesis of Alzheimer's disease (AD) is closely related to oxidative stress response and abnormal mitochondrial dynamics. Our previous research demonstrated that Fasudil has neuroprotective effect. Our aim was to explore whether Fasudil has beneficial effect on alleviating oxidative stress and regulating mitochondrial dynamics in APP/PS1 transgenic AD mice.

Methods:: Eight-month-old AD mice were randomly divided into the Fasudil group [i.p. 25 mg/(kg · d)] and normal saline group, and wild-type C57BL/6 mice served as normal controls, once daily for 2 months. Spatial cognition of mice was detected by MWM test and Y maze test. Nissl, TUNEL staining, commercial kits, Western blot, immunofluorescence were applied to observe the neuronal apoptosis, oxidative stress and mitochondrial dynamics.

Results:: Fasudil improved loss of learning, memory and exploration in AD mice. Compared with wild type group, apoptosis of neurons was increased, the expression of Bax and Cleaved Caspase-3 was increased, but Bcl-2 was decreased in AD mice. These changes were strongly reversed by treatment of Fasudil. Furthermore, Fasudil markedly elevated the concentration of antioxidative substances and decreased lipid peroxides, down-regulated the expression of p-DRP1 and FIS1 and up-regulated the expression of OPA1, Mfn1 and Mfn2.

Conclusions:: Fasudil significantly improves the spatial cognition in AD mice, which may be related to restraining oxidative stress and restoring the mitochondrial fission and fusion imbalance, therefore, inhibiting neuronal apoptosis. (NNSF of China 81473577, 81471412, 82004028; Natural Fund Project of Shanxi Province 201901D111334, 201901D211538; Shanxi University of Chinese Medicine 2018TD-012. Background and Aims:: Machine learning (ML) models can be utilized as a computer-aided detector of accelerated brain aging. We aimed to improve diagnostics of the early cognitive retardation by applying ML approach to psychophysiological and cognitive tests as predictors of age.

Methods:: We used free datasets that describe neurofunctional performance during healthy aging. POBA dataset consists of 231 cases of MRI and psychophysiological examination (reaction time, wrist dynamometry) of people aged 4–83 years. SSCT dataset has tests results (cognitive flexibility, inhibition, updating, and information speed processing) of 103 healthy volunteers in the age range 15-75 years. For the analysis we used ML.

Results:: Reaction time and variance estimates follow a U-shape function that approximates the known inverted U-function of the white matter volume with the optimal values in the early middle-age adulthood (aged 35 years), with a period of stability and accelerated decline only after the late middle age (aged 55-60 years). The shape of the age-related variance of cognitive tests results is close to the straight line. This is similar to the linear trend of the decrease of the gray matter volume.

Conclusions:: Cognitive age can be forecasted from a set of cognitive tests and compared with the actual age. In case of a big difference between the predicted and the actual value, the examinee is susceptible to accelerated brain aging. The performance of ML algorithms identifying subjects’ age groups is better with the cognitive rather than psychophysiological tests as predictors (96.5% versus 94% balanced accuracy; 95% versus 97% sensitivity; 98% versus 86% specificity).
Background and Aims:: The Alzheimer’s Disease Knowledge Scale (ADKS) was developed by Carpenter et al. in 2009 to assess knowledge about Alzheimer’s disease (AD) among general population, caregivers and health professionals. It is composed of 30 items to assess: risk factors, assessment, symptoms, course, life impact, caregiving, and treatment. We translated the Alzheimer’s Disease Knowledge Scale (ADKS) in Arabic to study knowledge about AD in Moroccan population taking into account demographic variables: gender, age, level of education and profession.

Methods:: The sample was consisted of 105 participants (women: 60%), mean age: 41.04 years, (SD:13.30), mean number of years of education (11.42: SD: 2.98).

Results:: The mean total score for the Arabic version of ADKS was 16.59 (SD ± 3.28); it dropped to 14.12 (SD ± 3.05) when excluding health professionals. Individuals with more than 12 years of education and those aged more than 50 years performed significantly well in the ADSK. The best responses were for the following items: course: 64.61%, risk factors: 59.58%, treatment: 61.13% and life impact: 54.03%.

Conclusions:: The use of the Moroccan version of the ADSK allowed us to assess the knowledge of AD among health professionals and general population and to identify the gaps. This allow us to set up appropriate training for professionals and conduct relevant information campaign for the population.
EVALUATION OF THE NEUROPSYCHOLOGICAL PROFILE OF THE ELDERLY POPULATION IN RUSE REGION, BULGARIA

Neli Petrova
Kaneff University Hospital, Department Of General And Vascular Neurology, Ruse, Bulgaria

Background and Aims:: The worldwide population is ageing and the proportion of elderly aged 65 and over is expected to dramatically rise in all the world. In Bulgaria patients with dementia are about 100 000 and their number is progressively increasing. The aim of the present study was to evaluate the neuropsychological and functional profile of patients with cognitive impairment and to compare it with healthy controls.

Methods:: 560 patients with cognitive impairment were prospectively evaluated with a comprehensive neuropsychological battery at Baseline, 6-th, 12-th, 24-th and 36-th month. Patients were recruited from Center for Clinical Neuropsychology and Dementology, Ruse, Bulgaria. A wide range of demographic, clinical and radiological (CT scan of brain) variables were examined, using a matched control group of 75 normal subjects (NCs), as a reference.

Results:: Our results showed significantly poorer performance on MMSE, memory, attention/executive functions and processing speed in patients with cognitive decline in comparison with controls (Fig.1). Significant changes were observed in measures of attention/executive functions, processing speed, short-term and episodic memory and language at follow-up investigations (Fig.2).
Conclusions: Executive functioning deficit appears to have a predictive power for cognitive impairment progression. Among all neuropsychological measures, only Isaac’s Set Test (IST) at 3-rd year follow-up showed significant decline reaching the baseline level impairments in comparison with the results at 12-th month. The executive functioning deficit appears to be the most affected cognitive domain after 3 years of follow-up.
VERTIGO AS UNSPECIFIC DEBUT OF CREUTZFELDT-JAKOB DISEASE: CASE SERIES

Mariam Afkir Ortega, Carmen De Rojas Leal, Lina Carazo Barrios, Virginia Delgado Gil, Omar Hamad-Cueto, Carlos De La Cruz

1Hospital Universitario Virgen de la Victoria, Neurology, Málaga, Spain, 2University Hospital Virgen de la Victoria, Neurology, Málaga, Spain, 3HOSPITAL VIRGEN DE LA VICTORIA, Neurología, Málaga, Spain, 4HOSPITAL CLINICO UNIVERSITARIO VIRGEN VICTORIA, Neurología, MÁLAGA, Spain

Background and Aims:: Creutzfeldt-Jakob disease (CJD) is a rare neurodegenerative disorder, rapidly progressive and universally fatal, caused by misfolded infectious proteins, called prions. The symptoms of CJD are progressive dementia, myoclonus, depression, psychosis, ataxia, etc. However, it is not clearly reported in the literature what symptom predominates in the debut of the disease.

Methods:: Cases series of six patients diagnosed with CJD, with dizziness as initial symptom.

Results:: Between September 2018 and July 2020, 6 patients (5 women, mean age 58.5) were diagnosed with CJD in our hospital. All patients consulted in the emergency department for dizziness. All of them were treated previously to the diagnosis with anti-vertigo medications, prescribed by their family doctors or by otorhinolaryngologists. On initial physical examination, all patients presented ataxia. Other common symptoms were cognitive alterations (6/6 patients) and myoclonus (4/6 patients). Time to death after diagnosis was between 2 and 5 months. In all patients, 14.3.3 protein resulted positive in cerebrospinal fluid, EEG showed bi-triphasic waves in anterior areas, MRI-brain showed increased signal at b1000 diffusion and SPEC-TC showed hypocaptation in predominantly anterior cortical areas and basal ganglia. Definitive diagnosis of CJD was not possible in any of the six patients, because of rejection of their families of performing autopsies.

Conclusions:: These cases highlight that a very unspecific but common symptom of debut of CJD is dizziness, being the initial and predominant symptom in our cases series. Neurologist should be aware that the debut of CJD can be as unspecific as dizziness, and can be confused with a peripheral vertigo.
ITALIAN CASE REPORT WITH A DOUBLE MUTATION IN PSEN1 (K311R AND E318G)

Annibale Antonioni¹, Raffaela Latino², Filomena Lo Vecchio³, Antonio Greco³, Maurizio Leone², Paola Bisceglia³
¹S. Anna University Hospital, Unit Of Clinical Neurology, Department Of Neuroscience And Rehabilitation, Cona (Ferrara), Italy, ²Fondazione IRCCS Casa Sollievo della Sofferenza, Complex Structure Of Neurology, Department Of Medical Sciences, San Giovanni Rotondo, Italy, ³Fondazione IRCCS Casa Sollievo della Sofferenza, Research Laboratory, Complex Structure Of Geriatrics,, San Giovanni Rotondo, Italy

Background and Aims:: Alzheimer’s disease (AD) is a progressive and irreversible neurodegenerative disorder that represents the most common dementia worldwide. It’s characterized by deterioration of cognitive skills and of ability to carry out normal daily activities. Most cases of AD are sporadic, but various genetic mutations are known in the literature, which are sometimes associated with clinical, instrumental and laboratory phenotypes not specific of AD. Mutations in PSEN1 are the most common cause of genetic AD. Over 300 different PSEN1 mutations have been identified until now; the majority of these variants are missense mutations, which cause amino acid substitutions. Here we described a double mutation in PSEN1, one of which, never reported in a patient of Italian origin. The two missense variants could modify the role of the protein.

Methods:: Genomic DNA was purified from fresh blood samples by the Salting-out method and a PCR products were sequenced in both directions using BigDye terminator v1.1 chemistry. Human β Amyloid (1-42) ELISA Kit Wako was used for the quantitative determination Aβ (1-42) in CFS sample.

Results:: Here we described a 67-year-old Italian man with Mild Cognitive Impairment (MMSE 24/30) and behavioral alteration, with a double mutation in PSEN 1 (K311R and E318G) but with instrumental investigations (PET, brain MRI and CSF) without evident pathological anomalies.

Conclusions:: This case deepens the role of genetics in pathophysiology of this disabling disease and offers ideas for further investigations. The patient undergoes a clinical, instrumental and laboratory follow-up to see whether he will develop AD.
PREVALENCE RATES OF EARLY ONSET ALZHEIMER’S DISEASE AND FRONTO-TEMPORAL DEMENTIA CLINICAL PHENOTYPES AMONG AGE GROUPS IN THE PROVINCE OF MODENA, ITALY

Simone Salemme¹, Giulia Vinceti¹, Giorgia Adani², Manuela Tondelli³, Chiara Galli³, Chiara Carbone³, Luigi Fiondella¹, Tommaso Filippini¹, Marco Vinceti¹, Chiara Annalisa², Giovanna Zamboni¹
¹University of Modena and Reggio Emilia, Dipartimento Di Scienze Biomediche, Metaboliche E Neuroscienze, Modena, Italy, ²Azienda Ospedaliera Universitaria di Modena, Neurologia, Modena, Italy, ³AUSL di Modena, Cure Primarie, Modena, Italy

Background and Aims:: In a recent study conducted in the province of Modena, Italy, we reported that the most frequent EOD in persons aged 30-64 years was the amnestic variant of AD, followed by the behavioral variant of FTD. Ageing increases prevalence of AD even in patients younger than 65, however, it is not known whether different variants of AD and other causes of EOD are equally affected. Here we studied prevalence of the different clinical variants of EOD by age group.

Methods:: We identified all EOD patients seen in the dementia services of the Modena province, from 2006 to 2019. We included all patients with a diagnosis of dementia with symptom onset before age 65 alive on census date, stratified them according to their age group and computed crude and sex-adjusted prevalence rates.

Results:: Prevalence of all AD showed an exponential growth ranging from 1.8/100,000 in the 40-44 age group to 141.4/100,000 in the 59-64 group. Among AD variants, prevalence of the amnestic variant was the most influenced by the age, while prevalence of PCA and lvPPA showed an almost flat growth curve. Prevalence of all FTD increased linearly from 1.8/100,000 in the 40-44 group to 86.6/100,000 in the 59-64 group, with such increase being all driven by the bvFTD.

Conclusions:: In patients younger than 65, prevalence rates of amnestic AD and bvFTD increase with ageing, while other clinical variants do not seem to show that pattern. These results contribute to a better understanding of the different clinical variants of EOD and their risk factors.
"CREUTZFELDT-JACOB DISEASE OR OTHER RAPIDLY PROGRESSIVE DEMENTIA? DIAGNOSTIC AND PROGNOSTIC VALUE OF EEG, BRAIN MRI AND CSF FEATURES"

Alessandro Castelli, Fabio Placidi, Chiara Giuseppina Bonomi, Claudio Liguori, Andrea Pagano, Luisa Mari, Natalia Manfredi, Nicola Mercuri, Francesca Izzi

1University of Rome "Tor Vergata", Epilepsy Center - Department Of Systems Medicine, Rome, Italy, 2University of Rome "Tor Vergata", Neurology Clinic - Department Of Systems Medicine, Rome, Italy

Background and Aims:: The ante-mortem diagnosis of Creutzfeldt-Jacob disease (CJD) is challenging because of resemblance with other rapidly progressive dementia (RPD). Our study aimed to evaluate diagnostic and prognostic value of EEG, brain MRI and cerebrospinal fluid (CSF) features, currently representing CJD diagnostic criteria.

Methods:: a retrospective study on RPD patients admitted at the Neurology Clinic of the University of Rome "Tor Vergata" between 2015-2020. CDC's 2018 Diagnostic Criteria for CJD were applied.

Results:: 13 probable CJD patients and 18 non-CJD RPD patients were included. Periodic sharp wave complexes (PSWCs) were present in 7/13 CJD patients and in 4/18 non-CJD RPD (p=.069). CJD MRI typical patterns were detected in 10/12 CJD and in 2/17 non-CJD RPD (p<.001). 14.3.3 protein was positive in 11/13 CJD and in 1/17 non-CJD RPD (p<.001). A sub-analysis of the CJD group according to EEG features revealed that PSWCs were present in 7/13 patients, non-periodic discharges in 4/13 and focal slowing in 2/13. Compared to patients without PSWC, the average survival time (2.5±0.7 vs 16.6±9.9 months; p=.003) and time to admission (1.4±0.5 vs 8.0±2.5 months; p=.003) were significantly lower in patients with PSWC. As for MRI, CJD patients with PSWC did not show signs of damage on FLAIR images (p=.004).

Conclusions:: In our cohort, EEG showed the weakest specificity among all CJD criteria, but could hold a potential prognostic value since PSWCs were significantly associated with a faster evolution and a reduced survival time. PSWCs might reflect a shorter course of disease, as witnessed by lack of FLAIR signal changes due to astrocytic reactive gliosis.
CORRELATIONS BETWEEN SYSTEMIC COMORBIDITY BURDEN AND CSF BIOMARKERS OF NEURODEGENERATION IN AGING INDIVIDUALS

Henri Zenuni\(^1\), Tommaso Schirinzi\(^2\), Giulia Maria Sancesario\(^3\), Nicola Mercuri\(^2\), Sergio Bernardini\(^2\), Piergiorgio Grillo\(^2\)

\(^1\)Università Tor Vergata, Neurology, Rome, Italy, \(^2\)University of Roma Tor Vergata, Department Of Systems Medicine, Rome, Italy, \(^3\)IRCCS Fondazione Santa Lucia, Irccs Fondazione Santa Lucia, Rome, Italy, Rome, Italy, \(^4\)University of Roma Tor Vergata, Rome, Italy, Department Of Experimental Medicine, Rome, Italy

**Background and Aims::** With the worldwide increase of life expectancy, the number of people living with dementia is going to rise dramatically in next years. Since systemic comorbidity is often associated to dementia, increasing the risk, it may represent an ideal target for prevention. In this study we assessed the correlations between systemic comorbidity and CSF biomarkers of neurodegeneration in aging individuals without overt neurological impairment, in order to understand the mechanisms of neuronal vulnerability and offer useful cues for potential neuroprotective interventions.

**Methods::** CSF neurodegeneration-related biomarkers, namely amyloid-β42 (Aβ42), amyloid-β40, total-tau, 181-phosphorylated-tau (p-tau), the Aβ42/p-tau ratio, neurogranin and lactate, of 55 cognitively intact subjects were correlated with the Charlson Comorbidity Index (CCI). The presence of brain lesions was also quantified by the age-related white matter changes (ARWMC) score.

**Results::** In the whole population, CCI had a raw direct association with A42/p-tau and p-tau, and a stronger, age-independent direct correlation with lactate. No correlations resulted with ARWMC score.

**Conclusions::** In normal subjects, systemic comorbidity might reflect at CNS level, affecting the CSF biomarkers profile. Specifically, we observed that concurrent medical conditions can increase oxidative stress (marked by lactate) and, together with aging, contribute to develop an Alzheimer’s disease-like biochemical profile. Although further confirmatory studies on larger samples are now necessary to confirm these preliminary findings, we provided support to neuroprotective strategies based on prevention and cure of systemic diseases.
HYPERCONNECTIVITY IN DEMENTIA IS EARLY AND FOCAL AND VANISHES WITH DISEASE PROGRESSION

Clinical And Experimental Sciences, University Of Brescia, Brescia, Italy, ⁴University G. d’Annunzio of Chieti-Pescara, Department Of Neuroscience, Imaging And Clinical Sciences, Chieti, Italy, ⁵University of Genova, Dipartimento Di Neuroscienze (dinogmi), Genova, Italy, ⁶Non Invasive Brain Stimulation Unit/Department of Behavioral and Clinical Neurology, Santa Lucia Foundation IRCCS, Rome, Italy; Stroke Unit, Tor Vergata Policlinic, Department Of Neurosciences, Roma, Italy, ⁷University of Padua, Department Of Neurosciences., Padova, Italy, ⁸Sapienza University of Rome, Department Of Physiology And Pharmacology “v. Erspamer”, Roma, Italy, ⁹University of Brescia, Neurology Unit, Department Of Clinical And Experimental Sciences, Brescia, Italy, ¹⁰University of Brescia, Dept. Clinical And Experimental Sciences, Brescia, Italy

Background and Aims:: In neurodegenerative diseases, including Alzheimer’s disease (AD) and frontotemporal dementia (FTD), functional brain network connectivity is altered, but counter-intuitively is enhanced and defined as hyperconnectivity. What is missing in the literature are data on the evolution of functional connectivity in neurodegeneration; when hyperconnectivity appears along the course of the diseases, and if and how connectivity changes with disease progression. We investigated in a longitudinal multicenter cohort study functional cortical connectivity changes along the course of FTD and AD from the prodromal stage of the diseases.

Methods:: A longitudinal evaluation of EEG activity was recorded in 18 FTD and 18 AD patients at the prodromal stage of dementia, at dementia onset, and 3 years after dementia onset. Twenty healthy controls (HC) underwent EEG recordings at the same time interval as the patients. Mutual information (MI) analysis measured the strength of functional network connectivity.

Results:: FTD and AD patients showed greater MI at the prodromal stage of dementia (FTD vs. HC P=2×10⁻⁸; AD vs. HC P=4×10⁻³). Local connectivity was higher in left and right frontal areas of FTD (P=7×10⁻⁵ and 0.03) and in left and right posterior areas in AD (P=3×10⁻⁵ and 5×10⁻⁵) versus HC.

Conclusions:: We showed cortical hyperconnectivity at the prodromal stage of dementia in areas involved in the specific pathological process of FTD (frontal regions) and AD (posterior regions). Hyperconnectivity disappeared during follow-up, thus suggesting that it is an early electrophysiological feature of dementia, potentially useful to identify prodromal FTD and AD.
Microstructural Damage of White Matter in the Frontal Aslant Tract in Amnestic Mild Cognitive Impairment Subtypes

Giulia Bechi Gabrielli1, Laura Serra1, Carlotta Di Domenico1, Andrea Bassi1, Carlo Caltagirone2, Mara Cercignani1,3, Camillo Marra4, Marco Bozzali3,5
1IRCCS Santa Lucia Foundation, Neuroimaging Laboratory, Rome, Italy, 2IRCCS Santa Lucia Foundation, Department Of Clinical And Behavioral Neurology, Rome, Italy, 3University of Sussex, Department Of Neuroscience, Brighton & Sussex Medical School, Brighton, United Kingdom, 4Università Cattolica del Sacro Cuore, Department Of Neuroscience, Rome, Italy, 5University of Torino, Department Of Neuroscience “rita Levi Montalcini”, Turin, Italy

Background and Aims:: Frontal Aslant Tract (FAT) is a bundle connecting Broca’s area to Supplementary Motor Area (SMA) and pre-SMA in both hemispheres, which has been traditionally implicated in speech functions (Catani et al., 2013). A previous study (Serra et al., 2017) showed microstructural damage of FAT in patients with Alzheimer disease (AD) at the stage of dementia. We assessed here microstructural integrity/damage of FAT in patients with amnestic Mild Cognitive Impairment (aMCI) and its potential role in cognitive dysfunctions.

Methods:: Fifty patients with aMCI (25 single-domain [aMCI-SD]; 25 multiple-domain [aMCI-MD]) and 25 healthy subjects (HS) underwent cognitive evaluation and MR scanning at 3T with collection of diffusion imaging data used for probabilistic tractography. FAT was successfully reconstructed in all subjects bilaterally. Microstructural FAT integrity/damage was assessed using fractional anisotropy (FA) maps. Group-comparisons were performed using voxel-wise approach in SPM-8. Mean FA values were used to investigate correlations with patients’ cognitive performance.

Results:: Voxel-wise analysis revealed a bilateral pattern of reduced FA in the FAT of aMCI-MD patients compared to both, aMCI-SD patients and HS. Conversely, aMCI-SD compared to HS did not show any significant difference. Positive associations were found between mean FA from the left FAT and scores at verbal fluency tests in aMCI-SD, and scores at verbal episodic memory tests in aMCI-MD.

Conclusions:: These findings indicate that FAT is bilaterally damaged in AD since the early clinical stage of MCI-MD, thus contributing to the progressive accumulation of cognitive disabilities. Correlations with patients’ cognitive performance suggests a functional role for FAT that goes beyond language abilities.
Background and Aims:: Sundowning, or sundown syndrome, is the emergence or worsening of neuropsychiatric symptoms in late afternoon or early evening in people with dementia. Despite this condition is well known among caregivers and healthcare providers, it has triggered limited scientific interest so far. We aimed to evaluate the prevalence and clinical manifestations of sundowning among patients with dementia and to investigate the clinical and environmental determinants associated with its occurrence.

Methods:: A cross-sectional study of patients with dementia was conducted at the Department of Human Neurosciences of the Sapienza University of Rome between June 2019 and April 2020. The presence of sundowning was investigated through a specifically designed questionnaire administered to caregivers. We compared the sociodemographic and clinical features of sundowners vs. non-sundowners. A logistic regression model was performed to identify the variables associated with sundowning.
Results: Among 152 recruited patients with dementia, 34 exhibited sundowning. The most common manifestations of the sundown syndrome were irritability (15%), agitation (15%) and anxiety (14%). At the univariate analyses, sundowners were significantly older, had more frequent nocturnal awakenings, hearing loss, more severe cognitive, functional and neuropsychiatric impairments and more frequently used medications with an anticholinergic profile and antipsychotics. None of these factors was found to be significantly associated with sundowning at the logistic regression.
CLINICAL MANIFESTATIONS OF SUNDOWNING

- Agitation: 15%
- Irritability: 15%
- Anxiety: 14%
- Delusions: 12%
- Hallucinations: 9%
- Aberrant Motor Behavior: 9%
- Depression: 7%
- Apathy: 7%
- Disinhibition: 4%
- Eating Disorders: 3%
- Other: 3%
- Elation: 2%
Conclusions: Sundowning represents a common neuropsychiatric manifestation among patients with dementia and it appears as a multiply determined condition. Its presence should always be evaluated in the routine practice and a multidimensional approach should be adopted to identify its predictors.

FLUENCY TYPE INDEX: A NEUROPSYCHOLOGICAL MARKER TO PREDICT AMNESTIC MILD COGNITIVE IMPAIRMENT PROGRESSION TO ALZHEIMER'S DISEASE.

Claudia Gendarini¹,², Alessandro Cocuzza¹,², Alessandra Romandini¹,², Silvio Mauri¹,², Matteo Mercurio³,⁴, Andrea Arighi³,⁴, Elio Scarpini³,⁴, Giacomo Pietro Comi²,⁵, Maria Cristina Saetti¹,² ¹Fondazione Ca' Granda, IRCCS Ospedale Maggiore Policlinico, Neurology Unit, Milan, Italy, ²Dino Ferrari Centre, Neuroscience Section, Department Of Pathophysiology And Transplantation, University Of Milan, Milan, Italy, ³Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Neurodegenerative Disease Unit, Milan, Italy, ⁴Dino Ferrari Centre, Neuroscience Section, Department Of Biomedical, Surgical And Dental Sciences, University Of Milan, Milan, Italy, ⁵Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Neuromuscular And Rare Disease Unit, Milan, Italy

Background and Aims:: Category fluency (CF), mainly dependent on linguistic functions, reveals a temporal dysfunction, while letter fluency (LF), mainly dependent on attentive-executive functions, reveals a prefrontal dysfunction. Fluency Type Index (FTI = adjustedCF – adjustedLF / adjustedCF + adjustedLF) quantifies relative proficiency of each subject on CF and LF. A positive value (FTI+) suggests an attentive-executive deficit and a negative value (FTI-) a semantic deficit, that has been shown to characterize AD.

\[
FTI = \frac{aCF - aLF}{aCF + aLF}
\]

\[
aCF = \text{adjusted CF}
\]

\[
aLF = \text{adjusted LF}
\]

The study aims to investigate FTI’s ability to predict amnestic Mild Cognitive Impairment (MCI) evolution in Alzheimer Disease (AD) and its correlation with a CSF parameter (Tau/Aβ) in aMCI patients.

Methods:: A total of 165 aMCI patients have been divided considering evolution (aMCI-E, n =41) or non-evolution (aMCI-NE, n =124) to AD within 1 year. FTI values and the prevalence of FTI- and FTI+ in each group have been compared. Pearson correlation coefficient between FTI and Tau/Aβ has been calculated and frequency of pathological (< -0.22 and > +0.5) and normal FTI in patients with pathological (> 0.52) and non-pathological Tau/Aβ has been compared with \(\chi^2\) test.

Results:: FTI values are significantly different in the 2 groups (t =2.28, p<.01). In aMCI-E group prevalence of FTI- is higher than FTI+, while no difference emerges in aMCI-NE (\(\chi^2 =5.36\), df =1, p <.05). FTI and Tau/Aβ result negative correlated (r =-0.18, p =0.05). Frequency of pathological/non-pathological FTI and pathological/non-pathological CSF result correlated (\(\chi^2 =3.45\), df =1, p<0.05).

Conclusions:: FTI is a neuropsychological marker that, similarly to T/Aβ, predicts aMCI evolution to AD.
ALZHEIMER’S DISEASE MRI PATTERNS: COGNITIVE, STRUCTURAL AND CEREBROSPINAL FLUID CORRELATES.

Background and Aims:: While hippocampal atrophy represents the prototypical MRI finding in Alzheimer’s Disease (AD), other MRI atrophy patterns are commonly found in this population. The differences in clinical and imaging longitudinal evolution associated with the diverse MRI atrophy patterns, however, are poorly understood. Here, we decided to assess the clinical and radiological atrophy progression in AD subjects stratified according to baseline MRI atrophy patterns.

Methods:: 234 amyloid-positive participants with MCI or dementia due to AD from the Alzheimer’s Disease Neuroimaging Initiative (ADNI) with baseline and at least 2-year follow-up MRI scans were included in the study. Subjects were divided in four groups based on the observed MRI-patterns (hippocampal-sparing [HpSpMRI], limbic-predominant [LpMRI], typical-AD [tADMRI], minimal-atrophy [MinAtrMRI]) based on cortical total volume (CTV) and hippocampal volume (HV) values, according to published criteria (Risacher et al., 2017). MRI metrics, clinical outcomes and CSF biomarkers were extracted from the database and compared between the groups at baseline and at 2-year follow-up.

Results:: Compared to other groups, in MCI participants tADMRI and LpMRI showed faster clinical decline than HpSpMRI or MinAtrMRI. At follow-up, 55% of LpMRI patients developed CTV loss and 49 % of MinAtrMRI developed CTV or HV loss. MinAtrMRI patients with a stable MRI pattern had lower baseline total-Tau and phospho-Tau compared to tADMRI and LpMRI.

Conclusions:: In AD, MRI patterns are associated with different clinical and imaging trajectories, suggesting the usefulness of quantitative baseline MRI regional volume evaluation as a possible prognostic marker.
PREVALENCE STUDY OF DEMENTIA WITH LEWY BODIES IN A PARKINSON DISEASE REFERENCE CENTER: CLINICAL AND LABORATORY ANALYSIS OF A RIO DE JANEIRO/ BRAZIL COHORT

Vanderson Carvalho Neri¹, Gabriela Pessanha², Ana Carolina Ribeiro², Carolina Rosas², Thalita Rocha², Lais Branco², Danielli Aparecida²
¹Hospital Federal da Lagoa, Neurology, Rio de Janeiro, Brazil, ²Faculdade de Medicina de Campos, Neurology, Campos dos Goytacazes, Brazil

Background and Aims:: Aims: To apply the diagnostic criteria for Dementia with Lewy Bodies (DLB) in a cohort of patients with parkinsonian syndromes in Rio de Janeiro; to estimate the prevalence of this syndrome; to analyze the clinical profile, pharmacological treatment and neuroimaging of this group of patients.

Methods:: Application of the diagnostic criteria for DLB (McKeith, 1996) in patients with parkinsonism and cognitive impairment (after neuropsychological assessment). Selection of patients who met criteria for DLB, clinical and laboratory evaluation of this group.

Results:: 750 patients with parkinsonian syndromes, 22 met the criteria for diagnosing DLB (2.9% of total). Average age 78.36 (SD ± 7.9); 54.5% were men. Mean time neurological symptoms 1.77 years (± SD 0.81). MMSE: 11.3 (SD ± 8.86), MOCA: 9.43 (SD ± 7.2). Domains applied for diagnosis are shown in Table 1. Most prevalent symptoms: bradykinesia (90.9%) and bilateral muscle stiffness (90.9%) [Table 2]. After clinical, laboratory and imaging evaluation, it was concluded that secondary causes were excluded. 100% of cases presented impairment in more than one domain of cognition, impacting their daily activities. Treatment: 18 (81.8%) used levodopa/benseraside, 4 (18%) pramipexole, 13 (59%) quetiapine, 8 (36.5%). MRI morphometric evaluation showed predominance of diffuse cerebral atrophy 21 (95.5%), dilated cerebral ventricles 15 (68.2%), and preservation of temporal lobe structures 17 (77.3%) [Table 3].

A CHALLENGING DIAGNOSIS OF NEURODEGENERATIVE DEMENTIA: PSYCHIATRIC ONSET OF FRONTOTEMPORAL LOBAR DEGENERATION

Giacomo Tondo¹, Davide Aprile¹, Barbara Sarasso¹, Paola Serra¹, Fabiana Tesser¹, Cristoforo Comi²,³
¹Neurology Unit, S. Andrea Hospital, Department Of Translational Medicine, University Of Piemonte Orientale, Vercelli, Italy, ²University of Piemonte Orientale, Interdisciplinary Research Center Of Autoimmune Diseases (ircad), Novara, Italy, ³Neurology Unit, S. Andrea Hospital, University of Piemonte Orientale, Department Of Translational Medicine, Vercelli, Italy

Background and Aims:: Frontotemporal lobar degeneration (FTLD) is a heterogeneous syndrome characterized by degeneration of the frontotemporal lobes associated with language, executive, and behavioral disturbances. Psychiatric symptoms have been reported over the disease course. When presenting at the onset, diagnosis can be highly challenging. We report three unusual cases of FTLD with psychiatric onset.

Methods:: Case1. A 69-year-old man presented with a late-onset major depressive disorder, lasting for two years slightly improved by antidepressant therapy; when developing progressive effortful and agrammatic speech, he underwent brain MRI showing left posterior frontal and insular atrophy. Case2. A 49-year-old woman with a one-year history of religious delusion complained of attentive and memory disturbances associated with socially inappropriate behaviors; brain MRI showed mild atrophy in the bilateral frontotemporal regions. Case3. A 63-year-old woman without a history of eating disorders had significant weight loss, associated with progressive language deterioration; brain FDG-PET revealed severe hypometabolism in left frontotemporal regions. All cases underwent CSF analysis or amyloid-PET.

Results:: Case1 received a diagnosis of progressive non-fluent aphasia, manifesting at the onset with depression. Case2 was diagnosed as a behavioral-variant of frontotemporal dementia. Case3 received a diagnosis of semantic dementia, with anorexia nervosa at the onset.

Conclusions:: Clinical differentiation of neurodegenerative dementia from a primary psychiatric disorder may be challenging, especially in FTLD with psychiatric onset. Neurodegenerative disorders should be suspected when a late-onset psychiatric disorder is associated with inadequate treatment response and cognitive deficits. Accurate clinical evaluation, CSF analysis, and neuroimaging are the main weapons for a physician.
CORTICAL BASAL SYNDROME IN A PATIENT WITH A CLINICAL AND PATHOLOGICAL OVERLAP BETWEEN TAUOPATHY AND SYNUCLEINOPATHY. EVIDENCE FROM THE TREDEM REGISTRY

Maurizio Gallucci1, Anna Paola Mazzarolo2, Vittorio Fiore3, Matteo Bendini4, Gianluigi Zanusso5, Laura Bonanni6

1Local Health Authority n. 2 Marca Trevigiana, 31100 Treviso, Italy, Cognitive Impairment Center, Treviso, Italy, 2Cognitive Impairment Center, Local Health Authority n. 2 Marca Trevigiana, 31100 Treviso, Italy, Cognitive Impairment Center, Treviso, Italy, 3Local Health Authority n. 2 Marca Trevigiana, 31100 Treviso, Italy, Nuclear Medicine, Treviso, Italy, 4Local Health Authority n. 2 Marca Trevigiana, 31100 Treviso, Italy, Neuroradiology Unit, Treviso, Italy, 5University of Verona, Verona, Italy, Department Of Neuroscience, Biomedicine And Movement, Verona, Italy, 6University G. d''Annunzio di Chieti-Pescara, Neuroscience, Imaging And Clinical Sciences, Pescara, Italy

Background and Aims:: An 82-year-old male right-handed retired teacher reported in 2019, that three years earlier he developed difficulties in moving his left arm and foot, tremor in left-hand and gestures of the left upper limb that appeared to be independent of the patient's will, characteristics of alien limb phenomenon. We present a patient with cortical basal syndrome (CBS) and amnestic MCI who showed the presence of α-synuclein aggregates in the CSF and in the olfactory mucosa samples.

Methods:: A clinical, neuropsychological, imaging and biomarker evaluation, including tau and amyloid proteins levels in the CSF and RT-QuIC assay for α-synuclein both in the CSF and olfactory mucosa, was conducted

Results:: At neurological examination the patient, on the left side, presented with resting tremor, mild extrapiramidal hypertonus, mild bradykinesia and severe apraxia on the left upper limb. Brain MRI showed a knife-edge posterior parietal cortical atrophy prevalent on the right hemisphere. 18F-FDG PET imaging showed hypometabolism of the right lateral parietal, temporal cortex, precuneus and posterior cingulate cortex. The DaTscan showed a mild thinning of the right putamen. Neuropsychological tests showed memory and visual-perceptual deficits. CSF tau and amyloid measurements did not show clearly pathological values (Tau protein 395 pg/ml; ratio Abeta42/P-Tau181: 6.8) while RT-QuIC for α-synuclein in CSF and olfactory mucosa samples were positive.

Conclusions:: Although in our patient the clinical diagnosis was of probable CBS, usually expression of tauopathies, unexpectedly RT-QuIC detected α-synuclein aggregates showing a probable α-synuclein pathology. RT-QuIC provides a better definition of underlying pathologies in neurodegenerative disorders with prognostic and potentially therapeutic implications.
COMPARISON OF PLASMATIC INTERLEUKINS PATTERNS AMONG COGNITIVELY UNIMPAIRED SUBJECTS, PATIENTS AFFECTED BY MILD COGNITIVE IMPAIRMENT AND SUBJECTS WITH ALZHEIMER’S DISEASE DEMENTIA

Alessandro Galgani¹, Nicole Campese¹, Annalisa Logerfo¹, Lucia Petrozzi¹, Filippo Baldacci¹, Gloria Tognoni¹, Roberto Ceravolo¹, Francesco Lombardo², Nicola Pavese³, Francesco Fornai⁴, Aldo Paolicchi⁴, Andrea Vergallo⁶, Harald Hampel⁶, Gabriele Siciliano¹, Filippo Giorgi⁷⁸

¹University of Pisa, Neurology Unit, Pisa, Italy, ²National Research Council/ G. Monasterio Foundation, Multimodal Imaging And Neuroradiology Unit, Pisa, Italy, ³Newcastle University, Institute Of Neuroscience, Newcastle upon Tyne, United Kingdom, ⁴University of Pisa, Department Of Translational Research And Of New Surgical And Medical Technologies, Pisa, Italy, ⁵Neuromed, Neurobiology Of Movement Disorders, Pozzilli, Italy, ⁶Sorbonne University/Pitié-Salpêtrière Hospital, Alzheimer Precision Medicine (apm), Paris, France

Background and Aims:: We investigated a panel of plasma interleukins (ILs) levels hypothesized to play a role in aging and AD pathophysiology, in a pooled cohort of clinically characterized (according to NIA-AA core clinical criteria) cognitively unimpaired (HC), Mild Cognitive Impairment (MCI), and Alzheimer’s Disease Dementia (ADD) individuals.

Methods:: In 137 subjects (43HC, 63MCI and 31ADD), the plasma levels of IL1-β, IL-6, IL-10, IL-12, IL-6 receptor (IL-6R), TNF-a and TGF-b were measured by ELISA kits on samples collected at 8.00 AM and quickly frozen. Principal component analysis (PCA) was performed as the initial exploratory step; parametric statistic was assessed to evaluate group differences and association between IL and biological factors (age, sex, APOEe4). An exploratory clustering approach was carried out to investigate distinct biological profiles.

Results:: In the total sample, IL12 was positively associated with age. We found a positive association between IL1β and IL12 and female sex and between IL12 and APOEe4 allele. MCI individuals, but not ADD patients, had higher concentrations of IL10 than HC. K-means clustering (k=3) showed a cluster predominately characterized by ADD over the other two populations and lower IL12 and IL10 than the other two clusters. A component, mainly characterized by the IL-6R was negatively associated with MMSE.

Conclusions:: Our preliminary results indicate a potential effect of critical biological factors such as aging, sex, and APOEe4 allele on some ILs hypothesized to be critical orchestrators of neuroinflammation. Speculative hypotheses based on translational data, are drawn upon the clusters found. Our results, support the investigation of IL-based profiles of neuroinflammation in AD.

This work is supported by the Italian Ministry of Health -Ministero della Salute, Ricerca Finalizzata #PE-2013-02359574 (P.I.: FSG).
LEXICAL-SEMANTIC SYSTEM DISRUPTION CORRELATION WITH ALZHEIMER’S PATHOPHYSIOLOGICAL PROCESSES

Emmanuele Maria Costantini¹, Guido Maria Giuffré¹, Salvatore Citro¹, Davide Quaranta¹, Antonio Daniele¹, Paolo Calabresi¹,², Camillo Marra¹

¹Catholic University of the Sacred Heart, A. Gemelli Hospital Foundation IRCCS, Neuroscience Department, Rome, Italy, ²Catholic University of the Sacred Heart, A. Gemelli Hospital Foundation IRCCS, Neurology, Rome, Italy

Background and Aims:: Semantic cognition is early affected in Alzheimer’s disease (AD), but its relationship with AD neuropathological hallmarks burden (i.e. amyloidosis, A; tauopathy, T; neurodegeneration, N) is controversial. We addressed this issue investigating the relationship between non-traditional semantic neurolinguistic metrics and AD pathology.

Methods:: Median typicality (TYP) and frequency of use (FU) of words produced in a semantic verbal fluency (SVF) task were assessed in a sample of 49 (AD n=29, non-AD, NAD, n=20) consecutive non-aphasic neurodegenerative patients who consented to CSF ATN biomarker assessment for categorization as per ATN system (NIA-AA 2018 criteria). The exploratory outcomes were: 1) differences in median TYP and/or FU between AD vs NAD groups; 2) correlation between median TYP and FU with CSF ATN biomarkers in AD vs NAD.

Results:: Median TYP and FU were found significantly higher in AD than in the NAD group only when A⁺T⁺ patients (n=22) were considered, while grouping them with the highly variable performances of A⁺T⁻ patients (n=7) diluted this difference to non-significance. No significant correlation with CSF biomarkers were detectable in the NAD group; conversely, in the AD group as a whole (n=29), TYP and FU inversely correlated with ABeta1-42/1-40 ratio and positively with tTau and pTau.

Conclusions:: Semantic competencies could vary widely at the earlier AD neuropathological stages (A⁺T⁻), but they seem to get worse with advancing tauopathy (A⁺T⁺), distinguishing this AD stage from NAD conditions and, consistently, correlating with A, T and N CSF biomarkers only in AD spectrum, acting as a putative proxy for ongoing AD pathophysiology.
EEG ABNORMALITIES IN PATIENTS WITH DELIRIUM AS A PREDICTIVE BIOMARKER OF DEMENTIA WITH LEWY BODIES

Matteo De Rosa¹, Dario Calisi¹, Stefano Consoli¹, Giacomo Evangelista¹, Rino Speranza¹, Anna Digiovanni², Fedele Dono³, Mirella Russo², Claudia Carrarini², Marco Onofrj⁴, Laura Bonanni⁴
¹"G. D'Annunzio" University of Chieti-Pescara, Department Of Neuroscience, Imaging And Clinical Science, Chieti, Italy, ²University G. d’Annunzio di Chieti-Pescara, Neuroscience, Imaging And Clinical Sciences, Pescara, Italy, ³University G. d’Annunzio di Chieti-Pescara, Department Of Neuroscience, Imaging And Clinical Sciences, Chieti, Italy, ⁴University G. d’Annunzio di Chieti-Pescara, Neuroscience, Imaging And Clinical Sciences, Chieti, Italy

Background and Aims:: Delirium is an acute neurological dysfunction, characterized by altered conscious state, akin to fluctuating cognition. It is frequent in elderly patients when hospitalized and is characterized by an increased risk of developing dementia, especially Dementia with Lewy Bodies (DLB). EEG Prominent posterior slow-wave activity in the pre-alpha/theta range is a supportive biomarker for DLB diagnosis from the prodromal stage. This EEG pattern correlates with fluctuating cognition and is the electrophysiological underpinning of the so-called thalamo-cortical dysrhythmia. We aim to assess whether non-demented hospitalized patients with delirium show specific QEEG abnormalities typical of thalamo-cortical dysrhythmia.

Methods:: 24 consecutive patients admitted to Neurology Clinic of University of Chieti were administered Mini Mental State Examination (MMSE) as per clinical routine. The presence of delirium was assessed by 4AT test. All subjects underwent resting state EEG recording.

Results:: 11 (7 females) presented delirium (delirium, D) according to 4AT (9 with hypokinetic, 2 with hyperkinetic type), 13 (5 females) did not show it (controls, C). The two groups did not differ for age and gender. In all but one D (91%), we observed alterations of EEG parameters (DF lower than alpha with increased DFV (>1.2 Hz)). In C, DF and DFV were normal in 92%, (alpha DF and DFV<1.2 Hz) (DF in D vs. C p=0.002).

Conclusions:: We found strong correlation between the presence of delirium and EEG abnormalities typical of thalamocortical dysrhythmia and of DLB. Our evidence suggests a pathophysiological explanation for delirium. EEG may represent a powerful tool to detect delirium.
A VITAMIN B12 DEFICIENCY PRESENTING WITH CLINICAL, LABORATORY AND RADIOLOGICAL FEATURES OF PRION DISEASE

Edoardo Bianchini¹, Michela Sforza¹, Marco Salvetti¹, Laura Conti², Francesco Pontieri¹, Franco Giubilei¹
¹Sapienza, University of Rome. Sant'Andrea Hospital, Nesmos, Rome, Italy, ²Sapienza University of Rome, Department Of Medical Surgical Sciences And Translational Medicine, Rome, Italy

Background and Aims:: Rapidly progressive dementias (RPDs) are severe cognitive impairments occurring over weeks to months. Prion disease is one of the most common cause of RPD. We report the case of a subject with RPD due to vitamin B12 deficiency mimicking prion disease.

Methods:: A 70-year-old man presented with rapidly progressive cognitive deterioration and behavioral changes starting 6 months before. Neurological evaluation showed sensory deficit and ataxia. The patient was disoriented and displayed severe verbal fluency reduction. Brain MRI showed hyperintensities of the heads of caudate nuclei and the left insular cortex in DWI (Figure A). The EEG showed diffuse non-specific slowing. Total-body CT were negative. A positive 14-3-3 protein in the CSF was found while RT-Quic resulted negative. The hypothesis of sporadic Creutzfeldt-Jakob Disease (sCJD) was then posed. Serum analysis demonstrated macrocitic anemia with hyperhomocysteinemia and low vitamin B12.

Results:: Supplementation therapy was then initiated. Two months later, neuroimaging, laboratory testing and neurological examination were unremarkable remaining stable at 12-months follow-up (Figure B). Thus, the diagnosis of dementia secondary to vitamin B12 deficiency was made.

Conclusions:: To our knowledge, this is the first report of vitamin B12 deficiency presenting with RPD, ataxia, DWI telencephalic gray matter alterations and 14-3-3 positivity. Vitamin B12 deficiency was not reported as a typical MRI mimic of sCJD. Furthermore, studies in rodents demonstrated CSF prion protein may occur in vitamin B12 deficiency. This case demonstrates the variability of vitamin B12 deficiency manifestations and underscores the importance for screening and management even in atypical presentations, considering the reversibility of abnormalities.
THE SCOT PROJECT: A MULTI-COMPONENTIAL INTERVENTION TO REDUCE LONELINESS IN THE ELDERLY POPULATION

Giulia Funghi, Claudia Meli, Francesca Zappini, Arianna Cavagna, Costanza Papagno, Alessandra Dodich
University of Trento, Center For Mind/brain Sciences (cimec), Rovereto (TN), Italy

Background and Aims:: Social isolation and reduced involvement in cognitive activities are associated with an impact on cognitive well-being and health status in elderly adults. In particular, loneliness and social isolation represent risk factors in favouring cognitive decline and dementia. Here, we present the study design and baseline features of the Social Cognition Online Training (SCOT) project, aimed to evaluate the beneficial effects of an online intervention on social-cognitive functioning in healthy elderly subjects.

Methods:: The study include 60 cognitively healthy elderly subjects. Subjects were randomly assigned to the experimental (SCOT) or the active control group. SCOT training was focused on reducing loneliness (i.e., improving social skills, increasing social contact, addressing maladaptive social cognition) and on promoting cognitive stimulation (i.e., executive functions). Outcome measures were the Italians’ Social and Emotional Loneliness Scale (ISELS), a new developed task of complex emotion recognition (EMOTI-COM) and the Tower of London (ToL).

Results:: Preliminary analysis on the first 27 enrolled subjects showed no significant differences between the SCOT and the control group in sex ($\chi^2(1)=0.03$, $p=0.8$), age ($t(25)=0.4$, $p=0.7$) and education ($t(25)=0.2$, $p=0.8$). No differences were found between groups at baseline in the outcome measures (EMOTI-COM: $t(25)=-0.439$, $p=0.6$, ISELS ($t(25)=-0.003$, $p=0.9$, ToL Accuracy: $t(25)=-1.970$, $p=0.06$).

Conclusions:: The development of interventions to prevent and delay cognitive decline represents a priority in an ageing World. If the SCOT program will prove an effect in promoting social well-being in ageing, this will represent the first step in the introduction of new preventive programs.
A MACHINE LEARNING-BASED HOLISTIC AND AGE-DEPENDENT APPROACH FOR THE DIAGNOSIS WITHIN THE ALZHEIMER'S DISEASE SPECTRUM

Noemi Massetti¹, Alberto Granzotto¹, Manuela Bomba¹, Stefano Delli Pizzi², Alessandra Mosca¹, Reinhold Scherer³, Marco Onofrj⁴, Stefano Sensi¹
¹University “G. d’Annunzio” of Chieti-Pescara, Department Of Neuroscience, Imaging, And Clinical Sciences (dnisc), Chieti, Italy, ²Università “G. d’Annunzio” di Chieti-Pescara, Department Of Neuroscience, Imaging And Clinical Science, Chieti, Italy, ³University of Essex, School Of Computer Science And Electronic Engineering, Colchester, United Kingdom, ⁴University G. d’Annunzio di Chieti-Pescara, Neuroscience, Imaging And Clinical Sciences, Chieti, Italy

Background and Aims:: Alzheimer’s disease (AD) is a neurodegenerative condition driven by a multifactorial etiology. No disease-modifying strategies are available and almost all the AD clinical trials have failed. However, a growing body of evidence indicates that early prevention strategies may delay AD onset and progression. The development of cost-effective approaches set to identify subjects at-risk of developing AD is, thus, critical.

Methods:: In this study, we employed a machine learning (ML) based algorithm and the wealth of information offered by the Alzheimer’s Disease Neuroimaging Initiative (ADNI) database to investigate the contribution of clinically relevant factors for identifying subjects affected by Mild Cognitive Impairment (MCI), a transitional status between healthy aging and dementia.

Results:: Our ML-based algorithm did not help to predict the conversion of MCI subjects to AD. On the other hand, non-converting (ncMCI) subjects were correctly classified and predicted. Two neuropsychological tests, the FAQ and ADAS13, were the most relevant features used for the classification and prediction of younger, under 70, ncMCI subjects. Structural MRI data combined with systemic parameters and the cardiovascular status were instead the driving factors for the classification of over 70 ncMCI subjects.

Conclusions:: Our results support the notion that AD is not an organ-specific condition and results from pathological processes inside and outside the brain. In addition, the study, by exploiting the unbiased computational capability offered by artificial intelligence-based approaches, provides a tool to understand the unique complexity of “individual” diseases affecting patients, thereby helping to take full advantage of precision medicine in the diagnosis and treatment of dementia.
Background and Aims:: According to the WHO today about 422 million people worldwide have diabetes and chronic course of diabetes leads over time to decrease the cognitive functions and the development of dementia. The aim of this study was to decipher neuromorphological changes in type 2 diabetes that potentially affect cognitive impairment.

Methods:: We have performed a clinical-morphological comparison of outpatient card data, disease histories and autopsy reports of 15 cases of type 2 diabetes.

Results:: The main cyto-angio-architectonic manifestations of diabetic brain damage are diffuse alteration of the basement membranes and vascular endothelium, capillary fibrosis and hyalinosis, pericyte proliferation, congophilic angiopathy accompanied by a sharp disruption on transcapillary transport. There is a combination of acute and chronic processes, reversible and irreversible changes in nerve cells: neuronal swelling, subtotal chromatolysis, karyopyknosis and cytoplasmic homogenization, satellite disease, perikaryon enlightenment, tigrolysis, lysis of neurons with the formation of "shadow cells". In areas of chronic ischemia there are neurons or groups of neurons with morphological signs of Alzheimer's neurodegeneration (pathological neurofibrils in the form of tangles), a large number of hematoxylin spheres and single Lafora bodies. Moreover, single terminal plaques are found in the impregnation of silver by the Bielschowsky staining method.

Conclusions:: Thus, the brain morphological changes in type 2 diabetes mellitus are formation neurofibrillary tangles are thought to contribute to the degradation of the neurons in the brain, congophilic angiopathy of small vessels and vessels of medium caliber. The combination of vascular and neurodegenerative components can mutually potentiate each other, causing clinical symptoms of cognitive deficits.
Background and Aims:: Binswanger disease or subcortical arteriosclerotic encephalopathy refers to slowly progressive white-matter vascular dementia. Patients usually present symptoms including forgetfulness, personality and emotional changes. The aim of this study was to investigate the neuropathological substrates of cognitive impairment and dementia in Binswanger disease for the reliability of the diagnosis.

Methods:: Seven patients with a clinical diagnosis of microangiopathic encephalopathy of Binswanger and cognition impairment were studied. The gross examination and microscopic study of brain tissue were done.

Results:: White matter pathology was accompanied ventricular enlargement and lacunar infarcts in the basal ganglia and thalamus. Gross pathology showed variable involvement of the white matter, which may be superficial and subcortical or extend deep into the white matter to periventricular sites. Microscopical changes were two types of capillaropathy, mainly subcortical structures: obstruction of the lumen of the vessel and capillary stagnation as a result of chronic "retrograde venous support", due to which the blood filling of the vessels remains at a relatively high level. Both types are accompanied by diffuse ischemia of the white subcortical substance and by the development to many pericapillary microinfarctions. The genesis of dementia in Binswanger's encephalopathy is associated with "disconnection-syndrom", with the separation of cortical subcortical connections as a result subcortical white matter damage, and with dysfunction of the basal ganglia and thalamus.

Conclusions:: Binswanger disease is characterised by arteriolosclerosis, lacunar infarcts and diffuse white matter changes with myelin loss, axonal abnormalities and evidence of neuropathological cognitive impairment and dementia.
MILD COGNITIVE IMPAIRMENT DUE TO PRIMARY PROGRESSIVE APHASIA: A NEUROPSYCHOLOGICAL AND NEUROIMAGING 9 YEARS-FOLLOW UP CASE REPORT.

Roberta Bencivenga, Chiara Criscuolo, Maria Tedeschi, Elena Salvatore
University of Naples "Federico II", Department Of Neurosciences, Reproductive, And Odontostomatological Sciences, Naples, Italy

Background and Aims:: Mild Cognitive Impairment (MCI) is a heterogenous clinical entity, that may represent the initial phase of different type of neurodegenerative disorders. Our aim is to elucidate the early phases of clinically suspect Primary Progressive Aphasia (PPA) in order to better focus the presenting neuropsychological profile for earlier diagnosis.

Methods:: Neuropsychological tests, language evaluation, brain morpho-functional imaging and cerebrospinal fluid (CSF) analysis allowed to diagnose a MCI converted to Semantic variant Primary Progressive Aphasia (SvPPA).

Results:: Disease onset was at age 69 years with memory impairment and word finding difficulty. First neuropsychological evaluation resulted in non-amnestic MCI (fluency and visuo-spatial skills deficiency). After seven years of clinical follow up, the patient presented behavioral disturbances and cognitive worsening. Brain magnetic resonance imaging showed left inferior, medial and anterior temporal atrophy. Fluorodeoxyglucose positron emission tomography (FDG-PET) scans of the brain evidenced left anterior temporal and anterior cingulate cortex hypometabolism. Amyloid-PET resulted negative. CSF tau and phospho-tau resulted increased. Detailed language testing revealed marked difficulty with confrontation naming, moderate improvement after cueing, word substitutions, circumlocution, impaired comprehension (token test), but spared speech, grammar and repetition. So that, he converted to Semantic variant Primary Progressive Aphasia.

Conclusions:: Primary Progressive Aphasia, like other progressive neurodegenerative diseases, can pass through an early (MCI) phase prior to the dementia phase. Clinical use of CSF and imaging biomarkers are of a great value in MCI etiopathogenetic differential diagnosis process. Our case suggests that earlier language evaluation may be a helpful tool especially in clinical evaluation of amyloid-negative patients associated to advanced neuroimaging.
THE EFFECT OF TRINUCLEOTIDE REPEATS IN THE HTT GENE ON THE PROGRESSION FROM SUBJECTIVE COGNITIVE DECLINE TO MILD COGNITIVE IMPAIRMENT: A 12 YEARS FOLLOW-UP STUDY

Filippo Emiliani¹, Salvatore Mazzeo¹,², Silvia Bagnoli¹, Vittoria Conti¹, Giulia Giacomucci¹, Assunta Ingannato¹, Camilla Ferrari¹, Sonia Padiglioni¹, Sandro Sorbi¹,², Valentina Bessi¹, Benedetta Nacmias¹,²
¹University of Florence, Florence, Italy, Department Of Neuroscience, Psychology, Drug Research And Child Health, Florence, Italy, ²IRCCS Fondazione Don Carlo Gnocchi, Ircss Fondazione Don Carlo Gnocchi, Florence, Italy

Background and Aims:: Intermediate alleles (IA) of HTT gene occurs for CAG triplet repeats between 27 and 35. IA seem to play a role in the pathogenesis of Alzheimer’s disease. The aim of our study was to assess the effect of IA on progression from Subjective Cognitive Decline (SCD) to Mild Cognitive Impairment (MCI).

Methods:: We enrolled 120 SCD patients. All patients underwent extensive neuropsychological assessment, estimation of premorbid intelligence, a proxy of cognitive reserve, APOE and HTT genes genotyping and neuropsychological follow-up every 6-12 months.

Results:: Ten patients (8.33%) were carriers of IA (IA+). During follow-up 39 patients progressed to MCI (p-SCD) in a mean time of 13.96 (± 6.56) years, while 81 remain stable (np-SCD) in mean follow-up time of 11.06 (± 7.55) years. A regression analysis considering progression to MCI as dependent variable and age at onset of SCD, cognitive reserve proxies, APOE genotype and IA showed that APOE e4 was the only significant variable in the predictive model. Therefore, we stratified the sample according to APOE genotype. In the e4 carrier group we found that IA+ patients had twice as high risk of progression to MCI compared to IA- patients. We also stratified the the sample by age at onset >60 years. In patients older than 60, IA+ had 1.84 times higher risk of progression to MCI compared to IA-.

Conclusions:: Our results suggest that IA of the HTT gene interact with age at onset of SCD and with APOE genotype increasing the risk of progression from SCD to MCI.
DOES APOE 2 POLYMORPHISM PLAY A PROTECTIVE ROLE AGAINST ALZHEIMER'S DISEASE?

Vincenzo De Lucia¹, Chiara Giuseppina Bonomi¹, Martina Di Donna¹, Francesco Ricci¹, Martina Assogna², Francesca Bernocchi³, Giacomo Koch², Alessandro Martorana¹

¹Tor Vergata Rome University, Memory Clinic-department Of Wellness Of Mental And Neurological Health, Dental And Sensory Organs, Rome, Italy, ²IRCCS Santa Lucia, Non Invasive Brain Stimulation Unit, Rome, Italy

Background and Aims:: Human apolipoprotein E (ApoE) genotype is the only confirmed genetic risk factor for Alzheimer’s disease. As the most common isoform, ApoE3 is believed to play a neutral role in AD, while ApoE4 exists in nearly 50% of AD patients. On the other hand ApoE2 is relatively rare and is considered to be a protective variant against AD via its effects on Amyloid beta metabolism. In this retrospective longitudinal study we analyzed a population inside of the AD continuum to investigate the effect of these Epsilon variants on the CSF biomarkers trending levels.

Methods:: We evaluate over 140 subjects, came in the Memory Clinic of Policlinico Tor Vergata (Rome), suffering one year history of memory deficit due to recent events or subjective one. Patients underwent neuropsychological assessment, ApoE genotyping and lumbar puncture to evaluate CSF biomarkers (Abeta-42, T-Tau, P-Tau) for diagnostic purposes.

Results:: Individuals with AD continuum and ApoE2 polymorphism despite the absence of tau pathology in CSF show different T-Tau levels then controls. Particularly ApoE2 subjects having neurodegeneration signs documented with T-Tau/Abeta42 and P-Tau/Abeta42 ratios didn't showed difference with ApoE3 and ApoE4 patients in terms of CSF biomarkers levels and neuropsychological scores, indicating some detrimental mecanism of epsilon 2 isoform still unknown.

Conclusions:: ApoE2 genotype role in the pathogenesis of AD has to be investigated yet and could give counteracting effects on the course of Alzheimer’s disease, especially in the presents of lesional load indices and initial Tau pathology. Its protective effects might vary with the stage of AD.
THE NEW SUDAN COGNITIVE ASSESSMENT TOOL (SUCAT) IS A POTENTIAL _EARLY DETECTOR FOR LOW-INCOME COUNTRIES _THAT SURPASSES THE _LIMITATIONS OF MMSE AND MOCA

Omer Eladil Hamid
International University of Africa, Neurology, Khartoum, Sudan

Background and Aims:: Dementia is characterized by a decline in one or more cognitive domains; WHO listed Alzheimer/Dementia accounts for 4,756 deaths (1.78% of 41.8 million in the total population, 2018 census) In Sudan, where the research proved the unsuitability Mini-Mental State Exam (MMSE) and the Montreal Cognitive Assessment (MoCA) to detect Mild Cognitive Impairment (MCI). This is based on the diversity of Sudan’s cultural, educational, and linguistic background where Arabic with three informal dialects (colloquial Arabic; El-Darigia الدارجية) is used. Moreover, they are literate dependant. Hence, SuCAT is developed to test the known SEVEN cognitive domains.

Methods:: This analytical cross-sectional study composed of four piloting and validation phases.

Results:: Phase I; two studies; the first concluded that the Arabic version of the MMSE was not suitable for Sudan, while the second showed that MoCA and MMSE scores have a strong association with educational level (P. value = 0.000). Phase II was conducted as a pilot test of the validity and reliability of SuCAT as Literacy independent adapted Arabic version. It concluded that SuCAT is a potential test for cognitive impairment among Sudanese patients. Phase three was for SuCAT standardization at a larger, in which it was found to significantly surpass MMSE and MoCA in five of the seven domains, neutral in one and inferior in “Coping” (P. value = 0.000). Phase IV is to validate SuCAT for certain cognitive disorders.

Conclusions:: In conclusion, SuCAT is a promising Neuropsychological test with expected good health impact in a low-income country like Sudan. This might pave the way for similar countries worldwide.
7,8-DIHYDROXYFLAVONE ATTENUATES COGNITIVE DEFICIT IN ICV-STZ RAT MODEL OF ALZHEIMER’S DISEASE REVERSING OXIDATIVE STRESS, MITOCHONDRIAL DYSFUNCTION, AND INSULIN RESISTANCE

Ansab Akhtar
UIPS, Panjab University, Division Of Pharmacology, Chandigarh, India

Background and Aims:: Sporadic Alzheimer’s disease (SAD) is the most commonly prevalent dementia and progressive neurodegenerative disease. A polyphenolic flavonoid, 7,8-dihydroxyflavone (7,8-DHF) was used to reverse the cognitive deficit in a rat SAD model by reversing oxidative imbalance, mitochondrial enzyme dysfunction, and insulin resistance.

Methods:: For the SAD model, streptozotocin (STZ-3 mg/kg) was injected intracerebroventricularly (ICV) in male Wistar rats to induce cognitive dysfunction. Cognitive functions were evaluated by Morris water maze (MWM) and novel object recognition (NOR) tests, while locomotor activity was determined in actophotometer. 7,8-DHF was given orally in doses of 5 mg/kg, 10 mg/kg, and 20 mg/kg, and reference standard drug rivastigmine in a dose of 2 mg/kg. Antioxidant enzymes, mitochondrial enzyme complexes were determined biochemically, insulin-degrading enzyme (IDE) and p-tau by ELISA, and histopathology by H&E staining.

Results:: 7,8-DHF attenuated cognitive deficit induced by ICV-STZ in MWM and NOR. Moreover, in the cortex and hippocampus regions of the brain, levels of reduced glutathione, catalase, superoxide dismutase, and mitochondrial complex enzymes and increased lipid peroxidation, protein carbonylation, and nitrite levels were subsequently reversed by 7,8-DHF and rivastigmine. IDE and p-tau protein were found to be altered. Histopathological examination revealed halted neurodegeneration.

Conclusions:: Conclusively, 7,8-DHF was found to be neuroprotective in the ICV-STZ rat model of SAD by ameliorating oxidative stress, mitochondrial dysfunction, and insulin resistance, thereby improving cognitive functions evident with the behavioral results. Hence, these results can further have clinical relevance in human AD.
ALTERATIONS OF INWARDLY RECTIFYING POTASSIUM CHANNELS AN AB(1–42)-INFUSED RAT MODEL OF ALZHEIMER’S DISEASE

Villa Chiara1, Enes Akyuz2, Merve Beker3, Birsen Elibol3
1University of Milano-Bicocca, Dept. Medicine And Surgery, Monza, Italy, 2University of Health Sciences, Dept. Of Biophysics, Faculty Of International Medicine, Istanbul, Turkey, 3Bezmialem Vakif University, Dept. Of Medical Biology, Faculty Of Medicine, Istanbul, Turkey

Background and Aims:: Alzheimer’s disease (AD) represents the most common form of dementia in elderly individuals. AD is clinically characterized by irreversible and progressive neurodegeneration leading to memory deterioration, behavioral changes and cognitive dysfunction. Despite its prevalence, the AD pathogenesis is not completely understood, and, currently, there are no effective treatments to slow or halt the progression of its symptoms. Emerging studies reported that a dysfunction of ion channels is associated with the pathophysiology of a wide range of neurological disorders, including AD. Among them, the inwardly rectifying potassium (K+) channels (Kir) play a key role in the maintenance of the resting membrane potential and in the regulation of cell excitability by the controlling of the intracellular and extracellular flow of K+ ions. Therefore, the aim of the study was to investigate the role of neuronal Kir channels in AD pathophysiology.

Methods:: The mRNA and protein levels of neuronal Kir2.1, Kir3.1, and Kir6.2 were determined by quantitative real-time PCR (RT-qPCR) and Western blot analysis in the hippocampus of an amyloid-β(Aβ)(1-42)-infused rat model of AD. Extracellular deposition of Aβ was confirmed by both histological Congo red staining and immunofluorescence analysis.

Results:: Significant decreased mRNA and protein levels of Kir2.1 and Kir6.2 channels have been observed in the hippocampus of the rat model of AD, whereas no differences were found in Kir3.1 channel levels as compared with controls.

Conclusions:: Data corroborated the hypothesis that Aβ can modulate the expression of Kir channels, which may represent potential therapeutic targets in the AD treatment.
DIFFERING GLIAL EXPRESSION PROFILES AS A MEANINGFUL MEASURE OF EARLIEST STAGES OF ALZHEIMER’S DISEASE (AD) PATHOGENESIS

Raquel Taddei¹, Ana Amaral², Cinthya Aguero², Dominique Denbow², Theresa Connors², Patrick Dooley², Teresa Gomez-Isla²
¹Massachusetts General Hospital and Harvard Medical School, Neurology, Massachusetts, United States of America, ²Massachusetts General Hospital and Harvard Medical School, Neurology, Boston, United States of America

Background and Aims:: Neuroinflammatory dysfunction is a well-known phenomenon encountered in brains of demented AD individuals, but little is known about its role in earliest stages of AD pathogenesis. We assessed glial immunoreactivity in brain regions where tau burden was just about to develop and evaluated differing expression profiles in cognitively diverging individuals.

Methods:: We performed immunohistochemical analysis and stereological cell-quantifications in brain tissue of demented and non-demented subjects who harboured identical tau burden (Braak III/IV) evaluating brain regions temporally matched to this incipient tau acquisition (temporal pole, occipital cortex) and compared expression levels of a subset of glial markers.

Results:: We found a distinct glial expression profile in demented compared to non-demented individuals, which was prior to overt tau deposition. In these preliminary results, the best discrimination between demented compared to non-demented was represented by an increase in activated glial responses. No significant differences in the expression levels of homeostatic microglia were observed.

Conclusions:: Our results suggest that differing glial expression profiles exist in brain regions of demented individuals even prior to overt tau deposition and that these dysfunctional patterns could contribute to diverging cognitive profiles observed in some individuals. Moreover, the predominance of activated glia in clinically relevant brain regions of demented individuals supports early and independent involvement of neuroinflammation in AD pathogenesis before tau accumulation ensues. Lastly, the persistence of a homeostatic glial profile in yet tau-free brain regions could indicate its dependence on tau for later dysfunction and suggest an early window of opportunity for treatment interventions targeting glia-salvaging pathways.
CASE REPORT ABOUT DELAYED ENCEPHALOPATHY AFTER CARBON MONOXIDE POISONING

Tungalag Enkhbat, Dulamragchaa Purev, Odgerel Ochirkhuu
Second State Central Hospital, Neurology, Ulaanbaatar, Mongolia

**Background and Aims:** We present a case report about Delayed Encephalopathy Carbon Monoxide Poisoning (DEACMP). DEACMP is a group of neuropsychologic disorders that occur after a transient improvement or a symptom-free interval of acute carbon monoxide poisoning. In Mongolia it is diagnosed rarely although during long winter a half of the population burn coal to keep their home warm.

**Methods:** We diagnosed based on course of the disease, clinical symptoms and MRI scans.

**Results:** 51-year-old woman was brought to the ICU by her son with a complaint of she was unable to take care of herself or speak, suddenly. Her co-worker first noticed that 14 days ago the patient did not understand what she was doing at work, with slow reasoning. The disease progressed and after 3 days she could not walk or sit on her own. After 7 days, she became urinary incontinent. When she was admitted to the hospital 14 days after the onset of the disease, the patient was awake but had severe dementia, no obvious paralysis, paresis in the limbs; had urinary incontinence, resting tremor in both hands, and severe ataxia. We initially suspected encephalitis and started treatment with methylprednisolone, but it was ineffective. There was gradual improvement in treatment with complete recovery achieved 90 days after the onset of the disease. We monitored higher mental functions with a Mini-Mental State Examination.

**Conclusions:** DEACMP can be missed because coal is used broadly in Mongolia. So we need accurately to distinguish DEACMP from other diseases that can lead to hyper-progressive dementia.
THE USEFULNESS OF PLASMA NEUROFILAMENT LIGHT IN PATIENTS WITH ALZHEIMER’S DISEASE

Yongsoo Shim
The Catholic University of Korea Eunpyeong St Mary's Hospital, Neurology, Seoul, Korea, Republic of

Background and Aims:: A growing body of evidence suggests that the plasma concentration of the neurofilament light (NFL) might be considered another potential biomarker for the clinical use in Alzheimer’s disease (AD).

Methods:: With a single molecule array method (Simoa, Quanterix), plasma NFL levels were measured in 113 subjects with subjective cognitive decline (SCD; n=14), mild cognitive impairment (MCI; n=37), or dementia of Alzheimer type (DAT; n=62). Plasma NFL levels were compared between three diagnostic groups, and its cognitive and clinical correlates were evaluated.

Results:: Plasma NFL levels were correlated with age (r=0.387, p<0.001). NFL levels in plasma were significantly elevated in participants with DAT (65.98±84.96 pg/mL) compared to both groups with SCD (16.90±2.54 pg/mL) and MCI (25.53±10.42 pg/mL), even after adjusting for age (p=0.004). Moreover, plasma NFL levels were different between two groups with amyloid positron emission tomography (PET) (-) (n=17, 25.95±13.25 pg/mL) and PET (+) (n=16, 63.65±81.90 pg/mL, p=0.010). Plasma NFL levels were related with scores of the mini-mental state examination (r= -0.242, p=0.021), clinical dementia rating (CDR) (r=0.291, p=0.005), or CDR-sum of boxes (r=0.276, p=0.008) for all samples.

Conclusions:: This study confirms increased levels of plasma NFL in patients with DAT compared to subjects with MCI and SCD. Plasma NFL levels correlated with global cognitive status and functional state, or dementia severity. Further longitudinal studies are needed to confirm the utility of plasma NFL as a biomarker in the evaluation of AD, as well as in predicting the rate of progression.
DEVELOPMENT OF NOVEL VACCINE TO REDUCE GALECTIN-3 FOR ALZHEIMER'S DISEASE

Kazuya Goto¹,², Wataru Akahata³, Takashi Sekida¹, Junko Nishita⁴, Misako Nakata¹, Akira Kuzuya², Yasuto Tanabe¹,², Ryosuke Takahashi², Ryuji Ueno³,⁴
¹Kyoto University Graduate School of Medicine, Department Of Regulation Of Neurocognitive Disorders, Kyoto, Japan, ²Kyoto University Graduate School of Medicine, Department Of Neurology, Kyoto, Japan, ³Kyoto University, Department Of Regulation Of Neurocognitive Disorders, Kyoto, Japan, ⁴Cyn-K, LLC, Neurology, Poolesville, United States of America

Background and Aims:: Alzheimer's disease (AD) is the major cause of dementia and one of the intractable neurodegenerative diseases. There are many reports that neuroinflammation is related to the pathomechanism of AD and microglia have an important role in neuroinflammation of central nervous system. Galectin-3 is a member of the lectin family and has the function related to proinflammatory processes. Recently, some reports said that serum or cerebrospinal fluid galectin-3 levels were elevated in AD patients. In this study, we developed a novel vaccine to reduce galectin-3 and examined the effect of vaccination using inflammation model of mice.

Methods:: We designed a TNF-alpha vaccine using virus-like particle (VLP) and C57BL/6J mice were vaccinated intramuscularly with 10 micrograms three times in 4 weeks (n=5). Two weeks after immunization, serum samples were obtained to measure anti-TNF-alpha antibody titer by ELISA. One week later, we injected 1000 micrograms of lipopolysaccharide (LPS) intraperitoneally and measured serum TNF-alpha and galectin-3 levels of immunized mice by ELISA. As a positive control, 100 micrograms of etanercept was given before LPS administration in the non-vaccinated group.

Results:: All immunized mice showed high titers of anti-TNF-alpha antibody and suppressed the LPS-induced TNF-alpha elevation. Moreover, serum galectin-3 were also suppressed to the vaccinated group. On the other hand, etanercept did not suppress galectin-3 while suppressing TNF-alpha.

Conclusions:: Our results revealed that our novel VLP-TNF-alpha vaccine reduces not only serum TNF-alpha but also serum galectin-3, which suggests our vaccine can be a possible treatment for AD.
DOSE-RESPONSE ASSOCIATION OF THE DURATION AND VOLUME OF PHYSICAL ACTIVITY WITH INCIDENT DEMENTIA: A COSMIC COLLABORATIVE COHORT STUDY

Wanqing Wu¹, Ding Ding¹, Qianhua Zhao¹, Zhenxu Xiao¹, Mary Ganguli², Mary Haan³, Maria Fernanda Lima-Costa⁴, Erico Castro-Costa⁴, Tze Pin Ng⁵, Oye Gureje⁶, Nikolaos Scarmeas⁷, Henry Brodaty⁸, Richard Lipton⁹, Mindy Katz⁹, Darren Lipnicki⁹, Perminder Sachdev⁹

¹Huashan Hospital, Fudan University, Department of Neurology, Shanghai, China, ²University of Pittsburgh, Department of Psychiatry, Pittsburgh, United States of America, ³University of California, San Francisco, Department of Epidemiology and Biostatistics, San Francisco, United States of America, ⁴Fundação Oswaldo Cruz, Instituto De Pesquisa Rene Rachou, Belo Horizonte, Brazil, ⁵National University of Singapore, Department of Psychological Medicine, Singapore, Singapore, ⁶University of Ibadan College of Medicine, Department of Psychiatry, Ibadan, Nigeria, ⁷Aiginition Hospital, National and Kapodistrian University of Athens, Department of Neurology, Athens, Greece, ⁸School of Psychiatry, University of New South Wales, Centre for Healthy Brain Ageing, Sydney, Australia, ⁹Albert Einstein College of Medicine, Department of Neurology, New York, United States of America

Background and Aims:: This study aimed to examine the dose-response relationship between the duration and volume of PA and incident dementia.

Methods:: We harmonized longitudinal data from ten community-based cohorts in seven countries. Each PA was recorded and given a specific metabolic equivalent value (MET) for intensity. Total duration of PA (hour) was calculated by summing time spent performing each PA per week. Total volume (MET-hour) of PA was calculated by summing the products of MET and time spent on each PA. Incident dementia was diagnosed after a median of 5.4 years of follow-up. We estimated the multivariate hazard ratio (HR) of each group with the lowest duration or volume as the reference group among five categorized groups by the Cox regression model. Age, sex, educational year, cohort, APOE4, body mass index, smoking, hypertension, diabetes, stroke, and depression were adjusted as confounders.

Results:: A total of 11988 participants were included in our analysis. Significant dose-response associations were observed for the duration and volume of PA and the dementia risk. After adjusted for potential confounders, the corresponding HR ranged from 0.88 (95%CI: 0.67, 1.15), 0.68 (95%CI: 0.52, 0.89), 0.68 (95%CI: 0.51, 0.90), to 0.68 (95%CI: 0.50, 0.93) (p for trend =0.002) with increasing duration, from 0.92 (95%CI: 0.70, 1.22), 0.70 (95%CI: 0.53, 0.93), 0.70 (95%CI: 0.53, 0.92), to 0.63 (95%CI: 0.46, 0.85) (p for trend<0.001) with increasing volume.

Conclusions:: Our study demonstrated significant dose-response relationships between the duration and volume of PA and risk of incident dementia. This evidence could potentially enrich current recommendations for preventing dementia onset.
VESTIBULAR SCHWANNOMAS AND COMMUNICATING HYDROCEPHALUS: A CLINICAL CHALLENGE

Anna Scarabello¹, Maria Tappatà¹, Patrizia Riguzzi¹, Elena Pasini¹, Lilia Volpi¹, Roberta Pantieri¹, Giorgio Palandri², Raffaele Agati³, Roberto Michelucci¹
¹IRCCS Istituto delle Scienze Neurologiche di Bologna, Department Of Neurology, Bologna, Italy, ²IRCCS Istituto delle Scienze Neurologiche di Bologna, Department Of Neurosurgery, Bologna, Italy, ³IRCCS Istituto delle Scienze Neurologiche di Bologna, Department Of Neuroradiology, Bologna, Italy

Background and Aims:: Vestibular Schwannomas (VS) can cause both obstructive and communicating hydrocephalus (CH). While the first is due to mass-effect, the pathophysiological mechanisms underlying VS-induced CH are still unclear. The main hypothesis links the proteins secreted by the VS in the cerebrospinal fluid (CSF) to the impaired CSF absorption through arachnoid granulations. Clinical picture and neuroimaging can mimic a normal pressure hydrocephalus (NPH), but the evolution can be much variable, as shown in this case-report.

Methods:: Clinical manifestations, CSF, and neuroimaging findings of a patient with CH and VS are described.

Results:: A 67-year-old man presented with a 2 week history of gait instability and cognitive impairment. Urinary disturbances were present but attributable to prostate hyperplasia. A CT brain scan showed significative ventricular enlargement, then a CSF analysis released extremely high proteins (180 mg/dL). The MRI scan matched the neuroradiological criteria for NPH with the absence of obstructions. Notably, a small VS (<3 cm) was found. In a few days the patient conditions rapidly worsened: he was unable to stand up, then became lethargic and dyspnoeic, finally requiring intensive care assistance for respiratory failure. A ventricular-peritoneal shunt was placed, after which the patient promptly recovered: at one month follow-up the ventricules were markedly reduced and he was independent and well-oriented.

Conclusions:: CH due to VS can easily be mistaken by NPH. Nonetheless, while NPH course is slow, in VS-induced CH the evolution to respiratory failure can be rapid. Therefore, the diagnostic workup is mandatory to rule out this hypothesis and neurosurgical treatment should never be delayed.
RELATION OF MIDDLE CEREBRAL ARTERY FLOW VELOCITY AND RISK OF COGNITIVE DECLINE: A PROSPECTIVE COMMUNITY-BASED STUDY

Zhenxu Xiao, Xue Ren, Qianhua Zhao, Wanqing Wu, Xiaoniu Liang, Jie Tang, Ding Ding, Jianhui Fu
Huashan Hospital, Fudan University, Department Of Neurology, Shanghai, China

Background and Aims:: Hemodynamic parameters measured by the Transcranial Doppler Ultrasound (TCD) are related to cognitive impairment in many cross-sectional studies, but the longitudinal evidence is scarce. This study aimed to verify the association between flow velocity of Middle Cerebral Artery (MCA) and the longitudinal cognitive decline in community dwelling older adults.

Methods:: Participants from the Shanghai Aging Study were administered TCD examination at the baseline. The Peak Systolic Velocity (PSV), Mean Flow Velocity (MFV), and Pulsatility Index (PI) of MCA segments on left middle (LmMCA), left proximal (LpMCA), right middle (RmMCA), and right proximal (RpMCA) were obtained. Mini-mental state examination (MMSE) and cognitive diagnosis were conducted at both baseline and follow-up. The multivariable linear regression model was used to detect the relationship between baseline MCA indexes and the annual rate of decline in MMSE scores.

Results:: One hundred and thirteen participants without dementia were followed up for 6.3 years in average. The mean annual rate of decline in the MMSE score was 0.15 (min to max: -1.0 to 1.2). Lower LpMCA PSV (β = -0.0034, r = -0.231, P = 0.022) and LpMCA MFV (β = -0.0049, r = -0.217, P = 0.031) were associated with higher annual rate of decline in the MMSE score after adjusting for age, gender, education year, APOE ε4, obesity, hypertension, diabetes mellitus, stroke, and coronary heart disease.

Conclusions:: Lower flow velocity of left proximal MCA was related to faster global cognitive decline. Cerebral blood flow velocity may impact the cognitive function.
Background and Aims:: Plasma biomarkers showed a promising value in the disease diagnosis and management of Alzheimer’s disease (AD). This study aimed to investigate the profiles of the biomarkers and the association with cognitive domains in diverse cognitive performance.

Methods:: We recruited 320 individuals with cognitive impairment and 131 cognitively normal participants from a memory clinic and the Shanghai Aging Study. Participants were classified into 6 groups based on their Clinical Dementia Rating (CDR) scores. Each participant was administered the neuropsychological tests assessing the global and domain-specific cognition. Plasma Aβ1-40, Aβ1-42, Aβ1-42/Aβ1-40, total tau (t-tau), neurofilament protein light chain (NfL), and phosphorylated tau at threonine 181 (p-tau181) were quantified using the Single molecule array platform.

Results:: Along with plasma Aβ1-40, Aβ1-42, Aβ1-42/Aβ1-40, t-tau, and NfL, p-tau181 significantly increased across the groups with the incremental CDR scores from NC (CDR = 0) to severe AD (CDR = 3). Compared with other biomarkers, p-tau181 had a stronger correlation with Global cognition (r = -0.536, P < 0.0001), Memory (r = -0.481, P < 0.0001), Attention (r = -0.437, P < 0.0001), Visuospatial function (r = -0.385, P < 0.0001), and Language (r = -0.177, P = 0.0003). Among participants with CDR ≥ 1, higher p-tau181 was correlated with worse Global cognition (r = -0.301, P < 0.001).

Conclusions:: Plasma p-tau181 had a stronger correlation with cognitive domains than other biomarkers, especially in moderate-severe dementia. It could potentially reflect the AD pathology in vivo and may be a promising blood-based biomarker in clinical settings.
EVALUATION OF A SIMPLE VERSUS COMPOSITE PLASMA BIOMARKER MODEL AS SCREENING STRATEGY FOR THE DIAGNOSIS OF COGNITIVE IMPAIRMENT IN CHINESE POPULATION

Xue Wu¹, Zhenxu Xiao², Jingwei Yi¹, Saineng Ding², Wanqing Wu², Hongchen Gu¹, Xiaoniu Liang², Li Zheng², Hong Xu¹, Qianhua Zhao², Ding Ding²
¹Shanghai Jiao Tong University, School Of Biomedical Engineering, Shanghai, China, ²Huashan Hospital, Fudan University, Department Of Neurology, Shanghai, China

Background and Aims: This study aimed to evaluate the diagnostic performance of plasma biomarkers in the Chinese population.

Methods: A total of 428 participants, including 159 AD patients, 148 amnestic mild cognitive impairment (aMCI) subjects and 121 cognitively normal controls, were recruited from a memory clinic cohort and the Shanghai Aging Study. Plasma Aβ 42, Aβ40, Aβ 42/Aβ 40, T-Tau, p-Tau 181 and NFL were quantified using an ultra-sensitive Single-molecule Array (Simoa) platform. The diagnostic models were established based on the plasma biomarkers and clinical characteristics.

Results: A comprehensive diagnostic model, which included all five plasma biomarkers and clinical characteristics, provided the best identification ability with a 95.1% AUC for the AD versus Controls, 78.9% AUC for the aMCI versus Controls and 79.4% AUC for the AD versus aMCI. The simplified diagnostic model that combined only plasma Aβ42 and p-Tau181, along with clinical features, also achieved ideal diagnostic value, with a 93.3% AUC for distinguishing AD from controls, 75.9% AUC for aMCI versus controls, and 77.6% AUC for AD versus aMCI. The comprehensive diagnostic model reached 96.6% AUC for the early-onset AD versus Controls and 95.9% AUC for the late-onset AD versus Controls. The simplified diagnostic model demonstrated 96.6% AUC and 94.0% AUC, respectively.

Conclusions: Our study firstly established AD diagnostic model using plasma biomarkers for Chinese subjects. The simplified diagnostic model could be considered an accessible and practical method for large-scale screening in the clinic and community.
Background and Aims:: Around 2/3 of people with dementia worldwide live in low- and middle-income countries. Alzheimer’s disease (AD) is frequent in Morocco, with an estimated number around 200,000 cases. Diagnosis of dementia in Morocco is challenging and AD is still under-diagnosed.

Methods:: Based on about 30 years’ experience of the Neuropsychological department and more than 22 years of the Memory Clinic, we will present the challenges of AD diagnosis in Morocco and our personal contribution in improving it.

Results:: Dementia in Morocco is still diagnosed at an advanced stage when behavioral disorders appear. This could be explained by more tolerability of cognitive disorders in the elderly, lack of knowledge but also insufficient number of specialists and neuropsychologists. Accessibility to neuro-imaging could also be limiting. Availability of adapted and validated Neuropsychological Tests (NPTs) is challenging. Indeed diagnosis of dementia needs suitable tools but most of NPTs are available in English or other European languages. Adaptation of NPTs in Arabic must consider the linguistic diglossia. In Morocco as in most Arab countries, people use two variants of Arabic, a colloquial Arabic and a standard Arabic. NPTs should use colloquial Arabic for oral parts and standard Arabic for written language. Our team adapted and validated more than 20 NPTs and contributed to the improvement of dementia’s diagnosis.

Conclusions:: To improve diagnosis of AD in Morocco it is necessary to train more specialized health professionals, develop memory clinics and improve accessibility to health structures. This should be coupled with the development of adapted cognitive stimulation therapies and the improvement of home help.
THE COOPERATIVE SUPPRESSION OF LARGE-CONDUCTANCE CALCIUM-ACTIVATED POTASSIUM CHANNEL BY AMYLOID BETA AND AMYLOID PRECURSOR PROTEIN IN CORTICAL NEURONS

Kenji Yamamoto¹,², Ryo Yamamoto², Nobuo Kato²
¹National Hospital Organization Utano National Hospital, Department Of Neurology And Clinical Research Center, Kyoto, Japan, ²Kanazawa Medical University, Department Of Physiology, Uchinada, Japan

Background and Aims:: We have reported the blockade of large-conductance calcium-activated potassium channel (BK channel) as amyloid-β-induced molecular dysfunction, which we consider leads to disruptive calcium homeostasis and neuron death. The possibility that not just the end product amyloid β but the amyloid precursor protein (APP) per se might be harmful, still remains to be fully studied. This study examined the mode of BK channel blockade mediated by not just amyloid β but also APP.

Methods:: Whole cell recordings were made from the pyramidal neurons in frontal neocortical slices of wild-type (WT) or triple transgenic AD model (3xTg) mice. Spike properties were examined under the intracellular application of recombinant full length APP or various antibodies against APP or Aβ through patch pipette.

Results:: An anti-Aβ-oligomer antibody (11A1), but not anti-monomer-Aβ-antibodies, was effective in recovering BK channel activity in 3xTg neurons. Antibodies against APP were also found effective. In WT neurons, APP as well as Aβ₁–42 suppressed BK channels by itself. In cortical neurons from 3xTg mice that bear Homer1a knockout (4xTg mice), neither anti-APP antibodies nor 11A1, but only the 6E10 antibody that binds both APP and Aβ, rescued the BK channel suppression.

Conclusions:: This study pointed to a different cooperativity of Aβ and APP in WT and 3xTg neurons. Considering that Homer1a expression is activity dependent and 3xTg neurons are hyperexcitable, Homer1a is likely to be expressed sufficiently in 3xTg neurons, thereby alleviating the synergistic suppressive influence of APP and Aβ on BK channel.
DIAGNOSTIC VALUE OF STUDYING NEUROSTEROIDS IN PATIENTS WITH PARKINSON’S DISEASE DEMENTIA

Diyorakhon Okhunova¹, Gulnora Rakhimbaeva², Abduqayum Babokhujaev²
¹Tashkent medical academy, Neurology, Tashkent, Uzbekistan, ²Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: Comparative assessment of the level of dehydroepiandrosterone sulfate (DHEA-S) and cortisol in blood plasma in patient’s with Parkinson's disease dementia (PDD) in the late stages of disease

Methods:: We examined 60 patients with PD, who were divided into two groups : the main group (30 patients) with PDD and the control group (30 patients) PD without dementia. Serum dehydroepiandrosterone sulfate and cortisol values were obtained, taking into account its characteristics depending on the time of day, measured in the early morning between 7:00 and 7:30 on an empty stomach. The state of cognitive functions was assessed using the following scales: Mini Mental State Examination (MMSE), Frontal Assessment Battery (FAB), Montreal Cognitive Assessmet (MoCA).

Results:: Test scales of cognitive impairments characterized by low data on MMSE, FAB and MoCa in patients of the main group. The study of cortisol revealed a tendency to its increase in the blood in patients of the main group, in relation to the control group. The significance of these changes is confirmed by a 2.5-fold increase in blood cortisol in patients with PDD. At the same time, the level of DHEA-S progressively decreased, reaching its minimum value in patients of the main group. The control group in this case occupied a borderline value. Correlation analysis between the studied biomarkers showed their inverse relationship (r = -0.991).

Conclusions:: The diagnostic efficacy of neurosteroids, including the level of dehydroepiandrosterone sulfate and cortisol in the blood serum of patients was established for the early diagnosis of cognitive impairments and monitoring the effectiveness of therapy and identifying a risk group in PD.
COGNITIVE IMPAIRMENT OF ELDERLY IN DALANZADGAD SOUM, UMNUGOVI AIMAG

Bolortsetseg Khatanbaatar
Regional Diagnostic and Treatment Center, Neurolgist, Zip code Regional Diagnostic and Treatment CenterUmnugobi aimag, Mongolia

Background and Aims:: As of 2015, there were 46.8 million people who had idiocy in the world, and by 2030 this number is expected to increase to 74.7. Cognitive impairment is one of the leading causes of disability in the elderly. This is an irreversible change in the structure and function of the brain, which is a condition for the regulation of family and socio-economic status, reducing the ability to disrupt the daily activities of physical therapy, reducing lifestyle activities.

Methods:: It is a cross-sectional, descriptive and analytical research conducted, and the questionnaire method was used to detect cognitive impairment and the factors that influenced them. From January 10, 2021 to March 10. The questionnaire consists of two general parts. The diagnostic part was the MMSE. An MMSE score below 24 is considered a cognitive change, statistical processing was performed using SPSS-25 software.

Results:: A total of 177 elderly people participated in the survey, with an average age of 69.63, Of these, 67.8% (n = 120) women, 45.0% (n = 54), 32.2% (n = 57) men, and 47.4% (n = 27) had cognitive changes. The study found that 37.8% (n = 67) had mild cognitive impairment and 8.0% (n = 14) had moderate cognitive impairment. Cognitive decline was associated with age (p value = 0.007), marital status (p value = 0.013), education (p value = 0.008), and body mass index (p value = 0.067)

Conclusions:: It was found that cognitive changes among the elderly increase with age, marital status and depend on the level of education.
SPORADIC CREUTZFELDT-JACOB DISEASE PRESENTING WITH CEREBRAL VASOCONSTRICTION

Aristotelis Karantzoulis, Laura Fusi, Ilaria Zivi, Giampiero Grampa

Università degli Studi di Milano - Bicocca, Medicine And Surgery, MONZA, Italy, Università degli Studi di Milano - Bicocca, Milan Center For Neuroscience, MONZA, Italy, Ospedale Sant'Anna, Neurologia, Como, Italy, Ospedale Sant'Anna, U.o Neurologia, Como, Italy, Ospedale Sant' Anna, U.o Neurologia, Como, Italy, Ospedale Sant'Anna, U.o. Neurologia, Como, Italy

Background and Aims:: CJD is a rare neurodegenerative disorder promptly leading to a vegetative state caused by abnormal deposits of misfolded prion protein. Due to its tumultuous course and variable clinical characteristics, it can constitute a diagnostic challenge at least in its initial stages. To our knowledge there are no reports to date describing the copresence of vasoconstriction during the course of CJD. By describing this case, we could give impulse to further investigate this fascinating association.

Methods:: A 54-year-old accountant with a 3-year history of recurrent severe headaches followed by variable periods of dizziness and nausea sought our attention lamenting unremitting symptomatology. Her condition was framed as of vascular etiology and underwent extensive workup including transcranial and carotid doppler, lumbar puncture, brain MRI, autoimmune, thrombophilia and tumoral marker search, brain catheter angiography and EEG.

Results:: All were negative save for the catheter angiography evidencing diffuse distal cerebral vasoconstriction, the EEG presenting generalized slowing, and MRI presenting DWI and FLAIR enhanced posterior cortical regions. Her condition steeply worsened in a couple weeks with prominent ataxia, visual field deficits, Balint syndrome and dyscalculia amongst others, until dystonia and myoclonus developed with EEG documenting generalized periodic triphasic delta waves, CSF testing evidenced elevated 14.3.3 levels and positive PrP RT-QuIC. PRNRP polymorphism and prion biochemistry are underway.

Conclusions:: We report for the first time a correlation between probable sporadic CJD and cerebral arterial vasoconstriction, etiologic hypotheses being currently all but presumptive. However, our observation could inspire new studies, hence shedding more light on this terrible yet fascinating disease.
A STUDY OF THE IMPACT OF HYPERTENSION IN COGNITIVE IMPAIRMENT

Darisuren Namjil1, Oyuntugs Byambasukh2,3, Byambasuren Dagvajantsan4, Puntsagdulam Byambajav5
1Mongolian National University of Medical Sciences, Department Of Neurology, Ulanbator, Mongolia,
2Mongolian National University of Medical Sciences, School of Medicine, Department Of Endocrinology, Ulaanbaatar, Mongolia,
3Mongolian National University of Medical Sciences, Department Of Endocrinology, Ulaanbaatar, Mongolia,
4Mongolian-Japan hospital, Mongolian National University of Medical Science, Department Of Neurology, Ulaanbaatar, Mongolia
5Mongolian National University of Medical Science, Department Of Neurology, Ulaanbaatar, Mongolia

Background and Aims:: The previous study of cognitive impairment prevalence and risk factor has shown 39.7% of Mongolian elderly population has cognitive impairment, but the study of cognitive impairment among people with hypertension has not been conducted yet. Objective: To study the impact of hypertension in cognitive impairment.

Methods:: The current study involved 1270 people from the 8 aimags, and 6 districts of Ulaanbaatar city. Mini-mental state examination was used to assess the cognitive function in each subject and cognitive impairment was defined as less than 24 scores. Hypertension was diagnosed if the patient had blood pressure higher than 140/90mmhg during the examination.

Results:: The mean age was 45.6±12.5 and 23.4% of the participants were male. 20.8% of the study population has hypertension and 24.8% has cognitive impairment. The mean MMSE score were statistically significant different between people with hypertension(25.3±4.6) and people without hypertension(26.5±3.5) which means the MMSE score was lower in people with hypertension (p=0.004). The prevalence of cognitive impairment was 33.1%, and 23.4% in people with and without hypertension respectively which was statistically significant (p<0.001). Although the mean MMSE score in people without cognitive impairment was statistically significant different in both groups which was (28.9±0.93) and (27.2±1.93) in people with hypertension and people without hypertension respectively (p=0.042). There was positive correlation between MMSE score and education in both groups, people with hypertension(r=0.370) and people without hypertension(r=0.41)(p<0.001).

Conclusions:: The current study shows that cognitive impairment prevalence is high among people with diabetes(33.1%) without the aging process. This suggests that people with hypertension has a high risk to have vascular(secondary)cognitive impairment.
PREDICTORS OF SURVIVAL IN DEMENTIA WITH LEWY BODIES

Alya Gharbi\textsuperscript{1}, Amina Nasri\textsuperscript{1,2}, Imen Kacem\textsuperscript{1,2}, Saloua Mrabet\textsuperscript{1,2}, Mouna Ben Djebara\textsuperscript{1,2}, Riadh Gouider\textsuperscript{1,2}
\textsuperscript{1}Razi University Hospital, Neurology And Lr18sp03, Mannouba, Tunisia, \textsuperscript{2}University Tunis El Manar, Faculty Of Medicine Of Tunis, Tunis, Tunisia

\textbf{Background and Aims::} Dementia with Lewy bodies (DLB), the second most common cause of degenerative dementia, is characterized by a faster progression and earlier mortality compared to Alzheimer’s disease. However, the predictors of survival are still controversial. Our aim was to investigate survival and its determinants in a Tunisian cohort of DLB.

\textbf{Methods::} We conducted a retrospective study over a period of 17 years (2003-2019) in the Department of Neurology of Razi University Hospital, including patients diagnosed with probable or possible DLB according to McKeith criteria. Survival was explored using Kaplan-Meier analysis. Demographic, clinical, neuropsychological features and frequency of Apolipoprotein Epsilon 4 (ApoE\textepsilon{}4) allele were analyzed in the survival analysis.

\textbf{Results::} We included 151 DLB patients (sex ratio=1.2; mean age of onset: 75.3 \pm 7.9 years). First symptoms were mainly non-motor (76.8%). Memory disorders were found in 94.7% and parkinsonism in 87.4%. ApoE\textepsilon{}4 allele was found in 20.5% of the patients. Median survival was 6 years from disease onset. Median survival was significantly shorter in men (6 versus 7 years in women, p=0.005) and in patients with memory impairment at onset (5 versus 9 years, p=0.012). Cognitive fluctuations, familial forms of DLB and ApoE\textepsilon{}4 did not predict the outcome.

\textbf{Conclusions::} Our results support the fact that only gender and inaugural memory disorders help predict survival in DLB patients. Larger prospective studies are needed to better investigate the various survival determinants.
OBSTRUCTIVE SLEEP APNEA IN SPECTRUM OF COGNITIVE DISORDERS ON THE ISLAND OF GUAM

Ramel Carlos
The Neurology Clinic, President, Tamuning, Guam

Background and Aims:: Emerging evidences suggest an association between Obstructive Sleep Apnea (OSA) and various cognitive disorders, including dementia. The degree of OSA has been directly correlated with the severity of cognitive impairment. Vascular disorders are significant comorbidities in these patients. We report the occurrence of OSA in patients with cognitive disorders on the island of Guam and correlate the severity of OSA with the results of the neuropsychological testing (NPT) and neuroimaging studies.

Methods:: A retrospective review and analysis of medical records of patients evaluated in The Neurology Clinic with the diagnosis of OSA in patients with cognitive disorders from July 2016 to July 2020 was conducted.

Results:: There were 762 patients with various cognitive disorders and 17% have been diagnosed with OSA. Among patients with OSA, 45% have severe OSA, 35% have moderate OSA, and 20% have mild OSA. Severe impairment on Global Cognitive Scores was seen in 30% of severe OSA, 40% of moderate OSA and 30% of mild OSA. Evidences of silent stroke were seen in 25% and leukoaraiosis in 35% of patients based on their neuroimaging studies. Vascular diseases including hypertension, diabetes mellitus, hyperlipidemia and cardiac disorders were higher in those patients with severe and moderate OSA compared to those with mild OSA and without OSA.

Conclusions:: OSA is a common comorbidity of patients with various forms of cognitive impairment. The severity of OSA correlated with the degree of impairment on NPT. Silent strokes, various cerebrovascular disorders and leukoaraiosis are more frequent in patients with OSA than those without OSA.
MECHANISM OF AD RISK GENE RIN3 IN AD EARLY PATHOGENESIS.

Ruinan Shen¹, Chengbiao Wu², Jiangqing Ding¹
¹Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Neurology, Shanghai, China, ²ucsd, Neuroscience Department, san diego, United States of America

Background and Aims:: In AD, about one-third of the risk genes identified by GWAS encode proteins that function predominantly in the endocytic pathways. Among them, the Ras and Rab Interactor 3 (RIN3) is a guanine nucleotide exchange factor (GEF) for the Rab5 small GTPase family and has been implicated to be a risk factor for both late onset AD (LOAD) and sporadic early onset AD (sEOAD). However, how RIN3 is linked to AD pathogenesis is currently undefined.

Methods:: Quantitative PCR and immunoblotting were used to measure mRNA and protein levels. Immunostaining was used to define subcellular localization of RIN3 and to visualize endosomal changes. Recombinant flag-tagged RIN3 protein was purified to define RIN3-interactomes by mass spectrometry. Live imaging of primary neurons was used to examine axonal transport of different proteins.

Results::

A

B

C

D

E
We have shown that RIN3 mRNA level was significantly increased in the hippocampus and cortex of APP/PS1 mouse brain. Basal forebrain cholinergic neurons (BFCNs) cultured from E18 APP/PS1 mouse embryos also showed increased RIN3 expression accompanied by early endosome enlargement. In addition, via its proline rich domain, RIN3 recruited BIN1 and CD2AP, two other AD risk factors, to early endosomes. Overexpression of RIN3 disrupts early endosome trafficking. Together with CD2AP, it increase APP CTFs in PC12 cells. Upregulation of RIN3 or the neuronal isoform of BIN1 increased phosphorylated Tau level. These effects by RIN3 was rescued by a dominant negative Rab5 (Rab5S34N).

**Conclusions:** Our current work has thus provided important insights into the role of RIN3 in regulating endosomal signaling and trafficking in AD early pathogenesis.
Background and Aims:: Ovocystatin has beneficial properties for cognitive function in young rats and might prevent aging-related cognitive impairment in older animals, as well as reduces memory decline in APP/PS1 mice model. Our study aimed at assessing the impact of ovocystatin on microglia activation and neurogenesis.

Methods:: Immunoactivation: Mouse wild type microglia were stimulated with ovocystatin at dose of 100 micrograms/ml. The effect of ovocystatin on nitric oxide production and interleukin 1 beta secretion were determined. Neurogenesis: Primary rat hippocampal neurons of H19-7 cell line was used. The impact of ovocystatin on proliferation, nitric oxide production, and expression of markers of neurogenesis: microtubule-associated protein 2 (MAP2, isoforms A/B and C/D) and Synapsin 1, were determined.

Results:: It was shown that ovocystatin does not stimulate microglial cells to produce inflammatory mediators. Whereas, no toxic effect of ovocystatin (1-100 ug/ml) on H19-7 cells viability, and dose-dependent down-regulation of proliferation were demonstrated. It was also shown that in primary hippocampal neurons of H19-7 cells incubated with ovocystatin (100 micrograms/ml), the expression level of MAP2 C/D (75kDa) - characteristic form of immature neurons is unchanged. However, the increased expression of MAP2 A/B protein (280 kDa) – characteristic for mature neurons was observed after 6 and 24h incubation with ovocystatin. Relatively to MAP2 A/B, increased expression of synapsin 1 was observed.

Conclusions:: The ovocystatin might be a potential activator of molecular mechanisms in primary hippocampal neurons, participating in regulation of neurogenesis. Nevertheless, further studies are needed.
VALIDATION OF AN ALGORITHM BASED ON DATA OF THE HEALTH INFORMATION SYSTEMS (HIS) FOR THE IDENTIFICATION OF DEMENTIA CASES.

Ilaria Bacigalupo1,2, Flavia Lombardo3, Anna Maria Bargagli4, Silvia Cascini4, Nerina Agabiti4, Marina Davoli4, Silvia Scalmana5, Annalisa Di Palma6, Annarita Greco7, Marina Rinaldi7, Daniele Imperiale8, Piero Secreto9, Natalia Golini10, Roberto Gnawi10, Carlo Biagini11, Elisa Gualdani12, Paolo Francesconi12, Natalia Magliocchetti13, Teresa Di Fiandra13, Nicola Vanacore1

Background and Aims:: The identification of dementia cases with routinely collected health data is a promising method to estimate prevalence and incidence, evaluate temporal trends and improve the interregional comparability. In Italy, a project aimed at the development and validation of an algorithm for the identification of dementia cases has been proposed.

Methods:: The project included four Italian regions (Piedmont, Tuscany, Latium and Campania) and the Italian National Institute of Health. A case of dementia was defined by using pharmaceutical prescriptions, hospital discharge records, residential setting and exemption from treatment co-payment, from 1 January 2012 to 31 December 2016. The validation study involved the comparison of the population identified by HIS through the algorithm with the cases (patients with dementia or Mild Cognitive Impairment-MCI) recruited at the Centers for Cognitive Disorders and Dementias (CDCD), and the controls (subjects without dementia or MCI) recruited at the geriatric centers. Sensitivity, specificity, positive and negative predictive value were calculated.

Results:: Clinical centers identified 1727 cases and 1425 controls. Sensitivity, specificity, positive and negative predictive value of the algorithm were 65.6%, 93.6%, 92.5% and 69.1%, respectively.

Conclusions:: In Italy, despite the presence of several information flows at national and regional level, an integrated information system specifically dedicated to dementias is still not available. Moreover, the results of this project can be used for international comparison with the WHO Global Dementia Observatory on the development of a "core set" of shared indicators on dementia to be routinely collected.
ANTI-DEMENTIA DRUGS: A DESCRIPTIVE STUDY OF PRESCRIPTION PATTERN IN ITALY

Ilaria Ippoliti\(^1\), Antonio Ancidoni\(^2\), Nicola Vanacore\(^2\), Roberto Da Cas\(^1\), Andrea Pierantozzi\(^3\), Francesco Trotta\(^4\)

\(^1\)National Institute of Health, Pharmacoepidemiology Unit, National Centre For Drug Research And Evaluation, Rome, Italy, \(^2\)National Institute of Health, National Center For Disease Prevention And Health Promotion, Rome, Italy, \(^3\)Italian Medicines Agency, Area/settore/ufficio, Rome, Italy, \(^4\)Italian Medicines Agency, Settore Hta, Rome, Italy

**Background and Aims::** More than one million people in Italy have dementia and nearly 900 thousand people are affected by Mild cognitive impairment (MCI). No effective treatments are yet to be approved and acetylcholinesterase inhibitors (AChEi) and memantine are currently used to reduce cognitive decline related symptoms. Aim of the study is to provide a comprehensive analysis of anti-dementia drugs consumption in Italy between 2014 and 2020 with an analysis of demographic characteristics of the prevalent and incident users. The association between AChEI and memantine or anti-dementia and antipsychotic drugs will be also considered.

**Methods::** Two data sources were used: OsMed database, for the consumption data of medicines and Pharmaceutical Prescriptions database collecting patient level data on medicines.

**Results::** In 2020 the anti-dementia consumption decreased by 3.3% compared to the previous year and increased by 7.7% compared to 2014. The prevalence of use in the population was 0.3% and reaches 2.3% in the over 75 age group, with a higher prevalence in women. Each user has been treated for 242 days, and 15.7% of the users received only one prescription. Acetylcholinesterase inhibitors represent 57% of the total and decreased by 7.5% in respect to 2019, this trend was mainly determined by donepezil (-7.1%) while the memantine consumption increased by 3.0%.

**Conclusions::** This descriptive study should be useful to have an exhaustive overview on appropriateness of anti-dementia drugs in Italy and to support future regulatory decisions to establish eligibility criteria for new therapeutic strategies.
Background and Aims:: In Italy, 1,100,000 people are estimated to have dementia, and almost 900,000 to have MCI. Establishing a relationship between general practitioners (GPs) and Centers for Cognitive Disorders and Dementias (CCDDs) specialists is essential to provide adequate care for patients with dementia (PwD) and their families. The Italian National Dementia Plan defines a specific role for GPs and specialists within diagnostic and therapeutic pathways.

Methods:: Health Search, a research institute of the Italian Society of General Medicine and Primary Care, includes 800 trained GPs, representative of about 40,000 GPs. These 800 GPs have in charge 1,014,016 adults who are representative, for both age and gender, of the Italian population. From 2005 to 2018, the number of contacts by specific cause, by doctor, and per patient per year, and the prevalence of dementia in the primary care setting were collected.

Results:: Results showed that despite an increase in the prevalence of dementia in the primary care setting (from 1.3% in 2005 to 2.9% in 2018), there was a reduction in the number of contacts by specific cause by doctor and per patient per year (from 4.8% in 2005 to 1.0% in 2018).

Conclusions:: Data showed reduction over the years in the level of care of PwD and their families in primary care. This should be further explored across the Italian territory, as it could suggest an increased referral to the CDCDs or specific issues in the level of assistance provided by the National Health System.
ACCURACY OF BIOMARKERS IN PREDICTING CONVERSION TO DEMENTIA IN MCI SUBJECTS: THE STATISTICAL ANALYSIS PLAN OF THE INTERCEPTOR STUDY

Flavia Lombardo¹, Marco Massari², Ilaria Bacigalupo¹, Paola Piscopo³, Giulia Remoli¹, Antonio Ancidoni¹, Francesco Sciancalepore¹, Marco Canevelli¹, Stefano Cappa⁴, Fabrizia Lattanzio⁵, Daniela Perani⁶, Fabrizio Tagliavini⁷, Camillo Marra⁸, Paolo Rossini⁸, Nicola Vanacore¹, Interceptor Study Group⁹, Flavia Mayer¹

¹National Institute of Health, National Center For Disease Prevention And Health Promotion, Rome, Italy, ²National Institute of Health, Pharmacoepidemiology Unit, National Centre For Drug Research And Evaluation, Rome, Italy, ³National Institute of Health, Rome, Italy, Department Of Neurosciences, Rome, Italy, ⁴University Institute for Advanced Studies, Human And Life Sciences, Pavia, Italy, ⁵Scientific Direction IRCCS INRCA, Ircs Inrca, Ancona, Italy, ⁶In Vivo Human Molecular and Structural Neuroimaging Unit, Division Of Neuroscience, Ircs San Raffaele Scientific Institute, Milan, Italy, ⁷Fondazione IRCCS Istituto Neurologico Carlo Besta, Division Of Neurology V/Neuropathology, Milan, Italy, ⁸IRCCS Policlinico Universitario "A. Gemelli", Institute Of Neurology, Rome, Italy, ⁹Catholic University of the Sacred Heart, A. Gemelli Hospital Foundation IRCCS, Neuroscience Department, Rome, Italy

Background and Aims:: Many clinical trials on potentially disease-modifying drugs are focused to mild cognitive impairment (MCI) prodromal-to-Alzheimer's disease. The MCI population actually includes patients with higher risk of progression to AD. Since the new drugs, if effective, will carry both elevated unit costs and not marginal side effects, they should be administered selectively to high-risk subjects. The Italian INTERCEPTOR project, promoted by the Italian Medicine Agency and the Italian Ministry of Health, is a multicenter, interventional, nontherapeutic cohort study in subjects with MCI, with the primary aim of identifying biomarkers that better predict the conversion to AD after 3 years of follow-up.

Methods:: A sample of 500 subjects with MCI was planned to be enrolled. The biomarkers under investigation obtained by the analysis of MMSE, CSF, FDG-PET, FCRST, APOE4, EEG, Volumetric MRI. Multivariate prediction model will provide the predictive performance of each biomarker and combinations. In applying biomarkers, three scenarios are considered: 1) use of cut-offs indicated by experts 2) defining new optimal cut-offs for the specific population 3) use of values in a continuous form in order to evaluate all predictive information. Finally, nomograms will be defined for use in clinical practice.

Results:: Due to COVID-19, the target sample size was not reached. The enrolment was closed on October 31st 2020. Overall 498 patients were screened, 362 recruited into the study and 17 dropped out

Conclusions:: The findings will support the diagnostic path redefinition to identify those patients in the early stage eligible to prescription for disease-modifying medications.
NON-PHARMACOLOGICAL THERAPY OF ALZHEIMER’S DISEASE IN MOROCCO. EXPERIENCE OF THE ALZHEIMER DAY CENTER OF RABAT.

Maria Benabdellil1,2, Abdelhak Azdad2, Mohamed Taibine3, Fatiha Khamlichi2, Chaymae Lammouri2, Ouafa Mouti2, Mouna Maamar2, Bahija Gorfiti2, Khadija Al Zemmouri2, Mustapha El Alaoui Faris3
1Mohammed V University. Faculty of Medicine and Pharmacy-Rabat, Department Of Neurology A And Neuropsychology, Hôpital Des Spécialités, RABAT, Morocco, 2Alzheimer Day Center, Rabat, Rabat, Morocco, 3Alzheimer Day Center, Rabat, RABAT, Morocco

Background and Aims:: Alzheimer’s disease represent a global public health problem. The effectiveness of non-pharmacological treatment is now well recognized and this therapy is used in developed countries. We present the pilot experience of the day center of Rabat, the first one dedicated to non-pharmacological therapy for AD patients in Morocco.

Methods:: The center of Rabat has been set up in 2017. Its operation is ensured by the Moroccan Alzheimer’s Association. Patients come for half a day, once to three times a week. The center offers cognitive stimulation and speech therapies, physical training, art therapy and occupational activities, as well as guidance and psychological support to the families.

Results:: A total of 80 patients (46 female, 34 male) comes at the center. The mean age is 74.15 (±5.74). The mean MMSE score at the entry is 15.70 (±5.77) for women and 16.74 (±5.75) for men. Patients are divided into 4 cases of amnestic MCI, 19 cases of mild AD and 57 cases of moderate AD. All patients benefit from cognitive stimulation, speech therapy and physical training. Twenty-four of them participate in singing workshops, 18 patients in cooking workshops, 35 in painting and coloring activities and 33 come to dance workshops. The majority of patients positively benefits from this therapy at a cognitive, psychological and behavioral level, specially those with MCI and mild AD.

Conclusions:: Combination of non-pharmacological therapy offer patients the opportunity to maintain cognitive and behavioral functioning, preserve social relations and reduce burden of caregivers. This pilot experience in Morocco should be multiplied in developing countries.
MORTALITY ASSOCIATED WITH ANTIPSYCHOTIC MEDICATIONS IN OLDER PATIENTS WITH DEMENTIA: A POPULATION-BASED STUDY IN THE LAZIO REGION, ITALY

Silvia Cascini¹, Nera Agabiti¹, Nicola Vanacore², Marco Canevelli²,³, Ursula Kirchmayer¹, Claudia Marino¹, Marina Davoli¹, Anna Maria Bargagli¹

¹Regional Health Service, Department Of Epidemiology, Rome, Italy, ²Italian National Institute of Health, National Center For Disease Prevention And Health Promotion, Rome, Italy, ³Sapienza University of Rome, Department Of Human Neurosciences, Rome, Italy

Background and Aims:: Antipsychotic drugs (AP) can be effective in reducing behavioral and psychological symptoms of dementia but they are associated to a wide range of serious adverse events. This study aimed to evaluate all-cause mortality at 30 and 180 days, and 1 year after the first prescription with an AP, and the risk of death associated with the use of typical versus atypical AP medications.

Methods:: A population-based cohort study was conducted in the Lazio region using data from administrative health databases. Individuals with dementia aged 65 years and over at 31/12/2016 were identified. Only new users with a first claim of AP between 01/01/2017 and 30/11/2019 were considered. For each new user, one age- and gender-matched non-user or typical vs atypical AP user was randomly selected. Adjusted estimates were obtained by using propensity score matching.

Results:: We identified an overall population of 34,625 patients (67% females). Three different cohorts were enrolled including 6047, 5529 and 4730 new users of AP, respectively in the 30-day, 180-day and 1-year mortality cohort. An excess of mortality at 30 days and 1 year since the first prescription of an AP was observed (HR: 1.30, 95%CI 1.01-1.68 and HR: 1.60, 95%CI 1.39-1.69, respectively). Typical APs users showed a significantly higher risk of death within 1 year than atypical APs users (HR: 1.30, 95%CI 1.01-1.62).

Conclusions:: AP use is associated with an increased short- and long-term mortality risk in elderly with dementia. The prescription of AP, especially typical AP, should be carefully evaluated and stringently monitored overtime.
BEHAVIORAL AND PSYCHOLOGICAL SYMPTOMS IN DEMENTIA, OFTEN REVERSIBLE CONDITIONS

Antonia Nucera1, Maria Vazzana2, Michela Papa3
1F Spaziani Hospital, Stroke Unit Neurology, FROSINONE, Italy, 2F Spaziani Hospital, Urgency Medicine, FROSINONE, Italy, 3F Spaziani Hospital, Stroke Unit Neurology, modena, Italy

Background and Aims:: In the later stages of dementia some people with develops what's known as behavioural and psychological symptoms of dementia, BSPD. Symptoms of BPSD can include increased agitation, aggression, delusions, hallucinations, sleep disturbance and night-time waking. Behaviour changes could be caused by brain-related issues or from changes to someone's environment, health or medication.

Methods:: Dementia is an umbrella term used to describe a group of symptoms that affect brains work. Many conditions, such as stroke, depression, infections, as well as normal ageing, can cause dementia-like symptoms. We describe 120 patients than have been admitted in the emergency setting because of acute symptoms. We examined the patients to see if they have any infection, pain constipation, depression or side-effects of their medicine that could be contributing to or causing the behavior.s change.

Results:: The mean age was 81,68 women and 52 men. Hypertension was present in 96 and vascular changes in the brain were found in the neuroimaging. 78 patients had reversible symptoms of dementia due to such conditions: urinary infection, hydration, costipation, fever and Covid infection.

Conclusions:: Dementia is always changing and unique for each person. Everyday life can be a stressful ordeal for a person with a dementia-related disorder. As the disease progresses, behaviors changes can occur. The pandemic worsened such situation. It is important in the acute setting to rule out any concomitant illness that can cause or worsen behavioral and psychological symptoms in dementia.
CLINICAL CHARACTERISTICS AND DEMOGRAPHICS OF PATIENTS WITH DEMENTIA TREATED AT THE NPZR

Elif Cindik-Herbrüggen, Rahman Demirkol
NPZRT- Neuro-Psychiatric Center Riem (Neuro-Psychiatrisches Zentrum Riem), Psychosomatik/psychotherapie, Munich, Germany

Background and Aims:: Dementia is considered as an important public health issue with high costs for the treatment of the patients. Previous studies demonstrate that low education and the age of people were significantly associated with a greater risk for dementia (Sharp & Gatz, 2011 and Gao, et al., 1998). Therefore, this study aims to analyze the relationship between sociodemographic parameters as well as the prevalence of depression of patients with dementia treated at the NPZR.

Methods:: A total of 283 patients (33.1 %, n=98 male and 62.5%, n=185 female) diagnosed with dementia between 2015 and 2021 were recruited in this research from our patient files of the NPZR. The participants were tested with the DemTect.

Results:: As expected, the prevalence of dementia increases with age. 47.3 % of patients with dementia (n=140) were over 85 years old. While 68.2% of patients with dementia were German citizens, the percentage of patients with Turkish immigrant background was 19.9 %. 57.3 % patients with dementia had severe depression. In particular, there is a significant relationship between gender and severe depression. Female patients with dementia had more severe depression (p<0.005). Furthermore, low education level and current employment status were significantly associated with dementia. The prevalence of dementia was higher among the participants with a primary school degree (p=0.002) and retired patients (p=0.001).

Conclusions:: Depression is a significant factor for dementia, particularly among female participants. Prevalence of dementia was higher among participants with over 85 years old, low education level as well as retired participants.
FREQUENCY OF DEMENTIA AMONG PATIENTS ADMITTED TO BENGHAZI MEDICAL CENTER OVER A SIX MONTHS PERIOD IN 2017

Heba El-Zawawi
Benghazi Medical Center, Neurology, Benghazi, Libya

Background and Aims:: Background: With the rising age of the general population in developing countries it is expected that age-related hereditary neurodegenerative disorders such as dementia will become important health issues. In many elderly patients cognitive decline is multifactorial and exists with other comorbidities. There are currently few data on dementia in Libya. Aims: To determine the size and thereby the impact of dementia in our hospital patient admissions.

Methods:: A retrospective study using a prepared study proforma of a sample of the case notes of 2000 patients admitted consecutively over a six month period to the Medical Department, and of whom 437 were of the Neurological Unit at Benghazi Medical Center in 2017, from 1st July 2017 to 31st December 2017.

Results:: Frequency of Dementia in Medical Admissions: 7.5/1000 Dementia was identified in 437 admissions to the Neurological Unit. Frequency of Dementia in Neurological Admissions: 34/1000 (3.4%). Alzheimer’s disease was identified in 9 patients 4.5/1000 of medical patients, and 20.6 /1000 (2.1%) of neurological admissions. Alzheimer’s disease age Range 65-95 Gender ratio: 1.25: 1 Dementia was documented in 15 patients of whom 5 had coexisting vascular pathology, 4 epilepsy, and one Parkinson’s disease.

Conclusions:: Dementia is a recognized cause for hospital admission. We found a rate just short of that of western countries. We may have underestimated the size of the problem. Prospective multicentre studies may give more accurate data regarding this condition in Libya. They would determine whether we had similar rates to others or that the condition is rare in Libya.
INTRANASAL DELIVERY OF INSULIN FOR THE RESTORATION OF MEMORY SIGNALING IN ALZHEIMER DISEASE

Mani Bhargava¹, Saurabh Bhargava²
¹GTB Hospital, R&D, Kanpur, India, ²Signa College of Pharmacy, Pharmacy, Kanpur, India

Background and Aims:: Alzheimer's disease (AD), is progressive, degenerative brain disease characterized by marked atrophy of cerebral cortex and loss of cortical and sub-cortical neurons. Weakening of insulin receptor signaling is involved in ageing-related brain degeneration like AD. Objective of this study is to develop delivery-system to overcome BBB by employing novel, non-invasive approach via nasal route i.e. delivery of antibody appended Insulin encapsulated carrier, PEGylated nanoparticle coated with chitosan to facilitate nasal absorption for efficient transfer to brain.

Methods:: PEGylated-PLGA-nanoparticles were prepared by modified Double Emulsification method and coated with chitosan. Characterization was done by FTIR and NMR. In-vivo study comprised biodistribution in various organs and fluorescence microscopy, estimation of Anti-Aβ antibody, PET- Imaging of Brain, Hemolytic Toxicity studies, Histopathology of Nasal Mucosa and Brain with Blood Glucose Level Monitoring.

Results:: Degree of hemolysis showed PEGylated(PEG-NP’s) and chitosan-coated nanoparticles(cPEG-NP’s) were less toxic. Blood glucose monitoring indicates reduction in blood glucose level in cPEG-NP’s. Biodistribution assessment suggests nanoparticles showed maximum availability at olfactory bulb entrance. Uptake study shows intense fluorescence in brain revealing higher uptake of nanoparticles. These studies highlight possible biological significance of cPEG-NP’s for delivery to brain.

Conclusions:: Results from various studies suggest nanoparticles are effective delivery system for targeted delivery of insulin in brain for an extended period. Coating with chitosan elicits associated benefits in addition to prolonging uptake via intranasal route. This project may provide sound platform towards employment of this modified nanoparticulate carrier for brain delivery of proteins and peptides towards intranasal delivery of insulin for restoration of memory signaling in Alzheimer patients.
PRESENT CLINICAL PRESENTATIONS OF SYPHILITIC DEMENTIA: STUDY OF 9 OBSERVATIONS AT DEPARTMENT OF NEUROLOGY, ACADEMIC HOSPITAL, UNIVERSITY OF CONAKRY

Cisse Amara, Guelingar Carlos Othon, Djibo Hamani Abdoul Bachir
Academic Hospital, University of Conakry (Guinea), Neurology, Sélectionner, Guinea

Background and Aims:: the goal of a reassessment of this pathology from a clinical and paraclinical point of view.

Methods:: We conducted a retrospective study of 298 patients hospitalized for dementia syndrome between 2010 and 2019 in the Neurology and Psychiatry Departments of the Academic Hospital, University of Conakry. Syphilitic etiology was selected for 9 patients.

Results:: L’étiologie syphilitique a été conservée chez 9 patients âgés de 55 à 76 ans (3 femmes et 6 hommes). Un tableau clinique dominé par des troubles de la mémoire avec une diminution de l'idéation, des troubles de la personnalité et du comportement et un syndrome pseudo dépressif a été noté chez les patients. Ce tableau était augmenté par la présence de signes neurologiques: signe d'Argyl-Robertson (5 cas), tremblement vermiculaire de la région labio-linguale (3 cas), troubles du sphincter (3 cas) et faciès pseudo-parkinsonien (6 cas). Le diagnostic était basé sur la positivité des réactions sérologiques (VDRL-TPHA) dans le sang et le liquide cérébro-rachidien, la présence d'une hypercellularité principalement lymphocytaire et d'une hyperprotéinorachie.

Conclusions:: These neurological syndromes, expression of a cerebral syphilitic attack, are the result of still poorly managed treatment of primary and secondary syphilis in our country.
QUALITY OF LIFE COMPARED IN MILD COGNITIVE IMPAIRMENT, ALZHEIMER’S, FRONTOTEMPORAL, LEWY BODY, AND VASCULAR DEMENTIA.

Andrew Kirk¹, Michelle Kushneriuk¹, Chandima Karunanayake², Debra Morgan², Megan O’Connell³
¹University of Saskatchewan, Neurology, Saskatoon, Canada, ²University of Saskatchewan, Centre For Health And Safety In Agriculture, Saskatoon, Canada, ³University of Saskatchewan, Psychology, Saskatoon, Canada

Background and Aims: Quality of life (QOL) is of great importance in dementia. We examined QOL across types of dementia in patients presenting to a rural and remote memory clinic (RRMC).

Methods: This analysis included 343 RRMC patients seen consecutively between 2004 and 2016. Patients were diagnosed with mild cognitive impairment (MCI, n=74), frontotemporal dementia (FTD, n=42), Alzheimer’s disease (AD, n=187), vascular dementia (VD, n=22), or Lewy Body dementia (DLB, n=18). Patients and caregivers completed questionnaires at their visit. Data collection included patient-rated patient QOL (QOL-PT), caregiver-rated patient QOL (QOL-CG), MMSE score, age, and other patient demographics. Statistical analysis assessed patient variables and differences in QOL across types of dementia using one-way ANOVA, χ² tests, and t-tests.

Results: QOL-PT did not differ by diagnosis, whereas QOL-CG did. QOL-CG was significantly higher in MCI (34.6±7.1) compared to FTD (30.9±5.2) and AD (31.7±5.9). QOL-PT and QOL-CG differed in certain dementia subtypes. QOL-PT was significantly higher than QOL-CG in MCI (QOL-PT=37.3±5.0, QOL-CG=35.3±7.3), FTD (QOL-PT=37.2±6.1, QOL-CG=31.7±5.5), and AD (QOL-PT=37.0±9.7, QOL-CG=32.1±5.9).

Conclusions: We found that QOL-PT does not differ across dementia subtypes, QOL-CG is higher in MCI compared to FTD and AD, and patients rate their own QOL higher than their caregivers do in MCI, FTD, and AD.
SUPERO-TEMPORAL RETINAL AMYLOID COUNT PREDICTS HIPPOCAMPAL VOLUME, VERBAL MEMORY AND COGNITIVE-RELATED QUALITY OF LIFE

Oana Dumitrascu¹, Dale Sherman², Keith Black³, Maya Koronyo-Hamaoui³
¹Mayo Clinic, Neurology, Scottsdale, United States of America, ²Cedars-Sinai Medical Center, Psychology, Los Angeles, United States of America, ³Cedars-Sinai Medical Center, Neurosurgery, Los Angeles, United States of America

Background and Aims:: As retinal amyloid deposition correlate with and even precede brain amyloidosis, retinal imaging may become a non-invasive and non-ionizing biomarker for Alzheimer’s disease. Retinal autofluorescence using a specific amyloid-binding fluorophore curcumin and laser ophthalmoscopy is an emerging methodology for retinal amyloid quantification. In this study, we aimed to evaluate the relationship between the retinal amyloid counts (RAC) in the supero-temporal quadrant and brain volumes, and cognitive performance.

Methods:: 29 patients with cognitive impairment underwent curcumin-enhanced retinal fluorescence imaging, 3-Tesla brain MRI and standard neuropsychometric testing. RAC was calculated in the supero-temporal quadrant. Automated NeuroQuant software was used for volumetric brain analysis. Logistic regression analyses were performed to appraise the association between RAC, brain volumes and various cognitive domains’ Z-scores.

Results:: Supero-temporal RAC was significantly higher in patients with lower MOCA scores (p<0.05). The total RAC significantly correlated with hippocampal volume (r = -0.39, P=0.04), but not with total brain volume (P =0.08). Total amyloid significantly predicted SF-36-Mental Component Score (Beta -0.004 (SE 0.002), P=0.046). On subregional analysis, proximal mid-periphery RAC significantly predicted verbal memory measures, CVLT-II Long Delay (Beta -0.009 (SE 0.003), P=0.027) and WMS-IV LM-II (Beta -0.007 (SE 0.003), P=0.028). Distal mid-periphery RAC predicted non-verbal memory, RCFT delayed recall (Beta -0.01 (SE 0.005), P=0.04) and SF-36-MCS (Beta -0.014 (SE 0.004), P=0.004).

Conclusions:: Supero-temporal quadrant RAC correlates with hippocampal volume and predicts cognitive related-psychological functioning. Proximal mid-periphery amyloid predicts verbal memory. Future larger studies should evaluate the utility of curcumin-enhanced retinal imaging in monitoring brain amyloidopathy.
COMPUTATIONAL MODEL OF THE FLANKER TASK IN PATHOLOGICAL AGING

Boris Velichkovsky
Moscow State University, Psychology, Moscow, Russian Federation

Background and Aims:: Attention control problems are typical of the aging brain. The aim of the study was to assess the functioning of attention control in mild cognitive impairment (MCI) via the application of a computational model of flanker task performance.

Methods:: 39 patients diagnosed with MCI took part in the study and 41 healthy older adults (mean age = 57.32, 19 female). They performed the arrows flanker task with two flankers on each side. The shrinking spotlight model (SSP) model was fit using the flankr package in R.

Results:: The MCI patients performed worse on RT in accuracy on average and, specifically, in the incongruent flankers condition. Comparing the SSP parameters between groups revealed significant differences in the $\text{sd}_\alpha$ parameter which reflects the dispersion of attention distribution over the stimuli with wider attention dispersion in the pathological case.

Conclusions:: It is concluded that MCI characterized by more dispersed attention and more perceptual distractability as a consequence. Using computational models of cognitive tasks used in neuropsychological and neurological research in pathological aging.
Background and Aims:: Frailty, a clinical syndrome characterized by vulnerability to stressors resulting from multisystemic loss of physiological reserve, predicts future cognitive decline. However, little is known about whether frailty is associated with risk for dementia. The study aim was to determine the cross-sectional association of frailty with dementia risk in older Veterans.

Methods:: Community-dwelling Veterans ≥50 years completed a mailed socio-demographic questionnaire and Self-Administered Gerocognitive Examination (SAGE), July 2019-May 2020. The information was complemented with electronic health record data. We calculated the CAIDE score, a validated tool predicting dementia (≥6 points=high risk 20 years later) and the 31-item VA frailty index (VA-FI) data (frail>.20, non-frail≤.20). After adjusting for socio-demographic characteristics, smoking, alcohol/substance abuse, obstructive sleep apnea and anticholinergic use, odds ratio (OR) and 95% confidence intervals (CI) were calculated using binomial logistic regression to assess the association between frailty and dementia risk (CAIDE≥6 points and MCI).

Results:: The survey response rate was 19.75% (1,073 of 5,432). Participants mean age was 68.38(SD=8.49) years, 57.50% (n=617) Caucasian, 69.34% (n=744) non-Hispanic, 95.81% (n=1,028) male, and 36.72%(n=394) frail. 11.84%(n=127) screened positive for MCI and 15.38% (n=165) for dementia. 689 (75.88%) veterans were at high risk for dementia of whom 426 (61.83%) were non-frail and 263 (38.17%) were frail. Frailty was associated with higher risk for dementia, adjusted OR:1.45 (95%CI:1.016-2.070), p=.041.

Conclusions:: Frailty was cross-sectionally associated with higher risk for dementia in older Veterans. Early identification of patients with frailty can help in the implementation of interventions aimed at preventing or delaying dementia.
MEDIAL TEMPORAL LOBE ATROPHY, BUT NOT CSF BIOMARKERS, CORRELATES WITH COGNITIVE IMPAIRMENT IN ALZHEIMER’S DISEASE

Edoardo Barvas, Chiara Monaldini, Roberto Frusciante, Mirco Volpini, Beatrice Viti, Susanna Guttmann
San Marino State Hospital, Neurology Unit, Cailungo, San Marino

Background and Aims:: The reliability of cerebrospinal fluid (CSF) biomarkers in reflecting the rate of cognitive decline in patients with Alzheimer’s Disease (AD) is still controversial (Williams et al., 2011). Our study aimed to correlate CSF biomarkers, MTL atrophy, cerebral white matter disease, and cognitive performance in patients diagnosed with AD.

Methods:: We retrospectively analysed the data of 24 patients meeting the IWG-2 criteria for typical AD. We tested for correlations between CSF levels of biomarkers for AD (β1-42, t-Tau, p-Tau and combined ratios) and measures of medial temporal lobe atrophy (MTLA), white matter disease, and cognitive impairment (neuropsychological tests for memory, attention, executive functions, and visuo-constructive abilities).

Results:: No statistically significant correlations between CFS biomarkers and any cognitive measure was detected; MTLA correlated negatively with episodic memory tests; cerebral white matter disease correlated negatively with attention and executive functions measures. No statistically significant correlation between CFS biomarkers and the MTLA was detected.

Conclusions:: Our results confirm the widely accepted correlation between medial temporal lobe atrophy and episodic memory impairment and between cerebral white matter disease and attention-executive dysfunction. Conversely, no statistically significant correlation between CFS biomarkers and cognitive measures were detected. Our results show that CFS biomarkers, although effective in providing early disease detection, may not be reliable as indicators of disease severity.
INTEREST OF CEREBROSPINAL FLUID BIOMARKERS FOR PRODROMAL ALZHEIMER'S DISEASE DIAGNOSIS: ABOUT 4 CASES

Soreya Belarbi, Samira Makri Mokrane
EHS Ali Ait Idir, Neurology, Algiers, Algeria

Background and Aims:: Alzheimer’s disease (AD) is the main cause of dementias. It is characterized neuropathologically by senile plaques, mainly made up of beta-amyloid peptide aggregates (especially in its AB42 form) and neurofibrillary degeneration (DNF), the main constituent of which is the Tau protein, in its hyperphosphorylated form. The prodromal phase of AD in its typical form is manifested by impairment of episodic memory, without major repercussions on autonomy. Biologically, the accumulation of the Tau protein precedes the first symptoms from 10 to 15 years. Biomarkers of AD in the cerebrospinal fluid (CSF) accessible during the patient's lifetime can testify to Alzheimer's disease. Indeed, the current stake of the diagnosis of AD, is at the pre-dementia stage, in the perspective of the development of drugs likely to act on the etiology of the disease.

Methods:: All the patients underwent a neuropsychological evaluation, cerebral imaging, a biological assessment. CSF biomarkers were carried out in all cases with assay for the AB1-42 protein, the total Tau protein (T-Tau), the phosho Tau (P -Tau) as well as the calculation of the 'IAT1 (INNOTEST amyloid tau index) and AB42 / P-Tau, Tau / AB42 and P-Tau / AB42 ratios.

Results:: On the basis of the diagnostic criteria of the NIA-AA "National Institute of Aging-Alzheimer's Association", was retained in the 4 cases: - MCI due to AD with an intermediate probability: 1 case. - MCI due at AD with a high probability: 3 cases.

Conclusions:: We highlights the advantages of CSF biomarkers for predicting the risk of progression from MCI to AD.
THE TIRNA&TREF EXPRESSION IN APP/PS1 TRANSGENIC MICE AND THE CHANGE OF RELATED PROTEINS EXPRESSION

Honglin Lu¹, Lin Liu¹, Shu Han¹, Binbin Wang¹, Jin Qin¹, Kailin Bu¹, Yingzhen Zhang¹, Zhongzhong Li¹, Lina Ma¹, Jing Tian¹, Kun Zhang¹, Tong Li¹, Huixian Cui², Xiaoyun Liu¹
¹Second Hospital of Hebei Medical University, Neurology, Shijiazhuang, China, ²Hebei Medical University, Neurology, Shijiazhuang, China

Background and Aims:: Alzheimers’ disease (AD) was the major reason of dementia worldwide. Recently some researchers focused their attention on transcriptomics, such as the non-coding RNA, which include the tRNA derived fragments (tiRNA&tRF). tiRNA&tRF was a fragment produced by the tRNA split at specific sites. The expression of tiRNA&tRFs in AD has not been fully illustrated.

Methods:: We screened the differentially expressed tiRNA&tRF fragments with next sequencing technology between APP/PS1 mice (Alzheimer’s disease model) and the healthy control WT mice, then observed the possible biological functions regulated by tiRNA&tRFs in APP/PS1 mice.

Results:: A total of 27 tiRNA&tRFs were found differentially expressed between APP/PS1 mice-14 up-regulated and 13 down-regulated, among which the tRF-Thr-CGT-003 and tRF-Leu-CAA-004 were found to regulate the calcium regulation related proteins (the voltage gated calcium channel γ2 subunit and the RYR1 endoplasmic reticulum calcium released protein) and the retinol metabolism related proteins (the retinoic acid metabolic enzymes CYP2S1, CYP2C68, CYP2S1).

Conclusions:: In general, we had found the expression change of some tiRNA&tRFs in APP/PS1 mice, which may be closely connected with the amyloid β production, but whether the tiRNA&tRFs expression change was a direct cause of Aβ production or just a secondary change of Aβ production need further research. Besides, we found the tRFs took part in the voltage gated calcium channel γ2 subunit expression and regulation, influencing the neuron calcium hemostasis. Moreover, we also found the tRF also participated the regulation of retinol metabolism. The present study provides novel insights for future investigations to explore the AD related mechanisms.
DIGITAL DEVICE USAGE AND SUBJECTIVE MEMORY COMPLAINTS DURING COVID-19 PANDEMIC AMONG YOUNG ADULTS

Amit Mathur¹, Vikas Dhirav¹, Bhargavi Jadeja¹, Asmita Das²
¹Indian Council of Medical Research-NIIRNCD, Mental Health & Neurological Research, JODHPUR, India, ²Delhi Technological University, Biotechnology, New Delhi, India

Background and Aims:: Digital devices have potential mental health impact impairing cognitive abilities. Digital dementia refers to memory impairment related to use of digital devices. The use of digital gadgets has exponentially increased during pandemic times; this study was planned to find correlation between digital devices and subjective memory complaints.

Methods:: Structured questionnaire was shared online with study participants followed by cognitive assessment through Montreal Cognitive Assessment (MoCA), performed online. The responses were kept anonymous and their consent was taken digitally. A total of 50 subjects were chosen for online assessment of their cognition level via MoCA.

Results:: There were a total of 208 responses collected, distributed in a ratio of (M:F=107:101). The mean age of participants was (25.92±6.35 years). All participants were using smart phones and 204 participants (98.1%) were surfing internets using a mobile phone. Mean duration of mobile phone usage was 359.8±219 minutes per day. Mean duration of internet usage was 327±233 minutes per day. A total of 47.1% of participants felt ‘addiction’ to the internet and 52.4% participants agreed forgetfulness in their daily routine. A total of 21.4% participants related their forgetfulness to usage of digital devices. A total of 50 subjects were assessed online through MOCA with scores 26.14±2.55 (max score=30) with 28 (56%) participants had MoCA scores ≤26. Out of these 28, 18 (64%) subjects felt they were forgetful.

Conclusions:: Widespread digital devices usage during pandemic is probably affecting cognition levels among young adults as shown by significant number of participants who agreed subjective memory complaints in the current study.
MECHANISMS OF DEVELOPMENT OF COGNITIVE IMPAIRMENTS AFTER OCCLUSION OF CAROTID ARTERIES

Sergey M. Gulyaev
Institute of General and Experimental Biology, Siberian Branch, Russian Academy of Sciences, Laboratory Of Experimental Pharmacology, Ulan-Ude, Russian Federation

Background and Aims:: The study was aimed at determining the role of vascular endothelial dysfunction in induction of molecular and cellular mechanisms of the development of cognitive impairments after occlusion of common carotid arteries.

Methods:: The experiments were carried out on Wistar rats divided into groups: sham; rats with cerebral ischaemia-reperfusion. The model of cerebral ischaemia-reperfusion was reproduced by occlusion of common carotid arteries for 5 min. The degree of endothelial dysfunction was assessed by determining the amount of circulating endotheliocytes and concentration of nitrogen oxide in plasma. In the brain, we measured the content of malonic dialdehyde, the activity of superoxide dismutase and catalase. Pathomorphological studies of cerebral structures were carried out by means of light microscopy. Cognitive functions in rats were assessed by means of conditioned reaction of passive avoidance and the object recognition test.

Results:: Occlusion of carotid arteries in rats induced an increase in the level of circulating endotheliocytes and a decrease nitrogen oxide in plasma; the content of malonic dialdehyde in the brain increased 2.6-fold, the activity of superoxide dismutase and catalase decreased 5.9-fold and 2.8-fold, respectively. The findings of morphological examination registered signs of vasoconstrictive reactions, damaged neurons in the neocortex and hippocampus. It was determined that occlusion of carotid arteries in rats resulted in memory decline.

Conclusions:: Occlusion of carotid arteries in rats becomes a cause of endothelial dysfunction, damage of neurons in the neocortex, hippocampus and cognitive impairments. Damaging factors of the brain are intensification of oxidative processes and a decrease in the level of antioxidant defence.

This research was funded by the Ministry of Education and Science of Russia, grant number - 121030100227-7
AN UNUSUAL PRESENTATION OF MEMORY LOSS

Naveen Prabu Md Dm(Neuro)
Dhanalakshmi Srinivasan medical college hospital, Neurology, Perambalur, India

Background and Aims:: Multiple system atrophy (MSA) is a neuro-degenerative disease, pathologically characterized by α-synuclein (αSyn)-immunopositive glial cytoplasmic inclusions (GCI). Comparing to other synucleinopathies such as Parkinson’s disease (PD) or Dementia with Lewy body (DLB), MSA has not been characterized by dementia. However, recent studies reported that various types of cognitive impairments could be presented in MSA.1 We report a case of MSA with severe cognitive impairment that proceeded 6 years before cerebellar dysfunctions of MSA.

Methods:: 65 year old female presented to neurology op with complaints of giddiness with frequent falls, difficulty in walking, memory impairment. Known case of hypertension and diabetes on treatment. Initially patient diagnosed as dementia on treatment now they are not taking medication. On examination, conscious oriented walking with support, extraocular movements decreased.

Results:: MRI imaging revealed diffuse cerebellar atrophy, mammillary body atrophy with humming bird sign in midbrain, periventricular and white matter changes. Other investigation within normal limits.

Conclusions:: This patient had shown rapid progressions of memory impairment, behavioral changes and impairment in executive functions, and been diagnosed with dementia initially. Thereafter, cerebellar ataxia with dysautonomia and had occurred, and finally he was diagnosed with MSA-C. MSA is a neurodegenerative disease, which usually occurs sporadically in adults, older than 30 years. Typically it is presented with parkinsonism, cerebellar ataxia, dysautonomia and pyramidal dysfunction. Pathologically, neuronal cell loss, gliosis and αSyn-immunopositive GCI are observed in structures of striato-nigral pathway and olivo-ponto-cerebellar pathway. In this case MSA with dementia is rare. This case may suggest that the clinical diagnosis of MSA could not be excluded by the presence of dementia.
CAN SPORADIC CREUTZFELD-JAKOB DISEASE BE STRESS-TRIGGERED? – A CASE REPORT

Miguel Miranda, Fernando Pita, Cátia Carmona, Sandra Sousa
Hospital de Cascais Dr. José de Almeida, Department Of Neurology, Alcabideche, Portugal

Background and Aims:: Affecting many cerebral areas simultaneously, Creutzfeldt-Jakob disease (CJD) mimics several neurological and psychiatric conditions, especially in the earlier phases of the disease, thus representing a challenging diagnosis. Scarce scientific literature based upon laboratory and retrospective cohort studies, suggests the existence of a stress hypothesis explaining an eventual association between stress and CJD expression and progression.

Methods:: A case of a 62-year-old patient, diagnosed with CJD, with symptoms onset after a family conflict is presented.

Results:: A 62-year-old female patient was admitted at the emergency department due to a progressive neuropsychiatric disorder, characterized by abnormal behavior and gait apraxia. Symptoms had been first noticed by relatives 8 weeks earlier after an intense family conflict. A brain MRI did not reveal significant findings, supporting an initial diagnosis of depressive catatonia. The patient was transferred to a psychiatric ward, where she rapidly evolved to refractory convulsive status epilepticus and later coma. An EEG with generalized periodic triphasic complexes, a CSF 14-3-3 protein level superior to 80000AU/mL and a new MRI with cortical ribboning supported a diagnosis of CJD, with progression to death in 11 weeks after symptoms onset.

Conclusions:: Despite strict temporal relationship between symptoms onset and a stressful event, causality cannot be established. One may argue both events are only coincidental or that conflict itself might have been the result of the disease’s behavioral presentation. Further studies are needed to clarify the relationship between stress and CJD.
THE FUNCTIONAL ROLE OF CEREBELLUM IN VISUAL HALLUCINATIONS

Giovanni Zorzi\textsuperscript{1,2,3}, Diego Cecchin\textsuperscript{2,4}, Davide Poggiali\textsuperscript{2}, Maurizio Corbetta\textsuperscript{1,2}, Annachiara Cagnin\textsuperscript{2,5}

\textsuperscript{1}University of Padova, Departement Of Neuroscience, Padova, Italy, \textsuperscript{2}University of Padova, Padova Neuroscience Center, Padova, Italy, \textsuperscript{3}Ospedale San Camillo IRCCS, Ospedale San Camillo Irccs, Lido Venezia, Italy, \textsuperscript{4}University of Padua, Nuclear Medicine, Via Giustiniani, Italy, \textsuperscript{5}University of Padua, Department Of Neurosciences, Padova, Italy

\textbf{Background and Aims::} The role of the cerebellum in behavioral symptoms of dementia is still largely unknown. We explore cerebellar structural and metabolic correlates of visual hallucination in dementia-with-Lewy bodies (DLB)-related VH

\textbf{Methods::} Thirty-five subjects with a diagnosis of probable DLB (21 without-VH and 14 with-VH) matched for age and sex (69.4 ± 6.93 years and 72.8 ± 6.18 years, respectively) were studied with brain FDG-PET/MR integrated scan 3T. We used SUIT algorithm for segmentation and anatomical parcellation to extract cerebellar volumes. Partial volume correction was performed with an inhouse algorithm based on the Symmetric Geometric Transfer Matrix of PET data. Brainstem was used as reference region to obtain regional cerebellar standard uptake value ratios (SUVr). Analysis of variance controlled for eTIV was done for the comparison of each anatomical volume of the cerebellum and corresponding metabolic region, adding age and sex as covariate

\textbf{Results::} Hallucinators showed lower FDG-uptake values in the right and left lobule VI and IX and Crus I, in the left lobule VIIb and VIIIa (p<0.05). Greater severity of VH correlated with lower metabolism in the left and right lobule IX (\(\rho=-0.52\) and \(\rho=-0.54\) respectively, pcorr<0.005). As for the analysis of atrophy we found in hallucinators atrophy of right Crus I, lobule IX and X (puncorr<0.05) but the results
Conclusions:: Cerebellar lobule IX belongs to functional dorsal attention and default mode networks. This results highlight the functional contribution of cerebellum in VH as part of functional networks of goal oriented attention and default mode.
Background and Aims: A proportion of patients with neurodegenerative dementia (DLB, FTD or AD) present with treatment-resistant affective disorder or psychosis and diagnosis is a challenge. We study: the prevalence and type of neurodegenerative diseases among a sample of patients presenting with late-onset depression or psychosis followed longitudinally for two years and the cognitive differences between neurodegenerative diseases and PDD.

Methods: 63-subjects with a first time late-onset-psychiatric episode were prospectively enrolled at Neurology-Clinic-of-Padova-Hospital and Casa-di-Cura-Parco-dei-Tigli. All patients were neuropsychologically and clinically tested. An epidemiological analysis was performed evaluating the prevalence of psychiatric diagnosis at admission and the diagnosis after clinical evaluations/follow-up. We conduct a data driven analysis with principal component. We validate the results of the analysis with a subsample of patients that receive a biological diagnostic markers.

Results: Patients enrolled obtained the following psychiatric diagnoses: 32/56 major depression, 12/56 bipolar-disorder, 8/56 psychosis, 4/56 obsessive-compulsive disorders. About 50% of patients with major depression had cognitive deficits, about 15% of BD, about 100% of psychosis and 75% of OCD (CHI2=14.35, p<0.01). Overall, about 50% of patients have a cognitive decline. The multivariate analysis showed that psychotic patients are had worse cognitive performances respect to patients with affective disorders. Considering the final diagnosis, multivariate analysis showed different cognitive profile between AD/DLB patients and FTD/PDD.
Conclusions:: A late-onset psychiatric symptom masks a diagnosis at follow-up of neurodegenerative disease in about 50% of cases. We encourage a multidisciplinary evaluation in the assessment of late-onset psychiatric manifestations and suggest some clinical and cognitive red flags of help in the differential diagnosis.
Background and Aims:: Chronic cerebrovascular disease is progressive pathology with gradual development of cognitive disorders. In the treatment of cognitive disturbances, drugs with comprehensive antioxidant, angioprotective, neuroprotective and neurotrophic action are usually used. The present study is aimed at evaluating the effect of the multicomponent herbal extract on cognition disturbance after unilateral occlusion of common carotid artery in rats.

Methods:: The Wistar rats were divided into three groups: sham, ischemia and herbal extract. The model of cerebral ischaemia was induced by occlusion of the left common carotid artery. Group 3 received extract 100 mg/kg p.o. for 4 weeks after ischemia. The extract was obtained from of Crataegus sanguine Pall., Hippophae rhamnoides L., Rosa canina L., Scutellaria baicalensis Georgi, et other. Effects of extract on the spatial memory in rats were examined, using the 8-arm radial maze. Error of reference and working memory were used as indices of spatial memory deficits.

Results:: The rats subjected to occlusion of the left common carotid artery exhibited a significantly more number of working errors and reference errors in 8-radial maze test compared with sham (p≤0.05). The course introduction of extract limited the development of cognitive disorders. The 4-weeks regimen with extract significantly improved spatial memory impairments induced by ischemia in the 8-arm radial maze test (working and reference errors, p≤0.05).

Conclusions:: The use of the extract limits the development of cognitive impairments in rats with cerebral ischemia due to the multitarget effect of herbs combinations. Effective nutraceutical prophylaxis can be explored as a approach to reduce the cognitive disturbances.

This research was funded by the Ministry of Education and Science of Russia, grant number - 121030100227-7.
Background and Aims:: Post-stroke dementia includes all dementias that appear following a cerebral infarction within a period of 3 months to 3 years. They are mainly represented by Alzheimer's dementia, whose preclinical phase is shortened by stroke. Vascular dementia represents 19 to 60% of post-stroke dementias depending on the diagnostic criteria used in the studies.

Methods:: We report the case of a 42-year-old female patient, with a history of arterial hypertension, hypercholesterolemia and ischemic stroke at the age of 36, manifested by a left hemiparesis with facial involvement, who presented cognitive and psychocomportemental disorders with a repercussion on the activities of daily life. The neurological examination revealed a left hemiparesis with brachiofacial predominance. The brain MRI revealed areas of hyperintensity on T2 Flair, T2 and T2* gradient echo, reaching the supratentorial white matter. We performed the following paraclinical evaluation: Neuropsychological evaluation: MMSE "Mini Mental State Examination", FAB "frontal Assessment Battery", ISAACS Set Test, Reflexive praxis, Dubois 5-Word Test, Digit span task, Clock Test, Hachinski Score and Instrumental Activities of Daily Living. Etiological assessment of stroke: Cardio vascular assessment, lumbar puncture, HLA B51 typing, Retinal angiography, Biopsy of the salivary glands, Autoimmune check-up, Inflammatory check-up, Standard biological check-up, Thyroid check-up and serologies (HIV, TPHA, VDRL, HBS, HCV,..), Thrombosis workup (protein C, protein S, antithrombin III, protein C resistance), ....

Results:: Patient has vascular dementia secondary to hereditary thrombophilia due to partial protein C deficiency.

Conclusions:: Once protein C deficiency is detected, family investigation should be performed to prevent the occurrence of ischemic stroke.
RESTORATION OF COGNITIVE FUNCTION BY HUMAN NEURAL STEM CELLS AND MICROGLIAL CELLS ENCODING FUNCTIONAL GENES IN ALZHEIMER DISEASE MICE

Sumin Cho
Chungbuk National University, Veterinary Medicine, Cheongju, Korea, Republic of

Background and Aims:: In Alzheimer’s disease patients, amyloid β peptide-mediated degeneration of cholinergic system utilizing acetylcholine for memory acquisition is observed. Since AD therapy using acetylcholinesterase inhibitors are only palliative for memory deficits without reversing disease progress, there is a need for effective therapies, and cell-based therapeutic approaches should fulfill this requirement.

Methods:: We established F3.ChAT human neural stem cells encoding choline acetyltransferase gene, an ACh-synthesizing enzyme, HMO6.NEP human microglial cells encoding neprilysin gene, an Aβ-degrading enzyme, and HMO6.SRA cells encoding scavenger receptor gene, an Aβ-uptaking enzyme. As an AD model, AF64A was selected to induce ACh depletion and cognitive dysfunction. The established NSCs and microglial cells alone or in combination were transplanted to the AD mice, and analyzed for biochemical, immunohistochemical, and neurobehavioral parameters.

Results:: Intracerebroventricular injection of AF64A induced Aβ accumulation, ACh depletion, and cognitive dysfunction of mice. ICV transplantation of NSCs and microglial cells were found to survive up to 4 weeks in the mouse brain and expressed their functional genes. Treatment with the NSCs and microglial cells encoding each functional gene restored the learning and memory function of AF64A-challenged mice by eliminating Aβ deposits and recovering ACh level. The cells also attenuated inflammatory astrocytic response by reducing Aβ accumulation. Furthermore, higher efficacies were obtained by combinational treatments of F3.ChAT and HMO6.NEP or HMO6.SRA cells.

Conclusions:: Taken together, it is expected that NSCs and microglial cells over-expressing ChAT, NEP or SRA genes could be candidates for replacement cell therapy of AD, and that their combinational treatments should be a good strategy for an enhanced effectiveness.
VISUAL RATING SCALE FOR ASSESSMENT OF THE CINGULATE ISLAND SIGN IN THE DIFFERENTIAL DIAGNOSIS OF DEMENTIA WITH LEWY BODIES AND ALZHEIMER DISEASE

Gianmarco Gazzola¹, Giovanni Zorzi¹, Martina Visonà¹, Cinzia Bussè¹, Stefano Mozzetta², Francesco Rossato³, Stefano Crivellani³, Diego Cecchin⁴,⁵, Annachiara Cagnin⁶
¹University of Padua, Department Of Neurosciences, Padua, Italy, ²University of Padua, Neurosciences, Padua, Italy, ³Neurology Clinic, Department Of Neuroscience, Padova, Italy, ⁴University of Padua, Nuclear Medicine, Via Giustiniani, Italy, ⁵University of Padova, Padova Neuroscience Center, Padova, Italy, ⁶University of Padua, Department Of Neurosciences, Padova, Italy

Background and Aims:: Typical brain 18-FDG PET findings in DLB consist on reduced occipital metabolism and the presence of cingulate island sign (CIS), defined by a relative preservation of the metabolism in the posterior cingulate cortex (PCC) compared with the precuneus and cuneus. We aimed to assess the utility of a semiquantitative CIS score on the differential diagnosis between DLB and AD.

Methods:: A neurologist blinded to the clinical diagnosis assessed the presence of hypometabolism in PCC, precuneus, and cuneus and thus the presence of CIS was rated as: 0 = absent; 1 = intermediate; 2 = present. The ratings from each hemisphere were summed to a visual CIS score (0-4).

Results:: 30 patients with AD (19 typical and 11 atypical, including 6 visuo-spatial variant), and 39 patients with DLB were analyzed. The mean CIS score was 0.4±0.8 for AD and 1.46±1.59 for DLB (p=0.002). CIS score 3 and 4 were found in 12 DLB and 1 AD (visuospatial variant). CIS score 0 was found in 17 DLB and 23 AD. With a defined cut-off CIS score >=2, sensitivity and specificity were 0.56 and 0.77, respectively. 6/17 of DLB with CIS 0 were in the very early stage of the disease, and 4 have concomitant posterior cingulate and precuneus hypometabolism.

Conclusions:: Visual rating of PET-CIS could differentiate DLB from AD at the higher values of the scale (CIS 3-4). Low sensitivity is expected in the early stage of the disease and in the comorbid DLB/AD cases. Atypical posterior variant of AD may have intermediate/high CIS scores.
FRONTOTEMPORAL RIGHT PREDOMINANT HYPOMETABOLISM IN BVFTD IS NOT FREQUENT AND ASSOCIATED WITH MORE SEVERE TEMPORAL ATROPHY

Stefano Mozzetta¹, Matteo De Nadai¹, Cinzia Bussè¹, Stefano Crivellari¹, Gianmarco Gazzola¹, Francesco Rossato¹, Diego Cecchin², Giovanni Zorzi¹, Annachiara Cagnin¹
¹University of Padua, Neurosciences, Padua, Italy, ²University of Padua, Nuclear Medicine, Via Giustiniani, Italy

Background and Aims:: Prosopagnosia, memory deficits and behavioural changes has recently proposed as the core symptoms of a further variant of frontotemporal dementia, associated with right temporal atrophy or hypometabolism and named right temporal variant (rtvFTD). Aim of the study was to evaluate frequency and clinical characteristics of patients with prevalent fronto and/or temporal right atrophy/hypometabolism.

Methods:: We revised clinical charts and neuroimaging of 52 bvFTD patients. Inclusion criteria were a diagnosis of probable bvFTD according to established criteria, presence of brain MRI and FDG-PET, full clinical history and cognitive assessment. All patients underwent neuropsychological evaluations, Neuropsychiatric Inventor (NPI) and Stereotypes rating inventory (SRI) questionnaires. Genetic analysis was assessed for all patients. Atrophy and vascular load were assessed using dedicated scales and brain hypometabolism was qualitatively evaluated on a scale from 0 to 3. Asymmetry was assigned for each lobe considering the highest values at the PET scan.

Results:: No-one patient had isolated right temporal atrophy/hypometabolism. 5 patients showed prevalent right temporal and frontal changes, 5 only frontal hypometabolism, versus 23 patients with prevalent left frontotemporal involvement. Cognitive and behavioural variables were similar between right, left or symmetric frontotemporal involvement a part from a worse memory for the left-side group. Onset with language disturbances was more frequent in left side patients. History of psychiatric disturbances was more frequent in symmetrically distributed neuroimaging abnormalities. Patients with right variant had the highest level of right and left medial temporal lobe atrophy at MRI.

Conclusions:: Prevalent right asymmetric brain dysfunction among bvFTD patients did not characterized specific phenotypes.
THE THERAPEUTIC EFFECTS OF EXERCISE ON THE COGNITIVE AND PHYSICAL FUNCTION OF PATIENTS WITH DEMENTIA

Vasileios Papatsimpas¹, Daphne Bakalidou¹, Marianna Papadopoulou², Sotiria Vrouva¹, George Papathanasiou²
¹University of West Attica, Physiotherapy Department, Egaleo, Greece, ²University of West Attica, Physiotherapy Department, Egaleo, Greece

Background and Aims:: Background and aims: Dementia is characterized by a decrease in cognitive and physical functions. Unlike in previous years, there is more interest in the role of exercise as a treatment strategy for people with dementia. The aim of this study is to investigate the effect of different types of exercise and its parameters on cognitive and physical function in patients with dementia.

Methods:: This is a study (hybrid narrative review), which includes almost all the steps of a systematic research but it is not included meta-analysis. The articles were selected through various sources such as PubMed / Medline, Scopus and Google scholar and according to additional criteria.

Results:: Were included fourteen studies with two (2) types of exercise. Aerobic exercise and mixed interventions have been studied more, while resistance interventions have been less studied. Both of the types of exercises have shown positive effects. Patients with dementia participating in aerobic exercise improved their aerobic ability and it seems to be related to changes in cognitive, neuropsychiatric symptoms and instrumental activities of daily life. Mixed exercise improved cognitive and physical function more effective than aerobic exercise alone.

Conclusions:: Conclusions: Exercise may help maintain or improve cognitive and physical function in patients with dementia but additional study is needed to clarify optimal intervention and established guidelines.
AMELIORATION OF COGNITIVE IMPAIRMENT AND NEURODEGENERATION BY NEW GENERATION PDE5 INHIBITOR IN STREPTOZOTOCIN-INDUCED EXPERIMENTAL DEMENTIA IN RATS

Jigna Shah, Srijan Mishra
Institute of Pharmacy, Department Of Pharmacology, Ahmedabad, India

Background and Aims: Background and Aim: Alzheimer’s disease is a neurodegenerative disorder that primarily depletes memory and other important mental functions. Studies reveal that PDE5 inhibitors (PDE5I) are capable of crossing Blood Brain Barrier and causes no disruption or damage. Recent studies indicates that PDE5 inhibitors can restore memory function in AD as well as non-AD models. The present study was designed to evaluate the neuropharmacological effects and mechanism of action of PDE5 inhibitor against Streptozotocin induced cognitive deficit in
Methods: Rats were pre-treated with different doses of PDE5I orally once daily for 21 days and then Alzheimer's disease was induced in the rats by bilateral ICV intracerebroventricular (ICV) administration of streptozotocin (STZ) (3mg/kg body weight) into the hippocampal region of the brain. Neurobehavioral parameters like Morris water maze test, Conditioned avoidance, Novel object recognition, Modified Y-maze, Fear conditioning, Resident-intruder aggression were assessed in the starting, at the mid and at the end of treatment. AchE activity, APP gene expression and antioxidant
parameters were studied. Histological examination of brain tissue was performed to detect presence of amyloid-beta plaques or tau protein.

**Results:** PDE5 inhibitor successfully attenuated the oxidative stress and averted the memory loss. AchE expression was decreased in ICV-STZ group and PDE5I pre-treatment improved the expression of AchE. Besides, inflammatory markers like Interleukin-6 and TNF-alpha levels were significantly reduced by PDE5I pre-treatment.

**Conclusions:** Conclusion: Our data is suggestive of promising role of PDE5I in preventing memory loss, ameliorating the oxidative stress and might be beneficial for the treatment of Alzheimer's disease.
MILD COGNITIVE IMPAIRMENT (MCI): EVOLUTIONARY DIVERSITIES IN 40 PATIENTS. AN ALGERIAN STUDY.

Mohamed Islam Kediha, Farida Mostefaoui, Lamia Ali Pacha
Medical school of Algiers, Neurology, ALGIERS, Algeria

Background and Aims:: Patients with MCI have a memory complaint with preserved autonomy. Nevertheless, this memory impairment remains inferior in comparison with the memory of a healthy subject of the same age. Several evolutionary nosological frameworks are possible: from normal cognitive ageing, through the so-called stable MCI, to dementia (in unstable MCI). The aim is to give the clinical and evolutionary characteristics of a sample of an Algerian population of 40 patients with an MCI phenotype and followed for a minimum of 5 years.

Methods:: Retrospective study with analysis of demographic data, measurement of cognitive functions at the time of diagnosis and on several occasions during the evolutionary follow-up. A detailed neurological examination as well as an exhaustive paraclinical assessment (biological and radiological) were also performed. 6 patients underwent a lumbar puncture with study of the biomarkers of Alzheimer’s disease.

Results:: Among the 40 patients studied, 11 (27.5%) had a stable, non-progressive MCI. 13 patients (32.5%) had an unstable form that evolved into dementia. In addition, 8 patients (20%) had normal cognitive ageing, 3 ones (7.5%) developed a depressive syndrome and 3 (7.5%) had a vascular form. 1 patient (2.5%) had a vitamin B12 deficiency and 1 patient (2.5%) a probable para-neoplastic form associated with Hashimoto's autoimmune thyroiditis.

Conclusions:: The results of this Algerian series demonstrate the heterogeneity of the evolution of MCI patients, and raise the interest of early diagnosis of possible other clinical signs (other cognitive domains) and/or biological signs (positive biomarkers) that may be precursors of dementia and already present at the MCI stage.
Background and Aims:: Background: Epilepsy is a well-known neurological disorder. Seizure severity emerges as an important aspect of epilepsy. The severity of seizures depends on many factors which can affect the patient's disease control and management. Aims: To assess seizure severity among patients with epilepsy attending Daoud charity clinic.

Methods:: A descriptive clinic based cross sectional study was performed using seizure severity assessment scale. 99 patients with epilepsy who attend Daoud charity clinic were included in the study between the period of 2019 to 2020.

Results:: Out of 99 patients, 66 (66.7%) were females and 33 (33.3%) were male. The most common age of the patients ranges from 15 to 31 years (67.7%). Almost 75 of the participants have generalize epilepsy (generalized tonic colonic (69.7%), myoclonus (3%), absence (3%)). 24 had focal epilepsy (21(21.1%) focal with impairment and 3(3%) focal without impairment). The patients who participated in the study had the following seizures severity assessment, very mild seizures (7.7%), moderate mild seizures (3%), mild seizures (11.1%), moderate seizures (6.1%), moderate severe seizures (19.2%), severe seizures (14.1%) and very severe seizures (18.2%).

Conclusions:: The study showed that epileptic seizures have different degrees of severity, and can be classified according to their severity. This type of classification can help a lot in the process of treatment, and taking into consideration different psychological issues in corresponding with the severity of seizures.
ANTIEPILEPTICS' DRUG RESPONSE AND SCN2A MUTATIONS IN SUDANESE PATIENTS WITH IDIOPATHIC EPILEPSY.

Rasha Elhassan¹, Hussein Diab², Abdalla Khwad³, Alsadig Gasoum⁴, Sawsan Aldeef⁴, Salma Elhassan⁴, Ghada Elhassan⁵
¹Alneelain university, Clinical Pharmacology, khartoum, Sudan, ²Daoud research group, Medicine, Khartoum, Sudan, ³university of medical science and technology, Postgraduate Colleague, khartoum, Sudan, ⁴National Center for Neurological Science (NCNS), Labrotary Cebter, kartoum, Sudan, ⁵Alneelain university, Pediatric, kartoum, Sudan

Background and Aims:: Sodium channel blockers are widely used for epilepsy in Sudan however some patients don’t respond to them. Since SCN2A mutations have a role in idiopathic epilepsy why does resistance develop? Aim: To detect SCN2A mutations and study their relation to Antiepileptic drug response.

Methods:: 28 patients from the National Center for Neurological Science (NCNS) and 71 from prof Doud clinic were selected during the period between September /2016 and February /2019. Their genetic profiles were investigated by ABGI sequencing and different bioinformatics soft-wares (blast NCBI, Bioedit software, mutation taster, and chimera software version 1.14.

Results:: These frameshift mutations at exon 2 near to the N –terminal mutations were detected: I25Ifs*68, E26nfs*67, and A23Ifs*70. They lead to change in the protein structure, and affect the drug-receptor binding. The last one was unique because it was detected in poor drug response patient and was not found even in his brother genetic profile (who have the same class of seizure but respond well to treatment) it may be behind the reduction in drug response, the mutation modifies the non-reactive Alanine to Leucine. It is a truncated protein mutation that will reduce the number of Na channels affecting drug-receptor binding.

Conclusions:: Since sodium channel blockers are the commonly used antiepileptic's in Sudan, there is a strong need to identify patients with SCN2A defect to modify their modality of treatments.
CLINICAL PREDICTORS FOR ANTIEPILEPTIC’S DRUG RESPONSE AMONG IDIOPATHIC EPILEPSY PATIENTS IN SUDAN

Rasha Elhassan¹, Hussein Diab², Abdalla Khwad³, Ghada Elhassan⁴, Salma Elhassan⁵, Alsadig Gasoum⁵, Sawsan Aldeef⁶, Sanna Abdulaziz⁵
¹Alneelain university, Clinical Pharmacology, khartoum, Sudan, ²Daoud research groub, Medicine, Khartoum, Sudan, ³university of medical science and technology, Postgraduate Colleague, khartoum, Sudan, ⁴Alneelain university, Pediatric, khartoum, Sudan, ⁵National Center for Neurological Science (NCNS), Labotary Cebter, khartoum, Sudan

Background and Aims:: Epilepsy was documented firstly by prof Daoud Mustafa (peace upon him) and prof Basheer Arbab in 1961 as a case report. This was followed by studing its clinical presentation, its pattern, treatment safty and efficacy ended with working through refractory epilepsy in tertiary center. AIM : To identify the clinical prognostic factors of idiopathic epilepsy among Sudanese patients.

Methods:: there were 71 patients with idiopathic epilepsy recruited from Prof Daud clinic , Osman Saleh Center, Omdurman, Khartoum state, Sudan; and 28 patients from NCNC ,Ibrahim Malik hospital, Khartoum between August 2016 and February 2019. Their demographic data, seizure characteristics, drugs, and concomitant conditions were recorded in dc-hoc forms. The data was analysed using excel and SPSS program .

Results:: over all response to treatment was good in 89%. This response was associated insignificantly with age group above 65 years, focal seizure, duration less than 5 years, or mono-therapy while frequency of seizure pretreatment and good response to first regiment has significant statistical response.

Conclusions:: There was good response to treatment especially if there was low seizure frequency before the intiation of treatment, and the patient respond well to the first treatment regimen.
Background and Aims:: Acute symptomatic seizures (ASS) are defined as clinical seizures that occur in an acute temporal relationship with the central nervous system (CNS). It is possibly due to several acute conditions. This study aims to describe profile of patients with acute symptomatic seizures.

Methods:: This is a descriptive cross sectional study of ASS patients in neurology ward of Moehammad Hoesin Hospital, 1 April-31 June 2019. A sample was patients >= 18 years old, experienced seizures that was provoked by acute conditions and EEG was performed before 7 days after seizure.

Results:: There were 62 samples. Most were women (56.45%). The highest age range is 40-69 years (64.52%). It is because the incidence of ASS increases progressively after 35 years old and for ASS with stroke especially increases in the 50-69 year age group. The most common type of seizure was general tonic clonic (37.10%). Most etiology was vascular (41.93%) then malignancy and other causes. Most of the EEG result were slowing (26%). Normal EEG were 30.64%, but not all of them had good clinical outcomes or no sequelae. Only 2 people who died with the etiology of stroke and sepsis. Both EEG are slowing with epileptiform discharge.

Conclusions:: The incidence of ASS increases in older age group as the incidence of acute underlying disease increases. The clinical outcome is determined by the severity of acute condition present. It may be because increased glutamate and aspartate during a brain injury trigger a seizure.
EEG RESTING-STATE NETWORK AND FUNCTIONAL CONNECTIVITY ANALYSIS IN SUBJECTS WITH PSYCHOGENIC NON-EPILEPTIC SEIZURES

Giovanni Mastroianni¹, Sara Gasparini², Giuseppe Varone¹, Edoardo Ferlazzo¹, Michele Ascoli¹, Sabrina Neri³, Concetta Lobianco³, Anna Mammi³, Valentina Bova², Vittoria Cianci², Umberto Aguglia⁴
¹Regional Epilepsy Center, Neurology Unit - Gom, Reggio Calabria, Italy, ²Regional Epilepsy Center, Neurology Unit, Reggio Calabria, Italy, ³Magna Graecia University, Department Of Medical And Surgical Sciences, Catanzaro, Italy, ⁴Magna Graecia University of Catanzaro, Regional Epilepsy Unit, Medical And Surgical Sciences, Reggio Calabria, Italy

Background and Aims:: Psychogenic non-epileptic seizures (PNES) are hypothesized to be related to functional brain network abnormalities.

Methods:: To test this hypothesis, we used an approach based on power spectral density (PSD) and graph theory to study whole-head surface connectivity by resting-state electroencephalography (EEG) of 20 participants with PNES and 19 unaffected controls. We also investigated synchronism between pairs of EEG electrodes and between inter-hemispheric brain areas using the phase lag index to develop readable synchronization bi-dimensional maps for an objective overview of changes in functional connectivity associated with scattered cortical abnormalities.

Results:: Compared with controls, participants with PNES showed some changes in the power spectral distribution, with notable alteration in the frontal lobe, a lateromedial trend in the delta and theta bands (p=0.002), and significant changes in the right central/left parietal regions in the alpha and beta (p=0.002) ranges. Participants with PNES also showed widespread changes in network metrics compared with controls, including decreased global efficiency, increased cluster coefficients, and shorter path lengths compared to controls.

Conclusions:: Our results suggest that PNES is associated with decreased prefrontal and parietal synchronization, possibly reflecting dysfunction of networks within these regions.
Background and Aims:: Epilepsy therapy is always chronic and often uses more than one drug. Almost 80% of patients experience adverse effects. It is a major cause of failure of treatment. This study aims to describe the adverse effects of antiepileptic drugs (AED) at neurology clinic, Muhammad Hoesin Hospital.

Methods:: This is a descriptive analytic study between 1 October to 31 December 2020. Inclusion criterias were epilepsy patients aged ≥ 18 years who have taken certain AED and same dose in the last 1 month. Data collected using the Liverpool adverse effect profile and the Naranjo questionnaire.

Results:: Of the 41 subjects, 30 patients (73.2%) experienced AED adverse effects. Most of patients had no more seizures (70.7%) and had consumed AED for ≥12 months (56.1%). Subjects with monotherapy were 48.8% and the most using phenytoin. The most polytherapy combinations were phenytoin and valproic acid. Subjects who used polytherapy experienced adverse effects were 85.7% and had a 1.43 times greater risk of adverse effects than monotherapy. The number of AED has a significant effect on side effects occurrence, both in bivariate (p 0.031) and multivariate analysis (p 0.038 OR 4.90 CI 95%). Common adverse effects include memory problems, drowsiness, difficulty concentrating, fatigue, and irritability. This is related to the most widely used AED, namely phenytoin, valproic acid, levetiracetam, and carbamazepine.

Conclusions:: Patients who used polytherapy experienced adverse effects had 1.43 times greater risk than monotherapy. Common adverse effect was memory problems.
COMPARING EPILEPSY TO PSYCHOGENIC NON-EPILEPTIC SEIZURES, IDENTIFICATION OF RISK FACTORS: A RETROSPECTIVE CASE-CONTROL STUDY

Richard Ho¹, Rachel Gorenflo¹, Jason Viereck², Catherine Mitchell², Enrique Carrazana², Kore Liow¹,², Arash Ghaffari-Rafi¹,²
¹University of Hawai’i at Mānoa, John A. Burns School Of Medicine, Honolulu, United States of America, ²Hawaii Pacific Neuroscience, Clinical Research Center, Honolulu, United States of America

Background and Aims:: Psychogenic Non-epileptic seizures (PNES) are commonly misdiagnosed as epilepsy. Approximately 20% of patients sent to epilepsy centers for intractable seizures were later confirmed with PNES, resulting in incorrect treatment and medical cost. The objective of this case-controlled study is to identify factors associated with the development of PNES.

Methods:: A retrospective case-control study was conducted at a Hawaii epilepsy center from 2014-2020. 101 patients with PNES were identified. Patients' socioeconomic and biopsychosocial co-morbidities were recorded. Four epilepsy patients were randomly selected per each PNES patient comparison. Statistical analysis was performed using univariant nonparametric tests, and multivariable logistic regression.

Results:: Odds of PNES in females was 2.34 (p=0.00046). Median age in PNES was 43 (30, 54) and 51 (33, 66) in epilepsy, p=0.00037. Medium household income in PNES was 77188 (59284, 100311), and 82742 (70110, 100311) in epilepsy, p=0.024. Statistically significant psychiatric variables: illicit drug use (p=0.00017), anxiety (p=9.39*10^-14), depression (p=7.76*10^-7), PTSD (p=5.44*10^-7), ADHD (p=0.030), and bipolar disorder (p=0.0089). Statically significant biological factors: median BMI (p=0.051), history of stroke (p=0.028), history of TBI (p=0.030), asthma (p=3.29*10^-5), migraines (p=7.18*10^-7), and chronic pain (p=0.013). Multivariable logistic regression identified the strongest predictors of PNES: females (p=0.026), drug use (p=0.014), anxiety (p=2.93*10^-5), PTSD (p=0.024), BMI (p=0.020), and traumatic brain injury (p=0.052).

Conclusions:: PNES patients are predominantly female, eight years younger, and have lower income. They have higher odds of psychiatric factors: illicit drug use, anxiety, depression, PTSD, ADHD, and bipolar disorder; and higher BMI and odds of certain biological factors: stroke, traumatic brain injury, asthma, migraines, and chronic pain.
AN ALGORITHM FOR CALCULATING KETOGENIC DIET PARENTERAL NUTRITION IN REFRACTORY EPILEPSY

Ya Zeng, Jie Mu
West China Hospital, Sichuan University, Neurology, chengdu, China

Background and Aims:: Refractory epilepsy is the most prevalent neurologic condition with significant morbidity and economic burden. Ketogenic diet parenteral nutrition (KD-PN) was a considerable choice for them when enteral feeding is limited temporarily. Objective was to create a computer based algorithm for accurate component calculating, with the aim to help doctors to tailor the dietary prescription

Methods:: The computer-based algorithm based on ESPGHAN/ESPEN/ASPEN guidelines and optimal clinical management of KD/KD-PN mainly. Summarize the formulas of energy, fluid, protein, lipid, carbohydrates, electrolytes, vitamins, and trace elements. relevant parameters include height, weight, age, gender, and VCO2 (if mechanically ventilated), etc. Conclude the specification, concentration, calorie, osmolar of each parenteral nutrition (PN) by instructions, parameter is volume. Edit formulas and parameters into Excel

Results:: The computer-based algorithm of energy (kcal/d) was calculated by formula 8.19×VCO2 (ml/min) or weight-based formula 20–65×weight(kg). The amino acids intake of 0.6–2.0 g/kg/d was considered for most patients, it was mainly affected by different phases of disease and age. Fat-intake not exceeding 4 g/kg/d. Reduced supply of carbohydrate is limited by the quantity of protein and lipids. the intake of electrolytes, vitamins and trace elements mainly affected by age and weight. The detailed dates of each PN, diet ratio, osmolar, etc were determined by the datas above.

Conclusions:: we provides a new computer based algorithm for accurate component calculating, with the aim to help doctors to tailor the dietary prescription of KD-PN according to individual PN needs.
LATE ONSET EPILEPSY IN CEREBRAL AMYLOID ANGIOPATHY PATIENTS: A CASE CONTROL STUDY

Michele Ascoli¹, Sara Gasparini¹, Anna Mammì¹, Edoardo Ferlazzo¹, Giovanni Mastroianni², Vittoria Cianci², Valentina Bova², Sabrina Neri², Concetta Lobianco², Emilio Africa³, Luciano Frosina³, Paolo Versace³, Antonella Concerto³, Antonio Armentano³, Umberto Aguglia¹

¹Magna Graecia University, Department Of Medical And Surgical Sciences, Catanzaro, Italy, ²Regional Epilepsy Center, Neurology Unit - Gom, Reggio Calabria, Italy, ³Neuroradiology Unit, Gom, Reggio Calabria, Italy

Background and Aims:: Sporadic cerebral amyloid angiopathy (CAA) is characterized by amyloid deposition in the walls of leptomeningeal and cortical arteries, arterioles of the central nervous system. To date, epileptic seizures at CAA onset have rarely been reported and its prevalence is unknown. In reason of the high frequency of CAA in the elderly population and of the expected epileptogenic role of cortical hemorrhagic lesions, it may be hypothesized that CAA can explain a proportion of late-onset epilepsies with unknown etiology. This study aims to assess the possible correlation between CAA and late onset (>55 years) epilepsy.

Methods:: We have consecutively included patients with late-onset epilepsy (defined as seizure onset after 55 years) and age-matched controls who underwent brain MRI for reasons different from epileptic seizures. All subjects underwent 1.5 Tesla MRI including: axial T1-weighted, T2-weighted, 3D fluid-attenuated inversion recovery (FLAIR), DWI images, Gradient-echo and/or SWI images. In patients with epilepsy, MRI has to be performed within 30 days from epilepsy onset. In order to evaluate differences between groups, Chi-squared test is performed.

Results:: To date, we have included 20 patients with late onset epilepsy (15 males, mean age 73 ± 8 years) and 44 age-matched controls (15 males, mean age 69 ± 8 years). CAA is significantly more frequent (p=0.01) in patients with late onset epilepsy (4/20) than in controls (1/44).

Conclusions:: These preliminary data demonstrate that CAA is more frequent in patients with late onset epilepsy than in age-matched controls.
ENHANCING MEMORY AND QUALITY OF LIFE THROUGH NOVEL HOME-BASED NEUROPSYCHOLOGICAL REHABILITATION FOR EPILEPSY: A RANDOMIZED CONTROLLED TRIAL

Shivani Sharma1, Ashima Nehra1, Manjari Tripathi2, P Sarat Chandra3, Ravindra Pandey4
1All India Institute of Medical Sciences, Neuropsychology, Neurosciences Centre, New Delhi, India, 2All India Institute of Medical Sciences, Neurology, New Delhi, India, 3All India Institute of Medical Sciences, Neurosurgery, New Delhi, India, 4All India Institute of Medical Sciences, Biostatistics, New Delhi, India

Background and Aims:: Memory impairment in epilepsy is a critical determinant of Quality of Life (QoL). Subjective complaints may reflect depression. 6-week home based Neuropsychological Rehabilitation (NR) program was developed for patients with Drug Refractory Epilepsy (DRE) [Post-Operative (PO) & Not Cleared for Surgery (NCS)]. This includes psychoeducation, compensatory training and cognitive retraining aimed at improving memory. Neuropsychological outcomes were studied.

Methods:: 27 adults with DRE were recruited in a single blind RCT (CTRI/2019/10/021777) with 14 patients in the Intervention (IG) (PO=13, NCS=1), and 13 in the Treatment As Usual (TAU) (PO=11, NCS=2) groups. They were aged 18-45 years with minimum primary level of education, IQ > 80 and available primary caregiver. Pre-post neuropsychological assessment included Auditory Verbal Learning Test, Everyday Memory Questionnaire (EMQ), Hamilton Depression Inventory and Quality of Life in Epilepsy-31. Due to COVID-19, a booster session (focused on internal & external aids) was given at 3 months and all follow-ups were done through tele-assessment at 6 months.

Results:: At baseline, there was no significant difference between the groups on objective and subjective measures. Linear regression analysis post adjustment for depression at follow-up revealed a significant difference between the groups on objective cognitive measures of learning (p=0.019), delayed recall (p=0.003), retention (p=0.045) with IG showing higher performance. Similar results were noted for subjective measures of EMQ (p=0.001) and cognitive (p=0.001), seizure freedom (p=0.030), overall QoL (p=0.046) subdomains of QoL with its total score (p<0.001).

Conclusions:: Despite depression, IG reported higher performance on objective tests, lower subjective complaints and better QoL at long term follow-up.
THE STUDY PSYCHOLOGICAL STATUS IN EPILEPTIC PATIENTS WITH DIFFERENT EEG LOCALIZATION OF PAROXYSMAL ACTIVITY

Alexander Ugnenko, Olga Yakunina, Ekaterina Korsakova, Natalya Sivakova, Alexandra Trushkina, Natalya Shova, Vladimir Mikhailov
FEDERAL STATE BUDGETARY INSTITUTION V. M. BEKHTEREV NATIONAL RESEARCH MEDICAL CENTER FOR PSYCHIATRY AND NEUROLOGY OF THE RUSSIAN FEDERATION MINISTRY OF HEALTH, Department Of Epilepsy Treatment, Saint-Petersberg, Russian Federation

Background and Aims:: The study of the cognitive, emotional-behavioral characteristics in adults patients with epilepsy (PE) with different lateralization of EEG paroxysmal activity (PA).

Methods:: 79 PE were examined, all underwent of EEG. Groups were distinguished: 1st - PA in the right hemisphere (38 PE), 2nd - PA in the left hemisphere (41 PE). Cognitive, emotional-behavioral spheres are studied using the battery of psychological techniques.

Results:: Cognitive-sphere: 1st group - instability of attention, errors in the digital proofreading sample-26.6, reduced scale assessment “Encryption” of the Wexler-7.7, 2nd group - 22.5 and 9.0, respectively (p<0.5). Emotional-behavioral: 2nd group are prone to polar emotional response, the “Activity” factor of the “SDF” - 3.3, the impulsivity scale of the MMPI-method - 65.6, in 1st group 1.5 and 70.2, respectively. In the 1st group, there is a reliable correlation between the indicators of the impulsivity and anxiety scale of the MMPI (r = 0.46, p≤0.05). The 2nd group choose non-adaptive emotional-behavioral strategies according of E. Khaimah - 32.1% and 28.6%, in 1st group - 17.9%; 14.3%, respectively.

Conclusions:: The attrition of the dependence of psychological parameters in epilepsy on PA is due to the prevailing of neuronal activity disorders determined in the structure of both single-focal and multifocal epileptic discharges. The level of involvement of hemispheric regions in the epileptic process masks the connection of psychological indicators with PA.
DIFFERENTIATION OF OCCIPITAL EPILEPSY FROM MIGRAINE HEADACHE WITH AURA: A COMPARATIVE ANALYSIS OF THE PATIENTS PRESENTED IN A TERTIARY CARE CENTER OF BANGLADESH

Reaz Mahmud
Dhaka Medical College Hospital, Neurology, Dhaka, Bangladesh

Background and Aims:: Occipital epilepsy is relatively uncommon and probably underdiagnosed, often misdiagnosed as migraine with aura. Early diagnosis requires clinical suspicion which leads the neurologist to advice electroencephalogram (EEG) and brain imaging, which are unnecessary in case of migraine with aura.

Methods:: We documented the patients presented in the department of Neurology, Dhaka Medical College from June, 2019 to January, 2020 with confirmed occipital epilepsy, presented with visual semiology, EEG changes and or structural abnormality in the occipital region. We compared the ictal visual hallucination with the aura of 18 confirmed patients with migraine.

Results:: We found 10 confirmed patients with occipital epilepsy with median (IQR) age was 22 (15-47) years, mostly female [8(80%)]. The etiology seems to be idiopathic in 3 patients. Among the symptomatic patients pathologic abnormality found in the occipital regions included, space occupying lesion, post hypoxic damage, post stroke encephalomalacia, gyral calcification due Sturge weber syndrome and Wilson's disease. EEG findings included focal or generalized epileptiform discharges and occipital rhythmic intermittent delta activity (ORIDA). The visual hallucinations included transient [median (IQR), 35(3-375) seconds] flushing of the light, formed visual hallucination and bright dots of colored lights. Where as in aura of the migraine colorless bright dots, scintillating scotoma and transient visual blurring were dominant. The ictal visual hallucination was associated with compressive headache [9(90%)], tinnitus [5(50%)], ictal vomiting, photophobia and phonophobia. In 6 (60%) instances there were associated convulsions.

Conclusions:: Patients presented with very transient, distinct elementary visual hallucination and associated convulsion warrant evaluation for occipital epilepsy.
A CASE OF EPILEPTIC “BELLY DANCING”

Michele Trimboli, Francesco Fortunato, Miriam Sturniolo, Angelo Labate, Antonio Gambardella
AOU Mater Domini - Magna Graecia University, Department Of Medical And Surgical Sciences,
Catanzaro, Italy

Background and Aims:: The “belly dancing” phenomenon is featured by undulating movements of the abdominal wall. Although several aetiologies have been reported, the epileptic origin is the most commonly described. Previously reported patients were known to have epilepsy, were already receiving antiepileptic drugs, presented with focal status epilepticus, and/or their seizure motor phenomenology also included the eyes, face, limbs, and even loss of awareness. Isolated epileptic “belly dancing” has been very rarely described so far.

Methods:: A 60-years-old man, with one-year history of lung adenocarcinoma (ACL-T1cN2M0, stage IIIa, TTF1+, p40-), presented with a cluster of self-limited, short-lasting (~one minute), involuntary, clonic-like contractions (1-2Hz) involving abdominal muscles on the right side, occurring at interval of 40-60 minutes. There was no loss of awareness.

Results:: Neurological examination was normal. Inflammatory and autoimmune work-up was unremarkable. Prolonged video-EEG/EMG polygraphy monitoring demonstrated interictal epileptiform EEG activity and documented a focal seizure of left centroparietal origin accompanied by surface EMG bursts activity recorded from right rectus abdominis muscle (Figure 1). Brain MRI revealed left parietal metastatic brain tumor at the gray–white junction with surrounding vasogenic edema (Figure 2). After intravenous administration of levetiracetam (500 mg bid), no further seizures were observed.
Conclusions: In most previous reports as in our case, the “belly dancing” epileptogenic zone correspond to the mesial frontal and/or parietal areas around the central sulcus, in agreement with the trunk somatotopic representation. The limited representation of abdomen and the overlapping representations of body parts over the sensory/motor homunculus, may account for the rarity of isolated epileptic “belly dancing” phenomenon.
IRF2BPL NONSENSE MUTATION ASSOCIATED WITH ADULT ONSET MYOCLONIC EPILEPSY AND CEREBELLAR ATAXIA: A CASE REPORT.

Stefano Pisano, Marta Melis, Michela Figorilli, Antonella Muroni, Lorenzo Polizzi, Claudia Molinu, Carlo Perretti, Giovanni Defazio
University of Cagliari and AOU Cagliari, Department Of Medical Sciences And Public Health, Neurology Unit, Monserrato, Italy

Background and Aims:: The Interferon Regulatory Factor 2 Binding Protein-Like (IRF2BPL) is a recently discovered gene, whose mutations are associated with heterogeneous neurological phenotypes, in most cases developmental and epileptic encephalopathies. We present the case of an IRF2BPL mutation associated with adult-onset myoclonic epilepsy and cerebellar ataxia.

Methods:: A 22 years-old female patient with mild learning disabilities developed a progressive decline in cognitive and motor functions, manifesting mental slowness, forgetfulness, unsteady gait with frequent falls, mild speech ataxia, action tremor, myoclonic jerks, and a single generalized tonic-clonic seizure. Family-history was negative, and brain imaging together with laboratory tests were normal. Prolonged EEG showed diffuse epileptiform abnormalities, frequent multifocal myoclonus, and a photo-paroxysmal response. The myoclonic jerks improved with Levetiracetam and Clonazepam, while cognitive and motor impairment persisted.

Results:: Whole-exome-genome sequencing showed a never-before-described heterozygous nonsense mutation (c.364C>T, p.Gln122Ter) in the IRF2BPL gene. Leading to the insertion of a premature STOP codon, this mutation is considered potentially pathogenic according to updated recommendations.

Conclusions:: IRF2BPL mutations are mostly associated with severe neurological regression. Our patient showed a different phenotype, resembling the clinical features of Progressive Myoclonic Epilepsy (PME): myoclonic jerks, seizures and progressive neurologic impairment. Although the most common PME phenotypes are attributed to specific genetic defects, almost 30% of PMEs are of undetermined cause and this is the first report of an IRF2BPL mutation. Our report needs confirmation by further studies; however, it contributes to the knowledge of the heterogeneity of the IRF2BPL-mutations phenotype and suggests that it should be considered in patients with PME.
ROLE OF INTENSITY OF ELECTRICAL STIMULATION (ES) IN THE CEREBELLAR ANTIEPILEPTIC EFFECTIVENESS UNDER CONDITIONS OF DIAZEPAM ADMINISTRATION

Leonid Godlevsky¹, Mykhailo Pervak¹, Olesya Poshyvak²
¹Odesa National Medical University, Department Of Biophysics, Informatics And Medical Devices, Odesa, Ukraine, ²Danylo Halytsky Lviv National Medical University, 2pharmacology Department, Lviv, Ukraine

Background and Aims:: Background. ES of brain structures combined with antiepileptic drugs is a promising approach for better pharmacological control of resistant seizures. Aims. To investigate the dynamic of penicillin-induced foci in cats’ brain cortex under conditions of paleocerebellar electrical stimulation (ES) delivered at different intensities and diazepam administration.

Methods:: Methods. Via penicillin solution (20.000 IU/ml) application upon posterior sigmoid gyrus epileptic foci have been created in anesthetized, myorelaxed, and artificially ventilated cats. ES of paleocerebellum (100 Hz, 1 ms, duration of trial 1 s) have been delivered to VI lobula of paleocerebellum with two bandwidths of intensities: 80-150 mcA (lower) and 200-500 mcA (higher) ones. Diazepam was administered in dose 2.0 mg/kg, i.v.. The monopolar EEG was registered, and i.v. saline administration to animals was used as control.

Results:: Results. The frequency of epileptic discharge generation at the maximal level of epileptic activity was 25-40 discharges per min. During ES delivered at a lower intensity, the decrease of discharges frequency by two-three times was observed. Higher frequency of ES induced activation of spikes generation up to 50-75 per min. In 30.0 min from the diazepam administration and 20 min from the moment of restoration of focal activity via additional penicillin application, lower intensity ES did not modulate spikes generation, while higher intensity caused up to twice reduction of spikes frequency or complete suppression of focal activity.

Conclusions:: Conclusions. Modulative effects of paleocerebellar ES on cortical penicillin foci depend on its intensity. Diazepam in high dose abolished effects of low-intensity ES while higher intensity induced suppression of epileptic activity.
THE EFFECTS OF ANTI-EPILEPTIC DRUGS ON HIGH-FREQUENCY OSCILLATIONS IN SOMATOSENSORY EVOKED POTENTIALS

Giovanni Assenza¹, Jacopo Lanzone², Marilisa Boscarino¹, Lorenzo Ricci³, Angelo Insola¹, Mario Tombini², Vincenzo Di Lazzaro³
¹Campus Bio-Medico University, Neurology Department, Rome, Italy, ²Università Tor Vergata, Department Of Systems Medicine, Neuroscience, Rome, Italy, ³University Campus Bio Medico, Unit Of Neurology, Neurophysiology, Neurobiology, Rome, Italy

Background and Aims:: High frequency oscillations (HFOs) of Somatosensory evoked potentials (SEPs) reflect the activity of thalamo-cortical and cortical neurons from the sensory pathway. Antiepileptic-drugs (AEDs) reduce seizures acting on the balance between excitation and inhibition. We aimed to study the effect of AED mono and polytherapy on SEP-HFO's components

Methods:: Twenty-five patients with focal epilepsy were enrolled for the purpose of this study. Patients were divided in 3 groups according to the number of AEDs (1, 2 or 3 AEDs). Patients in group 1 underwent SEP-HFOs recording in drug naïve condition and at 1 month after AED titration. HFOs were compared in duration, amplitude and latency among the three groups.

Results:: The amplitude and duration of late HFOs of the affected hemisphere (AH) are different between groups and inversely correlated with the number of AEDs. In naïve patients mono therapy reverts the asymmetry in totHFOs (total HFOs) duration.

Conclusions:: Our results demonstrate that SEP-HFOs are sensitive to the action of AEDs on cortical excitability. This effect seems to affect mainly the cortical component of HFOs in the AH and it is related to the number of AEDs taken. Significance: SEP-HFOs might be a viable tool to probe cortical excitability changes induced by AEDs. © 2020 International Federation of Clinical Neurophysiology
THE USE OF OPTICALLY PUMPED MAGNETOENCEPHALOGRAPHY (OP-MEG) IN EPILEPSY

Umesh Vivekananda
University College London, Department Of Clinical And Experimental Epilepsy, London, United Kingdom

Background and Aims:: Magnetoencephalography (MEG) has been used in specific cases of refractory epilepsy due to its inherent properties of excellent spatial resolution and relative immunity to muscle artefact. However current MEG systems are high maintenance and restrictive for the patient, meaning that recording sessions are usually brief (1-2 hours), thereby limiting its availability in the clinical setting. Our aim was to demonstrate the first use of Optically Pumped Magnetoencephalography (OP-MEG) in two epilepsy patients with unrestricted head movement. Unlike conventional MEG that uses a superconducting SQUID system, here we use a different type of sensor (OPM), which operates at room temperature and crucially can be placed directly on the patient's scalp, permitting free head movement.

Methods:: We performed three OP-MEG recording sessions in two patients with refractory focal epilepsy (right posterior temporal focus in patient 1 and left frontal focus in patient 2), who were able to perform natural movements within their environment. We then compared these recordings with clinical scalp EEG performed earlier. In the second patient we also incorporated motion capture in order to regress out head movement from the MEG signal.

Results:: OP-MEG was able to identify analogous interictal activity to scalp EEG including spikes, polyspikes, sharp waves and spike and wave activity. We were able to source localise this activity using both linearly constrained minimum variance (LCMV) beamformer and equivalent current dipole (ECV) methods to an appropriate brain region.

Conclusions:: This is the first application worldwide of OP-MEG in human epilepsy. Future directions include simultaneous EEG/OP-MEG recording and prolonged OP-MEG telemetry.
Background and Aims: Background. The suppression of epileptic activity follows TDCS. It was shown that blocking peroxisomal proliferator-activated γ-receptors (PPARγ) with BADGE, (100 mg/kg, i.p.) prevented antiseizure effects caused with cerebellar TDCS (Godlevsky L.S., Pervak M.P., 2019). Aim. To investigate effects of cerebellar TDCS under conditions of treatment with the agonist of PPARγ pioglitazone upon pentylenetetrazol (PTZ) - kindled seizures.

Methods: Methods. In rats the kindling was induced via PTZ (35.0 mg/kg, i.p.) for three weeks. TDCS was performed at 250 μA intensity for 10.0 min, with cathode on the skull surface oriented to the cerebellar cortex. Pioglitazone (100.0 mg/kg) was administered i.p. in 30 min before TDCS.

Results: Results. TDCS caused the tendency to increase the latency of first seizures by 26.3% when compared with control (70.89+14.20 s) (P>0.05) and reduced the seizure severity to 3.62+0.92 from 4.22+0.67 points in control (P>0.05). Pioglitazone (100.0 mg/kg i.p.) increased the latency by 31.4% up to 103.38+17.08 s (P<0.05) and seizures were reduced to 3.5+0.76 points (P>0.05). TDCS in rats treated with pioglitazone (100.0 mg/kg, i.p.) resulted in increasing the latency by 42.2% (P<0.05) (up to 122.7+31.84 s) and reduced seizures by 31.3% (P<0.05) (up to 2.9+0.74 points). Both TDCS and pioglitazone did not affect the length of ictal potential delivered separately. The length of ictal potential was shortened by 45.0% (P<0.05) (up to 15.92+9.66 s) when TDCS was performed after pioglitazone administration.

Conclusions: Conclusions. Under conditions of treatment with pioglitazone paleocerebellar, TDCS caused pronounced antiseizure effects. That leads to the role of PPARγ in the realization of cerebellar antiseizure action.
Background and Aims:: To determine the frequency and demographics of types of epilepsy presenting to a neurology outpatients facility in a private tertiary care JCIA Accredited University hospital in Islamabad, Pakistan.

Methods:: We extracted the data from our neurology outpatient database registry from July 2014 to November 2018. This registry is approved by the Institutional Review board and Ethics committee of our hospital. A patient was diagnosed with epilepsy if there was clear evidence of recurrent epileptic seizures, with the documentation being made by a neurologist on a standard diagnostic database form.

Results:: Out of 10,047 recorded in this time period, 1,265 patients (12.6%) had epilepsy, 57.9% were male and 42.1% were female with a mean age of 25.77 ± 16.6 years. Focal epilepsy with or without secondary generalization was the most common type, seen in 49.1% of cases, with mean age of 26.35± 17.2 years with 61% males; followed by generalized epilepsy in 45.2% with almost similar age (25.85 ± 16.2 years) and gender distribution (56.3% males vs 43.7% females). Juvenile Myoclonic epilepsy constituted 3.5% cases (mean age 25± 12). Lennox –Gastaut Syndrome (LGS) was seen in 1.1%; Benign partial epilepsy with centro-temporal spikes in 0.4%; febrile seizures in 0.4%; West Syndrome in 0.1%; and epilepsy not specified in 0.2% cases.

Conclusions:: The most common epilepsy was focal epilepsy with or without secondary generalization followed by generalized epilepsy and epilepsy in general is more common in males than females.
DRUG-RESISTANT EPILEPSY SECONDARY TO PERINATAL DAMAGE: DO INTERICTAL EPILEPTIC DISCHARGES MATTER?

Davide Fonti¹,², Antonella Muroni³, Lorenzo Polizzi³, Monica Puligheddu²,³, Giovanni Defazio²,³ ¹University of Cagliari, Department Of Biomedical Sciences, Cagliari, Italy, ²University of Cagliari, Department Of Medical Sciences And Public Health, Cagliari, Italy, ³Azienda Ospedaliero Universitaria di Cagliari, Institute Of Neurology, Cagliari, Italy

Background and Aims: Perinatal damage represents a frequent cause of drug-resistant epilepsy (DRE). Abnormal EEG findings have been described as a risk factor for DRE. Our aim was to explore the relationship, if any, between interictal epileptic discharges (EDs) and drug responsiveness in epilepsy secondary to perinatal causes.

Methods: We selected patients with focal epilepsy due to perinatal events from our Adult Epilepsy Centre database. DRE was defined as proposed by the International Ligue Against The Epilepsy (ILAE). Ambulatory EEG findings for each patient were classified by the presence or absence of interictal EDs.

Results: We recruited 53 patients, 33 men and 20 women aged 42.2 (SD, 11.7) years. Twenty-four patients had DRE. Patients who responded to drug treatment and those who did not were similar for age and sex but differed for interictal EDs that were more frequent in the DRE group (15/24 vs. 10/29; Pearson Chi square, p=0.04).

Conclusions: Among patients with epilepsy secondary to perinatal damage, EDs during ambulatory EEG are more frequently encountered in drug resistant patients. In this group, ambulatory EEG may be not only a diagnostic aid but may also have prognostic value.
SKULL-BASE TEMPORAL ENCEPHALOCELE: HIDDEN CAUSE OF TEMPORAL LOBE EPILEPSY

Akash Chheda¹, Rajit Pillai², Sangeeta Ravat³, Dattatray Mazumdar⁴, Shilpa Sankhe⁵, Shruti Agrawal⁶
¹Assistant Professor Seth GS Medical College and KEM Hospital, Neurology, Mumbai, India, ²Epilepsy Fellow Seth GS Medical College and KEM Hospital, Neurology, Mumbai, India, ³Professor Seth GS Medical College and KEM Hospital, Neurology, Mumbai, India, ⁴Professor Seth GS Medical College and KEM Hospital, Neurosurgery, Mumbai, India, ⁵Neuroradiologist Seth GS Medical College and KEM Hospital, Radiology, Mumbai, India, ⁶KEM HOSPITAL, Department Of Neurology, Mumbai, India

Background and Aims:: Among patients with Temporal lobe epilepsy (TLE), up to 30% can have normal (non-lesional) MRI scans. With increased use of high resolution MRI (3T) scans, many of the MRI-negative TLE cases turn out to be lesional TLE. Skull-base temporal encephalocele (TE), has to be suspected and specifically searched for among patients with apparent MRI negative TLE. The study aims to analyse patients with TLE for temporal lobe encephalocele.

Methods:: Patients with previously diagnosed MR negative TLE on long term video EEG monitoring were re-evaluated with 3T MRI brain over a period of 2 years (1st January 18-1st January 20) from a tertiary level comprehensive Epilepsy care centre to discover skull base temporal encephalocele.

Results:: Total 1024 VEEG were analysed. TLE was diagnosed in 104 patients based on semiology, Ictal, Interictal EEG data and brain PET studies. Out of 104 TLE patients, 99 patients had temporal lobe abnormality (78 patients had MTS, 8 patients had tumor, 3 patients had FCD, 10 patients had mixed pathology). Out of the 5 MR negative TLE patients, 2 patients were diagnosed with temporal encephalocele on subsequent high resolution 3T MR brain scans and one patient underwent EcoG guided tailored resection for complete removal of epileptogenic tissue with Engels class I seizure freedom at 1 year follow up.

Conclusions:: We propose that temporal lobe encephalocele (TE) should be searched for, as a cause
of refractory TLE, using high-resolution MRI sequences. PET positivity with an apparent negative MRI in patient presenting with TLE, should encourage one to search for TE.
CENOBAMATE AS ADJUNCTIVE THERAPY IN ADULTS WITH UNCONTROLLED FOCAL SEIZURES: TIME TO ONSET OF EFFICACY DURING TITRATION

Gabriele Camatti¹, Bernhard Steinhoff², Elinor Ben-Menachem³, Christian Brandt⁴, Irene García Morales⁵, William Rosenfeld⁶, Estevó Santamarina⁷, José Serratosa⁸
¹Angelini Pharma, Medical Direction, Ancona, Italy, ²Kork Epilepsy Center, Department For Adults, Kehl-Kork, Germany, ³Institute of Neuroscience and Physiology, University of Gothenburg, Department Of Clinical Neuroscience, Gothenburg, Sweden, ⁴Mara Hospital, Department Of General Epileptology, Bethel Epilepsy Centre, Bielefeld, Germany, ⁵Hospital Ruber Internacional, Servicio De Neurología, Programa De Epilepsia, Madrid, Spain, ⁶Comprehensive Epilepsy Care Center for Children and Adults, N.a., St. Louis, MO, United States of America, ⁷Vall d’Hebron University Hospital, Department Of Neurology, Epilepsy Unit, Barcelona, Spain, ⁸Fundación Jiménez Díaz, Department Of Neurology, Epilepsy Unit, Madrid, Spain

Background and Aims:: Cenobamate is a new antiseizure medication (ASM) approved in the US for uncontrolled focal (partial-onset) seizures in adults. Two international, double-blind, placebo-controlled trials (C013/C017) demonstrated cenobamate efficacy and safety. Here we report time to onset of efficacy during titration of cenobamate in these studies.

Methods:: Adults with uncontrolled focal seizures and taking 1-3 concomitant ASMs were enrolled in Study C013 and C017. Concomitant ASM changes were not allowed during the double-blind period. Time to onset of efficacy in patients receiving cenobamate versus placebo was evaluated during the 6 weeks of cenobamate titration (Table 1). Post-hoc analysis of efficacy examined the percent reduction in seizure frequency from baseline to each week during titration using a Wilcoxon rank-sum test (C013) or an ANCOVA model fit to the ranked values of baseline seizure rate and treatment group (C017).

Results:: Patients receiving cenobamate had significant reductions in median percent seizure frequency versus placebo starting from the first 1-2 weeks of cenobamate titration at the initial dose of 50 mg/day (C013: -26.7% cenobamate vs -15.1% placebo, P<0.05; C017: -36.4% cenobamate vs -20.0% placebo, P<0.05). Sustained significant decreases in seizure frequency versus placebo were seen throughout the 6-week titration in both studies. The median reduction in seizure frequency was progressively higher with increasing cenobamate doses of 100, 200, and 400 mg/day.

Conclusions:: Onset of cenobamate efficacy in significantly reducing seizure frequency occurs early and at lower doses than the target dose for maintenance therapy and it improves at higher doses.
A REAL-WORLD STUDY TO EVALUATE EFFICACY AND QUALITY OF LIFE OF PEOPLE WITH EPILEPSY ATTENDED OUTPATIENT DEPARTMENT OF EPILEPSY FOUNDATION

Nirmal Surya¹, Arti Sharma²
¹Founder Trustee & Chairman, Epilepsy Foundation, India., Neurology, Mumbai, India, ²Epilepsy Foundation, India., Psychologist, Mumbai, India

Background and Aims:: Epilepsy can have serious physical, psychological, and social consequences, and it can have a greater impact on a person's quality of life (QOL) than chronic conditions. People with epilepsy have been shown to have lower QOL because they are more likely to have low self-esteem, anxiety, and depression. Epilepsy Foundation runs the Epilepsy clinic to provide the comprehensive care to these patient

Methods:: It is prospective, observational study to evaluate the efficacy and QoL of life of people with Epilepsy. The efficacy parameters are collected through the case record form and QoL life data is collected by 1:1 interaction with patients and later, through the periodic phone calls. The data is collected from 2018 to 2021.

Results:: Total 72 patients were enrolled in to the trial. 53% are male and 47% are female with mean age 32.23 ± 12.5. our OPD, the majority of patients are less educated, with only 18% completing high school. 8 people, 18, 26 people, and 20 people have had epilepsy for more than 30 years, 21-30 years, 10-20 years, and 10 years, respectively. In the last four years, 64% of patients have achieved seizure freedom. Because of the comprehensive management provided by the Epilepsy Foundation, the majority of patients improved in their Quality of Life.

Conclusions:: Comprehensive approach provided by Epilepsy foundation improved the Epilepsy outcomes and QoL life of People with Epilepsy. The free medication provided by Epilepsy foundation improved the efficacy and adherence to the therapies.
SAFETY OF CENOBAmate AS ADJUNCTIVE THERAPY IN ADULTS WITH UNCONTROLLED FOCAL SEIZURES: TIME TO ONSET, DURATION, AND SEVERITY OF THE MOST COMMON ADVERSE EVENTS

Gabriele Camattari¹, Bernhard Steinhoff², Elinor Ben-Menachem³, Christian Brandt⁴, Irene García Morales⁵, William Rosenfeld⁶, Estevo Santamarina⁷, José Serratosa⁸

¹Angelini Pharma, Medical Direction, Roma, Italy, ²Kork Epilepsy Center, Department For Adults, Kehl-Kork, Germany, ³Institute of Neuroscience and Physiology, University of Gothenburg, Department of Clinical Neuroscience, Gothenburg, Sweden, ⁴Mara Hospital, Department of General Epileptology, Bethel Epilepsy Centre, Bielefeld, Germany, ⁵Hospital Ruber Internacional, Servicio De Neurología, Programa De Epilepsia, Madrid, Spain, ⁶Comprehensive Epilepsy Care Center for Children and Adults, N. a., St. Louis, MO, United States of America, ⁷Vall d’Hebron University Hospital, Department of Neurology, Epilepsy Unit, Barcelona, Spain, ⁸Fundación Jiménez Díaz, Department of Neurology, Epilepsy Unit, Madrid, Spain

Background and Aims:: Cenobamate is a new antiseizure medication (ASM) approved in the US for uncontrolled partial-onset (focal) seizures in adults. Two international, double-blind, placebo-controlled trials with open-label extensions (OLEs; C013/C017) and a large international open-label safety study (C021) demonstrated efficacy and safety. Here we characterize the most common adverse events (AEs) in these studies.

Methods:: Adults with uncontrolled focal seizures and taking 1-3 concomitant ASMs were enrolled (C013/C017/C021). Concomitant ASM changes were not allowed during the double-blind period (DB) but were allowed during OLEs (C013/C017) and C021. C021 cenobamate titration started lower and uptitrated slower than C013/C017. Time of first onset (pooled C013/C017 DB and OLEs; C021), duration of all AEs (pooled C013/C017 DB), and severity (pooled C013/C017 DB; C021 first 18 weeks) of somnolence, dizziness, and fatigue were examined.

Results:: First onset of the most common AEs emerged throughout both the DB and the OLE, mostly during titration. In C021 the peak occurred when dosing reached ≥50 mg/day. Median duration in days (DB, all occurrences) was: somnolence 32 cenobamate versus 22 placebo, dizziness 11 cenobamate versus 8 placebo, and fatigue 34 cenobamate versus 20.5 placebo. AEs in the DB were primarily mild or moderate, with few severe AEs. In C021, more patients reported mild AEs and fewer reported moderate and severe AEs.

Conclusions:: Onset of the most common AEs occurred primarily during titration and were mainly mild or moderate in severity. The slower titration reduced the severity of AEs.
Background and Aims:: Epilepsy is a common neurological disorder. During the attack, patients may lose their consciousness, body control, and may be injured, hence the prevalence of injuries among patients with epilepsy is high. The aim is to study the prevalence and predictors of SRIs.

Methods:: this was a cross-sectional hospital-based study. A multistage cluster sampling technique. A self-structured questionnaire was used for interviewing the patients

Results:: Among 112 interviewed patients with epilepsy, 49% were male and 51% females. 40% of the patients had a history of SRIs and the most common were head injuries 86%, followed by dental injuries 28%, soft tissue injuries 20%, and fractures 2%. The prevalence of SRIs was high among patients who had a history of status epilepticus 54%, then those on polytherapy 50%, and who were practising high-risk activities 46%. 41% of the patients received nonmedical treatment herbal and spiritual which did not influence the prevalence of SRIs. 69% of the patients interrupted taking their medications due to medications unavailability, freedom of fits, side effects of the drugs, and fasting in Ramadan, respectively. 46 patients discontinued their job/school due to the disease and the prevalence of SRIs among them was 37%.

Conclusions:: the prevalence of SRIs among our patients was high. Factors that increased the frequency of SRIs were; having a history of status epilepticus, being treated by more than one type of medications, treatment interruption, and practising high-risk activities. Nonmedical treatment had no influence. SRIs had a negative impact socially.
EEG SEIZURE ONSET PATTERNS IN STATUS EPILEPTICUS

Giulia Turchi1, Giada Giovannini2,3, Niccolò Orlandi1,4, Jessica Rossi1,4, Maria Cioclu1,4, Anna Vaudano1, Stefano Meletti2,4

University of Modena and Reggio Emilia, Modena, Italy, 4. University of Modena and Reggio Emilia, Department Of Biomedical Metabolic And Neurosciences, Modena, Italy

Background and Aims: Introduction: The seizure-onset (SOn) patterns have been studied especially with intracranial electrodes to improve the determination of the epileptogenic zone. Qualitative and quantitative EEG studies characterizing the onset pattern in status epilepticus (SE) are lacking. We aimed to classify the different SOn patterns and to compare them in order to determine any possible differences in terms of mortality, morbidity and treatment response.

Methods: Materials and methods: we reviewed retrospectively EEG recorded from adult patients admitted for focal and repetitive SE, from January 2015 to August 2019. In accordance with earlier studies of scalp seizure (Tanaka 2018), we identified 5 patterns of seizure-onset: (1) rhythmic slow activity: sinusoidal activity at <13 Hz; (2) paroxysmal fast activity: sinusoidal activity at ≥13 Hz; (3) repetitive epileptiform discharge (4) suppression of background activity to ≤10 µV; (5) no visible EEG pattern because of artifacts at seizure onset. For each patient from 1 to 5 seizures were analyzed.

Results: 307 seizures were analyzed from 100 patients; the most frequent SOn pattern was the number 3 (39 patients) followed by pattern 1 (34 patients) and pattern 2 (14 patients); pattern 4 and 5 were less frequent (1 and 3 patients respectively). Some patients presented with multiple patterns. Any statistical difference in demographics, etiology, semeiology and treatment response variables was observed; while in term of mortality the SOn pattern 3 showed higher mortality.

Conclusions: studying SOn patterns could improve our understanding on SE mechanism and could become a useful tool in every-day clinical practice.
Background and Aims:: The diagnostic of epilepsy and classifying seizure type are very difficult for the physician because of the relative infrequency of events or occurrences just during certain activities or in unique settings. In that context, smartphones are proposing as an alternative to helping clinicians, patients, and caregivers, to reporting seizures, using videos, etc., to help diagnosis. The purpose of this study is to conduct a systematic review and meta-analysis of applications or smartphone devices related to the diagnosis of epilepsy.

Methods:: A systematic review was performed to evaluate the use of smartphone devices to diagnose epileptic seizures compared with the encephalogram, using the databases of MEDLINE, Scopus, Web of Science, and Embase. We plotted studies estimates of sensitivity and specificity on forest plots and in receiver operating characteristics (ROC). The data were synthesized using a bivariate mixed-effects binary regression modeling framework.

Results:: We included only five studies for analysis that evaluated the use of one specific mobile app (n=2), to record an ECG video, and home video of the epileptic seizure using a smartphone (n=3). We found that the smartphone devices have a sensitivity of 66% (CI95% 44 - 83) and specificity 88% (CI95% 76 – 94) to diagnostic epileptic seizure, with an AUC of 0.86 (CI95% 0.83 – 0.89).
Conclusions: The smartphone devices have a good performance in diagnosis epileptic seizures. However, there need more studies to corroborate the results, especially stratifying for the type of smartphone devices.
SUPER REFRACTORY POST-TRAUMATIC STATUS EPILEPTICUS TREATED WITH COMBINING PERAMPANEL AND KETAMINE

Marta Cheli¹, Alessandro Dinoto², Francesco Biaduzzini¹, Marinella Tomaselli¹, Giulia Mazzon², Erik Roman-Pognuz³, Stefano Meletti⁴, Paolo Manganotti²
¹University of Trieste, Neurology Unit, Department Of Medical, Surgical And Health Sciences, Trieste, Italy, ²University of Trieste, Clinical Unit Of Neurology, Department Of Medicine, Surgery And Health Sciences, University Hospital And Health Services Of Trieste – Asugi, University Of Trieste, Strada Di Fiume, 447, 34149 Trieste, Italy, Trieste, Italy, ³University of Trieste, Department Of Anesthesia And Intensive Care, Trieste, Italy, ⁴Ospedale Civile di Baggiovara, AOU di Modena., Stroke Unit – Neurology Clinic, Department Of Neuroscience, Modena, Italy

Background and Aims:: Super refractory status epilepticus (SRSE) is a life-threatening condition with no compelling evidence regarding its best treatment. Ketamine and perampanel have shown, in limited case series, to have respectively a potential role in the management of this condition. The association of these two drugs may have potential synergic effects, but its clinical efficacy is still matter of debate

Methods:: We report a case of post-traumatic SRSE that was successfully treated with a combination of intravenous ketamine and oral perampanel and discuss the potential synergic role of these two anti-epileptic drugs.

Results:: A 23-years-old male was admitted for post-traumatic SE to the intensive care unit. His brain MRI scan revealed microhaemorragic diffuse axonal injury. He was unsuccessfully treated with levetiracetam, phenytoin, valproic acid and lacosamide. Weaning of sedation (midazolam and propofol) always resulted in recurrence of SE. Intravenous methylprednisolone did not exert any beneficial effect. The patient was then treated with intravenous ketamine combined with perampanel through nasogastric tube with dramatic response and SRSE cessation after 39 days of ICU. The patient was discharged to a neurological rehabilitation unit and 5 months after SRSE onset he was discharged home: his neurological and neuropsychological were unremarkable and he remained seizure-free. Glutamatergic transmission is crucial in SRSE and the association of perampanel and ketamine acts on this synaptic pathway by antagonizing both NMDA and non-NMDA glutamate ionotropic receptors.

Conclusions:: Targeting glutamatergic transmission with the association of perampanel and ketamine represents a safe and effective strategy in the treatment of SRSE.
LONG-LASTING MEMORY NO LONGER MEANS FOREVER: RELATIONSHIP BETWEEN ACCELERATED LONG-TERM FORGETTING AND AUTOBIOGRAPHICAL MEMORY DISORDERS AMONGST PATIENTS WITH TEMPORAL LOBE EPILEPSY

Monica Ricci, Ludovica Lispi, Carmela Gerace, Massimiliano Ruggeri, Carlo Blundo
San Camillo Forlanini Hospital, Unit Of Cognitive Disorders And Dementia, Rome, Italy

**Background and Aims::** Patients with temporal lobe epilepsy (TLE) have difficulties when they are asked to recall remote autobiographical memory. Also, some patients with epilepsy show accelerated long-term forgetting (ALF) over days or weeks for material demonstrated to have been retained when assessed after typical short-term delays. When remote autobiographical memory has been investigated in patients who show ALF, impairments have been detected in most cases, but the extent to which remote autobiographical memory impairments are explained by early consolidation deficits has not been clarified. The aim of this study is to find a relationship between more remote autobiographical memory impairments and ALF.

**Methods::** We are enrolling patients with late-onset TLE. For the present study, we considered 16 TLE patients and 5 healthy subjects. All the subjects underwent a neuropsychological assessment in order to test rates of forgetting over 1-week delay, and the Levine’s Autobiographical Interview to test autobiographical memory from 5 life periods. The scoring categories of the Interview involved recollection of Internal and External events, and their respective details of time and place, perceptual and semantic aspects, and related emotions.

**Results::** These preliminary results show that on recollection of Internal details we observed a temporal gradient amongst healthy subjects, (more memories recalled in recent decades), while patients who show ALF did not show a temporal gradient. Somehow surprisingly, we did not observe the same trend on External details recalled, with the groups showing the same trend of recollection over life periods.

**Conclusions::** The present study is still enrolling late-onset TLE patients and healthy subjects.
SLEEP-WAKE DISTRIBUTION AND CIRCADIAN PATTERN OF FOCAL SUBCLINICAL SEIZURES

Andrea Pagano¹, Fabio Placidi¹, Claudio Liguori¹, Sara Girolami¹, Natalia Manfredi¹, Alessandro Castelli¹, Luisa Mari¹, Valentina Bramato¹, Nicola Mercuri², Francesca Izzi¹
¹University of Rome "Tor Vergata", Epilepsy Center - Department Of Systems Medicine, Rome, Italy, ²University of Roma Tor Vergata, Neurology Unit, Department Of Systems Medicine, Roma, Italy

Background and Aims:: To examine the sleep/wake distribution and 24-h periodicity of focal subclinical seizures (FSS) recorded by 24-hour ambulatory EEG (AEEG) in adult patients affected by focal epilepsy.

Methods:: FSS, defined as ictal electrographic discharges with a temporal-spatial evolution lacking subjective or objective behavioral manifestations, with a duration longer than 6s, documented at AEEG, were retrospectively analyzed. The occurrence of FSS during wakefulness or sleep and within 3-h time blocks through a 24-h cycle (intervals I-VIII) was evaluated.

Results:: A total of 192 FSS (mean duration 29.51±15.36s) from 20 patients (11F,9M, mean age 53.6±20.36y) were studied. FSS occurred more frequently during wakefulness than in sleep (147/192, 76.5% vs 45/192, 23.4%, p=0.02). Mean duration of FSS during wakefulness was comparable to that of FSS during sleep (28.76±15 vs 31.93±16.42s, p=0.25). FSS during interval VII (38/192, 6-9pm) and V (37/192, noon-3pm) were higher than expected. The mean number of FSS during interval III was significantly lower than interval I (0.85±3.34 vs 1.2±3.76, p=0.038) and interval VI (0.85±3.34 vs 1.55±3.94, p=0.010). More patients had FSS in interval VI compared to interval III (11/20 vs 3/20, p=0.039).

Conclusions:: FSS do not occur randomly but follow a specific circadian pattern and a particular sleep-wake distribution. In fact, FSS mainly tend to occur during wakefulness and they have a significant propensity to arise in the time slot 3-6pm, whereas they are less likely seen on awakening. Relevance of FSS arises from the potential effect on cognitive functions and their circadian pattern deserves interest as to a possible chronotherapy.
Background and Aims:: Capgras syndrome is a condition characterized by the belief that a close relative has been replaced by an almost identical imposter. The disorder has long been associated with psychiatric diseases, but it has also been reported in several neurological disorders. In the context of epilepsy, the occurrence of Capgras syndrome has been documented mainly as a postictal or interictal manifestation. We report a case of a focal seizures presenting as transient Capgras syndrome, which, based on existing literature, represents an exceptional manifestation of this syndrome.

Methods:: We describe the case of a 83-year-old woman with focal temporal seizures manifesting as transient Capgras syndrome. The patient abruptly presented with the belief that her husband had been replaced by a nearly identical substitute; the symptoms gradually disappeared within 24 hours. The patient was admitted to our Department to perform further investigation.

Results::
Brain MRI showed the presence of a large right frontobasal meningioma with marked perilesional oedema and mild compressive effect on adjacent structures. Surgical treatment was postponed because of age, comorbidities and patient decision. The patient was started on levetiracetam 500 mg b.i.d. and dexamethasone without seizure recurrence.

**Conclusions:** Our patient represents an exceptional case of Capgras syndrome for several reasons, namely the association with meningioma, very rarely reported before, the transient manifestation of symptoms, and, most importantly, the epileptic etiology of reduplicative paramnesias. Lastly, our report also confirms the importance of frontal and right hemisphere dysfunction in generating Capgras syndrome-like delusions.
Background and Aims:: There is little historical and ethnographic work examining the impact of epilepsy on long-term relationships in Africa. Here, we take a culturally sensitive approach to try and better disentangle factors that may contribute to misconceptions about epilepsy in Zimbabwe.

Methods:: Initially, through a series of community-based workshops organised by the Epilepsy Support Foundation of Zimbabwe, we analysed stigmatisation of epilepsy in urban and rural settings. Workshops consisted of initial presentations on epilepsy followed by small group discussions. We implemented learning from these workshops to develop surveys, translated into native Zimbabwean languages, to capture, at scale, how both the person with epilepsy and those close to them perceive epilepsy.

Results:: Around 100 people participated in workshops based in Harare, Masvingo and Gweru. Considerable stigmatisation persists, particularly perpetuated by older members of local communities. Men with epilepsy felt disempowered by their ability to not work or participate in certain social activities. Both men and women agreed, however, that females with epilepsy were more likely to be subject to prejudice and potentially exposed to greater risk – for example having to cook on open fires away from other village members. While the survey questionnaires are prepared, deployment has not yet proved possible owing to the COVID 19 pandemic.

Conclusions:: Our study again emphasises that multiple misconceptions surround epilepsy, which can lead to severe stigmatisation. The surveys will provide the detailed insight necessary to develop tailored solutions to help empower those with epilepsy as well as the friends and family who help care for them.
SERUM NEUROFILAMENT LIGHT AS A BIOMARKER OF NEURODEGENERATION IN STATUS EPILEPTICUS.

Giada Giovannini\textsuperscript{1,2}, Roberta Bedin\textsuperscript{2}, Giulia Turchi\textsuperscript{1}, Anna Vaudano\textsuperscript{1}, Niccolò Orlandi\textsuperscript{1,3}, Maria Cioclu\textsuperscript{1,3}, Jessica Rossi\textsuperscript{1,3}, Stefano Meletti\textsuperscript{1,3}

\textsuperscript{1}Azienda Ospedaliero Universitaria Modena, Department Of Neurology, Modena, Italy, \textsuperscript{2}University of Modena and Reggio Emilia, Modena, Italy, \textsuperscript{3}Phd Program In Clinical And Experimental Medicine, Modena, Italy, \textsuperscript{3}University of Modena and Reggio Emilia, Department Of Biomedical Metabolic And Neurosciences, Modena, Italy

Background and Aims:: Neurofilaments (Nf) are intermediate filaments specifically expressed in neurons. Nf might be released from damaged or diseased axons in significant amounts into blood and cerebrospinal fluid (CSF) thus, they could be used as potential biomarkers of neurodegeneration. Elevation of serum Neurofilaments Light (sNfL) has been reported in drug resistant epilepsy and in post-anoxic electrographic status epilepticus. The purpose was to evaluate sNfL in patients with Status Epilepticus (SE).

Methods:: We retrospectively measured the serum NfL concentrations of age and sex-matched 30 prospectively collected adults with Status Epilepticus (SE) and compared them with 30 epileptic patients (EP) and 30 healthy controls (HC).

Results:: SE patients have significantly higher sNfL concentrations compared to EP and HC (p < 0.001). In SE patients, sNfL levels have a high correlation with CSF NfL and t-TAU concentrations (τ = 0.68, p < 0.001 and τ = 0.63, p < 0.001 respectively). SE sNfL levels demonstrated a positive correlation with the duration of SE (τ = 0.51, p = 0.003) and were significantly increased in patients with Refractory and Super-Refractory SE (RSE/SRSE, τ = 0.38, p = 0.048). Patients with 30-days worsening of clinical conditions compared to the baseline or death had higher levels of sNfL (τ = 0.38, p = 0.049).

Conclusions:: These exploratory data suggest the role of sNfL levels as a neurodegeneration biomarker in patients with SE. sNfL is a reliable and an easy obtainable biomarker in patients with SE that reflects CSF NfL and t-TAU levels.
CASE REPORT: FAVORABLE RESPONSE TO CARBAMAZEPINE IN SCN1A RELATED EPILEPSY

Matheus Klettenberg¹, Victor Rodrigues², Paulo Correia³, Lisiane Ferreira⁴
¹Universidade de Brasília, Department Of Pediatrics, BRASÍLIA, Brazil, ²Universidade de Brasília, Department Of Pediatrics, Brasília, Brazil, ³Universidade de Brasília, Faculty Of Medicine, Brasília, Brazil, ⁴Universidade de Brasília, Associate Professor Of The Faculty Of Medicine, Brasília, Brazil

Background and Aims:: Sodium Voltage-Gated Channel Alpha Subunit 1 (SCN1A) related epilepsies are known for being a contraindication to sodium blockers antiepileptics under the risk of seizures worsening. We aim to describe the response to carbamazepine (CBZ) at a patient with confirmed Dravet Syndrome.

Methods:: A case report was written with data from medical report of a 25 years-old man, collecting the cronomology that link seizure improvement to CBZ usage.

Results:: The subject had a tonic-clonic seizure after difteria vaccine with 6 months old. He evolved with reflex mioclonic seizures to fever and hot baths. After a status epilepticus (SE) with 4 years old, he presented developmental delay, intellectual disability, autistic features, behaviour disturbance and motor retardation. After SE, he started about fifty focal seizures a day and was unresponsive to several antiepileptic drugs. Carbamazepine (CBZ) was then started at age of 14 and kept due to response at seizure frequency reduction to 2-5 daily episodes, maintained until nowadays. When tried to suspend CBZ there was an epilepsy worsening, controled by reintroduction. The next-generation sequencing at 25 years old was positive for a frameshift SCN1A mutation. MRI at 4 years old showed periventricular nodular heterotopias. The electroencephalogram presented temporoparietal and generalized epileptiform activity.

Conclusions:: Several articles state that carbamazepine is contraindicated at SCN1A epilepsies due to risk of seizure worsening. Genetic polymorphisms of SCN1A could explain the variaty of responses to CBZ. This case shows an unusual response to CBZ to record that sodium blocker antiepileptics are a possible treatment for refractory SCN1A epilepsy.
STATUS EPILEPTICUS: INCIDENCE BEFORE AND DURING THE COVID19 PANDEMIC IN THE PROVINCE OF MODENA, ITALY

Giulia Monti¹, Giada Giovannini², Niccolò Orlandi², Anna Vaudano², Giulia Turchi², Annamaria Simone¹, Silvia Depasqua¹, Enrico Fileccia¹, Mario Santangelo¹, Stefano Meletti²
¹U.O. di Neurologia, Ospedale Ramazzini Di Carpi, Asl Di Modena, CARPI (MO), Italy, ²Azienda Ospedaliero Universitaria Modena, Department Of Neurology, Modena, Italy

Background and Aims:: Background. Many cardio-cerebrovascular diseases had a lower incidence in the initial phase of the spread of the SARS COV2 virus¹,². Some studies have evaluated the effect of the pandemic on status epilepticus (SE), in particular reporting the absence of significant variations between the cases that occurred before and those during the lockdown, except for the reduction of NCSE³.

Methods:: Methods. We evaluated the incidence of SE cases in the province of Modena, in the 5 months before the pandemic (October 2019-February 2020) compared with the same months of the following year (October 2020-February 2021), during the second and third wave.

Results:: Results. We identified 87 patients with SE in the 10 months analyzed, of which 43 in the pre-COVID19 era and 44 in the COVID19 era. The statistical analysis does not show significant differences between the two groups in terms of age, gender, average length of hospitalization and SE, etiology, semeiology, refractoriness, nor in terms of patient outcome (mRS). Instead, there is a trend in reduction of cases in the COVID19 era that performed EEG within the first 24 hours. There was a significant decrease in cases with in-hospital onset in the COVID19 era (p = 0.009).

Conclusions:: Conclusions. Our data confirm that the pandemic had no significant effect on the incidence of SE. The lower incidence of in-hospital onset SE, as well as the fewer patients with EEG within 24 hours, could indicate a reduced diagnosis of SE and consequently a decrease in SE treatment in the

NOCTURNAL ENURESIS AS A SYMPTOM OF IDIOPATHIC PARTIAL EPILEPSY.

Maruf Mavlanov, Farrukh Sailvaliyev
Tashkent medical academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: During a 6-year prospective follow-up were found 2 cases of a combination of nocturnal enuresis and partial convulsive syndrome in adults.

Methods:: The first patient T., 54 years old, complained of nocturnal enuresis for 3 years, focal seizures of the left arm for 1.5 years. Patient had not suffered from anything before, the beginning of the enuresis was every 2-3 months and became more frequent up to 1 time in 1-2 days. The seizures increased from 1 time in 2 weeks to 1 time in 2-3 days. MRI of the brain: vascular encephalopathy, EEG monitoring for 1 hour: acute-slow wave complexes in the fronto-parietal-temporal regions of both hemispheres of the brain. The second patient is 28 years old, since childhood there is nocturnal enuresis once 3-4 months. For the last 2.5 years, insomnia and continuous, large-sweeping, rhythmic twitching of the left leg have been troubling. The patient was treated for 1 month with a diagnosis of restless legs syndrome, but not effectively. After MRI and EEG monitoring, pathological activity was revealed in both fronto-parietal-temporal regions. No urological pathology was revealed in both patients.

Results:: Patients were diagnosed with focal epilepsy with nocturnal enuresis and given anticonvulsant therapy, with the disappearance of the both symptoms over time.

Conclusions:: Conclusion: Nocturnal enuresis may be a symptom of an epileptic seizure or the only symptom of idiopathic partial epilepsy, which requires further investigation.
PERAMPERAL AS ONLY CONCOMITANT ANTISEIZURE MEDICATION IN PEOPLE WITH EPILEPSY (PEROC STUDY). A REAL WORLD STUDY.

Michele Ascoli¹, Sara Gasparini¹, Edoardo Ferlazzo¹, Giovanni Mastroianni², Vittoria Cianci³, Anna Mammì¹, Valentina Bova², Michele Lo Giudice¹, Alfonso Iudice⁴, Umberto Aguglia¹, The Peroc Study Group The Peroc Study Group⁵
¹Magna Graecia University, Department Of Medical And Surgical Sciences, Catanzaro, Italy, ²Regional Epilepsy Center, Neurology Unit - Gom, Reggio Calabria, Italy, ³Regional Epilepsy Center, Neurology Unit, Reggio Calabria, Italy, ⁴University of Pisa, Department Of Clinical And Experimental Medicine, Section Of Neurology, Pisa, Italy, ⁵53 Italian Centers, Italy, Italy, Italy

Background and Aims:: the objective of this study was to assess the dose-related retention rate of Perampanel (PER), as a reliable proxy for overall tolerability and effectiveness, in adolescent and adults who received PER as a part of routine clinical care and as an adjunctive treatment to a previous monotherapy.

Methods:: we performed an observational, retrospective, multicenter study on people aged >=12 years with focal or generalized epilepsy consecutively recruited from 54 Italian epilepsy centers. All patients received PER as the only add-on antiseizure medication (ASM) according to standard clinical practice. Retention rate, seizure frequency and adverse events (AEs) were recorded at 3, 6 and 12 months after PER introduction.

Results:: In detail, 525 patients taking PER with at least 3 month follow-up were collected (215 males, mean age 40 years, SD 20.4). The retention rate at 3, 6 and 12 months follow-up was respectively 87%, 66% and 42%. The 50% responder rate at 3, 6 and 12 months was 66%, 69% and 69%. The seizure free rate at 3, 6 and 12 months was 39%, 59% and 59%.

Conclusions:: these preliminary data confirm the good efficacy of PER for focal or generalized epilepsy in real-life conditions. We provide the first data about its effectiveness as only add-on medication even in patients with a long-standing history of epilepsy and previously treated with many ASMs.
EPILEPSY AND COVID-19: IS INFECTION CORRELATED TO AN INCREASED RISK OF SEIZURE RECURRENCE?

Valentina Bannikova¹, Galina Odintsova², Anna Koloteva²
¹Pavlov First Saint Petersburg State Medical University, Medical Faculty, Saint-Petersburg, Russian Federation, ²Polenov Russian Neurosurgical Research Institute – a branch of federally funded institution “Almazov National Medical Research Centre” of the Ministry of Health of the Russian Federation, Epileptology, Saint-Petersburg, Russian Federation

Background and Aims:: The objective is to study the seizure dynamics in suffering COVID-19 patients with epilepsy, based on clinical observations and analysis of seizure progression.

Methods:: The study design was a single-centre retrospective uncontrolled open-label observational study of the impact of COVID-19 on the course of epilepsy. Suffering COVID-19 patients with epilepsy were interviewed between January and February 2021 using a questionnaire containing three sets of questions.

Results:: The study included 13 suffering COVID-19 patients with epilepsy: genetic (idiopathic) generalised (7/13; 54%), 6 cases of focal epilepsy (6/13; 46%). 2 questionnaires have not been answered yet. The mean age was 34.31±12.68. Seizure remission prior to COVID-19 was noted in 10 patients (77%), there was no seizure control in 3 cases of focal epilepsy at the time of COVID-19 (23%). No seizure frequency increase was observed in any case. No recurrent seizures were detected. EEG follow-up showed no exacerbation of seizures compared to the pre-outbreak indicators. AED monotherapy was used in 61% of cases. Levetiracetam monotherapy administered to 50% of patients and LEV taken as a part of a polytherapy regimen - in 100%.

Conclusions:: The research findings and literature data show that patients with epilepsy are at no greater risk than the general population. Young age, seizure remission, absence of somatic comorbidities, modern drug use with no interaction among AEDs and antibiotics and antivirals for the coronavirus disease treatment can be considered as positive predictive value of the course of epilepsy with COVID-19. Further studies with a large sample sizes are needed.
Background and Aims:: Aim: Cerebrovascular diseases (CVD) and their risk factors are the most frequent serious conditions in neurology that should be prevented. Epilepsy is one of the consequences of these conditions that affect not only elderly, but also younger adults. The aim is to show different vascular etiologies in epilepsy.

Methods:: Among different epilepsy etiologies we selected those with vascular etiologies and evaluated their presence under the umbrella of cerebrovascular etiology for epilepsy. We evaluated the characteristic features of each specific cerebrovascular etiology. 100 patients were selected and evaluated clinically, electrophysiologically, neuropsychologically and with imaging methods.

Results:: The most frequent etiology was stroke and cerebrovascular risk factors: hypercholesterolemia, high blood pressure, diabetes, obesity, smoking, carotid arteries stenosis, atrial fibrillation, lacunar cerebral insults present in 88 mostly elderly people, who were diagnosed with epilepsy with a time delay in some, as their seizures were not recognized at seizure onset, even in cases of nonconvulsive focal epileptic status, because of their comorbidities. Arteriovenous malformation (AVM) as a rare etiology, was present in 7 patients mostly children. Vasculitis as etiology was present in 3 young females with systemic lupus erythematosus. Cerebral venous thrombosis was present in 2 young females during postpartum period.

Conclusions:: Conclusion: Epilepsy is a frequent consequence of CVD and should be timely diagnosed and appropriately treated to prevent further disease burden and disability. Although CVD are typical for elderly, some less frequent CVD appear in young adults and even in children. CVD and their risk factors as etiology for epilepsy should be prevented.
GENDER-SPECIFIC TREATMENT FOR PHARMACORESISTANT EPILEPSY IN NEUROSURGICAL PATIENTS.

Valentina Bannikova¹, Galina Odintsova², Anna Koloteva²
¹Pavlov First Saint Petersburg State Medical University, Medical Faculty, Saint-Petersburg, Russian Federation, ²Polenov Russian Neurosurgical Research Institute – a branch of federally funded institution “Almazov National Medical Research Centre” of the Ministry of Health of the Russian Federation, Epileptology, Saint-Petersburg, Russian Federation

Background and Aims: In the XXI century, the range of antiepileptic drugs (AEDs) has significantly expanded, and gender aspects in AED treatment are urgent. The objective was to investigate gender-specific aspects of AEDs management in neurosurgical patients with pharmacoresistant epilepsy (PhRE).

Methods: In this retrospective study 60 neurosurgical patients with PhRE were examined in two gender groups: 1 - men (N 30) and 2 - women (N 30) at the PNI in 2020. The sex ratio was 1:1. The anamnesis of AED management was evaluated for 3 generations: 1-old and traditional, 2-new, 3-the newer. The frequency of use of AEDs of different generations was calculated on average per patient in the groups.

Results: The use of old AES in group 1 averaged 1.8 per person, more often in the female group - 2.6. New AEDs were used in both groups – 2 per person, newer AEDs were increasingly used in group 1 - 2 per person, 1 - in group 2. Attention was drawn to the percentage prevalence of valproic acid use in both groups compared to the others: in group 1 in 19.3% of cases, in group 2 – in 15.8%.

Conclusions: The use of old-generation drugs in the anamnesis was noted in all patients. The predominance of the use of valproic acid to treat epilepsy in both sexes shows that despite the pronounced side effects affecting the female reproductive system the effectiveness in severe and prolonged epilepsy determines the widespread use of valproates in both men and women despite new drug development.
ROLE OF PEROXISOMAL PROLIFERATOR-ACTIVATED Y-RECEPTORS IN ANALGESIA INDUCED WITH CEREBELLAR STIMULATIONS IN KINDLED RATS

Mykhailo Pervak¹, Olesya Poshyvak², Hanna Son¹, Kseniya Prybolovets¹, Kirill Latypov¹, Leonid Godlevsky¹
¹Odesa National Medical University, Department Of Biophysics, Informatics And Medical Devices, Odesa, Ukraine, ²Danylo Halutsky Lviv National Medical University, Pharmacology Department, Lviv, Ukraine

Background and Aims: Background. Antiepileptic effects induced with cerebellar transcranial direct current stimulation (TDCS), and the role of peroxisomal proliferator-activated y-receptors (PPARγ) in its development have been shown (Godlevsky, Pervak, 2017; 2019). Aims. To investigate the pronouncement of pain behaviors in rats with anodal TDCS of cerebellum and modulation of PPARγ activity.

Methods: Material and methods. Investigations were performed on rats with the kindling induced by pentylenetetrazol (PTZ) injections (30.0 mg/kg i.p., for three weeks). TDCS was performed with anode upon cerebellum (300 mcA for 10 min). BADGE (100.0 mg/kg, i.p.) was used for blockade PPARγ and pioglitazone (100.0 mg/kg, i.p.) for their activation. For the pain test formalin (50 μL; SC; 2%) was injected into either the glabrous skin of the hind limb and the severity of pain reactions was estimated in three points score (Erami, E. et al., 2017). False TDCS was used as a control.

Results: Results. The maximal level of pain behaviors was achieved at 21-27th min from the moment of formalin administration (2.32±0.30 points). TDCS induced a decrease of pain behaviors by 25.7% (P<0.05). After blockading PPARγ with BADGE the pronouncement of pain behaviors was 2.13±0.21 points and after pioglitazone 1.94±0.41 points (P>0.05). TDCS performed after pioglitazone administration caused the decrease of painful behaviors by 43,6% (P<0.05), while after BADGE the diminishment was at 16,3% (P>0.05).

Conclusions: Conclusions. Anodal cerebellar TDCS is effective against the second phase of formalin-induced pain in rats. Analgesic effects of cerebellar anodal TDCS were intensified with the agonist PPAR-gamma receptors administration and abolished with their blockade.
DYNAMICS OF INTERHEMISPHERIC COHERENCE IN CHANGING FUNCTIONAL STATES IN ADULTS WITH LOCALIZATION-RELATED EPILEPSY

Oleg Grebenyuk¹, Tatiana Kazennykh²
¹Siberian State Medical University, Clinics, Tomsk, Russian Federation, ²Mental Health Research Institute, Administration, Tomsk, Russian Federation

Background and Aims:: Study of the dynamics of interhemispheric coherence in patients with localization-related epilepsy with different responses to anticonvulsants in the physiological state (FS) of active, relaxed wakefulness and sleep.

Methods:: Research methods: 150 patients with symptomatic epilepsy of frontal-temporal localization aged 16 to 65 years with a disease duration of at least 2 years (group A - 78 individuals with a resistant form of the disease, group B - 78 individuals with controlled seizures) were monitored with the EEG in the interictal period in physiological states of wakefulness and physiological sleep in the daytime. Night sleep deprivation was used as a load. For coherent analysis, we used EEG regions devoid of artifacts during the period of relaxed wakefulness, active wakefulness, and during the 2nd-3rd stage of the slow-wave sleep phase immediately before the onset of α-sleep. Hyperventilation load and cognitive activation were used as stress tests in FS AB, which was performed by the method of cognitive evoked potentials P300 using auditory stimuli.

Results:: In groups A and B, there was an increase in interhemispheric coherence in the β-rhythm range during cognitive activation. Group B showed an increase in interhemispheric coherence in the δ-rhythm range during hyperventilation and a decrease in the β-rhythm range during cognitive activation. The dynamics of interhemispheric coherence was observed in the frontal zones, which are most dependent on the coordinating influences of the median structures of the brain.

Conclusions:: In patients with seizures, regardless of frequency, similar neurodynamic rearrangements were observed, manifested by unidirectional dynamics of coherence indicators.
Background and Aims: Seizures are a common manifestation of autoimmune encephalitis (AIE), and in some cases may not respond to antiseizure medications. Epileptogenesis in AIE is likely to arise from the synergistic effect of both innately driven neuroinflammation and antibody-induced hyperexcitability. We describe a case of concurrent anti-AMPAR encephalitis and thymomatous myasthenia with refractory focal status epilepticus.

Methods: Case report

Results: A 64-year-old man, with a thymomatous myasthenia gravis, presented dysautonomia, a 2-month history of memory deficits and mood disturbances. T2/FLAIR hyperintense temporal and frontal bilateral cortical lesions were detected on brain MRI, with hypermetabolism in the same areas on PET-CT. AMPAR Glur2 antibodies were identified in cerebrospinal fluid. The patient manifested prolonged episodes of confusion with inappropriate responses to questions, but he was able to understand simple instructions. EEG showed continuous focal seizure pattern over the left frontal and temporal regions consistent with focal status epilepticus. Intravenous benzodiazepines, levetiracetam, valproate and lacosamide were prescribed with no clinical/EEG improvement. There was a dramatic response to oral perampanel, with complete symptoms and EEG epileptiform abnormalities resolution over 3 days. Treatment with intravenous immunoglobulins, methylprednisolone, plasma exchange and surgical thymectomy was performed, with clinical benefit.

Conclusions: AIE provides a human model of neuroinflammatory epileptogenesis in which two components likely work synergistically. Preclinical studies evidenced AMPAR internalization in anti-AMPAR encephalitis, leading to reduced epileptic threshold. Moreover, Glur1-2 imbalance has been observed in status epilepticus. In our case, perampanel possibly contributed to seizures control by acting as selective and noncompetitive AMPAR antagonist.
TRANSIENT POST Ictal FEVER: AN INFREQUENT SYMPTOM.

Michalis Xifaras, Foteini Alourda, George Kalamaras, Georgia Limpitaki, Elli Kerezoudi
Athens General Hospital "Pammakaristos", Neurology, Athens, Greece

Background and Aims:: Fever is a response to stimuli leading to the deregulation of the central thermostatic control. It is well-known that hyperthermia is a significant seizure-inducing factor, but it is unusual to be observed in the post-ictal period.

Methods:: We present the case of a 41-year-old man, admitted to our Department due to multiple generalized convulsions since the early hours on the day of admission. He had a 20-year history of epileptic seizures, after sustaining head trauma in a car accident. He was taking valproate long-term, with poor adherence, and carbamazepine for 6 months. On admission the patient had full consciousness, and the neurological examination, blood pressure and blood glucose test were normal. His body temperature was 38.8°C.

Results:: An infectious cause of fever was investigated. A complete laboratory and imaging examination (WBC, ESR, CRP, liver biochemical tests, blood and urine cultures, PCR for SARS-CoV-2, CXR) was performed. Tests returned normal or negative, ruling out an infection. Brain CT revealed a porencephalic lesion on the left occipital lobe and signs of a craniotomy on the right temporal side. EEG showed slow theta activity in the left temporo-occipital area. The fever resolved spontaneously in about 12 hours.

Conclusions:: Fever is a well-known seizure-inducing factor, but an infrequent condition in post-ictal period. It is hypothesized that this symptom is a consequence of peri-ictal repetitive muscular contractions and disturbance of homeostasis in generalized convulsive seizures. It also seems possible that the upregulation of the hypothalamic thermoregulatory center can produce it. The investigation for infectious causes is necessary.
EPILEPSY ONSET IN PUBERTY

Galina Odintsova¹, Galina Odintsova²
¹Almazov National Medical Researcher Center, Epileptology, Saint Petersburg, Russian Federation, ²Almazov National Medical Researcher Center, Epileptology, Санкт-Петербург, Russian Federation

Background and Aims:: Purpose: to study onset age and features of onset in puberty at girls with epilepsy

Methods:: Research is part of a prospective observational uncontrolled comparative study of the antiepileptic drugs reproductive side effects. The age of epilepsy onset was studied at 155 female patients older than 16 y.o. Patients were divided into three groups according to WHO classification of puberty age (1997): 1gr. - before puberty- 1-9y.o., 2gr. – puberty- 10-18, 3g. – after puberty- older 18. The frequency of epilepsy onset was studied in 4 subgroups of puberty according to phases of maturing of the hypothalami-hypophysial system: 10-11y.o- beginning of hypothalami-hypophysial hormones secretion, 12-13- beginning menses, 14-15- becoming of an ovulatory peak, 17-18- establishment of a constant rhythm of hormones secretion

Results:: there were 23 patients (15%) in 1 gr., 92 (59%) – in 2gr, 40 (26%) – in 3 gr. Differences in the epilepsy onset in the comparison groups were statistically significant above in puberty (p <0,001). Epilepsy began in childhood (until 18y.o) in 75%. Epilepsy onset in 4 subgroups of puberty period: subgroup 1 — 18 patients (20%), subgroup 2 — 35 (38%), subgroup 3 — 24 (26%), subgroup of 4 — 15 (16%). Prevalence of epilepsy onset in the integrated age range of 12-16y.o. was statistically reliable (p<0,001).

Conclusions:: Thus, hormonal changes during the puberty period provoked epilepsy onset more often. The epilepsy onset occurred more often during the periods of the beginning oestadiol production and its ovulatory peaks (12-16y.o). It confirms proconvulsive effect of estrogens
COVID-19 AND EPILEPSY: DISEASE OR VACCINATION?

Galina Odintsova¹, Valentina Bannikova², Anna Koloteva², Oleg Nezdorovin²
¹Almazov National Medical Researcher Center, Epileptology, Saint Petersburg, Russian Federation, ²Almazov National Medical Researcher Center, Epileptology, Санкт-Петербург, Russian Federation

Background and Aims:: to compare the dynamics of epilepsy in patients with COVID-19 disease and the “Sputnik V” COVID-19 vaccination for the prevention of a new coronavirus infection (COVID-19) from a review of two clinical cases.

Methods:: The study design was a single-center retrospective uncontrolled open-label observational study of the impact of COVID-19 on the course of epilepsy. Patients with epilepsy were interviewed during the period January-March 2021 using a questionnaire. Two groups were identified: gr.1 recovered from COVID-19, gr.2 received the Sputnik V COVID-19 vaccine, a measure for COVID-19 prevention. To compare the dynamics of epilepsy we enrolled 1 patient from each group: group 1 patient – with no risk of recurrence after COVID-19 and group 2 patient – with the risk of complicated course of vaccine reactions after neurosurgical treatment for epilepsy.

Results:: Gr.1 included 19 patients who had had COVID-19 and Gr.2 included 2 patients who had been Sputnik V vaccinated for prevention the spread of the novel coronavirus infection. Gr.1 patient, 32 years old, with three-year remission, relapsed with mild COVID-19. Gr.2 patient with focal pharmacoresistant epilepsy with three-year remission after epilepsy surgery had no adverse effects after Sputnik V vaccination, and seizure remission sustained.

Conclusions:: The results of this study showed examples of good tolerability of the Sputnik-V vaccine in an older patient with drug-resistant epilepsy after neurosurgery and the recurrent seizures in younger patients with idiopathic epilepsy and mild COVID-19. The results will help practitioners to decide how to handle an epileptic patient. Further studies with large sample sizes are needed.
Background and Aims:: Epilepsy is a disease associated with myths and taboos, leading to poor understanding and knowledge regarding causes, effects and treatment availability. Public understanding of epilepsy has not been investigated sufficiently so the purpose of this study was to understand the opinions of Accredited Social Health Activist (ASHA) Workers in rural districts of Maharashtra.

Methods:: The survey was conducted before starting an online awareness lecture of the ASHA workers which was organized by Epilepsy Foundation in association with National Health Mission government of Maharashtra. A total of 89 ASHA workers were interviewed, a Marathi questionnaire survey was conducted. The questionnaires contained 15 questions based on Epilepsy and seizures.

Results:: For this study, responses from all included participants (N = 89) were noted. All the participants were divided into 4 regions of Maharashtra, the overall awareness of epilepsy was 58.14%, and the highest awareness was seen in Vidharbha Region and least in Rest of Maharashtra region 67.13% and 53.15% respectively.

Conclusions:: ASHA workers in Maharashtra are not very well acquainted with epilepsy and have many erroneous beliefs about the condition. Negative attitudes are pervasive within communities in Maharashtra. The National Health Mission government of Maharashtra should conduct the awareness programs to clarify the purported modes of transmission of epilepsy, available treatment options and care offered during epileptic seizures during community sensitizations in our settings.
LATE-ONSET EPILEPSY WITH UNKNOWN ETIOLOGY: NEUropsychological profile, CERebrospinal fluid BIOMARKERS, AND QUANTITATIVE EEG CHARACTERISTICS

Elena Nardi Cesarini1,2, Claudio Babiloni3, Nicola Salvadori2, Lucia Farotti2, Claudio Del Percio3, Maria Teresa Pascarelli4, Giuseppe Noce5, Roberta Lizio5, Fulvio Da Re5, Valeria Isella6, Lucio Tremolizzo6, Michele Romoli2,7, Jacopo Difrancesco6, Lucilla Parnetti2, Cinzia Costa2

1Ospedale di Senigallia, Uoc Neurologia, Senigallia, Italy, 2Neurology Clinic, S. Maria della Misericordia Hospital – University of Perugia, Medicine And Surgery, Perugia, Italy, 3Sapienza University of Rome, Department Of Physiology And Pharmacology “v. Ersipamer”., Roma, Italy, 4Institute of Research and Medical Care (IRCCS), Oasi, Troina, Italy, 5Institute of Research and Medical Care (IRCCS), Sdn, Naples, Italy, 6San Gerardo Hospital, Milan Center for Neuroscience, School of Medicine and Surgery, University of Milano-Bicocca, Department Of Neurology, Monza, Italy, 7IRCCS Istituto delle Scienze Neuroligiche di Bologna, Neurologia E Rete Stroke Metropolitana, Bologna, Italy

Background and Aims:: Despite epilepsy has been associated with cognitive decline, neuropsychological, neurobiological and neurophysiological features in patients with late-onset epilepsy of unknown etiology (LOEU) are still unknown. This cross-sectional study aims at investigating neuropsychological profile, cerebrospinal fluid (CSF) biomarkers of Alzheimer’s disease (AD), and resting-state quantitative electroencephalographic (qEEG) cortical rhythms in LOEU patients with mild cognitive impairment (LOEU-MCI) and with normal cognition (LOEU-CN), compared to non-epileptic MCI (NE-MCI) and cognitively normal (CN) controls.

Methods:: Consecutive patients diagnosed with LOEU-CN (19), LOEU-MCI (27), NE-MCI (21), and CN (11) were enrolled. Patients underwent standardized comprehensive neuropsychological evaluation and CSF core AD biomarkers assessment. Recordings of resting-state eyes-closed electroencephalographic (EEG) rhythms were collected and cortical source estimation with eLORETA was performed.

Results:: Most of LOEU patients had MCI status at seizure onset (59%). Patients with LOEU-MCI performed significantly worse on measures of global cognition, visuo-spatial abilities and executive functions compared to NE-MCI patients (p<0.05). CSF Aβ42 levels were lower in the LOEU-MCI compared with the LOEU-CN group. Finally, parietal and occipital sources of alpha (8-12 Hz) rhythms were less active in the LOEU-MCI than NE-MCI and CN groups, and the opposite was true for frontal and temporal cortical delta sources.

Conclusions:: MCI status was relatively frequent in LOEU patients, involved multiple cognitive domains, and might have been driven by amyloidosis according to CSF biomarkers. LOEU-MCI status was associated with abnormalities in cortical sources of EEG rhythms related to quiet vigilance. Future longitudinal studies should cross-validate our findings and test the predictive value of CSF and EEG variables.
INTERMITTENT LIGHT STIMULATION IN ON-DEMAND STREAMING TELEVISION SERIES, ACCURACY OF INFORMATION AND SEIZURE OCCURRENCE. THE STREAM-LIGHT STUDY.

Gemelli, Neurology Unit, Rome, Italy, ⁸University G. d”Annunzio di Chieti-Pescara, Neuroscience, Imaging And Clinical Sciences, Chieti, Italy

Background and Aims:: In about 3% of people with epilepsy (PWE), exposure to flashing light sequences (FLS) can trigger seizures. Exposure to FLS may as well induce other symptoms (i.e. headache and dizziness). On-demand streaming platforms (OSP) have become popular nowadays. Binge watching sessions involve the use of laptops and take place in conditions of low ambient light. The purpose of our study is to identify the presence of FLS in the catalogues offered by the main OSP, and to assess any correlation to seizure or discomfort symptoms recurrence. The presence of adequate information addressed to PWE was evaluated.

Methods:: We carried out a research in online patients’ forums, looking for warnings about FLS reports within TV-series and films offered by the main OSP. Data referred to seizure onset, as well as symptoms of discomfort associated with the vision of a specific show and the presence of adequate warnings, were collected. A re-watch of the TV-series/film by an epileptologist was performed to evaluate the definite presence of FLS.

Results:: 134 TV-series have been identified, with 3334 FLS warnings. Recurrence of seizures was reported in 2 TV-series, 12 were associated with the onset of discomfort symptoms. The platform with the higher number of reports was Netflix. Among all of the analyzed and reported shows, only in one case an FLS information banner was shown.

Conclusions:: The presence of FLS was very frequent in OSP catalogues of films and TV-series. Systematic improvement of information about FLS presence is necessary for greater safety of the audience suffering from epilepsy.
INTERICTAL QTC ABNORMALITIES IN PATIENTS WITH EPILEPSY: EFFECTS OF DISEASE DURATION AND ANTI-SEIZURE MEDICATIONS

Giovanni Falcicchio, Giammarco Milella, Maria Latorre, Angela Alicino, Teresa Francavilla, Maria Trojano, Angela La Neve

1University of Bari “Aldo Moro”, Department Of Basic Medical Sciences, Neurosciences And Sense Organs - Neurology Unit, Bari, Italy, 2Division of University Cardiology, Cardiothoracic Department Policlinico University Hospital, Bari, Italy

Background and Aims:: Epilepsy is associated with abnormalities in cardiac repolarization as corrected QT interval (QTc) prolongation. The aim of the study is to correlate QTc abnormalities to epilepsy duration and number and class of anti-seizure medications (ASMs).

Methods:: Interictal 12-lead electrocardiograms of 101 people with epilepsy (PWE) without cardiovascular risk factors or chronic diseases were collected. Mann-Whitney or Wilcoxon tests were used to assess QTc differences into PWE dichotomized according to the median value of epilepsy duration and ASMs as appropriates. Correlations between clinical parameters and QTc were assessed using Spearman’s correlation. Variables associated with QTc alterations were tested using logistic regression after dichotomizing QTc according to its median value.

Results:: 101 PWE (47M; 54F) assuming 1 to 3 ASMs were enrolled. Median epilepsy duration was 16 years. QTc median value was 407 msec. Patients with long-standing disease showed increased QTc (p<0.0001) compared to PWE with a shorter epilepsy duration. QTc increased proportionally to the years of disease (Rs:0.429;p<0.0001). No QTc differences were found according to the etiology of epilepsy or seizure type. QTc increased proportionally to the number of ASMs (Rs:0.396; p<.0001) independently from ASM type. Logistic regression confirmed epilepsy duration as the only variable associate to QTc prolongation (p<0.001;HR 4.5).

Conclusions:: Even if the number of ASMs may have a role in QTc alteration, epilepsy duration seems to be the only independent factor causing QTc prolongation.
ADVERSE EFFECT PROFILE OF ANTIÈPILEPTIC DRUGS

Charfi Rihab1, Sawsan Daoud2, Nouha Farhat2, Salma Sakka2, Khadija Sonda Moalla2, Nadia Bouattour2, Olfa Hdiji2, Mariem Damak2, Chokri Mhiri3
1CHU Hbib Bouguiba Sfax Tunisie, Of Neurology, Sfax, Tunisia, 2Universal Hospital Habib Bourguiba, Neurology, SFAX, Tunisia, 3Habib Bourguiba university hospital, Neurology, Sfax, Tunisia

Background and Aims:: L’épilepsie est une maladie neurologique affectant des millions de patients dans le monde. Le traitement par antiépileptiques (AED) est efficace chez environ 70 à 80% des patients, mais il est associé à de nombreux effets indésirables (EI) qui peuvent affecter l’observance des patients.

Methods:: Il concerne une étude transversale chez des patients atteints d’épilepsie (PWE). Un questionnaire a été administré à PWE pour connaître les EI ressentis par eux.

Results:: We included 406 PWE. Among 198 patients on valproate monotherapy, 17.17% developed AEs. Tremor and upset stomach were the most common AEs (4.04% and 3.53% respectively). Weight gain (2.52%), Sleepiness, hair loss (2.02% each), hepatic cytolysis (1.51%) and thrombocytopenia (0.50%) were also reported by our patients. The most frequent AEs reported by patients under carbamazepine were vertigo (7.14), skin rash (5.35), upset stomach (3.57%) and sleepiness (1.78%). Eight patients out of 28 taking phenobarbital presented AEs such as Sleepiness (14.28%) skin rash (7.14%) hepatic cholestasis (3.57%) and shoulder-hand syndrome (3.57%). Among 124 patients on polytherapy, 25 presented AEs (20.16%) which were mainly drowsiness and tremor (7.25%, 4.84% respectively). There was no significant association between AEs, duration of treatment and seizure frequency.

Conclusions:: Drug therapy is the mainstay of treatment of epilepsy. However, AEs often lead to unfavorable quality of life and impaired adherence. That’s why it’s important to examine the tolerability of AEDs.
EFFICACY AND TOLERABILITY OF ANTI-SEIZURE DRUGS IN THE TREATMENT AND PROPHYLAXIS OF BRAIN TUMOR RELATED-EPILEPSY (BRTE): A REAL-WORLD STUDY

Giacomo Evangelista¹, Fedele Dono¹, Annalisa Ricci¹, Mirella Russo¹, Claudia Carrarini², Rino Speranza³, Francesca Anzellotti³, Marco Onofri³, Stefano Sensi³, Laura Bonanni³
¹"G. D'Annunzio" University of Chieti-Pescara, Department Of Neuroscience, Imaging And Clinical Science, Chieti, Italy, ²University G. d'Annunzio of Chieti-Pescara, Department Of Neuroscience, Imaging And Clinical Sciences, Chieti, Italy, ³"SS Annunziata" Hospital, Epilepsy Center, Neurology Clinic, Chieti, Italy

Background and Aims: Brain tumour related-epilepsy (BRTE) is a condition characterized by the development of seizures in the context of a brain tumour pathology. In 40% of cases, seizures represent one of the onset symptoms of brain tumour. According to some studies, the high incidence of BRTE in patients with brain tumour would justify the use of a prophylactic anti-seizure therapy (EST) which in turn would not lead to major side effects (SE). However, such studies do not make an appropriate assessment of neuropsychiatric SE of anti-seizure therapy.

Methods: Thirty-two patients with brain tumour were consecutively selected and divided into two groups: patients with BRTE on AST (BRTE group) and patients with brain tumour on prophylactic AST (PROPHYLAXIS group). Neuropsychiatric SE of anti-seizure therapy were assessed using the Neuropsychiatric Inventory Questionnaire (NPI-Q) at the baseline visit and at 6-month follow-up. The evaluation of the efficacy of the anti-seizure treatment in subjects with BRTE was evaluated according to the percentage reduction in the frequency of seizures at 6 months.

Results: 17 patients in the BRTE group and 15 patients in the PROPHYLAXIS group were included. The drug most commonly used in the two groups was Levetiracetam. The mean scores obtained on the NPI were significantly higher in the PROPHYLAXIS group (p <0.05) as were the scores on the depression (p <0.02), motor activity (p <0.03) and sleep disturbances (p <0.05).

Conclusions: Prophylactic treatment with anti-seizure medication in the context of brain tumour can have a deleterious effect on the psychiatric sphere.
EFFECT OF COVID-19 PANDEMIC ON PEOPLE WITH EPILEPSY (PWE): EXPERIENCE FROM A TERRITORY CARE CENTRE FROM INDIA

Neetu Choudhary, Parampreet Kharbanda, Jitupam Baishya, Kamalesh Chakravarty
POSTGRADUATE INSTITUTE OF MEDICAL EDUCATION AND RESEARCH, Neurology, Chandigarh, India

Background and Aims:: Background-Epilepsy if one of the most common neurological disorder and in around 30-40% people with epilepsy sz are refractory. Among different causes (age of onset, aetiology, sz frequency) of breakthrough seizure non compliance to AED and missed dosage is the most common, followed by sleep deprivation and stress. During nationwide lockdown due to COVID-19 pandemic routine OPD services are stopped in most of the medical facilities and only emergency services are on run. AIM-To study the effect of COVID-19 pandemic and different measures taken by authority to contain the pandemic on people with epilepsy (PWE).

Methods:: A cross sectional observational study based on telephonic survey consisting of 15 questions addressing seizure control and reasons behind any change in seizure frequency was conducted in a group of PWE in India in May 2020.

Results:: 211 PWE participated in the interview. Sixteen (7.6%) reported an increase in seizure frequency of which 5 (31.25%, p<.001) were due to unavailability of anti-seizure medications (ASMs). Number of ASMs and time since the last visit to epilepsy clinic was not associated with increased seizure. ASMs were not available to 7 (3.3%), available with difficulty to 45 (21.3%) and freely available to 159 (75.3%) PWE. None of the PWE had COVID-19 infection and none with increased seizure frequency had any symptoms suggestive of COVID-19 infection.

Conclusions:: There is no predisposition to COVID-19 infection or increased seizure frequency due to symptoms suggestive of COVID-19 in PWE in this cohort. Unavailability of ASMs is the most important cause of increased seizure frequency during COVID-19 pandemic for which necessary steps should be undertaken.
Background and Aims:: Multiple sclerosis (MS) is a chronic autoimmune demyelinating disease of the central nervous system. Epilepsy is three times more frequent in patients with MS when compared to the general population. Focal and focal-to-bilateral seizures are the most frequent ones although they can be misdiagnosed as paroxysmal demyelination events causing a delay in diagnosis and treatment. This study aims to investigate clinical, radiological, electrophysiological and neuropsychological aspects between epileptic MS patients and non epileptic MS patients.

Methods:: Twenty-five MS patients with epilepsy (EPI+ group) and 25 age-and-sex-matched MS patients (EPI− group) were retrospectively selected from the database of the Multiple Sclerosis Center at the “SS. Annunziata” Hospital in Chieti. Patients underwent a comprehensive clinical assessment consisting of neurological examination, electroencephalogram (EEG), MRI and neuropsychological testing via the BICAMS (Brief International Cognitive Assessment for MS) - a set of 3 tests to assess cognitive domains: Information elaboration speed (SDMT), Verbal Memory (CVLT-II), Visuospatial memory (BVMT-R).

Results:: EPI+ group showed a significantly higher EDSS, a higher amount of cortical and juxtacortical T2+ lesions and performed worse in SDMT and BVMT-R, compared to the control group. Interictal EEG recording showed interictal epileptiform abnormalities in 13/25 patients in EPI+ group compared to 0/25 in EPI− group.

Conclusions:: Epilepsy causes an important increase in disability (EDSS) and worse neuropsychological score in MS patients suggesting the need for earlier diagnosis and precocious treatment. Interictal EEG recording may help clinician in diagnosis although the limitation due to its sensibility.
Background and Aims:: Poor adherence to medication is common especially in the case of chronic diseases like Epilepsy. Treatment satisfaction may impact adherence. The aim of this study was to measure medication adherence and its relationship to treatment satisfaction, duration of illness and Epilepsy control and to determine the causes of nonadherence in Sudanese patients with epilepsy.

Methods:: This cross-sectional study was conducted in Daoud Charity Clinic. A total coverage of patients with epilepsy fulfilling the inclusion criteria during a period of eight weeks was done. Patients were interviewed and assessed using Hill-Bone medication adherence scale (HB-MAS) and treatment satisfaction questionnaire for medication (TSQM) to measure medication adherence and treatment satisfaction.

Results:: 72 patients were studied. 43% were males and 57% were females. Mean age was 31.28 ± 11.46. Mean HB-MAS score was 34 ± 2.1 indicating high adherence. Adherence was not significantly correlated with duration of illness and there was no significant difference in mean HB-MAS score between patients with well and poorly-controlled epilepsy. 57% reported to have missed their medication more than once because of short supply. Mean treatment satisfaction scores regarding four domains of effectiveness, side effects, convenience and global satisfaction were 84.5 ± 17.7, 92.4 ± 17.1, 83.9 ± 12.8 and 83.4 ± 18.8 respectively. There was a significant correlation between adherence and the convenience domain (p = 0.002), but not the other domains.

Conclusions:: In our sample medication adherence and treatment satisfaction was found to be high in patients with epilepsy. Treatment satisfaction in regard to convenience was significantly correlated to medication adherence.
MEDICATION ADHERENCE IN PEOPLE WITH EPILEPSY

Flavia Narducci¹, Jacopo Lanzone², Lorenzo Ricci¹, Marilisa Boscarino¹, Mario Tombini¹, Vincenzo Di Lazzaro¹, Giovanni Assenza¹
¹Campus Bio-Medico University, Unit Of Neurology, Neurophysiology, Neurobiology, Rome, Italy, ²Università Tor vergata, Department Of Systems Medicine, Neuroscience, Rome, Italy

Background and Aims:: Medication adherence in people with epilepsy (PWE) is a crucial factor to reduce risk of seizure recurrence. Adherence to antiepileptic drugs (AED) increases PWE survival and quality of life, whereas non-adherence is associated with increased mortality and increased hospitalization. The MMAS-8 (Modified Morisky Adherence Scale-8) is a valid instrument to evaluate medication adherence in PWE. The aim of our study is to assess clinical and demographic factors that influence medication adherence in PWE.

Methods:: A population of 118 PWE was asked to answer online questionnaires, with particular attention to: MMAS8, QoLIE (Quality of Life in Epilepsy Inventory), BDI-II (Beck Depression Inventory), GAD (Generalized Anxiety Disorder) e Resilience. We used ANOVA test and Pearson correlation to define the relationship between medication adherence and demographic data, clinical variables (seizure frequency, number of AED) and individual features (quality of life, depression, anxiety and resilience).

Results:: We found that women were more adherent to therapy than men (p<0.01). Duration of illness was positively related to medication adherence. No significant correlation was found between medication adherence and number of AED (p=0.9). Adherence was significantly correlated with depression (BDI-II) and resilience (p<0.05). We found that people with higher scores of BDI-II (moderate and severe depression) were less adherent to therapy. People with higher scores of resilience were more adherent to AED therapy.

Conclusions:: In our study we confirmed that sex, duration of illness and depression are significantly related to medication adherence in PWE. For the first time, we demonstrated that higher resilience is associated with a better medication adherence.
Background and Aims:: Idiopathic generalized epilepsies (IGE) are syndromes diagnosed by clinical and electroencephalographic features. There are four syndromes recognized by the International League Against Epilepsy including childhood absence epilepsy (CAE); juvenile absence epilepsy (JAE); juvenile myoclonic epilepsy (JME); and epilepsy with generalized tonic–clonic seizures only (EGTCS). In the current study, we tried to determine distinctive features to distinguish these syndromes from one another.

Methods:: We conducted a cross-sectional retrospective study over a period of 3 years (2017-2019). We included all patients aged more than 18 years old, with a clinical diagnosis of IGE. We studied the demographic, clinical and electroencephalogram (EEG) findings in all IGE syndromes.

Results:: During the study period, 127 patients were diagnosed as having IGEs (EGTCS: 100, JME: 22; CAE: 3 JAE: 2). The age of seizure onset was 17.83±9.8 years. Epilepsy risk factors were reported to be as follows: parental consanguinity in 49 patients (38.58%), having family history of epilepsy in 40 (31.49%), febrile convulsion in 25 (19.68%). The sex ratio was significantly different in patients with JME compared to EGTCS. The male to female ratio was 0.69 in patients with JME. Interictal EEG was more frequently pathologic in patients with JME compared to EGTCS (P=0.036). In addition, generalized spike-wave complexes were more frequently reported in patients with JME (P=0.0001). Photoparoxysmal response was more frequently observed in patients with JME (P=0.023).

Conclusions:: IGE are common epilepsy syndromes. Additional epidemiological and genetic studies can be useful to better understand clinical and electrophysiological characteristics.
EPILEPSY AND STIGMATIZATION

Charfi Rihab1, Sawsan Daoud2, Olfa Hdijii3, Nadia Bouattour3, Nouha Farhat3, Khadija Sonda Moalla2, Mariem Damak3, Chokri Mhiri4
1CHU Hbib Bouguiba Sfax Tunisia, Of Neurology, Sfax, Tunisia, 2CHU habib bourguiba Sfax, Neurology, sfax, Tunisia, 3Universal Hospital Habib Bourguiba, Neurology, SFAX, Tunisia, 4Habib Bourguiba university hospital, Neurology, Sfax, Tunisia

Background and Aims:: Epilepsy is a common neurological condition. Stigma associated with epilepsy is common in many cultures. It has a negative influence on the lives of people with epilepsy (PWE) and it contribute to poor outcomes such as isolation, unemployment, lower prospects of marriage and not seeking treatment.

Methods:: We conducted a cross-sectional study of epileptics patients aged 18 to 59, who were followed up at neurological department over a 3-year period. (2017-2019). Demographic (age, gender, marital status, level of education, employment status) and clinical characteristics of the patients were recorded.

Results:: We included 518 people with epilepsy. The average age was 37.34 years (18 - 59 years). The sex ratio was 1.4 (303 M / 215 F). Most of our patients were single (49.4%). Regarding the type of seizure 56.8% had generalized epileptic seizures. Only 34.9% of our patients had a high school or university education level. At the time of the study, only 37.5% had a job. The factors associated with non-professional integration were generalized epilepsy (p = 0.001) and poor response to antiepileptic treatment (0.009).

Conclusions:: Epilepsy is a stigmatizing condition and this facet is rarely studied. Higher unemployment and lower marriage rates indicate that PWE suffer from social problems. Understanding this aspect of epilepsy is important for reducing the burden of epilepsy.
EFFECTS OF THE NONCOMPETITIVE AMPA RECEPTOR ANTAGONIST PERAMPANEL ON THALAMO-CORTICAL EXCITABILITY: A STUDY OF HIGH-FREQUENCY OSCILLATIONS IN SOMATOSENSORY EVOKED POTENTIALS

Marilisa Boscarino¹, Jacopo Lanzone², Lorenzo Ricci¹, Angelo Insola⁴, Mario Tambini¹, Vincenzo Di Lazzaro¹, Giovanni Assenza¹
¹Campus Bio-Medico University, Neurology Department, Rome, Italy, ²Università Tor Vergata, Department Of Systems Medicine, Neuroscience, Rome, Italy, ³Fondazione Europea per la Ricerca Biomedica Onlus, Fondazione Europea Per La Ricerca Biomedica Onlus, Trescore Balneario, Italy, ⁴CTO Hospital, Neurophysiology Unit, Rome, Italy

Background and Aims:: We designed a longitudinal cohort study on People with Epilepsy (PwE) with the aim of assessing the effect of Perampanel (PER) on cortico-subcortical networks, as measured by high-frequency oscillations of somatosensory evoked potentials (SEP-HFOs). SEP-HFOs measure the excitability of both thalamocortical projections (early HFOs) and intracortical GABAergic synapses (late HFOs), thus they could be used to study the anti-glutamatergic action of PER, a selective antagonist of the AMPA receptor.

Methods:: 15 PwE eligible for PER add-on therapy, were enrolled prospectively. Subjects underwent SEPs recording from the dominant hand at two times: PwET0 (baseline, before PER titration) and PwET1 (therapeutic dose of 4 mg). HFOs were obtained by filtering N20 scalp response in the 400-800Hz range. Patients were compared with a normative population of 15 healthy controls (HC) matched for age and sex.

Results:: We found a significant reduction of Total HFOs and mostly early HFOs area between PwET0 and PwET1 (p=0.05 and p=0.045 respectively) and between HC and PwET1 (p=0.01). Furthermore, we found a significant reduction of P24/N24 Amplitude between PwET0 and HC and between PwET0 and PwET1 (p=0.006 and p=0.032, respectively).

Conclusions:: Introduction of PER as add-on therapy reduced the area of total HFOs, acting mainly on the early burst, related to thalamo-cortical pathways. Furthermore P24/N24 amplitude, which seems to reflect a form of corticosubcortical integration, resulted increased in PwE at T0 and normalized at T1. Our findings suggest that PER acts on cortico-subcortical excitability. This could explain the broad spectrum of PER and its success in forms of epilepsy characterized by thalamo-cortical hyperexcitability.
DEVELOPMENT AND USE OF AN INSTRUMENT (EKAT) FOR ASSESSMENT OF COMPETENCE OF MEDICAL TRAINEES IN PROVIDING EPILEPSY CARE AT VARYING LEVELS OF THEIR TRAINING

Ankit Goyal, Mamta Singh, Mv Padma Srivastava, Rohit Bhatia, Vishnu V Y, Roopa Rajan, Anu Gupta
All India Institute of Medical Sciences, Neurology, New Delhi, India

Background and Aims:: BACKGROUND Epilepsy treatment gap in India and many other low and middle income countries can in large part be narrowed if competence to provide non-specialist (primary and secondary) epilepsy care is developed amongst medical trainees at the graduate, postgraduate and super-speciality levels. AIM To develop an instrument and use it for assessing the competence of medical trainees in providing epilepsy care at various levels of training.

Methods:: METHODS The questionnaire based instrument- EKAT (Epilepsy knowledge assessment tool) was developed with the help of epilepsy experts using the Delphi method. It was applied on a small pilot population to calculate its psychometric properties. A cut-off pass score was established using Modified Angoff method. It was then used to assess the competence of 360 medical trainees.

Results:: RESULTS The final version of EKAT was found to have very good internal consistency (Cronbach’s alpha - 0.84), item difficulty range of 11%-87% and good expert inter-rater reliability (ICC - 0.82). The assessment of 360 medical trainees showed statistically significant difference in mean scores and pass percentage across the pre-specified groups: Undergraduates (20.43 ± 7.68, 15%), Interns (23.85 ± 6.0, 20%), Postgraduates (27.57 ± 5.48, 43%), Neurology (34.82 ± 4.43, 97%) and Neurosurgery (26.73 ± 4.73, 32%) with a p-value of < 0.001. Intra-group comparisons and performance in pre-specified domains and levels of proficiency across all groups showed significant differences.

Conclusions:: CONCLUSIONS EKAT is a reliable and valid instrument to assess the competence of medical trainees in epilepsy care across varying levels of proficiency, specialty and training.
BE CAREFUL, ORAL PHENYTOIN CAN CAUSE SINUS ARREST

Dhawal Narang¹, Gopal Puduval¹, Ajay Bahadur², Vipin Kumar¹, Usha Misra¹
¹Apollomedics Superspeciality Hospital, Neurology, Lucknow, India, ²Apollomedics Superspeciality Hospital, Cardiology, Lucknow, India

Background and Aims:: Phenytoin(PHT) is widely used because of its efficacy in controlling seizures, easy availability and low cos. PHT may occasionally result in cardiac toxicity even death following IV infusion. We report a case of sinus arrest leading to bradycardia on oral treatment. We report this case highlighting cardiac toxicity even on oral treatment with PHT

Methods:: 42 y gentleman presented with new onset left focal seizures with secondary generalization due to arteriovenous malformation which was treated with glue embolization. He was prescribed PHT for focal seizures. Following breakthrough seizures 4y later, PHT dose was increased to 400 mg following which he developed acute onset distension of abdomen, dyspnea and unconsciousness. The patient was afebrile, his pulse was 32/min, BP 90/60 mmHg, respiratory rate 24/min oxygen saturation 55% on room air. His ECG showed bradycardia with atrial escape bigeminy secondary to sinus arrest. He was treated with inj atropine 0.6 mgSC and isoprenaline 5mcg/min. PHT was replaced by levetiracetam 500mg and carbamazepine 200mg twice daily. His pulse increased to 56/min. His white cell counts, blood glucose were normal, serum urea 67mg/dl, creatinine 1.1mg/dL, serum Na 133.0,K 4.8, Ca 8.5, Mg 1.8, PH 7.3 , T3 47.7, T4 6.9, TSH 1.2, serum cortisol 12.9mcg/dl, alkaline phosphatase 124KA, bilirubin 0.8/0.34 mg/dl, SGPT 290.0U/L, SGOT 795.0U/L. His serum phenytoin level done next day morning was 18.0 mcg /ml.

Results:: As he improved, isoprenaline was tapered and he was discharged on 3rd day of hospitalization.

Conclusions:: Serious sinus arrest can occur even on oral PHT
EPILEPSY AND SLEEP DISORDERS: A COMPLEX INTERPLAY

Sirine Belghuith, Sawsan Daoud, Nadia Bouattour, Salma Sakka, Nouha Farhat, Khadija Sonda Moalla, Olfa Hdiji, Mariem Damak, Chokri Mhiri
habib bourguiba hospital, Neurological Department, sfax, Tunisia

Background and Aims:: The interaction between sleep and epilepsy is reciprocal, with patients having sleep disorders that are frequently related to the severity of the disease. These disorders are underdiagnosed. They could affect the quality of life of people with epilepsy. We purpose to determine the prevalence of sleep disorders in patients with epilepsy and to evaluate their impact on the quality of life of these patients.

Methods:: This cross-sectional prospective study was carried on patients with epilepsy attending the Neurology outpatient department at Habib Bourguiba Hospital Sfax-Tunisia during 1 month. Data were collected in a questionnaire containing socio-demographic and clinical data. Sleep disorders was assessed using Epworth Sleepiness Scale and Athens Insomnia Scale. Quality of life was assessed using QOLIE-31.

Results:: 33 patients were included of whom 22 were males and 11 were females. 64% of patients had generalized seizures. Insomnia was observed in 78.8% of patients and daytime sleepiness in 45.5% of cases. No correlation was found between sex and insomnia or with daytime hypersomnolence (p = 0.19 and 0.24 respectively). Generalized seizures were associated with a higher frequency of sleep disturbances (p = 0.02). Prevalence of sleep disorders wasn’t affected by anti-epileptic drug. However, daytime sleepiness was correlated with polytherapy (p=0.04). A negative correlation between "emotional well-being" and day time hypersomnolence was noted (p = 0.03).

Conclusions:: Sleep disorders are frequent in our study in accordance with literature data. Hence the importance of a careful evaluation in order to detect and treat them.
NEURAL CD40 MODULATES NEURONAL NETWORK DURING SEIZURES

Alberto Musto¹, Esther Pototskiy², Katherine Vinokuroff¹, Kendall Howard¹
¹Eastern Virginia Medical School, Pathology & Anatomy And Neurology, Norfolk, United States of America, ²Eastern Virginia Medical School, Pathology And Anatomy, Norfolk, United States of America

Background and Aims:: Unregulated neuroinflammation mediates initiation and maintenance of seizures by inducing neuronal hyper-excitability, interneuron damage, and aberrant post-synaptic formation. CD40L, a small protein belonging to the TNF superfamily that interacts with the CD40 receptor protein, transduces molecular signaling that mediates neurite organization during brain development. The goal of this research was to determine whether CD40 modulates seizure.

Methods:: Adult male CD40 deficient mice (CD40KO) and its respective wild type were used in this study. To evaluate seizure susceptibility successive 35 mg/kg, intraperitoneal (i.p.) doses of pentylenetetrazole (PTZ) given at 5 min up to 6 doses and to test seizure severity PTZ (75mg/kg, ip) was given as single doses. Using a chronically implanted silicon probe in the cortex-hippocampal axis in a group of mice simultaneously, local field potential (LFP) were evaluated during spontaneously behavior and PTZ induced seizures. Seizures severity were evaluated using Racine’s score, including the latency to elicit seizure after PTZ. Frequency analysis from LFP including individual neuronal activity were analyzed using a signal analysis software. Then brain samples were collected to evaluate activation of CD40 and neuronal damage using immunohistology from hippocampal and neocortex.

Results:: CD40KO demonstrated reduction in seizure severity (CD40KO: 0.1± 0.14 S.E.M. vs., WT: 2.8 ± 0.54 S.E.M.; p=0.0003) and in latency compared to WT (CD40KO: 4.45 minutes ± 0.51 S.E.M vs., WT:1.09 minutes ± 0.005 S.E.M. p=0.0008). CD40 reduced seizure induced gamma activity in hippocampal region.

Conclusions:: These preliminary findings indicate that up-regulation of CD40L-CD40 could mediate ictogenesis by influencing inflammatory mechanisms that involve and propagate seizure-induced neuronal damage.
DIFFERENCES IN VISUAL INFORMATION PROCESSING BETWEEN IDIOPATHIC GENERALIZED EPILEPSY WITH AND WITHOUT PHOTOSENSITIVITY

Marzia Buonfiglio¹, Giuliano Avanzini²
¹Sapienza University, Department Of Clinical Medicine, Roma, Italy, ²Istituto Carlo Besta, Department Of Neurophysiology, Milano, Italy

Background and Aims:: Recently, altered visual cortical processes namely lack of habituation to visual evoked potentials, has been highlighted in both Photosensitive Epilepsy and in a specific i.e. analytic mode of processing visual inputs. In this study we aimed at evaluating the relationship between Photosensitivity and Analytic Style of processing visual information, in a sample of 30 IGE patients and matched Healthy controls.

Methods:: At our Epilepsy unit of the Sapienza University of Rome, we consecutively enrolled 15 IGE patients with Photosensitivity and matched them with 15 IGE patients without Photosensitivity and 15 Healthy Volunteers. All patients underwent EEG recording in basal conditions during hyperventilation (3 Min), and intermittent light stimulation. The instruments used to gather psychological cognitive behavioral data consisted of participation in two tests: the Sternberg -Wagner Self-Assessment inventory and Mariani Learning Style Questionnaire

Results:: In the Visual Style, scores of the photosensitive IGE individuals were significantly higher than the non-photosensitive IGE individuals (p<0.0001,Tukey'post hoc test).

Conclusions:: We discuss these data in the light of our previous evidence highlighting a link between analytic information processing style and altered neurotransmission in other neurological diseases such as primary headaches [. In conclusion an association between Analytic Style of processing visual information and Photosensitivity in IGE has been shown . The common neurophysiological features between these two factors, suggest the possibility to evaluate this cognitive behavior as a potential target for non pharmacological therapeutic strategies in Photosensitive Epilepsy.
CLINICAL FEATURES AND LONGTERM OUTCOME OF RECURRENT STATUS EPILEPTICUS: DATA FROM THE ADULT STATUS EPILEPTICUS POPULATION OF MODENA, NORTHERN ITALY

Niccolò Orlandi¹,², Giada Giovannini²,³, Maria Cioclu¹,², Jessica Rossi¹,², Giulia Turchi², Anna Vaudano³, Stefano Meletti¹,²
¹University of Modena and Reggio Emilia, Department Of Biomedical Metabolic And Neurosciences, Modena, Italy, ²Ospedale Civile di Baggiovara, Azienda Ospedaliero Universitaria di Modena, Neurology Unit, Modena, Italy, ³University of Modena and Reggio Emilia, Phd Program In Clinical And Experimental Medicine, Modena, Italy

Background and Aims:: Little is known about Status Epilepticus (SE) recurrence. We evaluated the clinical features and the longterm outcome of patients with recurrent SE and assessed the risk of recurrence after an incident event.

Methods:: We reviewed our prospective register of consecutive SE episodes of adult patients admitted to the OCB hospital (Modena, Italy), from September 1st 2013 to September 1st 2020. We performed a comparison between recurrent (rSE) and incident SE (iSE) and evaluated the risk of recurrence through a survival analysis. Post-anoxic events were excluded as well as those patients with a SE prior the study period.

Results:: 478 patients were observed. 44 patients (mean age: 67 y/o, 69% female) experienced SE recurrence, whereas 434 patients (mean age: 71 y/o, 61% female) presented an incident event. Among demographic and clinical variables, an acute symptomatic etiology was less frequently observed in relapsing patients (p<0.01), without differences in terms of previously known epilepsy (p=0.53). The highest risk of recurrence was observed in the first 6 months following the incident SE (7.6%), whereas the cumulative recurrence rate in our population was 1.5%, 9.1%, 12.8%, and 15.8% at 30-days, 6 months, 1 year, and 3-years respectively. Comparing iSE and rSE, we did not find any differences in terms of longterm survival (p=0.62).

Conclusions:: SE recurrence was less frequently observed after an acute symptomatic incident event, it was often experienced during the first 6 months of follow-up and apparently did not influence longterm survival in our cohort.
GELASTIC SEIZURES: GOING AFTER THE CAUSE OF LAUGHTER—A SERIES OF SEVEN CASES

Shivani Rath¹, Rahil Ansari¹, Sangeeta Ravat²
¹SETH G.S MEDICAL COLLEGE AND KEM HOSPITAL, Neurology, MUMBAI, India, ²Professor Seth GS Medical College and KEM Hospital, Neurology, Mumbai, India

Background and Aims:: Gelastic seizures are epileptic fits of laughter without emotion or joy. These are rare seizure types and particularly related to hypothalamic hamartomas. Neocortical origin is rare but are reported to originate from pathologies in frontal, temporal, and parietal cortex. The aim of the study was to evaluate patients with history of gelastic seizure and Surgical/medical outcome.

Methods:: Detailed birth developmental history along with history of puberty, seizure semiology of other types was obtained in patients with history of gelastic seizure. They underwent 3T MRI with special focus on hypothalamus and long term VEEG and other investigations as required. Surgical/medical outcomes were studied.

Results:: A total of 7 cases (5 male 2 female) with age of presentation from early second to mid of third decade was studied. The etiology consisted of hypothalamic hamartoma in four patients with seizure freedom of Engel class 1 post surgery in three patients. There was recurrence of lesion in one with seizure freedom with drugs and post revision surgery. A young male with focal unaware seizures besides gelastic seizure had right bulky amygdaloid hippocampal formation with uncal and entorhinal cortex FCD but with occipital discharges. A 12-year male with DRE had a history of HIE with developmental delay with focal unaware seizure, GTCS with bilateral perirolandicfrontoparietal gliosis on imaging. A 16-year male with focal unaware seizures, GTCS with normal imaging and generalized discharges with DRE.

Conclusions:: Gelastic seizures in hypothalamic hamartomas have a good surgical outcome. Gelastic seizure can also occur with other etiologies, and have multiple seizure types and DRE.
STATUS EPILEPTICUS AMAUROTICUS IN A PATIENT WITH FAMILIAL PHOTOSENSITIVE OCCIPITAL EPILEPSY

Francesco Fortunato, Oreste Marsico, Miriam Sturniolo, Vincenzina Rubino, Alessia Giugno, Michele Trimboli, Angelo Labate, Antonio Gambardella
Magna Graecia University, Institute Of Neurology, Department Of Medical And Surgical Sciences, Catanzaro, Italy

Background and Aims:: To report the electro-clinical and imaging features of status epilepticus (SE) amauroticus in a patient with subsequent resolution of MR abnormalities and visual deficits.

Methods:: the patient is an 18-year-old-man with photosensitive occipital epilepsy (pOE) that started at the age of 10, with relatively good seizure control, on therapy with valproate and topiramate. His 29-year-old brother had pOE evolving into genetic generalized epilepsy with absences and eyelid myoclonia. His 20-year-old sister also had pOE that spontaneously remitted from the age of 12 years. The proband was referred to our outpatient clinic since he had become complete blindness in the last 10 days without any evidence of other seizures.

Results:: neurological examination revealed complete blindness. EEG revealed sub-continuous focal epileptiform discharges over both occipital lobes. Brain 3T-MRI showed bilateral cortical parieto-occipital hyperintensities in DWI, T2 and FLAIR sequences. Subcortical white matter was relatively spared. Extensive laboratory investigation and cerebrospinal fluid analysis including autoimmune and infectious screening, serum lactate levels, antibodies against cell surface and intracellular neuronal antigens, were all unremarkable. The electroclinical findings fulfilled the criteria of SE amauroticus. Intravenous therapy with levetiracetam and methylprednisolone prompted the disappearance of SE on EEG, with complete resolution of MR abnormalities and visual deficits in a week.

Conclusions:: SE amauroticus represents a rare cause of potentially reversible blindness and should be considered in patients with acute visual loss and a history of epilepsy. It remains to be elucidated the etiopathogenetic mechanism underlying SE amauroticus as also the pathophysiology of reversible MRI alterations, alongside with the underlying genetic factors.
DNA METHYLATION SCREENING SUGGESTS BRAIN ORIGIN OF CELL-FREE DNA IN EPILEPSY

Ricardo Martins-Ferreira1,2,3, Bárbara Guerra Leal2,3, João Chaves2,4, Carlos Fabregat1, Tianlu Li1, Laura Ciudad1, Raquel Samões4, António Da Silva2,5, Paulo Costa2,3,6, Esteban Ballestar1
1Josep Carreras Research Institute (IJC), Epigenetics And Immune Disease Group, Badalona, Barcelona, Spain, 2Unit for Multidisciplinary Research in Biomedicine (UMIB), Autoimmunity And Neuroscience Group, Porto, Portugal, 3Instituto de Ciências Biomédicas Abel Salazar da Universidade do Porto, Immunogenetics Laboratory, Molecular Pathology And Immunology, Porto, Portugal, 4Centro Hospitalar e Universitário do Porto - Hospital de Santo António, Neurology Service, Porto, Portugal, 5Centro Hospitalar e Universitário do Porto - Hospital de Santo António, Neurophysiology Service, Porto, Portugal, 6Instituto Nacional de Saúde Dr. Ricardo Jorge, Department Of Human Genetics, Porto, Portugal

Background and Aims:: Cell-free DNA (cfDNA) are small circulating DNA fragments generally defined as cellular death debris. The profiling of the cfDNA methylome has been successfully used to track the origin of these circulating nucleic acids, which greatly upgraded the clinical applicability of liquid biopsies. The prediction of tissue specific cell death may represent a valuable tool in early disease diagnose and identification of undetermined pathology. The main histopathological feature of Mesial Temporal Lobe Epilepsy with Hippocampal Sclerosis (MTLE-HS) is severe neuronal death in the mesial regions. Increased cfDNA total levels have been previously reported in MTLE-HS, although the potentially cerebral origin is still undisclosed.

Methods:: We performed DNA methylation profiling, using Infinium MethylationEPIC BeachChips, in cfDNA isolated from serum of seven MTLE-HS patients (3M, 4F; 45.3±9.7 years of age) and seven non-epileptic controls (1M, 6F; 43.3±5.1 years of age). The meth_atlas algorithm, encompassing 25 specific cell and tissue types, was used to deconvolute cfDNA origin. Methylation array data processing and differential methylation was performed with the R statistical language.

Results:: A slight increase in the proportion of “cortical neuron”-derived cfDNA was observed in MTLE-HS patients. We identified 107 CpG positions differentially methylated between patients and controls. Gene ontology analysis revealed striking enrichment of terms associated with cerebral cortex GABAergic neuronal pathways.

Conclusions:: We demonstrate for the first time the presence of cfDNA derived from cerebral tissue in MTLE-HS patients. DNA methylation profiling of cfDNA in MTLE-HS can present major utility as early diagnostic or predicative biomarkers of hippocampal sclerosis.
MULTIPLE DRUG INTERACTIONS INDUCED HYPERAMMONEMIC ENCEPHALOPATHY IN DRAVET SYNDROME

Carmen Calvello, Angela Borrelli, Marialuisa Silla, Nicola Tambasco, Lucilla Parnetti, Cinzia Costa
Neurology Clinic, S. Maria Della Misericordia Hospital – University Of Perugia, Perugia, Italy

Background and Aims:: Metabolic encephalopathy is a rare and serious complication of some antiseizure medications (ASMs). Stiripentol (STP), valproic acid (VPA), and topiramate (TPM), alone or in combination, may facilitate this condition. Possible mechanisms for this drug-associated/drug-induced toxicity are debated.

Methods:: Case Report

Results:: A 28-year-old girl with Dravet Syndrome was treated with several ASMs, including a combination of STP, VPA, clonazepam, and TPM that determined a subtle management of seizures. After a month from the beginning of TPM she presented gait ataxia, dizziness, and drowsiness. Video-EEG revealed diffuse slow delta activity with isolated epileptic discharges in the frontal regions. Serum VPA and TPM levels were maintained within the therapeutic range. Liver function was normal. However, the serum ammonia level was elevated, over 10 times the normal range (1509ug/dL). Given the pharmacokinetic and pharmacodynamic interactions, especially between VPA and TPM, the latter was suspended. The patient also received lactulose, branched-chain amino acids and low protein diet. After several days, the serum ammonia level was back to normal, EEG showed no pathological activity, and the patient recovered the quo ante status. Brivaracetam has been introduced to achieve a better control of seizures, but has been rapidly discontinued for lack of response. Afterwards, cannabidiol was introduced with mild improvement of clinical behaviour and seizure control.

Conclusions:: Polypharmacotherapy raises the risk of drug interactions and severe side effects in patients with epileptic encephalopathy. Early diagnosis of hyperammonaemia is essential to reduce neurological consequences and TPM should be used carefully in patients receiving VPA or STP therapy.
AWARENESS OF DRIVING REGULATIONS AMONGST PERSON WITH EPILEPSY AND THEIR CAREGIVERS

Divya Radhakrishnan¹, Kusum Singal¹, Vinay Goyal², Priyanka Bhat¹, Arunmozhimaran Elavarasi¹, Achal Kumar Srivastava¹, Awadh Pandit¹, Kusuma Yadlapalli³, Animesh Das¹, Ayush Agarwal¹
¹AllIMS, New Delhi, Neurology, Delhi, India, ²Institute of Neurosciences, Neurology, South West Delhi, India, ³AllIMS, New Delhi, Centre For Community Medicine, Delhi, India

Background and Aims:: In India persons with epilepsy (PWE) are prohibited to drive by the law (The Motor Vehicles Act 1939). Though there can be hazardous consequences of a road accident like head injury, awareness about the same is poor amongst the PWE, caregivers and the public. The aim of the study was to assess the awareness of PWE and caregivers about the driving regulations in India and the consequence of driving by PWE.

Methods:: The study was conducted in a tertiary care center in Northern India; Institute Ethics Committee approved the protocol. All PWE (≥ 18 years) and their caregivers were asked to fill a pre-structured questionnaire assessing the awareness about driving and responses were analyzed.

Results:: A total of 196 PWE and 113 caregivers filled the questionnaire. Median age of PWE was 27 years (range 18-65 years); 64% were females. While 94.4% PWE understood about the implications of driving, only 14% were aware about the driving prohibitions by the law. About half of the PWE (54%) were explained about the hazards of driving by their physicians and were asked not to drive. Among the caregivers 43.4% were aware of the law prohibiting driving; 76% felt that driving by PWE is hazardous and 70% thought that PWE should refrain from driving.

Conclusions:: There is considerable lack of awareness about the driving regulations and consequences of driving in PWE; educating the PWE, caregivers and public about the same will help to prevent the road accidents. Funding Source: ICMR, New Delhi, India
UTILITY OF 8-CHANNEL EEG IN DETECTING INTERICTAL GENERALISED SPIKE AND WAVE DISCHARGES - A DIAGNOSTIC STUDY

Mamta Singh¹, Akash Gupta¹, Vinay Goyal¹, Sreenivas Vishnubhatla¹, Vishnu V Y¹, Jasmine Parihar², Mv Padma Srivastava¹
¹All India Institute of Medical Sciences, Neurology, New Delhi, India, ²Lady Hardinge Medical College, New Delhi-110001, Neurology, New Delhi, India

Background and Aims:: The EEG can be valuable in the diagnosis of generalized epilepsies. In low and middle-income countries, expertise in reading EEGs is extremely limited and inaccessible for most. EEGs with fewer channels are both easier to perform and read. Non-specialists can be trained to read 8-channel EEGs. We therefore tried to determine sensitivity of 8-channel EEG in detecting interictal GSWDs as compared to 21 channel EEG.

Methods:: In this study EEGs were reviewed by two independent reviewers R1 and R2 using both 8 and 21 channels. The sensitivity and specificity of 8-channel EEG was assessed considering 21-channel [R1] as gold standard. EEGs were reviewed randomly in 8 and 21 channels according to a pre-decided protocol. Background, GSWDs, focal discharges and localisation, focal slowing and localisation were reported.

Results:: A total of 1876 EEGs were evaluated. Of 169 EEGs showing GSWDs in 21-channel, 9 (5.3%) were missed in the 8-channel EEG, while 5 EEGs with GSWDs reported on the 8-channel EEG were not picked on 21-channel. In detecting GSWDs 8-channel EEG has positive predictive value of 97% (95% CI 93.1-99.0%) and negative predictive value of 99.5% (95% CI 99.0-99.8%). The sensitivity of 8 channel EEG in detecting GSWDs was 94.7% (95% CI 90.1-97.5%) and specificity 99.7% (95% CI 99.3-99.9%).

Conclusions:: An 8-channel EEG can reliably detect GSWDs. In resource-limited settings, 8-channel EEGs may be used by non-specialists to investigate and confirm generalised epilepsy.
ASSESSMENT OF COGNITIVE IMPAIRMENTS IN COMBINATION WITH ANXIETY-DEPRESSIVE DISTURBANCES IN OLD PATIENTS WITH EPILEPSY.

Charos Rustamova, Marhamat Yakubova
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: Many recent epidemiological studies have found the prevalence of depression and anxiety to be higher in people with epilepsy. Although cognitive deficits are common in epilepsy, anxiety-depressive disorders and their interaction to cognitive function in older adults with epilepsy is not studied in detail. Our study is aimed to evaluate cognitive disturbances and anxiety-depressive disorders and their relationship in older epileptic patients.

Methods:: We examined 44 older adults with epilepsy (men - 26 (55%) and women - 18 (45%) aged from 56 to 68 years) at the Tashkent Medical Academy in neurology department. The hospital anxiety and depression scale (HADS) was used for determining depression and anxiety disorders. The cognitive impairments were assessed with Mini Mental State Examination (MMSE) scale.

Results:: According to HADS scale, depression was observed in 18 patients (41%), and anxiety - in 26 patients (59%). All patients had severe anxiety. In 38 patients (86%), both depression and anxiety were clinically pronounced (21.67 ± 1.36), in 6 patients (14%) subclinical forms of depression and anxiety were observed (9.56 ± 1.02). According to the MMSE scale, mild dementia (26.17 ± 0.94) was observed in 32 patients (73%), moderate dementia (18.25 ± 1.68) in 12 patients (27%). The level of dementia does not always correspond to the age of patients with epilepsy, but the degree of anxiety and depression, correlates with the severity and duration of the disease.

Conclusions:: The current study identified depression and anxiety as a novel risk factor for cognitive impairments among older adults with epilepsy. Anxiety and depression may be an important treatment target. Therefore, diagnosing and treating anxiety-depressive disorders is of a great importance in old patients with epilepsy, as well as it declines cognitive impairments.
Background and Aims:: The voice changes following VNS implantation may be due to direct injury to the vagus nerve at the time of implantation, these patients present with a true vocal cord paresis, or may result from coactivation of the efferent fibers of the recurrent laryngeal nerve by the VNS. The object of the study was to objectively document the incidence of these two forms of voice disorder following VNS insertion.

Methods:: This prospective study describes 66 consecutive patients between the ages of 3 and 12 years who underwent VNS implantation. At baseline, prior to VNS insertion a Paediatric Voice Handicap Index (PVHI) was performed to assess voice related quality of life, and this was repeated at 3 months following VNS insertion.

Results:: Sixty six patients underwent VNS implantation. Mean age at time of insertion was 90 months. In total 63% of patients reported voice changes, all of which was entirely attributable to the active duty cycle of the VNS device. There were significant changes in the PVHI scores at 3 months follow up. The median change in the PVHI-total score was 2.67 points, and the median change in the PVHI-physical score was 2.12, both of which reached statistical significance (p<0.05). Less significant changes were found in the PVHI-emotional subgroup and functional component of the PVHI scores.

Conclusions:: VNS insertion is associated with a very low risk of true vocal cord paresis, it does however result in significant stimulation dependent alterations in voice related quality of life scores.
EVALUATION OF SUICIDAL IDEATION IN ADULT PEOPLE WITH EPILEPSY AND CAREGIVERS IN A TERTIARY CENTER

Rafael João, Mateus Henrique Nogueira, Lucas Scardua Silva, Ricardo Brioschi, Gabriel Baltazar, Marina Alvim, Márcia Morita-Sherman, Fernando Cendes, Clarissa Yasuda
University of Campinas, Department Of Neurology/neuroimaging Laboratory, Campinas, Brazil

Background and Aims:: Epilepsy is a risk factor for suicidal ideation (SI). SI still poorly investigated in caregivers of people with epilepsy (PWE). We aimed to analyze the prevalence and predictors of SI in adults PWE and caregivers.

Methods:: We analyzed 548 consecutive PWE (60% women; median age 41 [18-83]) and 191 caregivers (72% women; median age 47 [18-82]) followed at Outpatients' epilepsy clinics from a tertiary center. We used “item nine” (item scores ≥1) of the BDI-II to determine the SI presence. The presence of symptoms of anxiety (with BAI) and depression (with BDI-II) was defined with scores ≥14 (for both PWE and caregivers). The presence of anti-seizure drugs (ASDs) adverse effects was defined with the “Liverpool Adverse Events Profile” score ≥46. Epidemiological factors and anxiety were investigated as predictors of SI in caregivers and PWE (along with seizure frequency, epilepsy-type, and ASDs’ adverse events).

Results:: Depression was present in 41% of the PWE and 32% of the caregivers (p=0.04). Anxiety was observed in 37% of PWE and 33% of caregivers (p=0.32). The SI frequency was higher in PWE (19%) compared to the caregivers (11%; p=0.02). Logistic regression analyses were performed for both groups separately. For the PWE (model accounted for 17%-27%), the most significant predictors were anxiety (OR 4.4, p<0.001), presence of ASDs’ adverse effects (OR 2, p=0.021), recurrent seizures (OR 3, p<0.004), and younger age (OR 0.98, p<0.037). For the caregivers (model accounted for 18-37%), only anxiety (OR 43, p<0.001) predicted SI.

Conclusions:: Identifying SI predictors is equally necessary for PWE and caregivers.
Observational Study on Effect of Pulse Intravenous Methylprednisolone in Drug Refractory Epilepsy

Abeer Goel1, Parampreet Kharbanda2, Manoj Goyal3, Karthik Mahesh1, Ritu Shree4, Neeraj Balaini5
1PGIMER, Neurology, Chandigarh, India, 2PGIMER, Neurology, Chandigarh, India, 3Postgraduate Institute of Medical Education and Research (PGIMER), Neurology, Chandigarh, India, 4Postgraduate Institute of Medical Education and Research, Chandigarh, Neurology, Chandigarh, India, 5PGIMER, Chandigarh, Neurology, Chandigarh, India

Background and Aims:: Treatment options for management of Drug Refractory Epilepsy are limited and associated with poor results. One of the hypotheses being forwarded for genesis of drug refractoriness in epilepsy is inflammation. In this regard, corticosteroids, well known for their anti-inflammatory and anti-immune properties, have been used with variable results in different epilepsy syndromes. Steroids have also been seen to have a blood brain barrier repair thus helping in better penetration of Anti Epileptic Drugs. Thus, we aim to study the effect of pulse intravenous methylprednisolone in drug refractory epilepsy.

Methods:: All patients >12 years of age diagnosed with drug refractory epilepsy not willing or suitable for surgical treatment excluding the ones with known epileptiform encephalopathies were observed for a period of 6 weeks after their Antiepileptic drugs were optimized to determine seizure frequency. Thereafter, they were given monthly pulse dose of daily methylprednisolone for 5 days and their seizure frequency was noted.

Results:: A total of 22 patients were recruited. Three most consistent risk factors noticed in our study were abnormal MRI, abnormal EEG and history of perinatal distress. There was no significant improvement in any type of seizures after introduction of IV steroids. About 50% of the patients had side effects with one of them had a major side effect of avascular necrosis of left side head of femur.

Conclusions:: Present study did not show any significant beneficial effect of IV methylprednisolone in adult patients with Drug Refractory epilepsy.
SOMATIC COMORBIDITY OF PEOPLE WITH SINGLE SEIZURE IN MOSCOW

Igor Kamenskiy1, Iana Vavilina2, Flora Rider1,3, Alexander Yakovlev4
1Moscow Research and Clinical Center for Neuropsychiatry of the Healthcare Department of Moscow, Department For The Study Of Paroxysmal States And Dissomnii With Borderline Mental Disorders, Moscow, Russian Federation, 2Moscow Research and Clinical Center for Neuropsychiatry of the Healthcare Department of Moscow, Department For The Study Of Paroxysmal States And Dissomnii With Borderline Mental Disorders, Moscow, Russian Federation, 3Moscow Research and Clinical Center for Neuropsychiatry, Department Of Epidemiology, Moscow, Russian Federation, 4Moscow Research and Clinical Center for Neuropsychiatry, Neurology, Moscow, Russian Federation

Background and Aims:: The comorbidity of epilepsy is well-known, however the number of studies concerning with comorbidity of people with single seizure (PWSS) are limited. We looked at a somatic comorbidity in PWSS 18 years and older versus controls from Moscow population (MP).

Methods:: It was a case-control study of 70 PWSS (41.69±15.37 years, 32 females) and 211 age- and gender-matched controls (41.85±15.44 years, 95 females). Data source was from the “Unified medical information analytical system” of Moscow. Comorbidities were divided into 14 groups: sleep disorders; severe headache; cerebrovascular disorders; heart diseases; joint diseases; allergies; hypertension; diabetes mellitus; overweight; pulmonary disorders; cancer; ulcer and liver diseases; renal disorders; thyroid conditions. Pearson Chi-square test was used.

Results:: The most prevalent comorbidities in both groups were: arterial hypertension (328.6 per 1000 in PWSS and 241.7 per 1000 in MP) and joint diseases (171.4 per 1000 in PWSS and 170.6 per 1000 in MP). The significant differences between PWSS and MP were found only for ulcer and liver diseases (143 per 1000 in PWSS versus 66 per 1000, p=0.047) and pulmonary disorders (225.6 per 1000 in PWSS and 37.9 per 1000, p=0.000).

Conclusions:: The degree of somatic comorbidity seems to be higher in PWSS versus controls. Further studies are needed for the assessment of comorbidity in PWSS.
Background and Aims:: The study of the clinical and electroencephalographic characteristics of idiopathic generalized epilepsies (IGE) is relevant for accurate diagnosis and subsequent treatment. 

Methods:: Retrospective analysis of 90 continued electroencephalograms (EEG) recorded during wakefulness with the inclusion of functional tests and during sleep in 50 patients with IGE. The Revman 5.3 software with the calculation of the relative risk (RR) was used to compare the groups. Differences were considered significant at p>0.05.

Results:: The study included 12 patients with childhood absence epilepsy (CAE) (24% of all patients), juvenile absence epilepsy (JAE) – 12(24%), juvenile myoclonic epilepsy (JME) – 13(26%), epilepsy with isolated generalized seizures (EGS) – 13(26%). The index of generalized epileptiform activity (GEA) is higher during wakefulness than during sleep in CAE, JAE, JME. There are no differences in the activity index for CAE, JAE, JME when compared during wakefulness and sleep, but the GEA index is higher in sleep in CAE, JAE, JME compared to EGS: RR=0.12 [0.02, 0.81], p=0.03; RR=0.24 [0.06, 0.90], p=0.03; RR=0.33 [0.12, 0.96], p=0.04, respectively. In patients without seizures, GEA continues: CAE–33%, JAE–38%, JME–36%, EGS–33%.

Conclusions:: With EGS, epileptiform activity is more common in sleep than during wakefulness, in CAE, JAE and JME, GEA occurs more often during wakefulness and functional tests than in sleep. More than 30% of patients with IGE with clinical remission, regardless of the form, have GEA on the EEG. The study was funded by Russian Foundation for Basic Research (RFBR) according to the research project №17-29-09096.
FEATURES OF PHARMACORESISTANT EPILEPSY IN NEUROSURGICAL PATIENTS

Svetlana Kravtsova¹, Anna Koloteva², Galina Odintsova³
¹Almazov National Medical Research Centre, Polenov Neurosurgical Institute, Saint-Petersburg, Russian Federation, ²Polenov Russian Neurosurgical Research Institute – a branch of federally funded institution “Almazov National Medical Research Centre” of the Ministry of Health of the Russian Federation, Epileptology, Saint-Petersburg, Russian Federation, ³mazov National Medical Research Centre, Epileptology, St. Petersburg, Russian Federation

Background and Aims:: Epilepsy is one of the most common and stigmatizing diseases. The aim of the present study is to investigate the features of pharmacoresistant epilepsy in neurosurgical patients.

Methods:: We conducted a cohort study of clinical and demographic parameters among neurosurgical patients with verified diagnosis of pharmacoresistant epilepsy.

Results:: The final sample included 91 case histories of patients who underwent neurosurgical intervention for pharmacoresistant epilepsy. Particular attention was paid to the duration of the disease. According to the duration of the disease before admission to the hospital for neurosurgical treatment, patients were distributed as follows: 3-5 years - 7% (6 people), 6-10 years - 16% (15 people), 11-20 years - 36% (33 people); for more than 20 years, - 41% (37 patients) suffered from drug-resistant epilepsy. The analysis of the data obtained showed that this category of patients is characterized by a long history of the disease and a late request for neurosurgical help. When assessing the severity of seizures, it was found that with an increase in the duration of epilepsy, seizures become more severe and their frequency increases. There was also a tendency towards bilateral spread of pathological epileptiform activity on the EEG with a duration of illness of 10 years or more.

Conclusions:: The duration of epilepsy before admission to a neurosurgical hospital is a manageable indicator - this fact requires finding a solution to the problem of faster referral of patients with drug-resistant epilepsy for pre-surgical examination.
SODIUM VALPROATE INDUCED HYPERAMMONEMIC ENCEPHALOPATHY PRESENTING WITH PERSONALITY CHANGES AND DRESSING APRAXIA

Sithira Senevirathne¹, Dunya Luke², Bimsara Senanayake³, Vithoosan Sahathevan³
¹Colombo South Teaching Hospital, Geriatric Medicine, Kalubowila, Sri Lanka, ²National Hospital, Neurology, Borella, Sri Lanka, ³National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

Background and Aims: Sodium valproate is a widely used antiepileptic agent in practice and is rarely associated with hyperammonemia

Methods: Case report A 49 year old businessman with a history of adult onset epilepsy for last two years presented with behavioral changes since last 2 months. His family members complained of recent onset forgetfulness, changes in his personality and dressing apraxia. He had been started on Sodium valproate 200 mg twice daily and Carbamazapine 200 mg twice daily 2 years back when he developed generalized tonic clinic seizures. Recently Sodium valproate dose had been increased to 400 mg twice daily as he had a break through seizure. On examination he had loss of executive function, memory impairment and dressing apraxia. His Mini mental status examination was 15/30. At this point his serum ammonia level was 84 μmol/L (26.6-47 μmol/L). His MRI brain was normal. He was started on Levetiracetam after stopping valproate and his behavior shifted back to normal. Repeated values after 1 month and 3 months of stopping sodium valproate were 55 μmol/L and 35 μmol/L. Rest of his liver function tests and abdominal ultrasound scan were normal.

Results: Discussion Valproate induced hyperammonemia is very rare and considered as an idiosyncratic reaction. Valproate can cause hyperammonemia without altering the other liver function tests.

Conclusions: Being aware of this rare side effect of valproate and monitoring serum ammonia level if suspected will be helpful in the clinical practice
THE INCIDENCE OF ADVERSE DRUG REACTIONS IN MONOTHERAPY OF EPILEPSY WITH VALPROIC ACID: GENDER DIFFERENCES

Rimma Gamirova¹, Roza Shajmardanova², Elena Gorobets³
¹Kazan Federal University, Laboratory Of Clinical Linguistics, Department Of Fundamental Basis Of Clinical Medicine, Kazan, Russian Federation, ²A.Yu. Ratner’s Pediatric City Hospital №8, Department Of Pediatric Neurology, Kazan, Russian Federation, ³Kazan Federal University, Laboratory Of Clinical Linguistics, Kazan, Russian Federation

Background and Aims:: Adverse drug reactions (ADR) in patients treated with antiepileptic drugs (AEDs) require the study of gender differences. We present the retrospective analysis of ADR registered in medical records of patients who received monotherapy with valproic acid (VA) in 2015-2020.

Methods:: 184 patients (76 males, 108 females) were included into research (111 aged 18-, 73 aged 18+). Statistical processing: Excel (MS Office 2017), Statistica 10.0 software packages. The Revman 5.3 software with the calculation of the relative risk (RR) was used to compare the groups. The differences were considered significant at p<0.05.

Results:: ADR were in 111/184 (60.3%) patients treated by VA, 42/111 (37.8%) male and 69/111 (62.2%) female. 186 ADR were registered. The average age (AA) in patients with ADR is lower than in patients without ADR. Statistically significant differences (SSD) were found in general group (GG)(p=0.0006), in 18-(p=0.0001), in 18+(p=0.003). The same is observed in men: GG(p=0.01), 18(p=0.01). AA in women with ADR is also lower than in women without ADR in GG(p=0.01), 18-(p=0.003), 18+(p=0.002). In patients with ADR, the average daily doses of VA are higher than in patients without ADR. SSD were found in GG(p=0.04), 18+(p=0.03). Higher doses of valproate were in men with ADR in GG (p=0.008), in women with ADR in 18+(p=0.03) compared with patients of the same gender without ADR.

Conclusions:: A retrospective analysis showed the presence of gender differences of ADR in patients treated by VA. The study was funded by Russian Foundation for Basic Research (RFBR) according to the research project №17-29-09096.
SEXUAL DYSFUNCTION IN MEN WITH EPILEPSY

Jerbi Khouloud¹, Sawsan Daoud², Nadia Bouattour³, Olfa Hdiji³, Khadija Sonda Moalla³, Salma Sakka³, Nouha Farhat³, Mariem Damak³, Chokri Mhiri⁴
¹university hospital habib bourguiba sfax tunisia, Neurology, sfax, Tunisia, ²CHU habib bourguiba Sfax, Neurology, sfax, Tunisia, ³Universal Hospital Habib Bourguiba, Neurology, Sfax, Tunisia, ⁴Habib Bourguiba university hospital, Neurology, Sfax, Tunisia

Background and Aims:: Sexuality and epilepsy have been intimately linked since ancient time. Disturbances of reproductive and sexual health are common in men with epilepsy (MWE). This study aimed to evaluate the role of antiepileptic drugs in the genesis of erectile dysfunction and to determine the therapeutic implications of this complication.

Methods:: This was a cross-sectional study including MWE aged from 18 to 59 years old. Erectile function was assessed using the International Index of Erectile Function Questionnaire (IIEF-5) and the EQS questionnaire (erection quality scale). We have also defined therapeutic implications of this complication.

Results:: 157 MWE were included in our study. Among 109 patients on valproate monotherapy, 10.9% developed erectile dysfunction. Carbamazepine (CBZ) was associated with erectile dysfunction in 5.40% of cases. Phenobarbital had no effect on male sexuality. Among 76 men on polytherapy, this complication was noted in 6.57% of cases. 85.7% of patients having erectile dysfunction requested to switch the treatment. Poor adherence to therapy was described in 67.85% of these patients.

Conclusions:: Reproductive dysfunction is common among MWE. Both epilepsy and AEDs have been causally implicated. Our study highlights the negative effects of anti-epileptic drugs on erectile function. Thus, an evaluation of erectile function in men with epilepsy is necessary.
SAFETY AND TOLERABILITY OF ADJUNCTIVE ESLICARB AZEPINE ACETATE IN ADOLESCENTS WITH FOCAL-ONSET SEIZURES: DATA FROM THREE DOUBLE-BLIND, PLACEBO-CONTROLLED RANDOMIZED CLINICAL STUDIES

Juan-José García-Peñas¹, Fábio Ikedo², Miguel Fonseca², Guillermo Castilla Fernández², Ana Pereira², Joana Moreira², Helena Gama²
¹Niño Jesús Pediatric Universtary Hospital. Madrid. Spain, Epilepsy Unit. Neuropediatrics Section, Madrid, Spain, ²BIAL- Portela & Ca, S.A., S. Mamede do Coronado, Portugal, Division Of Research And Development, Porto, Portugal

Background and Aims:: Adolescence is a critical developmental period in which major metabolic changes occur.¹ We aimed at evaluating safety and tolerability of adjunctive eslicarbazepine acetate (ESL) in adolescents (ages 12-18) with refractory focal-onset seizures.

Methods:: Safety and tolerability data from Part I of studies BIA-2093-208 (phase II), -304 and -305 (Phase III)²-⁴ were pooled and analysed through the evaluation of treatment-emergent adverse events (TEAEs). These were randomized, double-blind, placebo-controlled studies of adjunctive ESL (1–2 antiseizure concomitant medications) in patients with refractory focal-onset seizures.

Results:: The safety population of the studies comprised 1077 patients, of which 186 (17.3%) were adolescents (n=73 placebo; n=113 ESL-arms). From the 186 patients, n=69, n=20 and n=97 were from BIA-2093-208, 304 and 305, respectively. The incidence of any TEAE was 10.7% (n=45) and 10.9% (n=72) of patients in placebo and ESL-arms, respectively; while related TEAEs were reported by 4.5% (n=19; placebo) and 5.2% (n=34; ESL-arms) of the patients. Most frequent related TEAEs were: somnolence (5.5% placebo; 8.0% ESL-arms), vomiting (0.0% placebo; 5.3% ESL-arms), diplopia (2.7% placebo; 3.5% ESL-arms), fatigue (4.1% placebo; 2.7% ESL-arms) and nausea (1.4% placebo; 4.4% ESL-arms). One patient (0.2%) in placebo arm experienced a serious related TEAE (convulsion). Three patients (0.5%) suffered related TEAEs leading to discontinuation in ESL-arms (1 patient: dermatitis allergic; 1 patient: asthenia, vomiting and nausea; 1 patient with oedema). No TEAEs led to death.

Conclusions:: Treatment with adjunctive ESL in adolescents with refractory focal-onset seizures was generally well-tolerated. The safety profile was consistent to the observed in adults, with no new findings.
EPILEPSY IN CHAD: THE EXPERIENCE OF THE NATIONAL REFERENCE TEACHING HOSPITAL

Foksouna Sakadi¹, Ngarndiguina Madjirabe¹, Kamis Dakissia¹, Cissé Abass²
¹National Reference Teaching Hospital, Neurology, Ndjamena, Chad, ²Ignace Deen Teaching Hospital, Neurology, Conakry, Guinea

Background and Aims:: Epilepsy remains a major public health problem in developing countries of development. However, it has received very little attention in Chad. To my knowledge, this is the first sighting reported in this country. We report the observations in order to describe the socio-demographic, clinical and therapeutic characteristics of epilepsies.

Methods:: We report a prospective and descriptive study lasting one year ranging from November 1st, 2019 to October 31st, 2020, carried out at the Neurology Unit of National Reference University Hospital Center. All patients seen for epileptiform manifestation during the study period were included. Socio-demographic, clinical, paraclinical and therapies were identified and analyzed using SPSS 2.0 software. P value <0.05 was considered significant.

Results:: Out of 603 observations, 532 patients (208 children and 258 women) responded to the diagnostic criteria. The mean age was 30 ± 16.9 years. Among adults, 24% were out of school, 19% had left primary school. Twenty-three school-age children were out of school. Fifty six patients had reported a history of head trauma followed by family history (31 patients) and meningitis (26 cases). Generalized seizures (62.2%), seizures of unknown onset (20.7%) and focal seizures (17.1%) were reported. The electroencephalogram was performed in 319 patients, computed tomography in 120 patients and MRI in 7.3% of cases. The cryptogenic causes were the most reported (46.6%) followed by causes symptomatic (40.6%). Phenobarbital (37.8%), carbamazepine (32%) and sodium valproate (22.6%) were used.

Conclusions:: The management of epilepsy remains a major problem, due to the awareness of the population, diagnosis, treatment and follow-up of patients.
EPIDEMIOLOGICAL, CLINICAL AND COMPARATIVE STUDY OF NEUROCOGNITIVE AND SLEEP DISORDERS IN PATIENTS WITH ONCHOCERCIASIS-ASSOCIATED EPILEPSY IN THE MONATÉLÉ HEALTH DISTRICT, CENTER REGION OF CAMEROON.

Leonard Ngarka¹, Noelar Mundih², Wepnyu Yembe Njamnshi³, Leonard Nfor⁴, Michel Mengnjo³, Samuel Angwafor⁵, Eric Chokote³, Godwin Tatah³, Alfred Njamnshi⁵
¹c. Neurology Department, Central Hospital Yaoundé/Faculty of Medicine and Biomedical Sciences (FMBS), The University of Yaoundé I, Neurology, Yaoundé, Cameroon, ²Bamenda Regional Hospital, Internal Medicine, Yaoundé, Cameroon, ³Brain Research Africa Initiative, Neuroscience Research, Yaoundé, Cameroon, ⁴Brain Research Africa Initiative, Research, Yaoundé, Cameroon, ⁵d. Brain Research Africa Initiative (BRAIN), Yaoundé, Cameroon/Geneva, Switzerland, Administration, Bamenda, Cameroon

Background and Aims:: Over the past decade, there has been mounting evidence from Onchocerciasis-endemic regions in Africa that onchocerciasis causes epilepsy. The term Onchocerciasis-associated epilepsy (OAE) has been used to describe this condition. Few studies have been done in our context to quantify the burden of onchocerciasis-associated epilepsy.

Methods:: This was a cross-sectional study conducted in an onchocerciasis-endemic zone in Cameroon. Door-to-door household visits were carried out to screen for persons with OAE. Clinical sleep and neurocognitive scales were used to screen for sleep disorders and neurocognitive disorders respectively.

Results:: In all, 1448 individuals from 202 households were screened. Fifty persons met the criteria for OAE and were included in the study. The crude prevalence of OAE was 4.7%. The most common seizure type was generalised tonic-clonic seizures. Sleep onset insomnia was the main sleep disorder. The main factors associated with sleep disorders were older age, female sex and having sand extraction as occupation. The most commonly affected cognitive functions were memory, verbal fluency, attention and executive functions. Factors associated with poorer neurocognitive outcomes were longer duration of epilepsy, frequent seizures, low educational level, generalised tonic-clonic seizures and early age of onset of epilepsy.

Conclusions:: The prevalence of OAE constitutes an additional argument for strengthening onchocerciasis elimination efforts in Cameroon and Africa.
TARGETING P-Glycoprotein Efflux Transporter Via the Selective COX2 Inhibitor Celecoxib Improves Levetiracetam Clinical Response in Epilepsy

Sahar Harby¹, Rasha Nassra², Jaidaa Mekky³, Samia Ali¹, Cherine Ismail¹
¹Alexandria Faculty of Medicine, Clinical Pharmacology, alexandria, Egypt, ²Alexandria Faculty of Medicine, Medical Biochemistry, alexandria, Egypt, ³Alexandria Faculty of Medicine, Neuropsychiatry, alexandria, Egypt

Background and Aims:: One of the major drug efflux transporters of concern in drug resistant epilepsy (DRE) is P-glycoprotein (P-gp). P-gp's reported overexpression in epileptic foci resected from patients intensifies its intimate link to DRE. The principal aim of the study was to assess the importance of P-gp as a potential therapeutic target in epilepsy. Can expression modulation of P-gp by celecoxib boost the antiepileptic effect of the P-gp substrate; levetiracetam?

Methods:: Forty epilepsy patients were included in a 3 month-prospective study. Patients were on levetiracetam 3000 mg/day. They were randomly allocated into two groups; levetiracetam only group including levetiracetam treated patients and levetiracetam + celecoxib group including patients on levetiracetam with add-on oral celecoxib 200 mg/day to be given daily in the last week of every month till the end of the study. During the 3 months of the study, four outpatient clinic visits were performed for each patient: A 1st baseline visit and 3 monthly follow-up visits. Clinical response was estimated by recording each patient's seizure frequency/month. For assessment of P-gp mRNA expression level, venous blood sampling was withdrawn from every patient twice (on the first and last visits).

Results:: At the end of the last month, levetiracetam only group showed a non-significant decrease in P-gp expression and seizure frequency compared to the 1st month. Whereas, in levetiracetam + celecoxib group, P-gp expression was significantly reduced and associated with a significant seizure control.

Conclusions:: Celecoxib by downregulating P-gp overexpression can improve levetiracetam brain availability and hence its clinical effect.
CHANGES IN THE CELLULAR COMPOSITION OF THE HIPPOCAMPUS IN DRUG-RESISTANT EPILEPSY

Daria Sitovskaja¹, Yulia Zabrodskaia¹, Tatiana Sokolova¹, Victoria Nezdorovina², Sofia Moschenko¹
¹Polenov Russian Scientific Research Institute of Neurosurgery – branch of Almazov National Medical Research Centre, Department Of Pathology, Saint-Petersburg, Russian Federation, ²Polenov Russian Scientific Research Institute of Neurosurgery – branch of Almazov National Medical Research Centre, Department Of Neurosurgery №2, Saint-Petersburg, Russian Federation

Background and Aims: Hippocampal sclerosis (HS) is a common morphological substrate in drug-resistant temporal lobe epilepsy. According to the classification of HS, developed by ILAE in 2013, this pathology is characterized by disorders of the cellular structure of the hippocampus, neuronal death and gliosis. The role of the hippocampus in epileptogenesis and the pathogenesis of HS are still unclear.

Purpose: To assess changes in the cellular composition in the hippocampus in patients operated on for drug-resistant epilepsy.

Methods: 17 patients with drug-resistant epilepsy at the age of 22 to 54 years. 6 women and 11 men, the average age of the patients was 34.4 years, the average duration of the disease was 18.7 years. The comparison group included patients who died from pathology that did not affect the central nervous system: 2 women and 5 men, the average age of the patients was 70.1 years.

Results: In 85.7% of patients focal cortical dysplasia of various types was found in the temporal lobe. The number of neurons in the dentate gyrus in patients with drug-resistant epilepsy and in the comparison group is significantly different according to Mann–Whitney U test (p <0.05). A significant correlation r = 0.54 was obtained in the conjugation of glial density in the CA1 and CA4 nuclei in all patients.

Conclusions: The revealed structural changes in the hippocampus in patients with drug-resistant epilepsy were characterized by elective neuronal death with a predominant lesion of the dentate gyrus.
THE ROLE OF A SHARED DECISION-MAKING PROCESS IN PAEDIATRIC EPILEPSY SURGERY

Michelle Gratton¹, Bonnie Wooten¹, Sandrine Deribaupierre², Andrea Andrade³
¹Children's Hospital, London Health Sciences Centre, Paediatric Neurology, London, Canada, ²Schulich School of Medicine and Dentistry, Western University, Clinical Neurological Sciences, London, Canada, ³Schulich School of Medicine and Dentistry, Western University, Paediatrics, London, Canada

Background and Aims:: Around thirty percent of children with epilepsy will become drug resistant and therefore potential surgical candidates. Little is known about parental decision making for/or against epilepsy surgery. Shared Decision Making (SDM) involves the collaboration of health care professionals and patients through a structured process that considers best evidence and patient values. Our aim is to determine if a shared decision-making process assists the family in knowledge and improves satisfaction when making an epilepsy surgical decision.

Methods:: A quality improvement project was initiated at our hospital where epilepsy surgical candidates were identified by the paediatric epileptologist and referred to the SDM coach. These visits provided patients/families with evidence-based education materials tailored to their specific decisional needs to assist with surgical choices. The decision process was assessed utilizing a Decisional Conflict Scale, the Ottawa Family Decision Guide, Preparation for Decision Making Scale, and the post Decision Coach Questionnaire.

Results:: Fifty families were offered SDM Coaching consults, forty-five families completed initial visits. The primary issue pre-test was mainly focused on needing more knowledge about the risks, benefits and options. All families were clear about their personal values and felt supported to make a choice but were unsure about risks/benefits for their child. Post consult scales on satisfaction/knowledge levels indicated a high level of preparation post consult.

Conclusions:: Although epilepsy surgery is a curative procedure in drug resistant epilepsy, families often experience anxiety, uncertainty and decisional conflict. SDM assists families in their need for more knowledge regarding risks, benefits for treatment prior to making a surgical choice.
SCHIZOPHRENIA FOLLOWING SUPER-REFRACTORY STATUS EPILEPTICUS (CASE SERIES)

Mohammed Asiry, Waad Alshammari, Mashael Alkhateeb Alkhateeb
KFSHRC, Neuroscience, Riyadh, Saudi Arabia

Background and Aims:: We are reporting new-onset schizophrenia following super-refractory status epilepticus in five cases to increase awareness about this rare complication of super-refractory status epilepticus.

Methods:: Case Series

Results:: All cases were seen in King Faisal Specialist Hospital and Research Center in Riyadh, Saudi Arabia, a tertiary center. Four males and one female. Their ages range between 20 and 46. They shared some clinical features, including that; they don’t have a history of epilepsy or its risk factors, all had super-refractory status epilepticus, lack a prior history of any mental illness or schizophrenia risk factor, and all of them developed schizophrenia at least 2-4 weeks after they recovered from status epilepticus. Four patients; their status epilepticus was secondary to autoimmune etiology, and one was secondary to viral encephalitis. Four patients had MRI T2/FLAIR hyperintensity in temporal lobe and other brain regions. Only one patient had a normal MRI brain. Three patients had abnormal CSF. Four patients were immunocompetent, and one patient only was immunocompromised (post-liver transplant). All patient is following with psychiatrist, and the majority of them are on antipsychotics. One patient has severe schizophrenia and refractory to medications.

Conclusions:: Schizophrenia following new-onset super-refractory status epilepticus is a rare complication of super-refractory status epilepticus.
SYSTEMATIC REVIEW OF THE ONGOING CLINICAL TRIALS EVALUATING THE UTILITY OF BRIVARACETAM ACROSS VARIED PATIENT POPULATION

Akta Trivedi¹, Shailesh Trivedi²
¹Anand Neurology Centre, Neurology, Baroda, India, ²Anand Hospital, Medicine, Baroda, India

Background and Aims:: Brivaracetam is currently approved for the treatment of partial-onset seizures in patients 4 years of age and older. The aim was to systematically evaluate study designs and outcomes being analysed in the ongoing trials evaluating brivaracetam across varied patient profiles.

Methods:: Two independent researchers reviewed contemporary protocols of trials currently recruiting patients for ongoing trials, through WHO- ICTRP (www.who.int/ictrp/search/en), www.clinicaltrials.gov trials registry databases. The latest evaluation was on April 10, 2021.

Results:: There are four trials registered in Japan registry of clinical trials and five in clinicaltrials.gov. All are multicentric studies across North America, Europe and Asia. The mean number of patients being enrolled is 177 (SD ± 146, maximum 444, minimum 10, range 434, 95% CI 42 to 312). Cumulatively, 1237 patients are targeted across seven unique trials. Two trials are evaluating brivaracetam in the pediatric population (cumulative n=142) with seizures. The extreme ages range from newborn to 80 years. The five trials in adults are enrolling patients with partial seizures with or without secondary generalization, epilepsy, and safety and tolerability of intravenous brivaracetam as a replacement for oral brivaracetam. There are six interventional phase 3 trials and one observational study. The primary endpoints include adverse events, change in seizure frequency, plasma concentration of brivaracetam

Conclusions:: Brivaracetam is distinctively being evaluated for pediatric population with age less than 4 years. The emerging outcomes, for brivaracetam, across the varied patient population, being evaluated, across the World appears to add to the current strength and level of published evidence especially in the pediatric age group
COMPARING PREVALENCE OF STATIN PRESCRIPTION BETWEEN ENZYME INDUCING ANTIΕPILEPTIC DRUGS VERSUS NON-ENZYME INDUCING ANTIΕPILEPTIC DRUGS IN ADULT PEOPLE WITH EPILEPSY: A PRELIMINARY STUDY

Young-Soo Kim
Gyeongsang National University Hospital, Neurology, Jinju, Korea, Republic of

Background and Aims:: There are many cross-sectional studies that people with epilepsy (PWE) taking enzyme-inducing antiepileptic drugs (EIAEDs) may have higher cholesterol levels. There is also a report that PWE taking EIAEDs have more chance to have statin prescription compared to PWE taking NEIAEDs. The aim of this study is to compare statin prescription prevalence between EIAEDs versus NEIAEDs among PWE in South Korea.

Methods:: We investigated the prevalence of statin prescription among adult PWE by using the claims data of the Health Insurance Review and Assessment Service-National Patients Sample. To minimize the bias of other drug’s effects, PWE who were treated with only monotherapy of carbamazepine (CBZ), phenytoin (PHT), levetiracetam (LEV), and lamotrigine (LTG) were included. PWEs having comorbidity were excluded because these patients have higher chance of taking statins without high cholesterol levels.

Results:: The enrolled number of adult PWE who were treated by AED monotherapy was 2760 in 2014. Among these patients 1056, 288, 877, and 539 patients were treated with CBZ, PHT, LEV, and LTG respectively. The prevalence rates of their statin treatment were 5.1, 3.5, 3.8 and 2.0 % in CBZ, PHT, LEV, and LTG respectively (p=0.026). Among EIAEDs (CBZ+PHT) users, 4.8 % received statin therapy, compared with 3.1 % of those who take NEIAEDs (LEV+LTG) (p=0.025).

Conclusions:: This study showed that PWE taking EIAEDs by monotherapy may have a higher tendency to take statins than those taking NEIAEDs in South Korea, 2014. Further risk-controlled and longitudinal studies will be needed.
OPTIMIZATION OF TREATMENT OF CATAMENIAL EPILEPSY IN WOMEN

Dilnoza Yusupova, Fakhmitdin Muratov
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: Optimization of the treatment algorithm for catamenial epilepsy in women of fertile age.

Methods:: All examined patients underwent included the study of the neurophysiological studies, laboratory studies of the level of female sex hormones during one cycle in the follicular and luteal phases. To optimize therapy, taking into account the minimal effect of topiramate on the development of oncological diseases of the female reproductive system, we gradually replaced the anticonvulsant drug valproic acid with topiramate at the rate of 3-5 mg/kg of body weight per day. At the same time, the average daily dose did not exceed 200 mg/day.

Results:: After 6 months of regular administration of topiramates at a dosage of 200 mg / day, the first group of patients showed a decrease in the frequency of attacks from 8-10 to 5 attacks per month. In addition, patients noted a decrease in the duration of seizures up to 1 minute, with initial values up to 3-5 minutes. In the second group, we also noted a decrease in the frequency of seizures up to 3-4 times a month. Studies have shown that the use of topiramates led to a decrease in estrogen levels and an increase in progesterone levels, which contributed to a decrease in the frequency of epileptic seizures.

Conclusions:: The results of our studies of changes in hormonal status revealed fluctuations in indicators in the follicular and luteal phases, which were positive against the background of taking topiramate. In the second group, our studies showed no positive effect of valproic acid on the change in the progesterone/estradiol ratio.
THE FREQUENCY OF EPILEPTIC SEIZURES IN PERSONS OF UZBEK NATIONALITY AND THE USE OF ANXIOLYTICS

Dilafruz Mirzaeva
Medical Sanitary Unit, Emergency Department, Zarafshan, Uzbekistan

Background and Aims:: Epilepsy is a chronic disorder, which is recurrent, unprovoked seizures. A person is diagnosed with epilepsy if they have two unprovoked seizures (or one unprovoked seizure with the likelihood of more) that were not caused by some known and reversible medical condition. The seizures in epilepsy may be related to a brain injury or a family tendency, but often the cause is unknown. Many people with epilepsy have more than one type of seizure and may have other symptoms of neurological problems as well.

Methods:: There were studied Uzbek patients which were hospitalized for the period 2018-2020. For researching were selected patients with prescription of the disease 10 and more years. Special attention was given to the age when the first signs appeared.

Results:: Gender analysis determined that women`s quantity dominated (55.07%, mean age 24±5.3 years), men's 44.93% (61.2%, mean age 26±3.2 and 38.7% with mean age 46±4.8 years). Average duration of seizures 8.5-12.1 minutes. The frequency of recurrent seizures in women from 25.43% to 30% per year. For men this indicator was equal to 17.2-20.3%. In 2.03% of men and 2.63% of women, convulsions recurred 2 times a month. In 2.15% of men and 3.5% of women were repeated 2 times a day. In each of the above cases, the anxiolytic (tranquilizer) “Sybasoni 0,5%” was used.

Conclusions:: The analysis of the register of epilepsy in Uzbek people demonstrated that epilepsy seizures was the most common disease in women (55.07%), in all patients used anxiolytic.
COMPARATIVE ANALYSIS OF EFFICIENCY OF SOME ANTIEPILEPTIC DRUGS MONOTHERAPY WITH THE ASSESSMENT OF THE DYNAMICS OF QUALITY OF LIFE IN PATIENTS WITH EPILEPSY

Alimardon Ismatov, Kamola Mirzaeva
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims: It is known that the frequency of seizures, working abilities and associated mental disorders are revealed to be risk factors for the QOL (quality of life). To evaluate the QOL of epilepsy patients with estimating its dynamics on the background of monotherapy with some AEDs (antiepileptic drugs) in the Republic of Uzbekistan.

Methods: Study included 52 patients aged 18-44 (23 men, 29 women). All patients completed a questionnaire QOLIE-31 before and after 4 months of beginning the therapy or its optimization.

Results: All patients were receiving monotherapy with following AEDs: Carbamazepine- 37%, Valproate-37%, Topiramate - 15%, Lamotrigine - 11%. Comparing total score of QOL in groups showed that the largest number of patients rated their QOL as the highest observed in groups treated with Lamotrigine (80%), Topiram (75%), Depakine (70%). At patients receiving Carbamazepine it was adequate to the good QOL (40%). The most significant anti seizure efficiency among all groups of drugs demonstrated Topiramate, the frequency of clinically significant side effects and negative impact on QOL were not observed, which does not distinguish it from Valproate, moreover, degree of changes in subscales “Emotional well-being”, “Cognitive functioning” in the course of treatment was significantly higher than in patients receiving Carbamazepine, Lamotrigine and Valproate.

Conclusions: A comparative evaluation of QOL before treatment, showed it was similar in all groups. The greatest anti seizure effect was detected in Valproates. The greatest influence on individual subscale , total score of QOL - at patients received monotherapy with Valproate or Lamotrigine, lower QOL were in other groups.
SEIZURE CONSEQUENCES AND PREDICTORS OF RECURRENCE POST-STROKE SEIZURE

Nargiza Ibrohimova, Shermukhamedova Feruza, Alimardon Ismatov
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: Seizure is considered one of the worst Post Stroke Complications. There is not any confidential predictors of Post Stroke Seizure (PSS) recurrence although many scientists have estimated outcomes and risk factors of PSS. In order to prognosis degree of recurrence, we compare baseline clinical characteristics and Post Stroke treatment regimens between recurrent and non-recurrent PSS patients.

Methods:: The retrospective cohort study included 75 patients with PSS that admitted to Clinic of Tashkent Medical Academy between June 2017 December 2019. Analyzed baseline clinical characteristics and recurrence rate. Cumulative recurrence rates at 80, 160, and 320 days post-stroke were evaluated by Kaplan—Meier analysis. Sovereign predictors of recurrent PSS were identified by Cox proportional-hazards analysis.

Results:: Overall 75 patients (42 men; 38 women medium age, 70.1±11.2 years) were analyzed. PSS recurred in 22 patients (30%) during the follow-up. Factors significantly associated with PSS recurrence by log-rank analysis included previous PSS, valproic acid (VPA) monotherapy, polytherapy with antiepileptic drugs (AEDs), frontal-parietal cortical lesion, and higher modified Rankin Scale score at discharge (all p<0.05). Independent predictors of recurrent PSS were age<72 years (HR 3.11, 95% CI 1.41–6.02), VPA monotherapy (HR 5.78, 95% CI 2.45–13.89), and convulsions on admission (HR 4.21, 95% CI 2.06–14.21).

Conclusions:: Approximately one-third of PSS patients experienced seizure recurrence within one year. The predictors of recurrent PSS were younger age, presence of convulsions and VPA monotherapy. Our findings should be interpreted cautiously in countries where monotherapy with second-generation AEDs has been approved because this study was conducted while second-generation AEDs had not been officially approved for monotherapy in Uzbekistan.
PERAMpanel Effectiveness and Tolerability in Patients with Epilepsy at Long-Term Follow-Up

Mariana Fernandes¹,², Filippo Dainese³, Francesca Operto⁴, Simona Lattanzi⁵, Sara Matricardi⁶, Rosaria Renna⁷, Fabio Placidi⁸,⁹, Francesco Paladin³, Grazia Maria Giovanna Pastorino⁴, Nicoletta Foschi⁵, Elisabetta Cesaroni¹⁰, Nicola Mercuri¹²,¹¹, Claudio Ligouri¹,²

Giovanni e Paolo Hospital, Epilepsy Centre, Neurologic Unit, Venice, Italy, ⁴University of Salerno, Child And Adolescent Neuropsychiatry, Medical School, Salerno, Italy, ⁵Marche Polytechnic University, Neurological Clinic, Ancona, Italy, ⁶Children’s Hospital “G. Salesi”, Department Of Child Neuropsychiatry, Ancona, Italy, ⁷A. Cardarelli” Hospital, Neurological Clinic And Stroke Unit, Naples, Italy, ⁸“A. Cardarelli” Hospital, Outpatient Clinic For Epilepsy, Naples, Italy, ⁹University of Rome “Tor Vergata”, Epilepsy Center - Department Of Systems Medicine, Rome, Italy, ¹⁰Children’s Hospital “G. Salesi”, Department Of Child Neuropsychiatry, Ancora, Italy, ¹¹IRCCS Fondazione Santa Lucia, Laboratory Of Experimental Neurology, Rome, Italy

Background and Aims:: Assess the effectiveness and tolerability of perampanel (PER) in association with one or two concomitant antiseizure medications (ASMs) in patients with epilepsy throughout a follow-up of 24 months or longer in a real-world setting.

Methods:: This retrospective, observational, multi-centre study collected data from both underage and adult patients who started PER in association with one or two ASMs and were followed for at least 24 months. Patients who interrupted PER in the first 3-month were excluded. Response to treatment was analysed at 24-, 36- and 48-month visits by considering the last visit. Subgroup analyses were performed according to age, gender, epilepsy type and number of concomitant ASMs to evaluate the factors influencing seizure freedom (SF) achievement at 24-month.

Results:: Ninety patients (95.74%), of the initial 94, were still continuing PER concomitantly with 1 or 2 ASMs at 24-month follow-up (mean age 36.89 years; 51.1% female). SF was achieved by 33 (35.1%) patients. Patients who started PER with only one ASM had a higher SF rate compared to those who started PER with two concomitant ASMs. Effectiveness was maintained also in the subgroups of patients with a 36- or 48-month follow-up. A lower number of previously failed ASMs was associated with a higher SF rate.

Conclusions:: PER demonstrated good effectiveness in association with one or two ASMs in both paediatric and adult patients. The possibility to present SF was higher when PER was added early. The maintenance of effectiveness was observed also in the subgroups of patients with a follow-up of 36 and 48 months.
A CASE OF MYOCLONIC STATUS EPILEPTICUS IN A PATIENT WITH BRAIN METASTASES: ROLE OF DYSFUNCTION OF THE THALAMUS-CORTICAL NETWORK AND INHIBITION OF THE SOMATOSENSORY CORTEX

Sancetta Biagio, Mario Tombini, Marilisa Boscarino, Lorenzo Ricci, Giovanni Assenza, Flavia Narducci

Background and Aims:: We present the case of a 55-year-old woman with chemo-treated left breast cancer and brain metastasis, who developed a myoclonic status epilepticus in conditions of full well-being. The patient came to our attention due to the onset of short episodes characterized by dysautonomia and motor stereotypies in the upper limbs. During the electroencephalographic recording, the patient presented a narrowing of the state of consciousness, followed by erratic and diffuse myoclonia, initially in the eyelids and with subsequent involvement of the axial, laryngeal-phonatory muscles and of the upper limbs, and finally by the appearance of motor automatisms. In a peculiar way, the tactile stimulation of the upper limbs induced a gradual reduction of the diffuse epileptiform anomalies, up to their complete regression.

Methods:: EEG showed the sudden appearance of spikes and irregular sharp-wave complexes on the bilateral fronto-central regions and at the vertex, with subsequent bihemispheric diffusion. MRI showed the presence of a metastatic lesion in the left nucleobasal site, characterized by inhomogeneous post-contrast enhancement with an abundant amount of perilesional vasogenic edema.

Results:: Levetiracetam therapy was started at a dose of 2000 mg/day, with clinical benefit.

Conclusions:: We discuss the hypothesis that the nucleobasal lesion, in close proximity to the thalamus, may have triggered the myoclonic state through a dysfunction of the thalamo-cortical network, with ictal activation of the primary motor cortex. Furthermore, we assume that the activation of the sensorimotor cortex triggered by tactile stimulation may have helped inhibit the dysfunctional epileptic circuit of the motor cortex, with remission of the electroclinical picture.
THE PROGRESS OF CONVULSION SYNDROME IN PATIENTS WITH HIV INFECTION

Doston Sultonov¹, Satima Kuranbaeva², Sevara Kalandarova², Sardorbek Khakimov¹, Gulnora Rakhimbaeva¹
¹Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan, ²Tashkent Medical Academy, Neurology, Farabi str., Tashkent, Uzbekistan

Background and Aims:: The aim of the study was to identify the causes of convulsive syndrome and investigate the characteristics of the progress in HIV-infected patients.

Methods:: The study is based on survey data among 25 HIV-infected patients with convulsive syndrome.

Results:: In terms of gender composition, men prevailed women, on average age was 35±2.5 years old. Among patients, 2 suffered from convulsive syndrome associated with alcohol withdrawal, the other 23 patients suffered from structural-metabolic and symptomatic forms of focal epilepsy. Among 25 patients: 12 (48%) of them knew their HIV-positive status before going to a neurologist, in 7 (28%) patients, the diagnosis was clarified upon admission to a neurosurgical hospital, in 6 (24%) patients HIV infection was diagnosed after the development of neurological complications (epileptic seizures, movement disorders). In 17 (68%) patients, seizures occurred before the diagnosis of HIV infection and in 8 (32%) patients after the infection. During hospitalization in a neurological hospital, patients often required a long diagnostic search to establish diagnosis of toxoplasmosis and HIV-associated leukoencephalopathy. The causes of epileptic seizures in these patients are different, among them, in 8 patients epilepsy developed as a complication of HIV infection in the CNS, HIV-associated leukoencephalopathy observed in 7 patients, 1 patient was diagnosed with toxoplasmosis.

Conclusions:: Seizure syndrome is an often-disabling complication of HIV infection. Early diagnosis of the disease and good patient compliance make it possible to achieve early drug remission of the convulsive syndrome.
SPECIFICATIONS OF EPILEPSY AND CEREBRAL PALSY IN CHILDREN

Jasurbek Sabirov, Azamatjon Umarov, Dilshod Tolibov
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: Determine the features of epilepsy with cerebral palsy in children and study clinical electroencephalography in this patients.

Methods:: We examined 70 children (from 1 to 16 years old) patients with various types of cerebral palsy and epilepsy in children. Research work was done at Tashkent Medical Academy Clinic’s Neurology Department. All patients underwent clinical examination, electroencephalography, computed tomography (CT), video-EEG monitoring and MRI.

Results:: From the all patients, only in 7.3% occurred epilepsy. The most common epilepsy with cerebral palsy was detected in age from 9 months to 3 years - 31.4% (22 children). At the age of 5 to 7 years it turned 22.9% (16), from 7 to 10 years - 20% (14), from 10 to 15 years - 14.2% (10 children) and teenagers from 14 to 17 years - 11.5% (8). With a little epilepsy prevalence was recorded in boys with cerebral palsy - 48.7%. Among all patients with cerebral palsy revealed a high incidence of epilepsy with spastic forms (double hemiplegia, spastic diplegia) to 69.7%. In children with hemiplegia and found 18.8% with other forms of cerebral palsy (atonic-astatic, hyperkinetic, mixed) - 11.5%. There were prevailed myoclonic seizures, tonic axial symmetric tonic spasms, multifocal, secondary generalized seizures in infants and early childhood.

Conclusions:: Diagnostic features of epilepsy in children with cerebral palsy has led to the achievement of rapid detection of seizures in 72.5% of patients, which made it possible to provide the rehabilitative treatment of children with cerebral palsy.
FEATURES OF EPILEPSY IN DIFFERENT GROUPS OF PATIENTS IN UZBEKISTAN

Jasurbek Sabirov¹, Azamatjon Umarov¹, Abdulla Khakimov², Sukhrob Sobirov¹
¹Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan, ²Tashkent Medical Academy, Neurosurgery, Tashkent, Uzbekistan

Background and Aims:: The aim of this study was to investigate the features of different types of seizures in group of patients in Uzbekistan

Methods:: The work is based on the results of examination of 85 patients with epilepsy (45 men and 40 women - 53.0% and 47.0%, respectively). Patients underwent a neuropsychological study, as well as neuroimaging techniques.

Results:: We observed a group of patients older than 50 years with epilepsy that began at a young and middle age. In three cases, a remission of the disease is achieved, in one, seizures are recorded with a frequency of 1 per year - one and a half years. In symptomatic and cryptogenic variants with only secondary generalized seizures, remission was achieved in only 3 cases (15.8%), rare seizures and drug-resistant frequent seizures were recorded in half of the cases and in 36.8% of patients respectively. Focal epilepsy dominate the structure of epilepsy in patients of mature age and elderly, of which symptomatic forms reach 83.9% of epilepsy and are more common than in middle age. Significantly more often in this age group there is a secondary generalization of seizures (>71.6%).

Conclusions:: In patients of mature age and elderly, mainly focal seizures with or without secondary generation are observed, in our study up to 90.0%, we did not receive the predominance of complex partial seizures in the elderly. Secondary generalization in this age of group reaches 71.6%, which is less than in children and young men. Diagnosed ideopathic generalized epilepsy in adulthood and old are rare.
DIFFERENCES BETWEEN MEDIAL AND LATERAL TEMPORAL LOBE EPILEPSY

Jasurbek Sabirov, Gulnora Rakhimbaeva, Dilshod Tolibov, Azamatjon Umarov
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: Aim of the research work was to study the differences between the changes of medial and lateral temporal lobe epilepsy (MTLE and LTLE).

Methods:: For the research work we were examined 48 patients with medial and lateral temporal epilepsy, who were on a stationary examination in the department of neurology of the multidisciplinary TMA clinic. During Video-EEG-monitoring we recorded 114 seizures of various types.

Results:: The most significant lateralizing features in this form of epilepsy were one-sided wrist automatism, a dystonic brushes and an unbalanced turn of the head. The most valuable lateralizing sings of the epileptogenic focus for this form of epilepsy are the dystonic setting of the wrist (85.7%, p = 0.02), the inverting turn of the head (88.9%, p=0.02) and after-seizure aphasia (100%). Also for this group, the prevalence of localization of pathological disturbances in the region of the anterior temporal electrode was found (75.0%, p = 0.02 in comparison with the LTLE group), and in cases of presence of additional zones of localization - their registration in the contralateral temporal lobe (63.6%, p=0.02 in comparison with the LTLE group).

Conclusions:: Taking into account the revealed features of seizures, differential diagnosis between lateral and medial forms of temporal epilepsy can be based on the lateralizing sings.
Background and Aims:: Introduction: Bone fractures in epileptic patients may be associated with trauma either induced directly by a seizure or resulting from a fall or other accident resulting from the seizure. In themselves, seizures can induce fractures of the femoral neck, humeral head, acetabulum, scapula, or vertebral column by violent contractions of skeletal muscles.

Methods:: CASE DESCRIPTION We describe a 48-year-old male with severe back pain from a lumbar fracture occurring in association with a seizure during hospitalization for treatment of renal inefficiency. Bone mineral densities in the lumbar spine and the femoral neck were normal. Bone Scintigraphy and tumour marques levels were normal. Patient underwent an orthopedics treatment with lumbar orthosis and bed rest for 2 months; radiographic control 3 months later demonstrated good respect of lumbar lordosis.

Results:: CASE DESCRIPTION We describe a 48-year-old male with severe back pain from a lumbar fracture occurring in association with a seizure during hospitalization for treatment of renal inefficiency. Bone mineral densities in the lumbar spine and the femoral neck were normal. Bone Scintigraphy and tumour marques levels were normal. Patient underwent an orthopedics treatment with lumbar orthosis and bed rest for 2 months; radiographic control 3 months later demonstrated good respect of lumbar lordosis.

Conclusions:: CONCLUSION Seizure-induced vertebral fracture has been recognized, but has rarely been reported in the neurosurgical literature. A complaint of back pain after a convulsive seizure should prompt radiologic investigation for vertebral fracture, even in the absence of external trauma.
INTAKES OF FATTY ACIDS WITH ANTI-INFLAMMATORY PROPERTIES AND SEIZURE OUTCOMES IN A POPULATION OF EPILEPTIC PATIENTS FOLLOWING A GENERAL DIET

Jana Ponce1, Arun Swaminathan2, Jenna Wuebker3, Jiri Adamec4, Alicia Johnson4, Ann Anderson-Berry5, Corrine Hanson1

1University of Nebraska Medical Center, College Of Allied Health Professionals, Omaha, United States of America, 2University of Nebraska Medical Center, Department Of Neurological Sciences, Omaha, United States of America, 3Nebraska Medicine, Department Of Pharmaceutical And Nutrition Care, Omaha, United States of America, 4University of Nebraska, Department Of Biochemistry, Lincoln, United States of America, 5University of Nebraska Medical Center, Department Of Pediatrics, Omaha, United States of America

Background and Aims:: Some evidence suggests individual fatty acids may elicit anti-seizure effects in patients unable to follow a ketogenic diet. We aimed to measure intakes of fatty acids with anti-inflammatory properties and determine the associations between those intakes and seizure outcomes in epileptic patients following a general diet.

Methods:: In a prospective cohort of patients admitted to an Epilepsy Monitoring Unit, seizure activity was monitored via continuous video electroencephalogram and seizure presence and severity was quantified. Dietary intake was determined via a food frequency questionnaire. A Mann-Whitney U test was used to compare median fatty acid intakes between groups of seizure activity. Linear and logistic regression models were used to analyze relationships between fatty acid intake and seizure presence and severity.

Results:: 82 participants were included. Overall intake of omega-3 was below recommended levels; intakes of saturated fat were high. Median intakes of short- and medium-chain saturated fatty acids were borderline statistically significant between groups, with the seizure presence group having higher intakes of both (0.65 gm vs. 1.01 gm for no vs. yes seizure presence, p = 0.07 and 2.92 gm vs. 3.82 gm for no vs. yes seizure presence, p = 0.07 for short-chain and medium-chain, respectively). Regression models did not identify any fatty acid as a predictor of seizure presence or severity.

Conclusions:: Patients with epilepsy who are not following a ketogenic diet consume diets that may adversely impact seizures. Further research in this population is warranted.
A STUDY OF SEIZURE RISK FACTORS IN CHILDREN WITH GASTROENTERITIS ADMITTED IN WEST BENGAL PEDIATRIC'S HOSPITALS

Mridul Mishra, Ashok Singh
University of Science and Technology, Department Of Molecular Biology, Howrah, India

Background and Aims:: Based on attention to the high prevalence of G/E in children and their complications like seizure we must research about the reasons and predisposing factors of it to find out the main reasons of the complications. G/E and seizure are important etiologies of mortality and morbidity in children, specially in children under 6 year old. Our aim was to determine the predisposing factors of convulsion in children having diarrhea hospitalized in West Bengal Hospitals through 2017-2019.

Methods:: In this case-control study we compared predisposing factors of convulsion in 507 children with diarrhea and convulsion in West Bengal pediatric hospitals. Age of children in two groups were between 1 month- 15 years. Risk factors in seizure for example age – leukocytosis... were studied in the research. Our study results statistically analyzed with Chi-square test.

Results:: In this study from 570 patients with G/E and convulsion 310 patients were males and 260 patients were females. In control group 310 patients were males and 26 patients were females that were under 3 years old, especially between 1 months–15 year old. 91 of patients were under 12 year old. 12.3% patients had positive familial history for convulsion. In this study most common types of seizure were generalized. More seizures had happened before the hospitalization. 94.2% of seizures had duration of lower than 15 minutes. The mostly dehydration was medium and most clinical manifestation was fever in two groups.

Conclusions:: This study detected predisposing factors for convulsion in G/E patients were lower age, positive familial history for seizure and leukopenia.
CONSENSUS FOR THE CLINICAL UTILITY OF BIVARACETAM IN INDIAN PATIENTS - SURVEY RESULTS OF THE INCLUDE COLLABORATIVE GROUP

Rajesh Iyer1, Rajashekar Reddi2, Jayanti Mani3, Rakesh Singh4, Vinay Agarwal5, Shalin Shah6, Sudhir Kumar7, S Kanna8, Joydeep Biswas9, Soumik Sarkar10
1Vikram Hospital, Neurology, Bengaluru, India, 2Max Hospital, Neurology, Delhi, India, 3Kokilaben Dhirubhai Ambani Hospital, Neurology, Mumbai, India, 4Jupiter Hospital, Neurology, Mumbai, India, 5Pragati Hospital, Neurology, Bareilly, India, 6ANSA Clinic, Neurology, Ahmedabad, India, 7Apollo Hospitals, Neurology, Hyderabad, India, 8Saveetha Medical College, Neurology, Chennai, India, 9Ruby General Hospital, Neurology, Kolkata, India, 10IQ City Medical College, Neurology, Durgapur, India

Background and Aims:: We conducted a nationwide perception mapping exercise to understand and draw consensus for clinical utility of brivaracetam in everyday clinical practice

Methods:: 317 thought leaders in neurology were invited through whatsapp and email, to respond to a structured questionnaire, developed through a customised technological virtual response system from March 24-April 30, 2021. Anonymised data were analysed by using GraphPad software version 8.4.3

Results:: Mean experience, across 250 respondents, was 13 years (SD 9.3, 95% CI 11-14). Cumulative man-years experience was 3128 years. Amongst the Newer Antiepileptic Drugs (AEDs), 43.6 % (n=109), 49.6% (n=124), 36.8% (n=92), 34% (n=85) ranked brivaracetam as the most preferred for safety, ease of titration, efficacy, potential as an efficacious monotherapy agent, respectively. Brivaracetam has a wide therapeutic window, for higher completion rates for higher doses and its higher level of evidence has created impact for the reason to choose brivaracetam was agreed/ strongly agreed by 86.8% (n=217) and 94.4 % (n=236), respectively. The patients in whom brivaracetam is initiated, 71.6% (n=179), reported that they are already on 1-2 AEDs and the duration of epilepsy is less than 10 years as reported by 84.4 % (n=211). Favorable tolerability was the most important reason for the choice for brivaracetam in Indian patients with uncontrolled focal epilepsy by 63.2 % (n=158). 88 % (n=220) opined that patients were satisfied with brivaracetam

Conclusions:: Virtual expert nation-wide consensus mapping exercise revealed favorable agreement for utilization of brivaracetam in Indian patients which is in concurrence with the emerging evidence for its favorable tolerability and efficacy
Background and Aims:: Introduction 20-40% of patients with epilepsy, have refractory epilepsy (ER) defined as the failure of the use of two tolerated oral antiepileptic drugs, suitably chosen to achieve sustained crisis control. Objective Describe the characteristics of patients submitted to the refractory epilepsy surgery protocol (PCER).

Methods:: Materials and methods Longitudinal descriptive observational study of patients undergoing PCER and surgically treated; description of general characteristics, differences before and after 8 months of quality of life, disability and frequency of crisis.

Results:: Results We reviewed 103 patients, female (57.8%), mean age 24 years, mean time of evolution of epilepsy 15.91 years; complete baccalaureate level of education (20.4%); history of prematurity, fetal distress and neuroinfection (33.9%), family nexus of epilepsy (34.9%); start with focal crisis (80.6%); mild mental deficit in neuropsychological evaluation (37.9%); The most common finding in MRI was left hippocampal sclerosis (27.1%); video-electroencephalographic monitoring with left temporal discharge (24.3%); FAES most prescribed carbamazepine and valproic acid. The main behavior was neurosurgical (69.9%) and total callosotomy the most performed procedure (30.6%). At 8 months after surgery, significant favorable changes were found (p <0.05) in number of seizures, quality of life measured by CAVE in children and adolescents, and QOLIE-10 in adults. No significant changes were observed in the Barthel scale of disability.

Conclusions:: Discussion and Conclusions The results support a significant positive impact in the patients who undergo surgery. Additional studies are required over time, which allow for improvements in the results of disability and medication use, as well as additional safety elements.
EPILEPSY CONTROL WITH CARBAMAZEPINE MONOTHERAPY FROM A GENETIC PERSPECTIVE

Shakir Ullah, Niaz Ali
Khyber Medical University, Pharmacology, Peshawar, Pakistan

Background and Aims:: Ethnicity variation is one of the main factors that may affect drug response in clinical practice. As MTHFR gene affects different transcriptome and proteome which affect the clinical response of drugs. Purpose of the current study was to observe possible variations in plasma levels of carbamazepine monotherapy and seizures’ control in Pakhtun population of Khyber Pakhtunkhwa (KP) in the context of MTHFR (C677T and A1298C) gene polymorphisms.

Methods:: Blood was collected from the epileptic patients treated with carbamazepine monotherapy for the first time following respective oral doses on its steady state concentration after 3 h of morning dose at 3rd and 6th month of the therapy. Plasma carbamazepine levels were determined using reverse phase high performance liquid chromatography after method validation. MTHFR (C677T, AA298C) gene was genotyped. Patients were followed on 3rd and 6th month of the therapy for monitoring of response to carbamazepine therapy.

Results:: Following for 3rd and 6th month of duration of carbamazepine therapy, poor seizure controlled patients were more likely noticed in heterozygous variants (677CT and 1298 AC) of MTHFR gene (P < 0.05). There was no significant (P > 0.05) difference in the dose and plasma level of carbamazepine among different genotypes of MTHFR (C677T and A1298C) gene. Similarly, the difference in dose and plasma level of carbamazepine was not significant (P > 0.05) in the responder and non-responder people with epilepsy.

Conclusions:: heterozygous variants of MTHFR (C677T and A1298C) gene are associated with poor seizure control in Pakhtun population of KP.
INFLUENCE OF WRIST TAPPING ON ALPHA RHYTHM SYNCHRONIZATION IN HEALTHY ADULTS AND ADULTS WITH JUVENILE MYOCLONIC EPILEPSY

Ekaterina Narodova¹, Natalia Shnayder², Vladislav Karnaukhov¹,³, Elena Vayman²
¹V.F. Voino-Yasenetsky Krasnoyarsk State Medical University, Neurology, Krasnoyarsk, Russian Federation, ²V.M. Bekhterev National Medical Research Center of Psychiatry and Neurology, Neurology, St. Petersburg, Russian Federation, ³Krasnoyarsk State Medical University, Neurology, Krasnoyarsk, Russian Federation

Background and Aims:: Background: The aim of this study was to assess the effect of wrist tapping (WT), according to the author's method, on the synchronization of alpha activity in healthy adults and patients with juvenile myoclonic epilepsy (JME).
Methods:: The study included 71 people of working age, including 51 clinically healthy volunteers (median age – 39 [21;56] years) and 20 patients with JME (median age 27 [23;35] years)
Results:: In JME patients, there were statistically significant changes in the alpha peak frequency (P<0.05) and alpha power (P<0.05), as well as a statistically significant increase in the the alpha range width (P<0.05) after WT. WT, according to the author’s technique, allows reducing the severity of alpha rhythm synchronization and leads to a shift in the peak frequency of the alpha rhythm in the occipital leads towards the alpha-2 sub-frequency range and a decrease in AP in both healthy volunteers and JME patients. At the same time, the alpha range width in the occipital leads is statistically significantly increased in JME patients.
Conclusions:: The nature of the change in the alpha rhythm, in comparison with the control, indicates the phenomenon of resonance with the frequency of the WT rhythm. The WT effect testifies to the prospects of the clinical application of WT in JME, since it was previously shown that if the selected external frequencies enter into resonance with the neurons of the antiepileptic system, then an antiepileptic effect could be obtained.
LATERALISATION OF PAROXYSMAL ACTIVITY AND ALEXITHYMIA IN EPILEPTIC PATIENTS

Natalia Shova, Olga Yakunina, Ekaterina Korsakova, Natalya Sivakova, Alexandra Trushkina, Vladimir Mikhailov, Alexandr Urgenko
V.M. Bekhterev National Medical Research Center of Psychiatry and Neurology, Department Of Epilepsy, Saint-Petersburg, Russian Federation

Background and Aims:: Background. In recent years, data have appeared on the relationship of alexithymia with cerebral deficiency and functional interhemispheric asymmetry. Aim. To study the relationship between paroxysmal activity (PA) and alexithymia in patients with epilepsy.

Methods:: The study involved 45 patients with epilepsy from 18 to 59 years: men 45% (N=20), women 55% (N=25). 3 groups were distinguished: 1 - PA in the left hemisphere (N=17); 2 - PA in the right hemisphere (N=9); 3 - without a predominant lateral accent PA (N=6). The level of alexithymia was determined by Toronto Alexithymic Scale (TAS). The data were processed by the SPSS 16.0.

Results:: There are 38% patients with alexithymia (N=17), 40% patients in zone of uncertainty (N=18), 22% patients without alexithymia (N=10) in the total sample. 1 group – 75±12.3 points; 2 group – 77±16.4 points; 3 group – 61±15.6 points (without alexithymia) by TAS. Significant differences were found in the level of alexithymia only between 2 and 3 groups (p = 0.002). 2 group patients, in contrast to the rest, had difficulties in identifying and describing feelings and an external type of thinking (p = 0.004, p = 0.001).

Conclusions:: Patients with epilepsy and alexithymia have cognitive features: a slowdown in the rate of mental performance, difficulty switching attention, specific situational way of thinking, and a decrease in communication capabilities. The level of alexithymia is more pronounced in epilepsy with paroxysmal activity in the right hemisphere. The results can be applied in the process of treatment and rehabilitation of patients with epilepsy.
DRUG AND SUBSTANCE ABUSE IN REFRACTORY EPILEPSY

Raafat Mandour¹, Maha Hazim²
¹Mansoura university, Toxicology, MANSOURA, Egypt, ²Mansoura university, Neurology, MANSOURA, Egypt

Background and Aims:: Seizures often occur in substance abusers. The aim of the present work; is to study the etiology of non-response to antiepileptic drugs by estimating their serum levels and screening of drugs and substance abuse in patients with resistant epilepsy.

Methods:: this study was conducted in epilepsy outpatient clinic, neurology department, Mansoura University Hospital. After exclusion those with organic brain lesion and who were not compliant to antiepileptic treatment, 924 patients with intractable epilepsy were included. They were subjected to: - Toxicology screen for detection of drug and substances abuse by analysis of urine and blood samples. - Measurements of the level of antiepileptic drugs in the blood (carbamazepine, valproic acid, phenytoin). All assays run on the system use of homogenous immunoassay technique EMIT (Enzyme Multiplied Immunoassay Test) and confirmed by GC/MS (gas Chromatography/Mass Spectrum).

Results:: Confirmed Positive results for drugs and substances abuse were detected in 246 of 924 patients (26.62%) by GC/MS. Cannabis was the first abused drug (29.27%), opiates was the second drug abused by patients (21.95%) followed by alcohol (17.88%), benzodiazepine (16.26%) tricyclic antidepressants (8.54%) and finally barbiturate constituted (6.1%). Only 17 patients show serum level of antiepileptic drugs (carbamazepine, valproate and phenytoin) within therapeutic range, but 169 patients’ levels were below it and 60 patients with levels above it.

Conclusions:: Substances abuse may be the cause of resistant epilepsy as they are epileptogenic by themselves or due to drug-drug interaction with the antiepileptic.
PSYCHOMETRIC PROPERTIES OF THE RUSSIAN LANGUAGE VERSION OF THE GAD-7 IN PATIENTS WITH EPILEPSY.

Mikhail Zinchuk¹, Georgii Kustov², Flora Rider³, Evgenii Pashnin⁴, Nadezhda Voinova⁵, Sofya Popova⁶, Alexander Yakovlev⁷, Anna Gersamiya⁸, Alla Guekht⁹

¹Moscow Research and Clinical Center for Neuropsychiatry, Suicide Research And Prevention, Moscow, Russian Federation, ²Moscow Research and Clinical Center for Neuropsychiatry of the Healthcare Department of Moscow, Russian Federation, Department Of Suicide Research And Prevention, Moscow, Russian Federation, ³Moscow Research and Clinical Center for Neuropsychiatry, Department Of Epidemiology, Moscow, Russian Federation, ⁴Moscow Research and Clinical center for Neuropsychiatry, Department Of Suicide Research And Prevention, Moscow, Russian Federation, ⁵Moscow Research and Clinical Center for Neuropsychiatry of the Healthcare Department of Moscow, Department Of Suicide Research And Prevention, Moscow, Russian Federation, ⁶Moscow Research and Clinical Center for Neuropsychiatry, Moscow, Russian Federation, ⁷Institute of Higher Nervous Activity and Neurophysiology of RAS (IHNA&NPh RAS), Laboratory Of Functional Biochemistry Of The Nervous System, Moscow, Russian Federation, ⁸Moscow research and clinical center for neuropsychiatry of the healthcare department of Moscow, Department Of Suicide Research And Prevention, Moscow, Russian Federation, ⁹Moscow Research and Clinical Center for Neuropsychiatry, Neuropsychiatry, Moscow, Russian Federation

Background and Aims:: Patients with epilepsy (PWE) are at higher risk of developing an anxiety disorder than the general population. The prevalence rate of generalized anxiety disorder (GAD) in PWE is about 10% (Scott et al., 2017). The Generalized Anxiety Disorder-7 (GAD-7) has been translated into numerous languages, and some versions were found to be a valid screening tool for detecting GAD in PWE. However, the screening properties of the Russian version of the GAD-7 in PWE have not been investigated yet. We aimed to investigate the Russian version of GAD-7 as a GAD screening tool in PWE.

Methods:: A consecutive PWE cohort was assessed with GAD Module of the Mini International Neuropsychiatric Interview (MINI) and the GAD-7. Demographic and clinical variables were collected. Receiver operating characteristic (ROC) analyses for GAD-7 scores, with higher Youden’s index identification, were used as statistical methods.

Results:: The cohort consisted of 233 PWE: 152 (65.4%) female; mean age was 41.1 (14.7); 213 (91.4%) had focal epilepsy; mean age at onset of the epilepsy was 24.8 (16.8), 61 (27.5%) had GAD. ROC analysis showed an area under the curve of 0.922 (95%CI 0.879-0.964). At the cutoff point >9 GAD-7 had a sensitivity of 96.6% (95%CI 80.7-96.5), a specificity of 88.7% (95% CI 83.0-93.1), a positive predictive value of 49.4% (95%CI 38.8%-60.0), a negative predictive value of 98.8 (95% CI 97.3-99.4)

Conclusions:: The GAD-7 was found to be an effective, reliable and valid screening tool for detecting GAD in PWE.
Background and Aims:: A prevalence rate of depression in persons with epilepsy (PWE) is higher than in the general population and ranges between 13-36% (Fiest KM et al., 2013). Depression in PWE is often underrecognized because of the lack of valid screening tools for this population. The depressive subscale of the Hospital Anxiety and Depression Scale (HADS-D) might be a useful screening tool for major depressive disorder (MDD), but the Russian language version has not been validated in PWE yet. We aimed to investigate the Russian language version of HADS-D as MDD screening tool in PWE.

Methods:: A consecutive cohort of PWE was assessed with the current major depressive episode module of the Mini International Neuropsychiatric Interview (MINI) and the HADS-D. Demographic and clinical variables were collected. Receiver operating characteristic (ROC) analyses for HADS-D scores, with the higher Youden's index identification, were used as statistical methods.

Results:: The cohort consisted of 175 PWE: 119 (68%) were female; mean age 41.5 (15.9); 160 (91.4%) had focal epilepsy; mean duration of epilepsy 14.33 (12.7) years, 99 (56.5%) had current MDD. The ROC analysis showed an area under the curve of 0.854 (95%CI 0.793-0.903). At the cutoff point >7 HADS-D had a sensitivity of 69.7% (95%CI 58.1-79.8), a specificity of 83.8% (95% CI 75.1-90.5), a positive predictive value of 56.4% (95%CI 44.7-67.5), and a negative predictive value of 90.2 (95% CI 86.6-92.9).

Conclusions:: Validity of HADS-D for detecting MDD in PWE is questioned by its modest sensitivity.
IMPACT OF COVID-19 PANDEMIC ON RURAL SOUTHERN INDIAN EPILEPTIC PATIENTS

M.A Aleem¹, A Hakkim²
¹ABC Hospital, Neurology, Trichy, India, ²KM Crescent Hospital, Neurology, Trichy, India

Background and Aims:: Background: During Covid-19 Pandemic, seizure control may worsen. During the Covid-19 Pandemic, Collateral damage may occur in epileptic management. This study was aimed to establish the impact of this covid-19 Pandemic on epileptic patients in terms of seizure control and emergency problems.

Methods:: Material and methods: This is a cross sectional study carried out in my epileptic Patients at ABC Hospital Trichy, Dhanlaxmi Srinivasan Medical College Hospital and KM Crescent Hospital. Epileptic Patients were assessed by telephonic contact during the lockdown period of 100 days at the central part of Tamilnadu in Southern India. Datas regarding the impact of lockdown economic effects of the Pandemic, AEDs availabilities, drug compliances, Seizure triggers, and the subjective perception of teleconsultation were recorded and analysed.

Results:: - Three hundred and sixty six patients were taken up for this study. Among them 266(72.67) were male and 100(27.32%) were female. AEDs were available for all the Patients. But regular specific brand of AEDs are Substituted in 293(80.05%) patients. Breakthrough seizures were recorded in 168 (45.90%) Reduction in Income were noted in 296(80.87%) patients during this pandemic. Teleconsultation were considered useful in 32 % of the epileptic patients during the lockdown.

Conclusions:: Conclusion: - The current covid-19 pandemic definitely has effects in the rural epileptic patients. Change of AED’s brand, skipping of AEDs, stress, sleep loss and economic difficulties are the risk factors for the increased seizure frequency. Teleconsultation awareness is less in rural population. A significant percentage of patients with epilepsy (PWE) had experienced difficulties in followup.
COMMUNITY AWARENESS OF WHICH SEIZURE TYPES SHOULD PRESENT TO HEALTHCARE PROVIDERS; A POTENTIAL RISK FACTOR OF EPILEPSY TREATMENT GAP

Ismat Babiker¹, Awab Elnaeim¹, Mohamed Elnaeim²
¹University of Medical Sciences and Technology, Medicine, Khartoum, Sudan, ²Alzaiem Alazhari University, Medicine, Khartoum, Sudan

Background and Aims:: The objective of this study was to assess the awareness of the highly educated community of which seizure type(s) should present to health care providers

Methods:: This is a cross-sectional descriptive internet based survey that was conducted in Sudan during the period from January to April 2018, using google forms. The survey consisted of demographic data (age, gender, educational level), a statement evaluating participants' sources of obtaining information regarding epilepsy, a statement assessing awareness about the primary care provider for people with epilepsy (PWE), and a statement describing the symptomatology of different seizure types in simple Arabic, asking what description(s) participants thought should present to health care providers. We included participants residing in Sudan, and those with college degree or higher education. Four hundred sixty seven participants completed the survey

Results:: 467 participants were included, of whom, 279 (60%) were females. The mean age of participants was 28 years. Two thirds of participants obtained their information from nonscientific sources. 84% of the participants were aware that doctors are the primary health care providers for people with epilepsy.

Conclusions:: this study demonstrated poor awareness about the necessity of presentation for focal and absence seizures. We hypothesize that this lack of awareness may contribute to epilepsy treatment gap, and we recommend further studies to examine this hypothesis.
« PEHO SYNDROME: A STUDY OF TWO (2) PATIENTS OBSERVED AT THE ACADEMIC HOSPITAL IN CONAKRY”

Cisse Amara, GueIngar Carlos Othon, Djibo Hamani Abdoul Bachir
Academic Hospital, University of Conakry (Guinea), Neurology, Sélectionner, Guinea

Background and Aims:: le but de faire une réévaluation de cette pathologie à partir du plan clinique, électrochimique et point de vue neuroradiologique. L'intérêt de ce travail réside dans le fait que ces observations illustrent les encéphalopathies en général et leurs difficultés diagnostiques comme présen

Methods:: L'intérêt de ce travail réside dans le fait que ces observations illustrent les encéphalopathies en général et leurs difficultés diagnostiques qu'elles présentent en milieu tropical en particulier.

Results:: We report two sporadic cases of PEHO (Progressive Encephalopathy with oedema, hypsarrhythmia, and Optic atrophy) which meet the electroclinical and neuroradiological criteria of the disease. In our knowledge, these cases are the first to be described in a Sub-Saharan African (SSA) country, a review of the literature through these two cases, with the aim of making a re-evaluation of this pathology from the clinical, electrochemical and neuroradiological point of view.

Conclusions:: Conclusion: the PEHO in the African environment is real and shows the difficulties of management which deserve the attention of pediatricians and neuro-pediatricians given the rarity of this syndrome.
Background and Aims:: Nihilistic views are sometimes expressed that finding a genetic cause does not alter management, and therefore genetic testing is unnecessary. It is underused in cases of epilepsy and wise use of genetic testing can improve outcomes in refractory epilepsy. We describe 4 cases paediatric refractory epilepsy in which genetics changed the management and prognosis.

Methods:: Case 1: 7/F born of nonconsanguineous marriage presented with absence seizures 100–200/d, head drop & occasional falls on 4 AEDs since 2 years of age. She had mild developmental delay, poor scholastic performance, microcephaly, lower limb spasticity. Case 2: 6/F, born of 2nd degree consanguineous marriage, falls 100-150/d, touch & sound sensitive myoclonic jerks on 5 AEDs Case 3: 7/M, Normal birth & developmental history Refractory right & left focal seizure with severe language & social decline. Partial response to IVIG and steroids, developed steroid toxicity Case 4: 18/M born of a consanguineous marriage, presented with clinical features of cerebellar ataxia, early cataracts, neuropathy, sub normal IQ and seizures

Results:: Analysis of these all 4 patients charted in following pictures
**Conclusions:** In absence of structural lesion, refractory seizures should prompt the physician to consider potentially treatable metabolic epilepsies, especially in poor scholastic performance. Suspect GLUT 1 deficiency in atypical and late onset presentations of refractory absences with/without movement disorders. Not all cases with myoclonic jerks are PME. Hyperekplexia should be kept as one of differentials. Long term cost of therapy and quality of life greatly outweighs cost of testing.
LOCALIZATION OF ICTAL ISLAMIC RITUALS: STUDY FROM EPILEPSY CENTER IN MAKKAH

Amal Alkhotani¹, Hanadi Abualela²
¹Um Al-Qura University, Medicine, MAKKAH, Saudi Arabia, ²King Abdullah Medical City, Neurology, MAKKAH, Saudi Arabia

Background and Aims:: Ictal semiology is important to aid the diagnosis of seizure type. Patients frequently requires admission to Epilepsy monitoring unit (EMU) in order to reach a correct diagnosis of epilepsy type. Some patients may exhibit unusual ictal phenomena that sometime lead to the diagnosis of psychogenic seizure. Some of unusual ictal phenomena are ictal kissing, praying and drinking. Ictal religious speech and praying are examples of the unusual ictal phenomena. The aim of this study is to assess the localization value of ictal Islamic rituals.

Methods:: We retrospectively reviewed all patients admitted to epilepsy monitoring unit at King Abdullah Medical City in Makkah between 2017 to 2021. Patients with ictal Islamic rituals were included in the study.

Results:: Nine out of 279 cases admitted to EMU have different ictal Islamic rituals. Two patients had hand automatism mimicking Islamic prayer. Four patients have Islamic religious speech including calling Allah to help, asking for forgiveness, and praying. Three patients exhibited fortification. All nine patients had seizure originating from the right temporal lobe.

Conclusions:: Islamic rituals are rare ictal phenomena that localized to right temporal lobe.
POSTERIOR REVERSIBLE ENCEPHALOPATHY SYNDROME. ABOUT 5 CASES

Jawad Oumerzouk
Military Hospital of Marrakech. Avicenne. CHU Mohamed VI, Neurology, Marrakech, Morocco

Background and Aims:: We herein present five case reports discussing the clinical and pathogenesis aspects of posterior reversible encephalopathy and the place of imagery in its management.

Methods:: We report the case of five patients, the first followed for systemic lupus erythematosus, the second is hypertensive poorly follow-up, the 3 other patients were in postpartum after cesarean delivery. All our patients had generalized tonic-clonic seizures associated with an hypertensive peak without edema syndrome.

Results:: Laboratory tests were unremarkable. The EEG showed epileptic abnormalities and brain MRI was in favor of a reversible posterior leukoencephalopathy.

Conclusions:: The PRE is an unusual neurological complication of post-partum with vasogenic edema by disrupting the blood-brain barrier (BBB) seems to be the main actor. The initial clinical presentation is variable, ranging from simple headaches to dramatic presentations of status epilepticus. The DWI MRI is the best diagnostic tool enabling rapid and appropriate treatment to prevent the occurrence of irreversible neurological damage and permanent sequelae.
INCIDENCE OF POST TRAUMATIC EPILEPSY IN KHARTOUM STATE, SUDAN BETWEEN THE PERIOD OF DECEMBER 2018 TO JANUARY 2020

Abbasher Hussien¹, Razaz Musa¹, Abdallah Mustafa², Amira Abdelgalil¹, Hussein Diab³, Radi Tofaha Alhusseini⁴, Rashed Abdalla⁵, Radi Alhusseini⁶, Faroug Mohammed⁷, Saddam Mohammed⁸, Abdalla Medani⁹, Mohamed Ahmed⁹, Mohamed Mohamed Ahmed⁹, Aziza Alrayah¹⁰, Fatimaalzahra Abdelgadir¹¹, Albokhary Abkar¹²
¹University of Khartoum, Neurology, Khartoum, Sudan, ²Daoud Research Group, Neurology, Khartoum, Sudan, ³Daoud Research Group, Neurology, Khartoum, Sudan, ⁴University of Alzaiem Alazhri, Anatomy, Khartoum, Sudan, ⁵University of Bahri, Medicine, Khartoum, Sudan, ⁶Alzaiem Alazhari University, Medicine, Khartoum, Sudan, ⁷Omdurman Teaching Hospital, Medicine, Khartoum, Sudan, ⁸University of Bahri, Medicine, Khartoum, Sudan, ⁹Al Neelain University, Medicine, Khartoum, Sudan, ¹⁰Ahfad University for Women, Medicine, Omdurman, Sudan, ¹¹Ahfad University for Women, Medicine, Khartoum, Sudan, ¹²Nahda College, Medicine, Khartoum, Sudan

Background and Aims:: Epilepsy is one of the commonest neurological disorders. It has a strong association with trauma to the brain, constituting of 5% of epilepsy cases. To determine the prevalence of post-traumatic epilepsy among Sudanese patients and to demonstrate the relation between traumatic brain injury and occurrence of epilepsy.

Methods:: A descriptive hospital-based cross-sectional study, conducted in Bashiar, Omdurman, and Ibrahim Malik Teaching Hospitals in Khartoum state, in the period from December 2018 to January 2020. Patients were interviewed by general emergency team. Relevant history was obtained, and both biochemical and neuroimaging investigations were done.

Results:: 70 patients with history of traumatic brain injury (TBI), 6 (11.3%) developed post traumatic epilepsy (PTE). (82.9%) were males and (17.1%) were females. In the 6 patients who developed PTE, the mode of trauma in two of them was gunshots, two due to fall, one by an automobile accident and one had missing data. Out of them, one had subarachnoid hemorrhage, one had bilateral subdural hematoma and one developed massive epidural hemorrhage. Statistically significant correlation was found between TBI and number of comorbid conditions. Older age was associated with more severe TBI. Significant correlation reported between the etiology of TBI and occurrence of PTE. Significant correlation between higher GCS at the time of trauma and not having PTE. People with TBI and GCS more than 12 had 1.8 less chance to develop PTE.

Conclusions:: Traumatic brain injury constituting of type of trauma, etiology, formed of brain injury, and GCS at presentation, has a significant implications to occurrence of epilepsy.
THE LONG-TERM EFFECTS OF TERATOGENIC INFLUENCE DURING THE PREGNANCY ON COGNITIVE DEVELOPMENT OF A CHILD IN CASE OF MOTHER'S EPILEPSIA.

Anastasia Krasko¹, Nadezhda Mikhailova¹, Galina Odintsova²
¹St. Petersburg State University, Psychology, St. Petersburg, Russian Federation, ²Almazov National Medical Research Centre, Epileptology, St. Petersburg, Russian Federation

Background and Aims:: Epilepsy is a severe stigmatizing disease that affects all areas of the patient's life and limits his social and individual opportunities and rights. Until recently, the birth of a child was often a pipe dream for women suffering from epilepsy, since high risks of cognitive violations. We claim, that with due responsibility it is possible to raise a healthy child, but we have to assess all the risks, which is our study aimed for.

Methods:: 80 people: 40 mothers with epilepsy and 40 children aged 3 to 9 years. We used Wechsler WSIC Intelligence Scale for Children and the Luria Battery of Neuropsychological Tests adaptated by J.M. Glozman, and several methods for observing child's behaviour. Data on the clinical condition of the mother during pregnancy and childbirth were also collected.

Results:: The study showed that intellectual development of children is affected by the form of mother's epilepsy, antiepileptic drugs taken by her, preparedness of childbirth, the presence of seizures during pregnancy, complications of pregnancy, the way of parturition and the type of feeding. The most important factors for reducing the impact of teratogenic effects were the preparedness of the birth, the absence of seizures during pregnancy and the absence of complications of pregnancy.

Conclusions:: It can be confirmed that teratogenic effects have a significant influence on the cognitive development of a child, but studying structure of these effects allows us to plan pregnancy as safe as possible for both the patient and the fetus.
THE PROBABILITY OF THE EPILEPSY IN CHILDREN AFTER THE SINGLE SEIZURE

Leanid Shalkevich, Iryna Zhauniaronak
Belarusian Medical Academy of Postgraduate Education, Pediatric Neurology, Minsk, Belarus

Background and Aims:: The diagnosis of epilepsy can be made based on a single seizure. Probability and time of recurrence of attack at different age periods not sufficiently studied.

Methods:: Case-control study. 556 children after a single seizure are included in a prospective two-year study. Five subgroups were formed on the age of the children at which the first attack occurred: up to 1 y.o. (n=202); 1-3 y.o. (n=134), 4-5 y.o. (n=45); 6-13 y.o. (n=133); 14-17 y.o. (n=42).

Results:: Two groups were formed: the 1st group (n=447) with a recurrent attack (epilepsy), the 2nd group (n=109) with only a single seizure. In the total cohort (n=556) the likelihood of a seizure recurrence is 0.799 (95%CI [0.762; 0.829]) 12 months after the first seizure; 0.804 (95%CI [0.768; 0.834]) 18 months after the first attack and remains approximately at this level until the end of the two years. The maximum increase in the likelihood of re-attack was in the first 3 months after the first attack: 0.700 (95%CI [0.659; 0.735]). The probability of developing a second attack in the age subgroups varies significantly (p log rank<0.001), the maximum likelihood of a recurrence of an attack occurs in children with the first attack before the age of 1 y.o. In this subgroup the probability is 0.856 (95%CI [0.799; 0.897]) 1 month after the first attack and 0.916 (95%CI [0.867; 0.947]) in 3 months.

Conclusions:: The results of the study make it possible to prognosis the relapse of the first seizure in children for their management improving.
IS INTELLECTUAL DISABILITY RELATED TO POOR CONTROL OF EPILEPSY? OMDURMAN, SUDAN (2020-2021)

Abbasher Hussien¹, Abdallah Mustafa², Amira Abdelgalil³, Khabab Mohamed Ahmed⁴, Mawahib Mergani⁵, Mohammed Sadialla⁶, Ahmed Ali⁷, Roaa Sidahmed⁸, Mohmed Alrayah⁹, Mwaez Ibrahim⁵, Mohajer Ismaiel⁹, Mohmmed Abdalla⁶, Aya Hassan Suliman Ahmed⁵, Hamda Abd Elrahman⁵, Anas Ali¹⁰

¹university of Khartoum, Neurology, Khartoum, Sudan, ²Daoud Research Group, Neurology, Khartoum, Sudan, ³Alneelen university, Community Medicine, Khartoum, Sudan, ⁴University of Khartoum, Faculty Of Medicine, Khartoum, Sudan, ⁵Ahfad University for Women, Medicine, Khartoum, Sudan, ⁶university of bahri, Medicine, Khartoum, Sudan, ⁷Daoud research grous, Medicine, Khartoum, Sudan, ⁸University of Khartoum, Faculty Of Medicine, omurman, Sudan, ⁹university of Alzaiem Alazhri, Medicine, Khartoum, Sudan, ¹⁰Napata Colleges, Medicine, Khartoum, Sudan

Background and Aims:: Epilepsy is one of the commonest neurological disorders. It has a well-known recognized association with intellectual disabilities. To assess the relation between intellectual disability and epilepsy control.

Methods:: This is a descriptive institutional-based cross-sectional study that was conducted in Daoud Research Group Charity clinic in sudan, during the period (November 2020-January 2021). A total of 34 patients with intellectual disabilities and epilepsy where included in this study. The IQ test, full history, relevant clinical examination and specific investigations were done.

Results:: Out of 34 patients, 26 were males (76.5%) and 8 were females (23.5%), age ranged from 2 to 35 years, with mean age 17 years. 25 of the participants (73.52%) have intellectual disability of unknown cause, 3 of them have Wilson disease (8.82%), 2 have meningitis (5.88%), while fragile-X syndrome, encephalitis, cerebral palsy and infantile hemiplegia accounted for 1 patient each (11.76%). 19 of the participants have generalized tonic-clonic epilepsy (55.88%), 7 have focal to bilateral (20.58%), 4 have focal with impairment (11.76%), 1 has focal without impairment (2.94%) and 2 have atonic epilepsy (5.88%). Most of the participants had high seizures frequency (76%), minority had low frequency (8%), and a middle frequency (16%). We also found that the majority of the patients had no period fits free(61%), whereas 23% of the patients had a less than one year fits free, and 16% of them had maximum a period free of fits of 1 to 2 years.

Conclusions:: Intellectual disability has a strong association with poor control of epilepsy.
PREVALENCE AND RISK FACTORS OF PSYCHOCENIC NON-EPILEPTIC SEIZURES AMONG ADULT SUDANESE EPILEPTIC PATIENTS WHO ATTEND DAOUD CHARITY CLINIC, KHARTOUM, SUDAN 2021

1University of Khartoum, Faculty Of Medicine, Khartoum, Sudan, 2University of Khartoum, Internal Medicine, Khartoum, Sudan, 3Daoud research group, Medicine, Khartoum, Sudan, 4Omdurman Islamic University, Faculty Of Medicine, Omdurman, Sudan, 5University of Bahri, Internal Medicine, Khartoum north, Sudan, 6Daoud research group, Neurology, Khartoum, Sudan, 7Ahfad University for Women, Faculty Of Medicine, Omdurman, Sudan, 8Ahfad University for Women, Medicine, Omdurman, Sudan, 9Omdurman Islamic University, Faculty Of Medicine, Khartoum, Sudan, 10Alzaeim Alazhari University, Faculty Of Medicine, Khartoum north, Sudan, 11Ahfad University for Women, Faculty Of Medicine, Khartoum, Sudan, 12Alzaeim Alazhari University, Medicine, Khartoum, Sudan, 13Al Neelain University, Faculty Of Medicine, Khartoum, Sudan, 14University of Khartoum, Community Medicine, Khartoum, Sudan, 15Omdurman teaching hospital, Internal Medicine, Omdurman, Sudan

Background and Aims:: Seizures can present in many diseases such as epilepsy which is one of the common neurological disorders. Some seizures can present as psychogenic seizures. Epilepsy can be associated with psychogenic non-epileptic seizures. To assess prevalence and risk factors of psychogenic non-epileptic seizures among adult Sudanese epileptic patients attending Daoud charity clinic.

Methods:: A descriptive cross-sectional facility based study was conducted during Jan-Feb 2021. Data collection was done via interview based structured questionnaire and a total number of 99 participants were included in the study.

Results:: Overall 99 adult epileptic patients were included. 57% were females, the majority of patients reside inside Khartoum (79%) and reach secondary schools (32%). The main type of epilepsy was generalized tonic clonic (68%) followed by focal with impairment (11%). The majority of patients have been diagnosed as epilepsy for more than three years (65%). 29 patients (29%) had a history of psychogenic non-epileptic seizure. The prevalence of psychogenic non-epileptic seizure was found to be significantly higher in patients with social problem and/or depression (p value 0.005, 0.00 respectively). Patients with depression were 14 times more likely to have psychogenic non-epileptic seizures (CI 95%: ##-##). Most of participants have no history of sexual abuse, physical abuse or school/University/work refusal and/or absence (94%,84% and 63% respectively).

Conclusions:: A considerable high prevalence rate of psychogenic non-epileptic seizures can be found among adult epileptic patients . Epileptic patients suffering from social problems, and/or depression are more vulnerable to develop psychogenic non-epileptic seizures especially during the last two years of treatment or above.
STUDY OF KNOWLEDGE ATTITUDE AND PRACTICE TOWARD EPILEPSY AMONG PARENTS AND CARE GIVERS OF CHILDREN WITH EPILEPSY SEEN IN FATHALRAHMAN ELBASHIR CLINIC, KHARTOUM 2019-2020

¹University of Khartoum, Medicine, Khartoum, Sudan, ²Ahfad university for women, Medicine, Khartoum, Sudan, ³Alzaeim Alazhari University, Medicine, Khartoum, Sudan, ⁴Neelain University, Medicine, Khartoum, Sudan, ⁵University of Khartoum, Faculty Of Medicine, omurman, Sudan, ⁶Daoud research group, Medicine, Khartoum, Sudan, ⁷Omdurman Teaching Hospital, Medicine, Khartoum, Sudan, ⁸Nahda college, Medicine, Khartoum, Sudan, ⁹Daoud research group, Neurology, Khartoum, Sudan, ¹⁰Ahfad University, Medicine, Khartoum, Sudan

Background and Aims:: Epilepsy is one of the most common pediatric neurological disorders. Lack of awareness regarding epilepsy among the general population influences the lives of epileptic children. The aim of this study was to assess the knowledge, attitude and practice toward epilepsy in parents and care givers of children with epilepsy in FathElrahman Elbashir clinic.

Methods:: 120 parents and care givers were included in the Case finding study conducted at FathElrahman Albashir clinic, Khartoum from (September 2019 - January 2020). An interviewing questionnaire was designed to collect data from the participant families.

Results:: Total of 120 parents and care givers were interviewed. 48.3% were mothers, the age of children ranged from 1-18 years. 41.7%, believed that epilepsy is caused by evil eye. About 85% said epilepsy is curable disease. 91.6% think the best treatment is antiepileptic drugs, but 51.6% still believed in nonmedical treatment usually traditional helps and 100% use holy Quran as a method of religious treatment for epilepsy.

Conclusions:: Many parents and care givers have significant misconceptions, negative attitudes, and poor practices toward epilepsy. These correlated with their educational levels and had significant implications on the medical management. Level of knowledge and understanding among parents and care givers of children with epilepsy needs improvement.
LANDAU-KLEFFNER SYNDROME: A 17-YEAR FOLLOW-UP WITH ATYPICAL OUTCOME

Isadora Cavalcante¹, Melina Marques¹, Paulo Correia², Lisiane Ferreira³
¹Universidade de Brasília, Department Of Pediatrics, Brasília, Brazil, ²Universidade de Brasília, Faculty Of Medicine, Brasília, Brazil, ³Universidade de Brasília, Associate Professor Of The Faculty Of Medicine, Brasília, Brazil

Background and Aims:: Landau-Kleffner syndrome (LKS) is a rare entity characterized by epilepsy and afasia, whose outcome is variable, usually initiating between three to seven years old. The aim of this case is to describe a follow-up for 17 years of a patient with LKS.

Methods:: This case report was written based on data of the medical record of a 21 year-old male patient, accompanied since four years old due to LKS.

Results:: Subject started, at the age of four, with abrupt aphasia, although there wasn’t reports of seizures. The electroencephalogram showed temporal and parietal epileptiform discharges, during NREM sleep. Brain CT with cerebral perfusion demonstrated moderate hypoperfusion in the right medial frontal lobe, mild in the left, in addition to mild hypoperfusion in medial temporal lobe in both hemispheres. He was treated with carbamazepine, valproate, clonazepam and oral corticosteroids, but the progressive improvement occurred after the beginning of sulthiame at six years old. Currently, the patient remains stable, with good communication and social interaction, without new events, attending higher education, with an intelligence quotient of 117.

Conclusions:: LKS is a heterogeneous entity. It is known that the electroencephalogram findings tend to improve as around 15 years of age, while the long term prognosis of afasia remains poor, probably due to the early age of onset, which is the most limiting factor for a low psychosocial result. This case evidenced a long-term follow-up of a patient with Landau-Kleffner syndrome, with a favorable outcome in speech and cognition, unusually seen in the literature.
SLOW TAPERING OF ANTI-EPILEPTIC DRUGS VERSUS RAPID TAPERING AMONG SUDANESE EPILEPTIC PATIENTS ATTENDING DAOUD CHARITY CLINIC, KHARTOUM, SUDAN 2019-2020

Abbasher Hussien¹, Abdallah Mustafa², Mawahib Mergani³, Mohammed Fadlalla⁴, Aziza Alrayah⁵, Lina Ahmed⁶, Fatimahzahra Abdelgadir³, Mohammed Abdalla⁷, Rufida Sali⁵, Anas Mohammed⁶
¹University of Khartoum, Neurology, Khartoum, Sudan, ²Daoud research group, Neurology, Khartoum, Sudan, ³Ahfad University for Women, Medicine, Khartoum, Sudan, ⁴University of Bahri, Faculty Of Medicine, Khartoum, Sudan, ⁵Ahfad University for Women, Medicine, Omdurman, Sudan, ⁶Ahfad University for Women, Faculty Of Medicine, Omdurman, Sudan, ⁷University of bahri, Medicine, Khartoum, Sudan, ⁸Nabta college, Medicine, Khartoum, Sudan

Background and Aims:: Treatment of epilepsy should be for at least two years. After successful treatment, the drug withdrawal should be gradual. This study aimed to study the rapid versus slow withdrawal of antiepileptic drugs in Daoud charity clinic in the period between January 2019 to January 2020.

Methods:: A descriptive cross-sectional, clinic-based study. A total of 32 epileptic patients who had already undergone tapering were included. Data collection was via a structured questionnaire by a neurology consultant. Patients were dividing into two groups, the slow withdrawal group was considered in more than 3 months, while the rapid withdrawal in less than 3 months.

Results:: 14 patients (43.8%) underwent rapid tapering and 18 patients (58.3%) underwent slow tapering. 53.1% were males and 46.9% were females. The majority had a generalized tonic-clonic (62.5%) followed by complex partial (15.6%). Sodium valproate users were 66%, while carbamazepine ones were 33%. The most common trigger factors for epileptic fits were infections (46.9%). Among 32 patients, 25% had abnormal MRI while 41% had abnormal EEG. The most common type of seizure after relapse was generalized tonic-clonic (65.6%) followed by complex partial (15.6%). The recurrence rate of epilepsy was found to be higher in rapid tapering (12.5%) in the first three weeks compared to slow tapering (6%). A higher rate of reoccurrence in the first year was for slow tapering (40.6%) compared with rapid tapering (34.4%).

Conclusions:: The recurrence of rapid withdrawal in short term was higher and regarding slow withdrawal, the recurrence was higher in the long term.
PATTERNS OF CLINICAL PRESENTATION OF EPILEPSY AMONG ADULT SUDANESE EPILEPTIC PATIENTS SEEN IN SINGA SUDAN A RURAL AREA STUDY EXPERIENCE

Radi Alhusseini¹, Mohajer Ismaeil²,³, Radi Tofaha Alhusseini³, Rashed Abdalla⁴, Roaa Siddahmed⁵, Aziza Alrayah⁵, Wishah Mohammed⁵, Mwaez Ibrahim⁵, Mohammed Abdalla⁶,⁷, Fatimaalzahra Abdoalgadir⁹, Mohamed Abdulrahim⁷, Saddam Mohammed⁶, Hussein Diab⁹, Amira Omer⁹, Mohamed Ahmed¹⁰, Farouq Mohammed¹⁰, Mohamed Abbasher¹, Abdallah Mustafa¹¹, Ahmed Ali⁹
¹university of Khartoum, Medicine, Khartoum, Sudan, ²Alzaiem Alazhari University, Medicine, Khartoum, Sudan, ³Alzaeim Alazhari University, Medicine, Khartoum, Sudan, ⁴university of bahri, Medicine, Khartoum, Sudan, ⁵Ahfad University, Medicine, Khartoum, Sudan, ⁶university of bahri, Medicine, Khartoum, Sudan, ⁷Omdurman Islamic University, Medicine, Khartoum, Sudan, ⁸university of Bahri, Medicine, Khartoum, Sudan, ⁹Daoud research group, Medicine, Khartoum, Sudan, ¹⁰Omdurman Teaching Hospital, Medicine, Khartoum, Sudan, ¹¹Daoud Research Group, Neurology, Khartoum, Sudan

Background and Aims:: Epilepsy is one of the commonest neurological disorders in which brain activity becomes abnormal, causing seizure and periods of abnormal behavior, sensation, and sometimes loss of awareness. The study aims to study the Patterns of clinical presentations of epilepsy among adult Sudanese epileptic patients seen in singa rural Sudan.

Methods:: A prospective cross-sectional study was conducted at Daoud mobile charity clinic in singa Sudan on 13 November 2020. 40 Patients with epilepsy were included in this study. Full detailed history and proper clinical examination were done for each patient.

Results:: Out of 40 patients 21 (52.5%) were females and 19 (47.5%) were males. Age of the patients ranged from 20 to 70 years, 20-30 year was found to be the most common age group (62.5%). 32 patients (80%) had generalized epilepsy. We found that most of the patients had a higher seizure frequency per month (62%). The prodromal and neurological sings were found just in (32.5%) of the patients. Fever was found to be the most seizure provoked factor (35%). 14 patients (35%) with well controlled epilepsy While 26 patients (65%) were poor controlled. There is strong relation between type of medication and increase frequency of attack convolution. Carbamazepine was the most common drug used among the patients that have been seen in singa rural Sudan, followed by sodium valproate, lamotrigine and levetiracetame.

Conclusions:: Generalized epilepsy is the most common type of epilepsy. Patients who live in the singa (a rural Sudan area) have a poor controlled epilepsy.
EPILEPSY SURGERY; WHEN THE EPILEPTOGENIC ZONE CORRESPONDS WITH THE SUPPOSED WERNICKE’S AREA

Ginevra Giovannelli1,2, Veronica Pelliccia2, Belen Abarrategui2, Martina Revay2, Laura Tassi2
1Careggi University Hospital, Epilepsy Center, Department Of Neurology 2, Florence, Italy, 2Niguarda Hospital, Epilepsy Surgery Center "claudio Munari", Milan, Italy

Background and Aims:: An epileptogenic lesion in highly eloquent cerebral areas does not necessarily contraindicate epilepsy surgery, but it may require further diagnostic procedures, also invasive. If a language area is involved, functional study is greatly complex.

Methods:: Woman 26 years old, right handed. Drug-resistant seizures from the age of 7, characterized subjectively by a shiver on the right side of the body, then auditory hallucinations from the right ear; objectively patient incapable to verbally warn of the arrival of the seizure, then psychomotor arrest without automatisms or dystonic postures. At the end a language disturbance was not clearly definable. Seizures with brief duration, weekly. Brain MRI revealed a left mid-posterior superior temporal gyrus (STG) blurring of the gray-white matter junction, consistent with focal cortical dysplasia type II (FCD). fMRI for language showed a bilateral activation for comprehension and a left activation for fluency. Interictal EEG demonstrated left temporal spikes and polyspikes and waves with rhythmic and subcontinuous occurrence during sleep.

Results:: A left temporal-perisylvian Stereo-EEG was performed, with two electrodes exploring the right STG. Spontaneous seizures were recorded, with onset from the FCD. Intracerebral stimulations were crucial in determining a right lateralisation of Wernicke’s area. Stereo-EEG-guided radiofrequency thermocoagulations in the left mid-posterior STG were performed, without complications. Patient is seizure free (short follow-up).

Conclusions:: Stereo-EEG, with the substantial contribution of intracerebral stimulations, allows to localize/lateralize language areas and to accurately define the boundaries and reciprocal relationship with the epileptogenic zone and the anatomical lesion.
KNOWLEDGE OF WOMEN ISSUES AND EPILEPSY AMONG DOCTORS IN SUDAN

Mohamed Elnaeim¹, Awab Elnaeim², Ismat Babiker²
¹Alzaiem Alazhari University, Medicine, Khartoum, Sudan, ²University of Medical Sciences and Technology, Medicine, Khartoum, Sudan

Background and Aims:: The objective of this study was to assess the knowledge of doctors in Sudan about women issues related to epilepsy.

Methods:: In this cross-sectional study that was conducted in Sudan during the period from October to December 2017, we used Google forms to collect data from 154 doctors using Knowledge of Women Issues and Epilepsy (KOWIE) II standardized questionnaire.

Results:: Our studied group included house officers (n = 34), medical officers (n = 60), registrars (n = 52), and specialists (n = 8). The majority of participants were aware of the role of folic acid in reducing teratogenicity of antiepileptic drugs (AEDs) (89%) and that women with epilepsy (WWE) should continue taking their AEDs during pregnancy (76.6%). Two-thirds of participants knew that most WWE have healthy children (68.2%) and that enzyme-inducing AEDs may reduce effectiveness of some contraceptives (72.1%). Half of participants were aware of the association between AEDs and osteomalacia (50%), and more than one-third (38.3%) knew that women taking AEDs can safely breastfeed (38.3%). Only (20.1%) knew that WWE have a higher incidence of sexual dysfunction compared with women without epilepsy, and only some (15.6%) knew that estrogen has a proconvulsant effect while progesterone has anticonvulsant qualities. The mean score of our participants was 5.53 out of 10 (standard deviation (SD) ± 1.64).

Conclusions:: In this small cross-sectional study, Sudanese doctors' knowledge was not satisfactory regarding the majority of questions on KOWIE II. Further education and training are indicated to decrease this knowledge gap and to improve care of WWE.
Background and Aims:: Perampanel is a once-daily oral anti-seizure medication (ASM) for focal-onset seizures (FOS) and generalized tonic-clonic seizures. The AMPA Study (501; NCT04257604) was a multicenter, prospective, observational study conducted in Italy to assess the effectiveness and safety of perampanel received as add-on therapy in patients aged ≥12 years with FOS in a real-world setting. We present the design of the AMPA Study.

Methods:: Inclusion criteria included: aged ≥12 years; diagnosis of FOS with or without focal to bilateral tonic-clonic seizures (FBTCS); prescribed perampanel according to the Summary of Product Characteristics (decision to initiate perampanel had to be independent of study participation); seizures inadequately controlled with 1–3 ASMs; available seizure-frequency data at baseline. Exclusion criteria included: any contraindication to perampanel use; pregnant/lactating women; clinically significant psychiatric illness or psychological/behavioral problems; moderate-to-severe renal impairment; severe hepatic impairment. Patients were assessed at baseline, and following 3 (visit 1), 6 (visit 2), and 12 months (final visit) of perampanel treatment. The primary endpoint was median percentage change from baseline in the frequency of all seizures at 6 months. Secondary endpoints included: retention rates; responder and seizure-freedom rates; median percent change in FBTCS frequency; adverse drug reactions; the Quality of Life in Epilepsy Questionnaire and Epworth Sleepiness Scale scores (adults).

Results:: Overall, 243 patients have been enrolled at 19 sites across Italy.

Conclusions:: The AMPA Study will provide important prospective, observational, real-world data on the use of perampanel as an add-on treatment in patients aged ≥12 years with FOS. Funding: Eisai s.r.l.
ORAL HEALTH STATUS OF PATIENTS WITH EPILEPSY IN RURAL POPULATION

Ashish Sharma
AIIMS BILASPUR, Neurology, BILASPUR HP, India

**Background and Aims:** The present study was undertaken for assessing the oral health status of patients with epilepsy in rural population of Himachal.

**Methods:** A total of 100 epilepsy patients were enrolled in the present study. Complete demographic details of all the patients were obtained. A Performa was prepared and separate assessment of clinical and medical details of all the patients was done. After obtaining the informed consent, patients were made to sit in supine position and complete oral examination was carried using mouth mirror, William probe and explorer. OHI-S (Oral hygiene index- simplified) was used for assessing the oral health status. All the results were recorded in Microsoft excel sheet and were analysed by SPSS software.

**Results:** It was seen that significantly higher proportion of patients with history of seizure of more than 4 didn’t brushed their teeth regularly. Incidence of bleeding gums was significantly higher among patients history of seizure of more than 4 per month in comparison to patients which were seizure free. Out of 14 patients with history of seizure of more than 4 per month, bad breath was present in 12 patients while out of 20 patients which were seizure free, 6 patients had bad breath. While analysing statistically, it was seen that bad breath was strongly associated with frequency of seizures. Also, significantly higher proportion of dental caries and gingivitis was seen in patients with higher frequency of seizure per month.

**Conclusions:** Conclusion: Epilepsy patients have compromised oral health and hence; regular oral examination is advocated in these group of patients.
Background and Aims:: In the first year of life, epilepsy causes a serious neurological problem. Severe sequelae are possible in the preterm child with the cerebral immaturity. This study aims to establish the relationship between premature birth and the epilepsy through our two populations study.

Methods:: This is a retrospective case-control study conducted at the Antsakaviro Neuroscience and Mental Health Laboratory from January 2015 to January 2017. We selected as cases all children aged 0 to 12 months old with epilepsy and compared them with control children aged 0 to 12 months without epilepsy in the laboratory of neurosciences and mental health.

Results:: We have 530 epileptic patients aged 0-12 months and 530 children aged 0-12 months without epilepsy as controls. The average age was 5.52 months and the sex ratio was 1.5. Twenty-two percent were premature (n = 97) and 81% not premature (n = 433). Among non-epileptics 5.84% (n = 31) were premature. Being premature would increase the occurrence of epilepsy 4 times more (OR: 3.6).

Conclusions:: Prematurity is a risk factor for epilepsy in the first year of life. A neurological oversight of premature is necessary to detect the epilepsy.
ELECTROCLINICAL ASPECTS OF OCCIPITAL EPILEPSY SEEN IN THE NEUROSCIENCES AND MENTAL HEALTH LABORATORY ANTSAKAVIRO

Lemahafaka Jemissair Glorien¹, Alain Djacoba Tehindrazanarivelô²
¹CHU Antanambao, Medicine, toliara, Madagascar, ²Faculty of Medicine of Antananarivo, Neurology, Antananarivo, Madagascar

Background and Aims:: Occipital epilepsy occurs when the initial site of epileptic discharge involves part or all of the occipital lobe. Occipital epilepsy is the least common of the other types of epilepsy and is rarely described in the literature. However, the manifestation located initially in the occipital cortex, which is a functional zone of vision, leads to its protean aspect. It can be a source of diagnostic wandering. The purpose of this study is to describe the electroencephalographic clinical characteristics of patients seen for occipital epilepsy at the Laboratory of Neurosciences and Mental Health, Antsakavigro, Madagascar

Methods:: This is a retrospective and descriptive study that took place over a one-year period (January 2016 to December 2016). Included in this study were all patients diagnosed with clinically and EEG-confirmed occipital epilepsy. A correlation between clinical manifestations and electroclinical data is sought.

Results:: We retained 66 patients with male predominance (sex ratio: 1.4). The age of the patients ranged from 3 to 55 years with a mean age of 13.77 years. Patients reside in urban areas and the majority are of non-school age. The clinical manifestations of occipital epilepsy are mainly paroxysmal visual hallucinations lasting on average 3 minutes and of variable frequency. EEG signs are predominantly paroxysmal activities with a predominant or occipital starting point.

Conclusions:: The clinical and electroencephalographic manifestations of occipital epilepsy deserve special attention in order to make a proper diagnosis.
Background and Aims:: Tuberous sclerosis complex (TSC) or Bourneville’s disease, first described by Desiree- Magloire Bourneville in 1880, is a rare genetic disorder of autosomal dominant inheritance with the prevalence of one in 6000 live birth, affecting both sexes and all ethnic groups1,2. It is a multisystem disorder involving brain, skin, kidneys, heart, eyes, and lungs which becomes apparent only in late childhood, limiting the usefulness for early diagnosis in infancy. Tuberous sclerosis is a rare neurocutaneous syndrome and the major neurological manifestations are seizures, autism, developmental delay and behavioral and psychiatric disorder. Epilepsy is the most common nervous system performance in children tuberous sclerosis complex (TSC), and the main types of onset are partial seizures and spasms.

Methods:: 7 year old boy referred from paediatric op with complains of involuntary movements of right upper limb with up rolling of eye ball and loc for 5min. he had similar episodes in the day before. no history of any fever. on examination conscious, oriented, head to toe examination revealed Doliophealy, adenoma sebaceum, ash leaf Macules in over back, thigh

Results:: Routine blood investigation are normal, mri imaging suggestive of tuberous sclerosis, dermatologist opinion also confirmed the same

Conclusions:: TSC is one of the neurocutaneous syndromes inherited in autosomal dominant fashion with almost complete penetrance with variable expressivity, affecting almost all organs. The quality of life depends on the neurological manifestation like seizures and mental retardation which is improved by multidisciplinary approach and symptomatic organ specific treatment. Clinical diagnosis complementing with DNA testing allows precise genetic counseling, which is important.
SLEEP DISORDERS IN CHILDHOOD EPILEPSY

Zahira Barka Bedrane1,2, Naziha Chiali1, Mehdi Bouchenaki1, Oussama Dendene1, Brahim Belahcene1, Khadidia Medini1, Djoued Bouchenak Khelladi1
1University hospital center, Neurology, Tlemcen, Algeria, 2centre hospitalo universitaire, Neurology, Tlemcen, Algeria

Background and Aims:: sleep has a great influence on epileptic seizures and epilepsy significantly affects the quality and restorative functions of sleep. Clinical research has found a fairly high prevalence in children with epilepsy compared to healthy children .The aims of our study: -Study the risk factors for sleep disorders in children with epilepsy -Identify the most frequent sleep disorders

Methods:: This is a case-control study, carried in the neurology department of Tlemcen University Hospital. The questionnaire on children's sleep habits (CSHQ) was used. A total score of 41 is a sensitive threshold for clinically significant sleep problems. The Children's Quality of Life Questionnaire (KINDL-R) . Factors related to epilepsy were evaluated, in addition to questioning with parent. Patient informations were collected such as age at diagnosis, type of epileptic seizures, duration of epilepsy, and treatment. Statistical study was carried SPSS(22).

Results:: 59 children and adolescents with epilepsy and 28 controls were included in the study. The mean age of the epilepsy and control groups was 12.2 ± 2.45 and 1.8 ± 1.25, respectively. In the epilepsy group, 54.2% presented with generalized epilepsy, 32.2% with partial epilepsy. The majority of patients had seizures once a year (79.6%). 76.2% of patients were on antiepileptics monotherapy. Comparison of CSHQ scores between children with epilepsy and controls concluded that the total score and CSHQ subscores were higher in the epilepsy group (p <0.005). The KINDL-R total score was lower in children with epilepsy.

Conclusions:: Sleep disorders in epilepsy childhood not only predispose to mood, cognitive and behavioral disturbances, but also have a significant impact on physical health.
PREDICTORS OF ACUTE SYMPTOMATIC SEIZURE IN PATIENTS WITH CENTRAL NERVOUS SYSTEM INFECTIONS IN THE NEUROLOGY DEPARTMENT OF MOEHAMMAD HOESIN PALEMBANG HOSPITAL PALEMBANG INDONESIA

Sri Handayani¹,², Andika Okparasta¹, Sri Yani¹, Muhammad Irsan Saleh³
¹Universitas Sriwijaya, Neurology, Palembang, Indonesia, ²Universitas Sriwijaya, Biomedical Program, Palembang, Indonesia, ³Universitas Sriwijaya, Pharmacological, Palembang, Indonesia

Background and Aims:: Acute symptomatic seizure (ASS) is defined as a clinical seizure occurring in acute temporal relationship close to the central nervous system (CNS) which may be due to metabolic, toxic, structural lesions, infection or inflammation. Seizures and coma are known predictors of poor outcome in patients with CNS infection. This study aims to identify various factors that can be predictors of ASS incidence in patients with CNS infection.

Methods:: This is a cross sectional analytic observational study at Mohammad Hoesin Hospital Palembang from January 1, 2019 to December 31, 2020. The populations were all CNS infections inpatients. Sampling was carried out through medical record data.

Results:: A total of 56 CNS infection patients were included as samples and 27 people had ASS. ASS was more common in the 18-30 years age group, female, with clinical fever, with > 4 neurological manifestations, with history of HIV, normal leukocytes, hyponatremia, hypocalcemia and GCS <12. Patients with GCS <12 who experienced ASS had a poor prognosis, as evidenced by 71.43% of them died. The majority of the etiology is cerebral toxoplasmosis and the most common head CT scan is cerebral edema. After analyzing bivariate and multivariate statistically, there was not even one variable that had a significant result as a predictor of ASS in patients with CNS infection (P>0.05).

Conclusions:: In this study, the proportion of independent variables studied as predictors of ASS in CNS infection patients was quite significant according to theory, literature and previous studies, although not statistically significant.
Background and Aims:: DNETs are the primary tumor etiology of drug-resistant temporal epilepsies in children and young adults. It is a benign neuroglial and neuronal or mixed tumor, with a cortical site, involving 23.4% of all tumors associated with epilepsy. We illustrate through 3 cases the clinical and radio-diagnostic characteristics of DNETs as well as their different therapeutic and evolutionary modalities.

Methods:: We report the cases of 3 patients followed in our department for DNET
We note the recurrence of EMEs for the 1st patient with neuropsychiatric disorder, occasional epileptic seizures for the 2nd patient, paroxysmal headache for the 3rd patient.
Conclusions: Status epilepticus or early-onset drug-resistant complex partial seizures are the classic inaugural pictures of DNETs. Late onset after the age of 20 and immediately generalized seizures are rare. These tumors can be asymptomatic. Radiologically, these tumors have cortical site, often temporal in 60%, or frontal in 30% rarely. Surgical excision is the basic treatment.

PROGRESSION OF NEURONAL DAMAGE IN MESIAL TEMPORAL LOBE EPILEPSY MEASURED BY PROTON MAGNETIC RESONANCE SPECTROSCOPY

Eloisa Granussio1, Gabriela Silva2, Luciana Pimentel-Silva2, Fernando Cendes2
1University of Campinas, Neurology, Campinas, Brazil, 2University of Campinas - UNICAMP, Neurology, Campinas, Brazil

Background and Aims:: Mesial temporal lobe epilepsy (MTLE) presents with pharmacoresistance. Progression of structural damage has been reported, but it is unclear whether there is progression of metabolic damage. We aimed to longitudinally investigate metabolic changes in patients with MTLE with and without pharmacoresistance, using proton magnetic resonance spectroscopy (1H-MRS), to quantify N-acetylaspartate (NAA), a marker of neuronal damage and dysfunction.

Methods:: We measured ipsi- and contralateral hippocampal NAA ratios to creatine (NAA/Cr) using 1H-MRS from 167 individuals: 66 pharmacoresponsive patients, 95 pharmacoresistant patients and 6 controls. We selected up to four 1H-MRS per patient. We performed generalized linear models with identity link function. The main effects were pharmacoresponse, time, and pharmacoresponse*time interaction. We covaried for age at each scan. We set p<0.05 as significant.

Results:: There were effects of time (p=0.039), and pharmacoresponse (p=0.024) but no pharmacoresponse*time (p=0.082) interaction on ipsilateral NAA/Cr. We found reduced ipsilateral NAA/Cr in pharmacoresistant patients compared to pharmacoresponsive patients (p=0.043) and controls (p=0.004). Both pharmacoresponse groups showed reduced NAA/Cr comparing scan-1 to scan-3 (p=0.006) and scan-4 (p=0.051); and comparing scan-2 to scan-3 (p<0.001) and scan-4 (p=0.012). We found no effect of pharmacoresponse nor interactions on contralateral NAA/Cr (p>0.12) and only effect of time (p=0.037) on contralateral NAA/Cr (p=0.037). There was reduced contralateral NAA/Cr comparing scan-1 to scan-2 (p=0.034), regardless pharmacoresponse.

Conclusions:: Our data suggest unilateral effects of pharmacoresponse and bilateral effects of time in neuronal damage. Acknowledgements: This study was funded with grants Pibic-CNPQ (129161/2020-9) and Fapesp (2013/07559-3)
EARLY AND LATE SEIZURES IN MALIGNANT MIDDLE CEREBRAL ARTERY STROKE TREATED WITH DECOMPRESSIVE CRANIECTOMY AND: PRELIMINARY RESULTS OF A SINGLE CENTER REGISTRY.

Livio Picchetto¹, Giuseppe Borzi¹, Laura Giacobazzi¹, Niccolò Orlandi¹, Francesca Rosafio¹, Steffano Baroni², Giovanni Pavesi³, Guido Bigliardi¹, Stefano Meletti¹

¹Ospedale Civile di Baggiovara, AOU di Modena, Stroke Unit – Neurology Clinic, Department Of Neuroscience, Modena, Italy, ²Azienda Ospedaliera Universitaria Policlinico di Modena, Ospedale Civile Di Baggiovara, Icu, Modena, Italy, ³Azienda Ospedaliera Universitaria Policlinico di Modena, Ospedale Civile Di Baggiovara Neurosurgery Unit, Department Of Neuroscience, Modena, Italy

Background and Aims:: More than 40% of patients with malignant middle cerebral artery (MCA) stroke undergone craniectomy may develop both early or late seizures, mainly partial with generalization. The median onset of seizures was seven months; delayed craniectomy (>42h) has been identified as a risk factor for seizure (1, 2). The aim of our study was to identify factors related to the occurrence of seizures.

Methods:: All patients who developed malignant MCA infarction and undergone decompressive craniectomy in Modena Stroke Unit between september 2008 and june 2021 were evaluated. Clinical features -including mRS at 3 and 12 month follow up- and neuroradiological parameters were collected.

Results:: We evaluated a total of 61 patients. Seizures occurred in 42,6 % of all patients (26/61 pt). The median time from stroke onset to craniectomy was 47,1 hours all patients, but was 72 h in epyleptic. The median onset of seizures was 162 days but in 8/26 pt they started within 20d from stroke onset. The majority of these were focal motor seizures with generalization. Large craniectomy were slightly related with early seizures. At 1 year follow up 3/26 pt were died (mRS=6) and 20/26 presented good functional outcome (mRS<=4). Two of them needed a second cranioplasty intervention because of a major seizure.

Conclusions:: Epileptic seizures in patients with malignant MCA infarcts submitted to DHC is very frequent and can occur early or lately, affecting the clinical outcome.
VIOLENCE AND EPILEPSY: DESCRIPTIVE STUDY OF 33 CASES

Syrine Brahimi, Walid Bouali, Mohamed Habib Aoun, Ahmed Hadj Mohamed, Lazhar Zarrouk

1University Hospital of Mahdia, Psychiatry, Mahdia, Tunisia, 2University Hospital of Mahdia, Psychiatry, Mahdia, Tunisia

Background and Aims:: Questions are often raised about the relationship between recurrent seizures and the behaviour of the epileptic person. However, some people who have seizures have behavioural problems and are responsible for medico-legal procedures despite the progress of anticomitial chemotherapy. The objective of this work is to develop the sociodemographic and clinical profile found in epileptic patients who committed violent acts.

Methods:: This is a retrospective study of epileptic patients hospitalized at the psychiatry department in the university hospital of Mahdia.

Results:: A total of 33 files were collected, 75% of patients were admitted according to the mode of involuntary hospitalization. The most frequent reason for hospitalization was motor instability (80% of cases). The average age was 31.8 years old, sex ratio was 2.2. The level of education was low in 93% of cases, the majority (90%) of cases was without professions, single in 81% of cases. The criminal record was found in 21% of cases whereas the psychiatric history in 37% of cases: depressive disorder represents the first comorbidity found 25% of cases, psychotic disorders in 12% of cases and bipolar disorder in 6% of cases. Mental retardation and personality disorders associated with epilepsy are objectified in 62% and 12% of cases respectively. These patients were all treated with antiepileptics, 56% with thymoregulators, 37% with antipsychotics, 25% with antidepressants and 18% with benzodiazepines.

Conclusions:: It is important to recognize a psychiatric disorder related to epileptic seizure to adopt the therapeutic measures and to prevent the passage to the violent act.
THE WHITE ROSE PETAL EXTRACT ABROGATES EXCITOTOXIC NEURONAL DAMAGE THROUGH ANTIOXIDATIVE AND ANTI-INFLAMMATORY ACTIVITIES

Wang Cuicui
Chungbuk National University, Veterinary, Chungbuk cheongju, Korea, Republic of

Background and Aims:: Since oxidative stress and inflammation are involved in seizure-related neurotoxicity, the neuroprotective effect of a white rose (Rosa hybrida) petal extract (WRPE) in mice that are challenged with kainic acid (KA) were examined using behavioral epileptiform seizures as well as biochemical and morphological parameters of oxidative stress and inflammation.

Methods:: WRPE was orally administered to ICR mice for 15 days, and intraperitoneally challenged with KA. Seizure activity, lipid peroxidation, inflammatory cytokines, and related enzymes were analyzed in the brain tissue, and the morphological alterations in the hippocampal pyramidal neurons. Antioxidant ingredients in WRPE were analyzed, and antioxidant, anti-inflammatory, and neuroprotective activities of WRPE were investigated in human neural stem cells.

Results:: Total polyphenol and flavonoid contents in WRPE were 303.3 ± 15.3 mg gallic acid equivalent/g extract and 18.5 ± 2.2 mg catechin/g extract, respectively. WRPE exhibited strong radical-scavenging activities and inhibited lipid peroxidation in vitro, and protected glutamate-induced cytotoxicity in NSCs by suppressing inflammatory process. Treatment with WRPE attenuated epileptiform seizure scores in KA-challenged mice, and decreased hippocampal pyramidal neuronal injury and loss as well as astrocyte activation. Lipid peroxidation was inhibited, and mRNA expression of antioxidant enzymes (GPx, PHGPx, SOD1, and SOD2) were recovered in the brain tissues. Inflammatory parameters including NF-kB, IL-1, TNF-α, IL-6, HMGB1, TGF-β, iNOS, COX2, and GFAP mRNAs and proteins were also down-regulated by WRPE treatment.

Conclusions:: Taken together, the results indicate that WRPE could attenuate KA-induced brain injury through antioxidative and anti-inflammatory activities, and that WRPE and their active ingredients could be candidates for neuroprotective drugs and functional foods.
MENTAL HEALTH AND EPILEPSY: A SURVEY EXPLORING PERSPECTIVES OF HEALTHCARE PROVIDERS IN SUB-SAHARAN AFRICA

Chloe Gilkinson¹, Tolu Olaniyan², Rohit Shankar³, Michael Mckinney¹
¹Queen's University Belfast, School Of Medicine, Dentistry And Biomedical Sciences, Belfast, United Kingdom, ²Pretola Global Health Consulting Limited, Ilae Uk, Isle of Wight, United Kingdom, ³University of Plymouth, Peninsula School Of Medicine, Plymouth, United Kingdom

Background and Aims:: Epilepsy is the most common neurological diagnosis reported in sub-Saharan Africa, and psychological distress, particularly depression, is highly comorbid. Yet most patients fail to receive appropriate multidisciplinary care. This study addressed attitudes towards epilepsy and comorbid mental illness, as well as management practices among healthcare providers in sub-Saharan Africa. Additionally, we explored the perceived local barriers to adequate psychiatric care.

Methods:: A cross-sectional survey was conducted, and distributed using a snow-balling method, among healthcare providers in sub-Saharan African settings who were attending virtual training from Pretola Global Health and Consulting Ltd.

Results:: Our survey received responses from 203 healthcare professionals in sub-Saharan African countries. Most (80.0%) recognised a positive association between mental illness and epilepsy. However, only a small proportion reported that they screen for (14.4%) or provide education on the risk of developing mental illness (12.4%) in epilepsy populations. The vast majority (93.5%) reported that treatment improvements within their local healthcare settings are required. The major themes identified as local barriers to adequate psychiatric care were a lack of confidence in how to assess for mental illness; lack of awareness that there is a heightened risk of mental illness in patients with epilepsy; and limited access to psychological services.

Conclusions:: Our study highlights the need for improving access to quality treatment of mental health disorders in epilepsy populations in sub-Saharan Africa. Our practical recommendation is to provide accessible training to sub-Saharan African healthcare providers by way of a validated, online education programme detailing optimal multidisciplinary care of mental illness in epilepsy populations.
HYSTERO-EPILEPSY, DIAGNOSTIC AND THERAPEUTIC DIFFICULTIES

Syrine Brahim1,2, Walid Bouali2, Samira Younes2, Sabria Khouaja2, Samia Younes3, Lazhar Zarrouk4
1University Hospital of Mahdia, Psychiatry, Chebba, Tunisia,
2University Hospital of Mahdia, Psychiatry, Mahdia, Tunisia,
3Department of Neurology, Mahdia, Taher Sfar University Hospital, Tunisia,
4University Hospital of Mahdia, Psychiatry, Mahdia, Tunisia

Background and Aims:: The problem of the differentiation between epileptic seizures and hysterical attacks recurs constantly in the history of medicine. Hysteroepilepsy or non-epileptic psychogenic seizures (NEPC) can be defined as paroxysmal manifestations clinically evoking epileptic seizures but related to unconscious psychogenic processes. The clinical diagnosis is particularly difficult. The objective of this work is to determine the epidemiological and evolutionary characteristics.

Methods:: This is a retrospective study of the files of patients hospitalized in the department of Medicine who have been diagnosed with hystero-epilepsy.

Results:: We collected 32 patients. The average age was 26 years. The sex ratio was 0.61. The reason for hospitalization was the recrudescence of pharmaco-resistant paroxysmal manifestations. Three had a history of epilepsy, the others were free of all organic and psychiatric pathologies. The crises described were of tonicoclonic type in 6 cases. The clinical symptomatology is insufficient to carry the diagnosis requiring the use of biological and radiological explorations (cerebral computed tomography performed in 14 patients returned normal). Video-ectroencephalographic (EEG) done in all patients were without abnormalities. The treatment initiated was intravenous benzodiazepines in 21 patients. The evolution was marked by the recurrence of the symptomatology for 25% of the cases for which they were hospitalized.

Conclusions:: Hysteroepilepsy is a significant cost to the health care system. Early diagnosis avoids anticonvulsant therapy, which is ineffective and has frequent side effects.
MOTOR AND COGNITIVE DYSFUNCTIONS IN RELAPSING-REMITTING MULTIPLE SCLEROSIS: THE ROLE OF STRUCTURAL BRAIN DAMAGE

Damiano Mistri1, Laura Cacciaguerra1,2, Claudio Cordani1, Maria Rocca1,2,3, Massimo Filippi1,2

1IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Division Of Neuroscience, Milan, Italy, 2Vita-Salute San Raffaele University, Na, Milan, Italy, 3IRCCS San Raffaele Scientific Institute, Neurology Unit, Milano, Italy, 4IRCCS San Raffaele Scientific Institute, Neurology Unit, Neurorehabilitation Unit And Neurophysiology Service, Milan, Italy

Background and Aims:: A deeper understanding of the relationship between motor and cognitive dysfunctions in multiple sclerosis (MS) could highlight overlapping mechanisms of impairment. We assessed the influence of brain structural damage and cognition on motor performance in a large group of MS patients.

Methods:: Eighty-six healthy controls (HC) and 127 relapsing-remitting (RR) MS patients underwent 3.0T MRI, the Brief Repeatable Battery of Neuropsychological tests and a functional examination including finger tapping test (FTT), nine-hole peg test (9-HPT), 25-foot walk test (25-FWT) and expanded disability status scale (EDSS). Clinical outcomes were converted to z-scores and analyzed according to the side of greatest upper-limb impairment. Univariate analyses and hierarchical linear regression were computed to investigate the association between demographic and clinical features, cognitive scores, MRI measures, and functional outcomes.

Results:: In RRMS patients, spatial recall test correlated with FTT performed with the preserved side (PS), bilateral 9-HPT and T25FW (p≤0.033); Symbol Digit Modalities Test was associated with FTT performed with the impaired side (IS) and bilateral 9-HPT (p≤0.022); while Word List Generation (WLG) correlated with PS-FTT and bilateral 9-HPT (p≤0.045). After adjusting for the side of impairment, hierarchical regression models selected clinical and demographic features as predictors of bilateral FTT (R²=0.15-0.23), while EDSS and normalized brain volume (NBV) were significant for T25FW (R²=0.21) and for IS-9-HPT (with the additional contribution of T1 lesion volume, R²=0.32). EDSS, sex, NDGMV and WLG predicted variability in PS-9-HPT (R²=0.31).

Conclusions:: In RRMS patients, motor and cognitive dysfunctions are related, and their association is mediated by structural brain damage.
WORSENED VISUAL HALLUCINATION IN DEMENTIA LEWY BODY RELATED TO SYMPTOMATIC THERAPY

Neila Raisa, Kartika Agustina, Sri Rianawati, Ria Damayanti
Faculty of Medicine Universitas Brawijaya, Neurology Department, Malang, Indonesia

Background and Aims:: Lewy Body Dementia (DLB) is consists of fluctuating cognition, recurrent visual hallucinations, REM sleep behaviour disorder, and cardinal features of Parkinsonism. This case report purposes of describing progressivity of visual hallucination in DLB who get symptomatic therapy.

Methods:: A case report: a woman, 84 years old, with progressive cognitive dysfunction (orientation, attention, calculation) since two years ago then worsened in 6 months and affected her daily living activities, so the patient received symptomatic treatment for dementia (donepezil 5 mg) since these last 6 months. She has a history of visual hallucinations for more than ten years, which has improved in the past year but worsens in these three months. On the other side, she was diagnosed with Parkinson's Disease 3.5 years ago and got therapy: Levodopa/Benserazide for 3.5 years.

Results:: This case illustrates worsening visual hallucinations by increasing frequency and form of visual hallucinations in DLB related to symptomatic therapy (dopaminergic/levodopa). Levodopa is related to intrinsic striatal pathology, reduced caudal putamen dopamine D2 receptors, and D3 receptors on corticostriatal projection neurons, with the strongest association in anterior cingulate, develop visual hallucinations.

Conclusions:: DLB is a progressive disease that could be getting worse in the patients. We have to select DLB patients' treatments as substantial since the treatment of non-motor and motor symptoms might be interacting with one another. Hence, it aggravates clinical manifestation in DLB. Non-pharmacological strategies should be conducted as soon as possible to prevent worsening conditions.
Background and Aims:: Raising a child with developmental delay is a profoundly difficult experience for parents of these children. This study was aimed to compare the stress level and life participation among mothers of children with Down Syndrome (DS) and Cerebral Palsy (CP). And to identify whether the stress and life participation of the mothers differ significantly based on the functional skills of children. Methods:: A total of 78 parents (of children with CP, n = 42; of children with DS, n = 34) were examined using Pediatric Evaluation of Disability Inventory (PEDI) and Perceived Stress Scale (PSS) and Life Participation for Parents (LPP). Results:: It was found that mothers of children with CP had significantly higher perceived stress scale scores and had significantly lower life participation scores than mothers of children with DS (p=0.010; p=0.046, respectively). It was found that children with CP had lower functional level (FL) scores than children with DS (p=0.011). The children’s FL may have been related to the stress level and life participation of their mothers. Conclusions:: Findings indicated a significant difference between mothers’ stress levels and life participation according to the functionality level of the children. These findings highlight the need for family support services for these mothers. Further studies may also compare the stress level and life participation of fathers who had children with a disability.
STUDY OF SELF CONCEPT AND SOCIAL SUPPORT PERCEPTION: NEURODEVELOPMENTAL DISORDERS

Gokcen Akyurek¹, Hilal Murattoğlu²
¹Hacettepe University Faculty of Health Sciences, Occupational Therapy, Ankara, Turkey, ²Hacettepe University, Occupational Therapy, Ankara, Turkey

Background and Aims:: This study were planned to investigate self-perception, self-esteem, and social support perception among children with Attention Deficit and Hyperactivity Disorder (ADHD) and/or Specific Learning Disabilities (SLD).

Methods:: In this study, 31 children with ADHD and/or SLD between the ages of 9-13 who are registered in Hacettepe University Faculty of Health Sciences, Department of Occupational Therapy were included as a research group (RG). Thirty typically developed children between the same age (9-13 years old) were included as the control group (CG). For this study, Self-Perception Profile for Children (SPPC), Coopersmith Self-Esteem Inventory (CSEI), and Social Support Questionnaire for Children (SSQC) were used. Mann-Whitney U test was used for analysis.

Results:: The analyses showed that the SPPC score of the RG was significantly lower than that for CG (Z=-3.125; p=0.002); the CSEI score of the RG was significantly lower than that for CG (Z=-2.464; p=0.014) and the SSQC score of the RG was significantly lower than that for CG (Z=-2.887; p=0.004).

Conclusions:: In this study, it was found that self-concept, self-esteem, and social support are low from the typical developed peers. Children with ADHD with/or SLD have problems these psychosocial areas and need support. Therefore, it is important to include practices that support their identity development and social support in their rehabilitation programs.
Background and Aims:: The sporadic nature AD suggest that aside from biological determinants, environmental factors such as stress plays a role in the development of disease. This study aims to analyze the relationship between stressful life events and AD.

Methods:: We studied 118 patients with diagnosis of AD. Medium age was 73 years. Meantime elapsed from the initial symptoms was 2.6 years. A control group of 81 healthy individuals was studied. A questionnaire looking for stressful life events in the 3 years before diagnosis of AD was performed to patients, caregivers and controls.

Results:: In the AD group, 85 patients (72%) presented a history of significant stressful life events, 2.1 years (SD 1.4 y) before the onset of symptoms. The most common findings in the AD group were: couple death (24 cases), child death (15 cases), history of assault (21 cases), history of car accident (11 cases). Other stressful situations were marked financial problems, bereavement, retirement, adaptive changes due to migrations and diagnosis of severe somatic disease in the family. In the control group, only 21 individuals (26%) recognized similar previous stress factors.

Conclusions:: We observed an association between stressful life events preceding the onset of dementia in a high percentage of our patients. Stress could trigger the degenerative process in AD and growing evidences suggest a dysfunction in neuroendocrine and immune system. According our results, we can establish a relationship between several stressful life events and the onset of dementia. It is an observational finding and does not imply direct causality.
SPEECH-LANGUAGE PROFILES IN EARLY-STAGE PRIMARY PROGRESSIVE APHASIA: NON-FLUENT VERSUS SEMANTIC VARIANT

Soomin Kim¹, Jae-Hong Lee², Miseon Kwon²
¹Asan Medical Center, Neurology, Seoul, Korea, Republic of, ²Univ. Ulsan, Asan Medical Center, Neurology, Seoul, Korea, Republic of

Background and Aims:: Primary progressive aphasia (PPA), a clinical syndrome caused by neurodegenerative pathology, is subdivided into three variants depending on the profiles of language impairment: non-fluent, semantic, and logopenic variant (nfvPPA, svPPA, lvPPA). This study compared the language characteristics of the patients in their early stage of PPA.

Methods:: Fifty-five patients were referred to our speech-language clinic from 2007 to 2019 to rule out PPA. Among them, 34 patients demonstrate mild language impairment (more than 80 of AQ score in K-WAB). Finally, 5 nfvPPA and 3 svPPA cases were included after the review of neuroimaging and follow-up studies for analysis. The results of a language battery (K-WAB), naming deep-tests (K-BNT and COWAT) and acoustic analysis of spontaneous speech were compared.

Results:: The patients in both groups presented mild anomic profile of aphasia and had no significant differences in each subtest (fluency, informativeness, auditory comprehension, repetition, and naming) as well as AQ score in K-WAB. However, in naming deep-tests, the nfvPPA was significantly impaired in phonemic generative naming, whereas the svPPA presented significant decline in confrontation naming and semantic generative naming. Acoustically, the nfvPPA produced shorter length of utterances, prolonged pause, and slower speech rate during their spontaneous speech compared to the svPPA.

Conclusions:: The results of this study demonstrated different speech-language characteristics between two subtypes of PPA even in their early stage, which were not distinguished by a standardized language battery. It may provide clinically useful information for early differential diagnosis of PPA subtypes. Further researches including all three variants with larger participants group are needed.
CONSUMPTION OF PROCESSED MEAT MAY INCREASE THE RISK OF INCIDENT LATE-ONSET DEPRESSION

Antonio Daniele¹, Emanuele Maria Costantini¹, Madia Lozupone², Francesco Panza²
¹IRCCS Fondazione Policlinico Gemelli, Neurology, Rome, Italy, ²National Institute of Gastroenterology "Saverio de Bellis", Research Hospital,, Healthy Aging Phenotypes Research Unit, Castellana Grotte, Italy

Background and Aims:: The possible relationship between dietary habits and the incidence of late-onset depression (LOD), defined as first onset depression in mild-life (between 45 and 65 years), is unclear. The present study was aimed at investigating the relationship between consumption of different foods and incident LOD.

Methods:: In a longitudinal population-based study with a 12-year follow-up, 546 community-dwelling subjects in Southern Italy aged ≥ 65 years (mean age = 66 years) were recruited. Dietary intake was assessed with a food frequency questionnaire. Depressive disorders, classified on the basis of the age of onset at follow-up, were assessed by means of the Semi-structured Clinical Diagnostic Interview for DSM-IV-TR Axis I Disorders.

Results:: At baseline, subjects with incident LOD had lower scores on a test assessing global cognition (Mini-Mental State Examination), lower total cholesterol levels, and higher body mass index. Only processed meat (with high content of salt, saturated fats and preservatives) significantly increased the risk of incident LOD of about 10% by 5 g/day intake (fully-adjusted model, hazard ratio:1.13, 95% confidence interval:1.04-1.22). The average consumption of processed meat was 21 g/d in subjects with incident LOD and 15 g/d in individuals without incident LOD. A similar risk relation was found for intake of single foods forming processed meat group (sausages, salami, and mortadella, baked ham), but not for raw ham.

Conclusions:: These findings suggest that in midlife a higher intake of processed meat might not only increase the risk of cardiovascular- and metabolic-related chronic diseases, but also increase the risk of LOD.
EXAMINATION OF THE RELATIONSHIP BETWEEN PARENTAL BEHAVIORS AND EXECUTIVE FUNCTIONS-SOCIAL SKILLS OF TYPICALLY DEVELOPED CHILDREN

Gokcen Akyurek¹, Büşra Sipahi²
¹Hacettepe University Faculty of Health Sciences, Occupational Therapy, Ankara, Turkey, ²Aktivtoo Ergoterapi ve Gelişim Merkezi, Occupational Therapy, İstanbul, Turkey

Background and Aims:: Children's developmental, social and cognitive skills are of great importance. It is thought that various skills are associated with parental behaviors in childhood. This study was aimed to investigate the relationship between parental behavior and children's executive functions and social development.

Methods:: Assessments were conducted with 103 parents with typically developing children between the ages of 7-12. Sociodemographic Information Form, the Social Skills Assessment Scale, the Childhood Executive Function Inventory, and the Parental Behavior Scale were administered to parents. Correlation analysis (Pearson Correlation coefficient) was a statistical method used to evaluate the strength of the relationship between these three variables.

Results:: There was a relationship between the score of the Childhood Executive Function Inventory and the score of the Social Skills Assessment Scale (r = 0.472; p < 0.001); the Parental Behavior Scale (r = 0.300; p = 0.002). In addition, there was no relationship between the score of the Social Skills Assessment Scale and the Parental Behavior Scale (r = -0.048; p = 0.629).

Conclusions:: According to the findings, only executive functions were found to be associated with parental behavior. Although these executive functions and social skills are related, social skills are not related to parental attitudes. Therefore, it is thought that parents' attitudes can be positively affected when executive functions are developed with training.
MENTAL DEPRESSION AND ASSOCIATED FACTORS AMONG ADULTS CONSULTING AT THE BAMENDA REGIONAL HOSPITAL, CAMEROON

Samuel Angwafor¹, Mbome Ebenyea², Basseguin Atchou¹, Wepnyu Yembe Njamnshi³, Leonard Ngarka⁴, Alfred Njamnshi³
¹d. Brain Research Africa Initiative (BRAIN), Yaoundé, Cameroon/Geneva, Switzerland, Administration, Bamenda, Cameroon, ²a. Faculty of Health Sciences, University of Bamenda, Cameroon, Department Of Clinical Sciences, Bamenda, Cameroon, ³Brain Research Africa Initiative, Neuroscience Research, Yaounde, Cameroon, ⁴d. Brain Research Africa Initiative (BRAIN), Yaoundé, Cameroon/Geneva, Switzerland, Administration, Yaounde, Cameroon

Background and Aims:: Depression is a common mental disorder, characterised by low mood that lasts for long and affects everyday life. It has serious consequences on quality and length of life but is still frequently misdiagnosed and underdiagnosed in low- and middle-income countries. This study was designed to estimate the burden of depression among adults consulting at Bamenda Regional Hospital, in the North-West Region of Cameroon.

Methods:: This was a cross-sectional study carried out over a period of 4 months, in the Bamenda Regional Hospital. Adults consulting at the Outpatient Department were included in the study and screened for depression using the PHQ-9 questionnaire. People with past diagnosis of mental illness, presenting primarily for a psychiatric consultation, and cognitively impaired subjects were excluded. Data were entered and analysed using SPSS version 25 for Windows.

Results:: A total number of 151 people were screened for depression. The prevalence of depression was 47%. Female gender and smoking were significantly associated with depression. Suicidal thought (and even attempt) was observed in 0.7% of participants, while suicidal ideation (1 in 6 participants) and self-harm (6%) were common in this population.

Conclusions:: There is high prevalence of depression in the general outpatient population in the Bamenda Regional Hospital. Therefore, it is important to ensure efficient depression screening at the outpatient department, especially for female patients and smokers. Physicians should be aware of this burden.
DEPRESSION AND ANXIETY AMONG STUDENTS OF THE FACULTY OF HEALTH SCIENCES OF THE UNIVERSITY OF BAMENDA, CAMEROON

Samuel Angwafor¹, Ndanjeu Freddy¹, Leonard Ngarka², Wepnyu Yembe Njamnshi³, Alfred Njamnshi², ⁴
¹Faculty of Health Sciences, University of Bamenda, Clinical Sciences, Bamenda, Cameroon, ²Neurology Department, Central Hospital Yaoundé/Faculty of Medicine and Biomedical Sciences (FMBS), The University of Yaoundé I, Neurology, Yaoundé, Cameroon, ³Brain Research Africa Initiative, Neuroscience Research, Yaoundé, Cameroon, ⁴Brain Research Africa Initiative (BRAIN), Yaoundé, Cameroon

Background and Aims:: Mental health among university students represents an important and growing public health concern for which epidemiological data are needed. The main aim of this study was to estimate the magnitude of anxiety and depression among the students of the Faculty of Health Sciences of the University of Bamenda.

Methods:: This was a cross-sectional study among students of Faculty of Health Sciences of the University of Bamenda. The participants were screened for depression and anxiety using the 9-Item Patient Health Questionnaire (PHQ-9) and the 10-item Kessler Psychological Distress Scale questionnaire (K10) respectively. The questionnaires were self-administered through an online survey targeting students of the Faculty of Health Sciences. Data was analysed using Statistical Package for Social Sciences SPSS software.

Results:: About 17.4% of participants had major depressive disorder (PHQ-9 Score ≥ 10) while 15% had psychologically distress (K10 Score ≥ 25). Major life-changing crisis, regrets studying medicine, enrolment in medical laboratory sciences or nursing studies, low self-reported GPA, and resit examination were all significantly associated with depression. Major life-changing crisis, regret studying medicine, medical laboratory sciences or nursing were significantly associated with anxiety. There was no association between anxiety and self-reported academic performance (GPA), OR: 0.63(0.32-1.24) and p-value=0.182.

Conclusions:: Depression and anxiety are common among students of the Faculty of Health Sciences of the University of Bamenda. Major life-changing events, having regrets of studying Medicine, enrolment in medical laboratory sciences or nursing studies, and poor academic performance were associated with depression.
PREVALENCE OF DEPRESSION AMONGST STROKE SURVIVORS IN TWO REGIONAL HOSPITALS IN CAMEROON

Samuel Angwafor¹, Ticha Tembi¹, Nkouonlack Cyrille², Wepnyu Yembe Njamnshi³, Leonard Ngarka⁴, Alfred Njamnshi³
¹Faculty of Health Sciences, University of Bamenda, Clinical Sciences, Bamenda, Cameroon, ²b. Faculty of Health Sciences, University of Buea, Clinical Sciences, Buea, Cameroon, ³Brain Research Africa Initiative, Neuroscience Research, Yaoundé, Cameroon, ⁴c. Neurology Department, Central Hospital Yaoundé/Faculty of Medicine and Biomedical Sciences (FMBS), The University of Yaoundé I, Neurology, Yaoundé, Cameroon, ⁵d. Brain Research Africa Initiative (BRAIN), Yaoundé, Cameroon/Geneva, Switzerland, Research And Innovation, Yaounde, Cameroon

Background and Aims:: Stroke has numerous complications, with a major being post-stroke depression (PSD). This condition, which has significant impact on functional recovery and rehabilitation of stroke survivors, unfortunately is often unrecognized and underdiagnosed. The aim of this study was to estimate the prevalence and associated factors of PSD in two secondary hospitals in Cameroon

Methods:: This was a cross-sectional study including all stroke survivors who were at least 2 weeks post the event with good verbal communication. Stroke survivors with pre-existing depression, mental illness and those with post-stroke aphasia were excluded. The presence and severity of depression was measured using the Patient Health Questionnaire 9 (PHQ-9). Impairment in activities of daily living was assessed with the Barthel's Index.

Results:: Of 68 participants, males predominated (sex ratio: 1.13). Mean age was 59.76 (SD= 11.51 years). Majority of strokes were ischemic (n=49: 72.1%) and just over half (n=17: 54.8%) of those with PSD were within 3 months of onset of stroke. The prevalence of PSD was 45.6% (95% CI: 33.5%-58.1%), with a higher proportion in females (n=16: 50%) than males (n=15: 41.7%), (not statistically significant). One third of those with PSD had thoughts of self-harm or suicide. Impairment in activities of daily living was the only associated factor, significantly associated with PSD (p<0.001). There was no association between socio-demographic as well as the types of stroke and time since stroke and occurrence of PSD.

Conclusions:: The prevalence of post stroke depression is high and is strongly associated with impairment in activities of daily living.
LALLEMANTIA ROYLEANA BENTH MEDIATE ANXIOLYTIC LIKE EFFECT VIA MODULATION OF IONOTROPIC GABAA AND 5HT1A RECEPTOR TRANSMISSION: POSSIBLE MECHANISM OF ACTION

Noorulain Hyder¹, Syed Naqvi², Muhammad Raza²
¹International Center of Chemical and Biological sciences, Pharmacology, Karachi, Pakistan, ²Hamdard University, Faculty of Pharmacy, Pharmacology, Karachi, Pakistan

Background and Aims:: Lallemantia royleana (Lamiaceae) is a part of Iranian folkloric medicine to treat various ailments, including mental illnesses. The aim of this study was to evaluate the anxiolytic-like and sedative effects of methanolic extract of L. royleana Benth. seeds (MeLRS) in NMRI male mice.

Methods:: MeLRS (75, 100, 250 and 500 mg/kg) was orally administered for seven days before subjecting to the behavioral battery of test for anxiety, Diazepam (DZP; 1 mg/kg, p.o.) and Buspirone (BUSP; 10 mg/kg, p.o.) were used as reference drugs. Mechanism of anxiolytic-like effect was also evaluated. Later, neurotransmitter analysis of GABA and monoamine was performed.

Results:: MeLRS was found to be non-toxic. Repeated oral administration MeLRS at (100 and 250 mg/kg) significantly increased time spent in open arm percent (TOAP) and entries in open arm percent (EOAP) in elevated plus maze paradigm (EPMP) as compared to vehicle (VEH) and similar to those observed in DZP and BUSP. Furthermore, MeLRS did not affect spontaneous locomotor activity. GC-MS analysis revealed linalool (27.2, 39.8%) mannitol (27.8, 14.78 %), glycerol (12.2, 10.43%) among monoterpene alcohol, sugars, and fatty acids. Pre-treatment with flumazenil (FLZ; 3mg/kg, i.p.)

Conclusions:: Results showed the significant anxiolytic-like effect of MeLRS and confirmed the traditional use L. royleana seeds as anxiolytic agent via activation of 5-HT1A and ionotropic GABAergic benzodiazepine receptors. These effects are mediated by modulation of GABA and monoamine neurotransmitter.
Background and Aims:: Apathy is a prevalent and disabling syndrome after traumatic brain injury (TBI), yet mechanistic understanding of apathy remains poor. This research examined the ability to process intrinsic (e.g., enjoyment) and extrinsic (e.g., money) reward underlying apathy after TBI.

Methods:: The study included 71 individuals with TBI (subdivided into with-apathy (TBI+A) and without-apathy (TBI−A) groups) and 41 demographically matched healthy controls. Participants completed a computerised task in which they decided whether to go to collect gifts ('go' option) or wait for the identical gifts delivered to their house ('wait' option). After this first section for intrinsic reward, a questionnaire was given to assess their evaluation on each option. In the second section for extrinsic reward, the procedure was the same, but with extra money given when participants chose to 'go' instead of to 'wait'. Throughout the task, a higher number of 'go' decisions indicated better performance.

Results:: For intrinsic reward, similar performance was observed in people with TBI+A, TBI−A and controls (p=.36, η^2=.018). However, the TBI+A group had a significantly higher percentage of people rating the "go" option as effortful compared to the control group (p=.01, w=.37). For extrinsic reward, the TBI+A group had the worst performance, then TBI−A, and control groups performing the best (p<.001, η^2=.194).

Conclusions:: For the first time, dysfunctional intrinsic and extrinsic reward processing underpinning apathy was demonstrated through TBI. This highlights the importance of strategies that tackle reward processing abnormalities in interventions and management of apathy in clinical practice.
PREMORBID PERSONALITY IN THE FRONTOTEMPORAL DEMENTIA - AMYOTROPHIC LATERAL SCLEROSIS SPECTRUM

Chiara Galligani¹, Giulia Vinceti¹,², Chiara Carbone¹, Luigi Fiondella¹,², Elisabetta Zucchi¹,², Ilaria Martinelli¹,², Manuela Tondelli³, Simone Salemme¹,², Jessica Mandrioli¹,², Annalisa Chiari², Giovanna Zamboni¹
¹Università di Modena e Reggio Emilia, Dipartimento Di Scienze Biomediche, Metaboliche E Neuroscienze, Modena, Italy, ²Azienda Ospedaliera Universitaria di Modena, Neurologia, Modena, Italy, ³AUSL di Modena, Cure Primarie, Modena, Italy

Background and Aims:: Frontotemporal dementia (FTD) and amyotrophic lateral sclerosis (ALS) are recognized as part of the same neurodegenerative continuum (FTD-ALS spectrum). Factors determining phenotypic expression are unknown. However, it is common observation that personality differs between phenotypes: ALS patients often display a pleasant and nice attitude, while FTD patients frequently exhibit antisocial behaviors and lack of empathy. We therefore aimed at testing if FTD and ALS patients have different premorbid personalities, assuming that they reflect different vulnerabilities in brain circuits related to social behavior and motor function.

Methods:: We prospectively recruited patients presenting to our Memory and Motor Neuron Disease Clinics between December 2018-December 2020. Patients’ personality was assessed through the NEO Personality Inventory 3 (NEO-PI-3), which evaluates five domains (Neuroticism, Extraversion, Openness, Agreeableness, Conscientiousness). NEO-PI-3 was administered to caregivers with reference to patient’s personality at two timepoints: at diagnosis and 15 years prior to symptoms onset. Differences in personality factors between groups at each timepoint were tested with ANOVA.

Results:: 46 patients (30 FTD, 13 ALS, and 3 FTD-ALS assigned to the FTD or ALS group, based on first symptom) were recruited. A significant difference emerged in the Openness domain, showing that ALS patients (mean value 153±15) had been more open to experience, ideas and emotions than FTD patients (132±21, p=0.049).

Conclusions:: We found that premorbid personality differed among groups in at least one domain (Openness), supporting the hypothesis that premorbid personality may represent a vulnerability marker to the development of behavioral or motor disturbances. Our finding needs to be further explored with imaging.
IMPAIRMENT OF BIMANUAL MOVEMENT ON THE WAY TO RECOVERY FROM FRONTAL LOBE TUMOR SURGERY

Kozue Takada¹, Masako Kinoshita¹, Kazuaki Sato¹, Takeshi Satow²
¹National Hospital Organization Utano National Hospital, Neurology, Kyoto, Japan, ²Nagahama City Hospital, Neurosurgery, Shiga, Japan

Background and Aims: The mechanism of bimanual coordination has not been fully elucidated. Here we evaluated the clinical features of bimanual movement impairment in frontal lobe tumor after respective surgery.

Methods: An elderly male patient with brain tumor in the right superior frontal gyrus was investigated. Five days previously he underwent subtotal resection which was histologically diagnosed as malignant lymphoma diffuse large B cell type, and subsequently receiving high-dose methotrexate based chemotherapy. After surgery he showed difficulty in bimanual movement that could not be attributable to weakness. Temporal change in characteristics of manual movement was analyzed.

Results: Bimanual diadochokinesis (opening / closing of hands, pronation / supination of forearms, and sequential movement of fingers) was more disturbed than unilateral hand movement of the same task. Both in-phase and anti-phase movements were impaired. Performance of bimanual movement was better when cued by auditory metronome. After ten days, these movements were improved.

Conclusions: Besides disturbance of anti-phase bimanual movements, resection of the frontal lobe involving the supplementary motor area can cause transient impairment of in-phase bimanual diadochokinesis. Effect of auditory cueing on bimanual skill is possibly useful for diagnosis and rehabilitation patients with brain tumor, as in the case of degenerative movement disorders.
ASSOCIATION BETWEEN LIPID PROFILES AND COGNITIVE FUNCTION IN TYPE 2 DIABETES MELLITUS PATIENTS

Pahala Simanjuntak, Aldy Rambe, Fasihah Fitri
Universitas Sumatra Utara, Neurology, Medan, Indonesia

Background and Aims: Type 2 Diabetes Mellitus (T2DM) remains a significant major health problem with several complications, including cognitive impairment. Modifiable risk factors affecting cognitive function in T2DM are various and still needed to be elaborated further, especially in people aged below 60 years, such as dyslipidemia. This study aimed to determine the association between lipid profiles and cognitive function in patients with T2DM.

Methods: This study was a cross-sectional study using consecutive sampling technique, at Endocrinology clinic General Hospital Haji Adam Malik Medan, from October to December 2020. All patients underwent laboratory examination to measure lipid profile levels, including total cholesterol, triglyceride (TG), HDL-C and LDL-C. Cognitive function was assessed using visual cognitive assessment test Indonesian version (VCAT-Ina)—a visual-based tool that is suitable for multicultural, multilingual society like in Indonesia.

Results: This study included 30 patients consisted of 16 females (53.3%) and 14 males (46.7%) with a mean age of 51.20±6.34 years. The mean of lipid profile levels were 194±46.6 mg/dl, 188.33±107.8 mg/dl, 36.73±10.6 mg/dl, 139.10±49.5 mg /dl, for total cholesterol, TG, HDL-C and LDL-C, respectively. The mean VCAT-Ina score was 21.63±2.69. Most of the patients (60%) were in MCI category. There were significant association between cognitive function with total cholesterol (p=0.006), TG (p=0.024) and LDL-C (p=0.012), but not with HDL-C (p=0.955).

Conclusions: Lipid profiles are significantly associated with cognitive function in T2DM patients. These results suggest that dyslipidemia should be addressed and may serve as an additional treatment target to prevent cognitive decline in T2DM patients.
SYNBIOTIC EFFECT OF PROBIOTIC COMPLEX WITH POLYPHENOLS COMBINATION FOR TREATMENT OF VALPROIC ACID-INDUCED PRENATAL MODEL OF AUTISM

K Sunand¹, G Krishna Mohan², Vasudha Bakshi¹
¹Anurag University, School Of Pharmacy, Hyderabad, India, ²JNTUH, Centre For Pharmaceutical Sciences, Hyderabad, India

Background and Aims:: Gut Dysbiosis contributing to major pathogenesis in autism, there is a possible connection between the GI microflora and behavioral abnormalities. microbiota-gut-brain-axis is the ability of gut microbiota to communicate with the brain and regulate behavior. To improve these conditions modulation and daily supplementation of useful probiotics are needed.

Methods:: To the pregnant rats on Embryonic day 12 administer a single dose of valproic acid at 400mg/kg intraperitoneally. After weaning offspring on 7th-day rats with autistic features were separated for study and divided into groups. Treatment groups were daily supplemented with probiotic complex with Polyphenols and their combinations for the duration of Postnatal day (PND 8-50). During the treatment days, rats were assessed for various behavioral abnormalities. On PND50 rats were euthanized for biochemical analysis and Histopathological examination. All the experimental procedures were performed between 1.30 to 4.00 pm daily to maintain circadian rhythms.

Results:: Many born rats exhibited autistic features. Treatment with Probiotic complex with polypHENols alone and combination effectively reversed the autistic behaviors observed in Negative geotaxis, T-maze, Morris water maze, Social interaction, Repetitive Behavior. Biochemical alterations were recovered such as IL-6, TNF-α, BDNF, 5-HT, AchE as compared with the autistic group. Along we observed restoration of areas of the cerebellum like the Molecular layer and the Granular layer and they were looking normal.

Conclusions:: It is emphasized that the Probiotic complex with Polyphenols is synergetic, their combination augments the modulation of the dysbiotic gut, supports the Gut-Brain-Axis and this combination provides diversified benefits suitable to treat autism.
DOES NEUROCOGNITION FUNCTIONING IMPACT DRIVING HABITS IN OLDER ADULTS WITH HIV?

Josiah Robinson¹, Brittany Bradley¹, Peggy Mckie¹, Teresa Walker², Caitlin Pope³, Pariya Fazeli¹, David Vance¹
¹University of Alabama at Birmingham, School Of Nursing, Birmingham, United States of America, ²San Diego State University, Psychology, San Diego, United States of America, ³University of Kentucky, Graduate Center For Gerontology, Lexington, United States of America

Background and Aims:: Nearly 30%-50% of people living with HIV (PLWH) have HIV-Associated Neurocognitive Disorder. With half of PLWH being 50 and older, concerns mount that the prevalence and severity of neurocognitive impairment will increase with age. Yet, neurocognitive functioning can impact driving safety in older adults, but may also impact driving in older PLWH. Impairment in the neurocognitive domains utilized in driving may put PLWH at risk for decreased mobility that impacts their treatment adherence and quality of life. This study is the first to examine the driving habits of PLWH 40+ years and determine whether impairment in particular neurocognitive domains are predictive of driving habits.

Methods:: A sample of PLWH (N=260) were administered comprehensive norm-based neurocognitive tests and a measure of self-reported driving habits

Results:: While 166 (63.60%) participants possessed a driver’s license, 213 (81.61%) reported currently driving. Participants with a driver’s license had higher global neurocognition as well as better neurocognitive functioning in speed of processing and working memory. Participants with poorer neurocognition self-reported driving fewer miles. Those with more driving experience exhibited better neurocognitive functioning in global neurocognition, speed of processing, motor function, verbal fluency, working memory, and executive function. Participants who self-rated their driving as good/excellent demonstrated better neurocognitive abilities in global neurocognition, speed of processing, executive function, motor function, and verbal fluency.

Conclusions:: Neurocognitive functioning among older PLWH was associated with self-reported driving habits. Furthermore, neurocognitive functioning’s impact on driving can hinder PLWH’s access to medical care. Implications for public health, clinical practice, and research are posited.
NEUROPROTECTIVE POTENTIAL OF CHEBULIC ACID IN Aβ (1-42) INDUCED MODEL OF AD; TARGETING MITOGEN ACTIVATED PROTEIN KINASE

Rimpi Arora
IKGPTU INDIA, Rac, DHANDRA ROAD BASANT AVENUE, India

Background and Aims:: Stress activated protein kinases such as p38 MAPK have been implicated in the pathogenesis of AD. The present study was designed to investigate neuroprotective mechanisms and therapeutic effect of chebulinic acid (ChA) in ICV-Aβ induced oxidative/nitrosative stress, neuroinflammation and alteration in neurochemistry resulting in cognitive deficits via p38 MAPK.

Methods:: Aβ 1-42 peptides at the dose of (3nmol/3 µL) twice on day 0 were infused bilaterally (ICV) after surgery to male wistar rats to induce dementia. ChA (25, 50 and 100 mg/kg/p. o) administered from 7th day onwards up to 21st day following Aβ infusion. The MWM and ORT were applied to measure learning and memory performance in animals. On day 22, following the behavioral tests, all the rats were sacrificed for evaluation of molecular alterations.

Results:: Rat with ChA, showed higher performance in MWM and ORT than rats treated Aβ whose memory performance declined compared to sham group. In addition, an elevation in neuroinflammatory cytokine (IL-1 β, IL-6 and TNF- α), p38 MAPK, Aβ levels and decrease in AchE and monoamines neurotransmitters (DA, Nadr, 5-HT, GABA and glutamate) was observed with Aβ injection. ChA reversed Aβ -triggered cognitive and molecular alterations.

Conclusions:: Results of the present study have thus demonstrated the role of p38 MAPK in cognitive deficit, cholinergic hypofunction, increase in oxidative-nitrosative stress and neurochemicals and histological alterations following Aβ infusion. To sum up, we can say that the healing effect of ChA on Aβ induced neurodegeneration opens a new door for the development of AD treatment.
PSYCHOLOGICAL IMPACT OF COVID-19 PANDEMIC ON MEDICAL STUDENTS IN SUDAN, 2020

Mohammed Eltahier Omer¹, Ahd Shareef¹, Ala’A Al-Lahawi², Hassan Alhaj¹, Khalid Mohammed³
¹Gadarif University Faculty of Medicine and Health Sciences - Sudan, Medicine, Omdurman, Sudan, ²Khartoum University, Medicine, Omdurman, Sudan, ³Gadarif University/ Faculty of Medicine, Internal Medicine, Khartoum, Sudan

Background and Aims:: The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is an emerging infection causing a widely spread pandemic of (COVID-19). The current COVID-2019 pandemic is prompting fear of falling sick, dying, helplessness and stigma so urgent and timely understanding of mental health status is needed to help the community.

Methods:: A cross-sectional descriptive research was done among medical student in Sudan during COVID 19 pandemic in August 2020. DASS-21 scales were used to determine the level of depression, anxiety and stress among medical students through an online questionnaire, their responses were taken relatable to 21 items of DASS scale. The data was analyzed by means of SPSS version 25.0.

Results:: The mean (SD) age of our study participants was 21.8 (2.4) with female to male ratio of 2.1. Interestingly, more than 40.5% of the study participants were free of depression while more than 13% had extremely severe depression. On the other hand, only 4.4% had extremely severe stress. However, anxiety ranked the higher numbers with 23% had extremely severe anxiety. Adjusted linear regression model revealed that lower levels in the medical school and open colleges during the lock down period were associated with more anxiety (p value 0.01,0.006 respectively).

Conclusions:: It's important to support high-risk groups especially those with preexisting mental illness to offer advanced psychological interventions. So our study can be used to construct and formulate a psychological intervention and implement mental health strategies directed toward vulnerable groups during the COVID-19 epidemic.
BRAIN TARGETED POLYMERIC NANOPARTICLES OF ALENDRONATE CONFERS IMPROVED PHARMACOKINETIC AND NEUROPROTECTIVE EFFECT AGAINST ALZHEIMER’S DISEASE LIKE PATHOLOGICAL CHANGES IN HIGH FAT DIET FED MICE

Saima Zameer¹,², Mohd Akhtar², Divya Vohora¹,², Javed Ali²
¹Jamia Hamdard, Department Of Pharmacology, New Delhi, India, ²Jamia Hamdard, Pharmacology, New Delhi, India

Background and Aims:: Increasing prevalence of Alzheimer’s disease (AD) has presented it as one of the major neurodegenerative disorder worsening the quality of life of elderly. AD is one of the complex forms of dementia which is affecting millions of people. AD is a progressive neurodegenerative disorder with short-term memory impairment, successive cognitive disabilities, Aβ deposition, neurofibrillary tangles, neuronal death. The unclear etiology and lack of therapy reveals an urgent need to investigate the potential therapeutic approaches. Furthermore, alendronate (bisphosphonate) was cited to exhibit neuroprotective role by modulating the components of Mevalonate pathway. Thus, the present study was designed to develop the brain targeted polymeric nanoparticles of alendronate (ALN-NPs) to overcome its side effects and poor pharmacokinetics and to investigate its effect against high fat diet (HFD)-induced AD-like pathological symptoms in mice.

Methods:: ALN-NPs were developed using ionic-gelation technique and characterized for particle size, TEM, SEM, in-vitro, ex-vivo release, pharmacokinetic profile. The optimized ALN-NPs were administered intranasally in mice to deliver ALN to brain following investigation against neurobehavioral, neurochemical (β-secretase, Aβ, neuroinflammation, isoprenoids, GSK-3β, oxidative stress) and histopathological changes (Aβ deposition).

Results:: The developed ALN-NPs acquired the particle size within 200nm along with improved pharmacokinetica. Additionally, ALN-NPs were found to alter remarkably the HFD-induced neurobehavioral, neurochemical changes and reduced Aβ in mice hippocampus. ALN-NPs also reduced the hippocampal isoprenoids level in mice which corresponds to the reduced AD-like symptoms.

Conclusions:: Our current outcomes suggest the prominent role of ALN-NPs against AD-like pathologies by targeting Mevalonate pathway, supporting this bone drug a potential target for AD treatment.
ANALYSIS OF COGNITIVE DISORDERS ON INTERNET GAMING DISORDER (IGD) PATIENTS IN RURAL AREA OF YOGYAKARTA, INDONESIA

Cempaka Thursina, Ismail Setyopranoto, Alfi Medikanto, Giga Alkarani
Universitas Gadjah Mada, Neurology, Yogyakarta, Indonesia

Background and Aims:: Internet Gaming Disorder (IGD) phenomenon arises due to the inability of controlling internet usage and its related contents. The prevalence of IGD tends to arise (0.3%-10.8%). In 2016 World Health Organization (WHO) informing that IGD was part of gaming disorders in ICD-11. IGD was one condition that may affect cognitive status. This condition may happen due to long hours of internet usage, including playing games. This study aims to analyze the cognitive disorders of junior high school students with IGD in the rural area of Yogyakarta, Indonesia.

Methods:: This study was using an observational analytic design with a cross-sectional approach towards junior high school students. The respondents were divided into two groups (students with IGD and without IGD) containing 37 respondents each. Both groups performed cognitive status examinations using MMMSEC-Ina. Analysis of the cognitive status of both groups includes the diagnosis of IGD, the types of games, and the duration of internet usage with Mann Whitney test followed by linear regression test.

Results:: From the results, the Mann-Whitney test results on cognitive status showed a trend of decreasing the average cognitive value of each domain, especially the calculation/attention domain p = 0.000; and cognitive total p = 0.029. Bivariate correlation test results with outside variables were not found to be significant. The multivariate test results showed that IGD was significantly correlated with cognitive status with B = 1.293; p = 0.024.

Conclusions:: Patients with IGD in the rural area of Yogyakarta experience cognitive dysfunction, especially in the domain of calculation or attention.
PREVALENCE, CLINICAL CHARACTERISTICS OF HEADACHE IN MEDICAL STUDENTS AT ALZAIEM ALAZHARI UNIVERSITY IN 2020, KARTOUM, SUDAN

Radi Alhusseini, Mohajer Ismaeil, Ali Idriss, Mohammed Abdalla
Alzaiem Alazhari University, Medicine, Khartoum, Sudan

Background and Aims:: Headache is one of the most common disorders of the nervous system. Headache means pain in the head. The (WHO) reports that almost half of the adults worldwide will experience headache in any time at any given year. The study aims To determine the prevalence rate and clinical characteristics of headache among medical students in Alzaiem Alazhari university in Khartoum state, Sudan in 2020.

Methods:: A descriptive cross-sectional study using a 41 items questionnaire was introduced to 71 medical students from Alzaeim Alazhari university in the period from January 1st to 15th of February.

Results:: Out of the 71 respondents 35 (49.3%) were Male and 36 (50.7%) were female while most of them were in the (21-24) age group by (69.01%). Most of the participants responded that they headaches (74.65%) with (32.31%) of them having continuous and (67.69%) of them with no continuous headache. 32 (45.07%) of them had headaches, half of them lasted for 1-2 hours and the other half lasted more than 10 hours per day. The most common location for the headache was both sides (23.02%) followed by the forehead (22.22%). The most common characteristic of headache was pulsating (48.48%) followed by pressure like (37.88%).

Conclusions:: There is a high prevalence rate of headache among medical students with migraine as the most common cause of headache.
Foteini Alourda, Michail Xifaras, Elli Kerezoudi
Athens General Hospital "Pammakaristos", Neurology, Athens, Greece

Background and Aims:: Recent studies indicate the coexistence of migraine and restless leg syndrome (RLS). This correlation cannot be attributed to one single mechanism. A possible hypothesis might be the dopaminergic dysfunction in the hypothalamic nuclei in both of these entities.

Methods:: We present a 56-year-old female patient who presented to our outpatient clinic with recurrent episodes of headache that fulfilled the criteria of migraine without aura (ICHD-3 criteria). Because of the frequency of the episodes the patient was put on prophylactic treatment with topiramate. One month after treatment initiation her symptoms were improved, regarding both the duration and the intensity of the pain. Four months after her first visit she complained for dysesthesia of her lower limbs, accompanied by an urgent need to move them, especially at night and improvement of these symptoms with movement. The investigation made to exclude other causes that could cause these symptoms was negative. Pramipexole was initiated in order to treat RLS.

Results:: The migraine attacks were diminished after one month treatment with pramipexole. The last twenty days the patient experienced no pain at all. The discomfort from her lower limbs disappeared too.

Conclusions:: The beneficial action of pramipexole to our patient and the further relief of her migraine attacks can be attributed to the improvement of her sleep. Furthermore, past studies suggest impairment in dopamine synthesis in patients with migraine. Pramipexole – a dopamine agonist – could be involved in this therapeutic path too.
HYPEREXCITABILITY AND DYSFUNCTION OF CORTICAL EXCITATION / INHIBITION MECHANISMS IN MIGRAINE: A PAIRED PULSE TMS STUDY

Salvatore Di Marco, Laura Pilati, Angelo Torrente, Salvatore Ferlisi, Filippo Brighina
University of Palermo, Department Of Biomedicine, Neuroscience And Advanced Diagnostics, Palermo, Italy

Background and Aims: Paired-pulse TMS paradigms can be used to test connectivity within the primary motor cortex. Aim of the study was to provide additional information on short intracortical inhibition (SICI) and intracortical facilitation (ICF) using different intensities of the test stimulus (TS) in episodic and chronic migraine (CM, EM) patients.

Methods: We enrolled 24 patients with EM, 13 with CM and 24 healthy subjects. EM and controls were randomly assigned to two groups for assessment of SICI and ICF. While in patients with CM we tested both ICF and SICI during the same experiment. We assessed SICI and ICF at three different suprathreshold intensities of the TS (110%, 130% and 150% of the resting motor threshold). Interstimulus intervals of 2 ms and 10 ms were used for testing SICI and ICF respectively.

Results: When testing ICF, maximum increase in conditioned MEP amplitude was observed in EM at the lower stimulation intensity of the TS (p<0.005). This intensity was indeed to induce significant facilitation in the CM and healthy subjects. No significant differences were observed as regards SICI.

Conclusions: Our results strengthen the notion of altered tuning of cortical excitability in migraine. The increased ICF cannot be detected at higher stimulation intensities in EM probably due to the induction of homeostatic regulatory mechanisms of cortical excitability that could aim to protect against the risk of neuronal damage. CM have a greater cortical excitability than EM and the homeostatic regulatory mechanisms of cortical excitability are activated early, even at 110% of TS.
A NOVEL SCORING APPROACH TO IDENTIFY RESPONDERS TO ERENUMAB IN CLINICAL PRACTICE

Roberta Messina\textsuperscript{1,2}, Ilaria Cetta\textsuperscript{1,2}, Alessandro Meani\textsuperscript{2}, Maria Rocca\textsuperscript{1,2,3}, Bruno Colombo\textsuperscript{1}, Massimo Filippi\textsuperscript{2,3,4}
\textsuperscript{1}IRCCS San Raffaele Scientific Institute, Neurology Unit, Milano, Italy, \textsuperscript{2}IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Division Of Neuroscience, Milan, Italy, \textsuperscript{3}Vita-Salute San Raffaele University, Na, Milan, Italy, \textsuperscript{4}IRCCS San Raffaele Scientific Institute, Neurology Unit, Neurorehabilitation Unit And Neurophysiology Service, Milan, Italy

Background and Aims:: In clinical practice, a successful therapeutic response depends not only on a 50\% reduction in migraine days, but also on improved migraine symptoms severity and patients’ disability. In this study, we aimed to develop a multidimensional composite score that combines measures that are clinically relevant to establish migraine patients’ response to erenumab.

Methods:: The primary outcome of the study was erenumab efficacy, established following standard clinical evaluation. A composite treatment response score was calculated as a linear combination of response criteria evaluating significant changes in migraine frequency, headache frequency, severity of the migraine attack and migraine-related disability. Logistic regression models were run to assess the association of the composite response score, as well as different response criteria, with the primary efficacy outcome. The Brier Score and receiver-operating characteristic (ROC) analyses were performed to assess model discriminative ability.

Results:: Thirty-eight (53\%), 42 (68\%) and 24 (73\%) patients achieved the primary efficacy outcome after 3, 6 and 12 months of erenumab, respectively. The composite response score achieved the lowest Brier scores at each time point, suggesting a higher predictive accuracy. Compared to the other response criteria, the composite response score had the highest AUC values at month 3, month 6 and month 12.

Conclusions:: Here, we proposed a simple and exhaustive multidimensional score that is reliable and stable to follow-up migraine patients’ treatment response over time. The use of a simple and comprehensive score may facilitate patients’ management in clinical practice and may expand patients’ access to effective therapies.
Hiba Abugabal¹, Hussam Ali², Etedal Abuelbasher¹
¹The National Center for Neurosciences, Neurology, Khartoum, Sudan, ²Fedail Hospital, Neurology, Khartoum, Sudan

Background and Aims:: Trigeminal neuralgia is a disorder characterized by agonizing facial pain paroxysms which are triggered by innoxious ordinary activities. It is noted to be more prevalent in females and in ages >50 years. Aims: To outline the clinical profile in patients with trigeminal neuralgia and define the management protocols under use.

Methods:: Cross-sectional, analytical, hospital-based study including 45 patients enrolled from three neurology outpatient clinics and the pain management centre- Khartoum State- Sudan during October 2020- February 2021. Semistructured questionnaire was used for data collection, different statistical parameters were calculated and P-value of <0.05 was considered as significant.

Results:: Female predominance was noted (64.4%) with mean age of disease onset being 48.04 ± 12.79 years. Patients’ first presentation was in dental and general medical clinics (77.8%) and the mean diagnostic delay was 44.24 ± 43.24 months. Acute attacks were affecting the right facial side (53.3%) at areas of both maxillary and mandibular divisions (37.8%), having trigger zones (64.5%) and triggering factors (86.7%) with associated autonomic features (8.9%) and facial spasm (2.2%). Persistent dull pain was mentioned by 57.8% of the patients. Treatment was based on carbamazepine either as daily regimen (71.1%) or interrupted courses (28.9%) with add-on procedures performed to 24.4% of the patients. Significant correlations were found between the treatment regimen and the clinical profile as well as the diagnostic delay time.

Conclusions:: Patients’ demographics and clinical profile were coinciding with the previously published data. Variable treatment modalities are available and the period of diagnostic delay significantly affects the protocol to be used.
EVALUATION OF PSYCHOLOGICAL PREDICTORS OF REAL-LIFE EXPERIENCE WITH ERENUMAB IN CHRONIC MIGRAINE WITH OR WITHOUT MEDICATION OVERUSE: DATA FROM A 1-YEAR FOLLOW-UP

Sara Bottioli1,2, Roberto De Icco2,3, Gloria Vaghi2,3, Giuseppe Fiamingo3, Elena Guaschino2, Marta Allena2, Alessia Putorti2,3, Natascia Ghiotto2, Cristina Tassorelli2,3, Grazia Sances2

1Giustino Fortunato University, Faculty Of Law, Benevento, Italy, 2IRCCS Mondino Foundation, Headache Science And Neurorehabilitation Centre, Pavia, Italy, 3University of Pavia, Department Of Brain And Behavioral Sciences, Pavia, Italy

Background and Aims:: To evaluate the psychological predictors of the outcome of real-life experience with the anti-CGRP monoclonal antibody Erenumab in a 1-year follow-up in chronic migraine (CM).

Methods:: Seventy-one patients (age: 49.1 ± 9.5, F: 72%) with CM+MO (ICHD-III criteria) who had already failed at least two preventive therapies received Erenumab (70 or 140-mg dose s.c.). At T0 patients received also a full psychological evaluation comprising mood, anxiety, and personality disorders as well as alexithymia traits, childhood traumas and current stressors. They were followed up at 1 year for their clinical condition.

Results:: At the 1-year follow-up, 50 patients (mean age:49.0 ± 9.5) reported a reduction of at least 50% in migraine days/month (Responders, R); whereas 21 (mean age:49.3 ± 9.7) did not (non Responders, NR). When compared to R, NR were characterized by a higher prevalence of anxiety (90% vs 60%, p=.012) and Cluster C (avoidant, dependent, and obsessive-compulsive) personality disorders (87% vs 38%, p=.002). They also showed more alexithymic traits (53.2 ± 12.9 vs 43.7 ± 14.2, p=.03) and a higher number of stressors (1.2 ± 2.5 vs 0.3 ± 0.7, p=.012). The two groups were similar for mood disorders and childhood traumas.

Conclusions:: Erenumab is an effective option for patients with difficult-to-treat migraine. These patients are often characterized by relevant psychological comorbidities. Our findings, even if preliminary, show a further distinction within difficult-to-treat CM+MO patients, highlighting the impact of current stressors, anxiety and an “anxious-fearful” personality in those patients being refractory to many preventive treatments, including Erenumab.
Background and Aims:: Alexithymia is a personality trait characterized by the inability to identify and express emotions. Several studies evidenced a positive association between alexithymia and psychological distress in patients with chronic migraine (CM) and fibromyalgia (FM). Here we evaluated the prevalence of alexithymia and distress in FM and CM, compared to healthy controls (HC).

Methods:: Two-hundred and fifty women with CM (mean age: 46.1 ± 11.5, disease duration: 7.9 ± 7.3yrs) and 250 FM (mean age: 51.2 ± 10.5, disease duration: 7.9 ± 7.8yrs) were assessed by the Toronto Alexithymia Scale (TAS-20), and the Hospital Anxiety and Depression Scale (HADS). A HC group (n=280; mean age: 51.8 ± 9.0) was also enrolled and assessed by TAS-20 and HADS.

Results:: Differences between groups showed significantly higher levels of alexithymia [F(2,755) = 11.7, p < .001] and psychological distress in FM patients [F(2,763) = 31.7, p < .001], compared to CM and HC. Post-hoc analysis showed that CM patients reported higher levels compared to HC group in the total score (p < .001) and in the Difficulty Identifying Feeling subscale of the TAS-20 (p < .001). A moderation analysis was performed to examine the moderation effect of the group (CM vs. FM) on the relationship between alexithymia and psychological distress. Besides a strong relationship between alexithymia and distress, the group variable was not a significant moderator.

Conclusions:: These findings might suggest a common psychological dysregulation in patients suffering from chronic migraine and fibromyalgia, which manifests into a different expression of the physical symptom.
Background and Aims:: Lifestyle, behaviours, physical activity (PA) and working habits had been influenced by COVID-19 lockdown. Aim of the study is to assess the impact of lockdown on migraine.

Methods:: Migraineurs who attended the Headache Centre from 01.06.2019 to 31.12.2019 were interviewed. Patients were prophylaxis free or they were on the same prophylaxis from at least 3 months. Demographics, working routine, lifestyle, migraine characteristics and disability (HIT-6) were compared between the first month of the lockdown (March 2020) and a reference month prior the lockdown (January 2020).

Results:: Thirty-seven patients were analysed in two groups, migraine without aura (MwoA) (n=26, 45 y [31-53]) and migraine with aura (MwA) plus migraine with and without aura (MwA/MwoA) (n=11, 38 y [26-47]). No changes were reported for food/fluid/alcohol intake, smoke and sleep, while PA decreased (65% vs 31%; p=0.012). Time spent working outside the habitation reduced (MwoA, p=0.001; MwA plus MwA/MwoA, p=0.005) with an increase of remote working (MwoA, p=0.011; MwA plus MwA/MwoA, p=0.039). Patients with MwoA reported mean headache duration [3h, (2-12) vs 2h (1-8); p=0.041] and HIT score [59 (51-63) vs 50 (44-57); p=0.001. Patients with MwoA living in urban area had a higher HIT score than those living in rural area [53 (46-57) vs 42 (36-49) (p=0.033)]. Severity of the attack and symptomatic drug intake didn't change.

Conclusions:: Pain duration and disability improved in MwoA during lockdown, probably due to possibility to rest during attack. Living in rural area might have a protective role.
HEADACHE DURING COVID-19 FIRST WAVE: A STUDY ON HEADACHE ADMISSIONS AND “REPEATER” MIGRAINEURS IN EMERGENCY DEPARTMENT

Laura D’Acunto¹, Fulvio Pasquin¹, Alex Buoite Stella¹, Sasha Olivo¹, Antonio Granato¹, Franco Cominotto², Paolo Manganotti¹
¹University of Trieste, Neurology Unit, Headache Centre, Department Of Medical, Surgical And Health Sciences, Cattinara University Hospital, Asugi, Trieste, Italy, ²ASUGI, Emergency Department, Cattinara University Hospital, Trieste, Italy

Background and Aims:: During the first Italian COVID-19 lockdown a reduction in Emergency Department (ED) attendances due to non-SARS COV2 related acute/chronic neurological diseases was observed. The aim of this study was to analyze the influence of COVID-19 outbreak on total ED admissions due to headache as the principal presenting symptom and on “repeater” migraineurs

Methods:: We retrospectively evaluated frequency, features and management of ED attendances for headache in the tertiary-care University Hospital of Trieste during the lockdown period (from 8th March to the 31st May 2020) comparing it with the pre lock down period (January-February 2020) and the first five months of 2019.

Results:: A reduction of all headache ED attendances was observed in the first five months of 2020 compared to the same period of 2019 (174 and 339 respectively; -49%). During the lockdown only a reduction of female ED access rate (p= 0.03) was found, while no significant variation was detected in repeaters prevalence, diagnostic assessment, and acute treatment. The ratio of Not Otherwise Specified (NOS), Secondary and Primary Headaches remained unchanged during the lockdown period, in comparison to control periods. NOS headache remained the most frequent discharge diagnosis (48.4%), followed by Primary and secondary headache (21.0% and 30.6 %).

Conclusions:: COVID-19 pandemic impacted the number of ED attendances for headache but not their management and discharge diagnosis distribution. A quote of secondary dangerous headaches did not arrive to ED, while a portion of repeaters continued to refer to ED despite COVID-19 lockdown.
HEADACHE WITH FILLING OF THE BLADDER AS ONE OF THE VARIANTS OF PRIMARY HEADACHES

Maruf Mavlanov, Farrukh Sailvaliyev
Tashkent medical academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: There are many types of primary headaches such as cold headache, postcoital headache, and others.

Methods:: At the reception, 3 patients were examined with a headache during filling of the bladder. The sex of all patients was male. Age 26, 30 and 40. no concomitant pathologies were identified. The duration of headaches is 5, 3 and 6 years respectively. In patients, the nature of the headache was of a pulsating, burning character, periodically there was nausea during the headache. The pain is localized on half of the head and it lasts until the act of urination. After urination, as a rule, the pain stops or decreases, rarely the pain lasts until the end of the day. In one patient, this condition appeared after receiving craniocerebral trauma. Laboratory analyzes of urine and prostate without pathology. MSCT of the abdominal and pelvic cavity was normal. Sonography, Cystoscopy of the bladder was without pathological changes. urologist excludes diseases of the urinary system. MRI of the brain without any significant changes, no pathological waves were observed on the EEG.

Results:: The patient was prescribed treatment according to the standard as a primary headache: NSAIDs, as a preventive G. B. antidepressant drugs. Inspection after 3 and 6 months is recommended. During repeated examinations headache are not marked. Improvement of symptoms in dynamic.

Conclusions:: Conclusion: In this patient's example, primary headaches have a very variable clinic. It is possible to consider G.B. when urinating, one of the options for primary GB, as a postcoital headache.
Background and Aims:: Headache disorders have a strong impact on sufferers' lives; however, the “content” of assessment instruments addressing concepts, such as disability and quality of life (QoL), is poorly defined. The aim of the present review is to provide information on the content coverage of the most commonly used assessment instruments (for disability, QoL or work-related difficulties) in primary headache disorders.

Methods:: We searched SCOPUS for research papers in which outcome measures were used in adult populations of patients with migraine, tension-type headache (TTH), and cluster headache (CH). The content of single instruments was then mapped against the International Classification of Functioning, Disability, and Health (ICF).

Results:: A total of 150 papers and 26 instruments were included: 15 addressed disability or impact, 2 addressed work-related difficulties, and 9 addressed QoL. Few instruments (e.g. the MIDAS, the HIT-6, and the SF-36) were commonly used across the conditions and covered domains of functioning such as: impact on daily life activities, homework, school, and work-related tasks, leisure time, informal and family relations, pain, emotional difficulties, energy level, and impulse control.

Conclusions:: Most of the research is based on instruments that poorly acknowledge the role of environmental factors and the impact of headache disorders on work-related activities. Moreover, most of the measures were developed for migraine, which is critical for CH. Further research is needed to expand the scope of measures exploring headaches impact on daily life activities, and to raise knowledge on the less represented areas, e.g., TTH impact.
EXTENSIVE CEREBRAL VENOUS THROMBOSIS SECONDARY TO ESSENTIAL THROMBOCYTHEMIA TREATED WITH LUMBO-PERITONEAL SHUNTING

Vithoosan Sahathevan, Chulika Makawita, Kasun Udenika, Bimsara Senanayake
National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

**Background and Aims::** Essential thrombocythemia (ET) is a myeloproliferative disease with megakaryocytic hyperplasia in bone marrow. Even though thrombo haemorrhagic complications are common in ET, cerebral venous thrombosis (CVT) is an unusual presentation. We describe a Sri Lankan female with severe CVT due to ET treated with lumbo peritoneal shunting.

**Methods::** Case Report A 35-year-old female presented with chronic headache for four months. Examination revealed papilledema without other focal neurological signs. She did not complain of visual obscurations or diplopia. MRI brain was normal. MRV confirmed severe CVT involving bilateral superior sagittal and transverse sinuses extending up to jugular bulb. A Lumbar puncture revealed CSF opening pressure of 330mm H2O and therapeutic removal of 30cc CSF was performed. She was started on oral acetazolamide and anticoagulation. However her symptoms persisted hence a lumbo peritoneal shunt was inserted, after which she made a significant recovery.

**Results::** FBC revealed thrombocytosis with normal haemoglobin level and WBC count. Bone marrow examination revealed megakaryocytic hyperplasia. These findings were in keeping with a myeloproliferative disease, essential thrombocythaemia. Genetic test for myeloproliferative neoplasm (MPN) was positive for JAK2p.V617F mutation. Rest of the thrombophilic screening was negative. Hydroxyurea was added as treatment.

**Conclusions::** CVT as the first presentation of ET is very rare with only a few cases reported in literature. This case emphasizes the need for extensive evaluation of patients with CVT in order to find an underlying cause. Lumbo peritoneal shunting is a treatment option in extreme cases of CVT. Ours is the first such procedure performed in Sri Lanka.
HEADACHE BURDEN IN A HIV POPULATION OF SUB-SAHARAN AFRICA

Luca Giani¹, Monica Mwazangati², Derya Uluduz³,⁴, Tayyar Sasmaz⁵, Maureen Kamponda², Victor Tamba Tolno², Giovanni Guidotti⁶, Maria Cristina Marazzi⁶, Timothy Steiner⁴, Massimo Leone¹
¹Fondazione IRCCS Istituto Neurologico Carlo Besta, Neuroalgology Unit, Milano, Italy, ²Comunity of S. Egidio, Dream Program, Blantyre, Malawi, ³Istanbul University, Department Of Neurology And Algology, Istanbul, Turkey, ⁴Lifting The Burden, The Global Campaign Against Headache, London, United Kingdom, ⁵Mersin University, Department Of Public Health, Mersin, Turkey, ⁶Comunity of S. Egidio, Dream Program, Rome, Italy

Background and Aims:: About 26 million people are living with HIV in sub-Saharan Africa (SSA). The DREAM programme in SSA provides free healthcare for HIV/AIDS and a range of chronic non-communicable diseases. HIV is a risk factor for neurological disorders including stroke and epilepsy, which themselves are associated with headache, and HIV may be a direct risk factor for headache. We investigated the prevalence and burden of headache in a HIV+ population in SSA.

Methods:: At the DREAM Centre in Blantyre, Malawi, a low-income country with 18.5 million population and 9.2% HIV prevalence, a structured questionnaire was administered by a trained lay interviewer to consecutively attending HIV+ patients aged 18-65 years. All were monitored with regular viral load detection.

Results:: Of 513 eligible patients invited, 498 were included (15 declined; mean age 34.1±12.8 years; 72% females). All were on antiretroviral treatment (ART), with viral load undetectable in 83.9%. The 1-year prevalence of headache was 80.3% (females 83.6%, males 71.9%); 3.8% had ≥15 headache days/month, 1.4% had probable medication-overuse headache. Mean overall headache frequency was 4.4±5.4 days/month. Those reporting headache lost means of 2.7% of paid workdays and 3.9% of household workdays because of headache. Only a third had sought advice for their headache.

Conclusions:: Headache is very prevalent among HIV+ patients in Malawi, imposing additional burden and costs on individuals and the community. Management of headache disorders should be implemented in HIV centres, as it is for other chronic non-communicable diseases. The study was supported by Lifting The Burden and ANIRCEF
ENLARGING THE SPECTRUM OF CLUSTER HEADACHE: CAN VOICE ANALYSIS REVEAL AN EXTRACRANIAL AUTONOMIC INVOLVEMENT?

Fabrizio Scotto Di Clemente¹, Alessandro Tessitore¹, Marcello Silvestro¹, Francesca Dovetto², Virginia Corvino³, Pasqualina Apisa³, Rita Malesci³, Paolo Milizia³, Elio Marciano¹, Gioacchino Tedeschi¹, Antonio Russo¹

¹University of Campania Luigi Vanvitelli, Headache Center, Department Of Advanced Medical And Surgical Sciences, Naples, Italy, ²University of Naples Federico II, Department Of Humanistic Studies, Naples, Italy, ³University of Naples Federico II, Department Of Neurosciences, Reproductive And Odontostomatological Sciences, Naples, Italy, ⁴University of Naples l’Orientale, Naples, Department Of Asia, Africa And The Mediterranean, Naples, Italy

Background and Aims:: Despite a well-characterized clinical phenotype, cluster headache (CH) is frequently burdened by misdiagnosis or diagnostic delay. In our experience, we noticed a typical voice quality with low and croaking tone in CH patients. We evaluated, by means of digital voice analysis, whether a typical voice quality characterizes CH patients when compared to healthy controls (HC).

Methods:: By means of an accurate, reproducible and feasible digital voice analysis, voice measures has been studied including the traditional measures of fundamental frequency, calculations of jitter and shimmer, and noise-to-harmonics ratios as well as quantities related to the spectral tilt (i.e., H1-H2, H1-A1, H1-A2, H1-A3) in 20 CH patients and in 13 matched healthy controls (HC). A video-laryngostroboscopy, was performed in all the subjects.

Results:: CH patients, explored during the cluster-bout period, showed a peculiar voice quality, the so-called creaky voice, characterized by lower values of H1-H2 in comparison with HC. By using a laryngoscopy investigation, bilateral mild to marked vocal cord oedema and signs of laryngo-pharyngeal reflux have been found in CH patients.
Conclusions: Creaky phonation is a “physiological normal mode of laryngeal operation” usually subtended by shortened and thickened vocal folds. Creaky voice phonation can be due to a reduced vocal folds capability to become slack or flaccid secondary to vocal cords oedema subtended by laryngo-pharyngeal reflux affecting the phonatory mechanisms in CH patients. The laryngo-pharyngeal reflux may represent a dysautonomic sign related to the increased parasympathetic tone during in-bouts period, reinforcing the hypothesis of an extracranial autonomic dysfunction as part of the CH clinical picture.
Background and Aims:: Idiopathic intracranial hypertension (IIH) is a well-established entity with increased intracranial pressure of unknown etiology. However, physicians are less aware of drug induced hypertension. Some of the commonly used medications in dermatology, especially those for acne vulgaris, have been associated with IIH. To our knowledge, only two cases of IIH reported in the literature have been associated with mesalasine treatment, which is a product of 5 aminosalicylate (5 ASA).

Methods:: Case report

Results:: A 51 year-old woman was admitted to our department with the complaint of headache and binocular horizontal diplopia. She had been on sulphasalazine treatment (2000 mg per day) for ulcerative colitis one year previously. Neurological examination revealed a bilateral sixth nerve palsy with bilateral papilledema. Brain MRI showed a partially empty sella with a distension of the optic nerve sheaths. Lumbar puncture (LP) revealed an opening pressure of 320-mm H2O with a normal cerebrospinal fluid composition. After elimination of other causes of intracranial hypertension, the diagnosis of IIH associated with sulphasalazine was suspected and this drug was accordingly discontinued. The patient was continued with azathioprine for ulcerative colitis and acetazolamide 750 mg/day with improvement of all the symptoms.

Conclusions:: Although the mechanism of intracranial hypertension associated with sulphasalazine treatment still unknown, it is imperative that clinicians recognise this causal relationship to prevent irreversible visual complications.
EFFECTIVENESS AND SAFETY OF CGRP-MABS IN MENSTRUAL RELATED MIGRAINE: A REAL-WORLD EXPERIENCE

Ilaria Orologio¹, Marcello Silvestro¹, Alessandro Tessitore¹, Simona Bonavita²,³, Fabrizio Scotto Di Clemente¹, Carla Fasano¹, Gioacchino Tedeschi¹, Antonio Russo¹
¹University of Campania Luigi Vanvitelli, I Division Of Neurology, Department Of Advanced Medical And Surgical Sciences, Naples, Italy, ²University of Campania “Luigi Vanvitelli”, Department Of Advanced Medical And Surgical Sciences, Napoli, Italy, ³University of Campania “Luigi Vanvitelli”, II Clinic of Neurology, Department Of Advanced Medical And Surgical Sciences, Napoli, Italy

Background and Aims:: Migraine shows a higher prevalence in women especially during reproductive age. Over 50% of patients report a higher occurrence of migraine attacks during perimenstrual window. Menstrual migraine attacks are referred as more disabling, less responsive to symptomatic treatments, longer in duration, and more prone to relapse than non-menstrual migraine attacks. Several evidences suggest that estrogen fluctuations are involved in migraine attacks worsening during the perimenstrual window through several mechanisms involving CGRP pathway. We aimed to evaluate whether mAbs blocking CGRP-ligand or receptor (CGRP-mAbs) could represent an effective and safety preventive treatment for menstrual migraine attacks in patients with menstrual related migraine (MRM) with previous treatment failures.

Methods:: Forty patients with MRM with previous treatment failures received monthly CGRP-mAbs. At the baseline and after six CGRP-mAbs administrations, patients underwent to extensive interviews to assess frequency, duration, intensity and responsiveness to painkillers intake of migraine attacks during the perimenstrual window.

Results:: After 6 administrations of CGRP-mAbs we observed a reduction of median menstrual migraine frequency (from 5 to 2 days per month), pain intensity (from 8/10 to 6/10), attacks duration (from 24 hours to 8 hours) and a significant increase in the percentage of responding to painkillers (from 42.5% to 95%) (p<0.001).
Fig. 1
Conclusions:: CGRP-mAbs could represent a safety and effective preventive therapeutic strategy able to reduce the disabling burden of menstrual migraine attacks frequency, duration, intensity and significantly improve the response to painkillers. These findings could be related to and prove the greater influence of CGRP-mediated mechanisms in the pathophysiology of menstrual migraine attacks.
MANNITOL EFFECTIVENESS IN LOWERING INTRACRANIAL PRESSURE IN IDIOPATHIC INTRACRANIAL HYPERTENSION: A CASE SERIES

Lucia Manzo, Angelo Pascarella, Francesco Bono
A.O.U. Mater Domini, Center For Headache And Intracranial Pressure Disorders, Neurology Unit, Catanzaro, Italy

Background and Aims:: Headache, transient visual loss, papilledema are the most frequent clinical features of idiopathic intracranial hypertension (IIH). If untreated, papilledema can result in progressive and irreversible vision loss. Mannitol is an osmotic diuretic commonly used to reduce high ICP in traumatic brain injuries, but its action in IIH is still unknown. Here we report effects of mannitol on CSF pressure in patients with IIH and papilledema.

Methods:: Four female with refractory headache and visual loss showing clinical, funduscopic and radiological signs suggestive of IIH were treated with intravenous infusion of mannitol 18% (0.6 g/kg, infusion speed: 125 ml/h) during continuous short-lasting CSF pressure recording through a spinal needle.

Results:: Mannitol administration stably normalized CSF pressure (<200 mmH2O) with abnormal waves disappearing and headache improvement in two out of four patients within 40’ and 45’. All four patients had evidence of: high opening (>250 mmH2O) and mean (>300 mmH2O) pressure and B-waves, papilledema and bilateral transverse sinus stenosis on cerebral-MR-venography. However, the two mannitol-responder patients showed all MRI signs (posterior sclera flattening, peri optic subaracnoid space distension, empty sella and optic nerve tortuosity) suggestive of IIH, whereas in the remaining two patients only the last two abnormalities were evident.

Conclusions:: We firstly report in vivo evidence of mannitol effect on CSF pressure in subjects with IIH. Mannitol normalized CSF pressure only in two subjects, in which more severe MRI signs of IIH were evident. Larger population study should be useful to confirm mannitol efficacy in IIH patients and to better identify predictor factors of mannitol efficacy.
WHOLE BRAIN SURFACE-BASED MORPHOMETRY STUDY IN SUBTYPES OF MIGRAINE WITH AURA PATIENTS

Chiara Abagnale1, Antonio Di Renzo2, Emanuele Tinelli3, Barbara Petolicchio4, Mariano Serrao1, Vincenzo Parisi2, Marco Fiorelli3, Francesca Caramia3, Vittorio Di Piero3, Gianluca Coppola5, Gabriele Sebastianelli5

1Sapienza University of Rome, polo Pontino, Department Of Medico-surgical Sciences And Biotechnologies, Latina, Italy,
2IRCCS, Fondazione Bietti, Rome, Italy,
3Sapienza University of Rome, Department Of Human Neurosciences, Rome, Italy,
4Sapienza University of Rome Polo Pontino, Department Of Medico-surgical Sciences And Biotechnologies, Roma, Italy,
5Sapienza University of Rome Polo Pontino, Department Of Medico-surgical Sciences And Biotechnologies, Latina, Italy

Background and Aims:: Little is known about the pathophysiologic basis of the clinical variability of migraine aura presentation. We were aimed to study intracerebral white matter fiber bundles, using a tract-based spatial statistics (TBSS) analysis of diffusion tensor imaging (DTI), and grey matter cortical thickness from structural magnetic resonance imaging data in migraine patients with pure visual auras (MA), and in patients with complex neurological auras (MA+), i.e. with the addition of at least one of sensory and language symptoms.

Methods:: 3T MRI data from 20 patients with MA and 15 with MA+ were collected and compared with data from 19 healthy controls (HCs). For everyone, we performed DTI to calculate diffusivity metrics and we obtained cortical thickness maps from structural MRI.

Results:: TBSS showed no significant differences in the diffusivity maps between both patients’ groups and HCs. As compared to HCs, both patients with MA and MA+ significantly showed thinner temporal cortices, frontal areas, insula, post-central area, and primary and associative visual areas. In the MA group, the high-level visual-information-processing areas, including lingual gyrus, were thicker, in contrast to the MA+ group where they were thinner than in HCs.

Conclusions:: These findings suggest that clinical heterogeneity of migraine with aura is associated with common cortical surface morphological features as well as with an opposite morphological involvement of the high-level visual-information-processing areas.
A 67-YEAR-OLD WOMAN WITH RECURRENT HEADACHE, MIGRATORY FOCAL SYMPTOMS, AND IMPAIRED CONSCIOUSNESS

Lorenzo Tartaglione, Alessandro Tessitore, Marcello Silvestro, Antonio De Mase, Mario Cirillo, Gioacchino Tedeschi, Antonio Russo
University of Campania Luigi Vanvitelli, Headache Center, Department Of Advanced Medical And Surgical Sciences, Naples, Italy

Background and Aims:: We present the clinical story of a 67-years-old woman with a previous diagnosis of migraine with aura developing stereotyped episodes, lasting for several hours, of focal visual, sensorimotor and aphasic neurological symptoms, and altered state of consciousness associated with a headache with migraine features.

Methods:: We discuss a case report including an up-to-date review of all previous cases in the field. To apply the Popper’s conjectures refutation paradigm, we carry out a differential diagnosis evaluating the pros and cons of possible hypotheses to confirm or refute HaNDL syndrome diagnostic hypotheses. A written informed consent was obtained from the patient for description of this case report.

Results:: The neuroimaging finding ruled out the diagnosis of hemorrhagic or ischemic stroke. EEG non-epileptiform changes characterized by an asymmetrical generalized slowing and triphasic waves allowed to exclude the diagnosis of migraine aura triggered seizure with prolonged ictal state. CSF analysis showed a pleocytosis in the absence of fever, meningism and with negative microbiological investigations disavowed infective encephalitis/meningitis. The absence of neuronal antibodies in both CSF and plasma did not support the diagnosis of autoimmune encephalitis. Finally, blood laboratory tests made the plasma hyperviscosity syndrome improbable. Altogether these findings supported the diagnosis of transient headache and neurological deficit with CSF lymphocytosis (HaNDL).

Conclusions:: HaNDL syndrome is one of the most frequent “stroke mimicker” that should be taken into account in patients with recurrent episodes of acute, migratory and transient neurological symptoms not respecting a single vascular territory but probably reflecting a cortical spreading depression (CSD).

Fabrizio Scotto Di Clemente, Alessandro Tessitore, Marcello Silvestro, Giorgia Battista, Gioacchino Tedeschi, Antonio Russo
University of Campania Luigi Vanvitelli, Headache Center, Department Of Advanced Medical And Surgical Sciences, Napoli, Italy

Background and Aims:: Refractory migraine (Ref-M) represents a conundrum that headache experts have to face with. We aim to investigate whether a peculiar profile may characterize patients with Ref-M according to 2020 European Headache Federation criteria. Furthermore, to substantiate a dysfunctional dopaminergic pathway involvement in these patients, we explored the effectiveness of olanzapine.

Methods:: Eighty-four patients (fitting previous Ref-M criteria of the 2014) were treated with erenumab for six months. Differences between clinical and demographic features of responder (Ref-M according to 2014 criteria) and not-responder (Ref-M according to 2020 criteria) patients to CGRP-mAbs were investigated and their predictive values assessed. In fifteen patients with Ref-M not-responders to CGRP-mAbs, olanzapine was administered (5 mg/die) for 3 months and frequency and pain intensity of migraine attacks were estimated.

Results:: Patients with Ref-M not-response to CGRP-mAbs (29/84) when compared with Ref-M responsive to CGRP-mAbs showed higher baseline frequency of migraine attacks, medication overuse and pain catastrophizing scale (PCS) scores. Logistic regression analyses showed that frequency of attacks, medication overuse and PCS score represent independent negative predictors of CGRP-mAbs response. A ≥50% reduction of headache days/month was observed after olanzapine treatment in 67% of patients with Ref-M not-responsive to CGRP-mAbs.
Conclusions:: We outline that higher frequency of migraine attacks, medication overuse and pain catastrophizing characterize patients with Ref-M not responsive to CGRP-mABs. In this frame, olanzapine effectiveness on frequency and pain intensity of migraine attacks supports the hypothesis that migraine refractoriness may be subtended by a prominent involvement of the dopaminergic pathway.
SAFETY, EFFICACY AND SLEEP EFFECT OF ERENUMAB IN CHRONIC MIGRAINE: 12 MONTHS REAL LIFE DATA

Laura Pilati, Angelo Torrente, Salvatore Di Marco, Giulia Notaro, Marika Romano, Salvatore Ferlisi, Filippo Brighina
University of Palermo, Department Of Biomedicine, Neuroscience And Advanced Diagnostics., Palermo, Italy

Background and Aims:: Erenumab, human monoclonal antibody directed against CGRP receptor, is first approved specific treatment for migraine. In this real-life study, we evaluate the efficacy and safety of erenumab associated with a multidisciplinary impact including sleep and circadian effect in 12 months treatment.

Methods:: Data are collected From Headache Center in Policlinico of Palermo and Messina, IRCSS Neurolesi Center "Bonino Pulejo". Patients with chronic refractory migraine received 140mg or 70mg of Erenumab every 28 days. Neurologists administrate MIDAS, HIT-6 and BDI and scales to study sleep impact of erenumab(MEQ-SA, PSQI, SCI, ESS), every month for first 3 months treatment, and then every 3 months.

Results:: We enrolled 88 patients: 38 migraineurs underwent to 140mg and remaining to 70mg. Erenumab reduce significantly monthly-migraine-days (MMD) from 1st month to 12-month treatment(Graph1,2), improving disability and depression(Graph3). Drug overuse is eliminated in 80% of patients as early as 3-month treatment. Dosage of 140mg is more effective than 70mg up to 6-month treatment in reduction of MMD(Graph2). At 3 month there is a reduction of the morning chronotype in favor of the intermediate one(Graph4) and in insomnia. Most common adverse event is constipation, which is observed in 9 patients(10%). No adverse events led to withdraw.

Graph 1: Decrease in MMDs compared to baseline
Graph 2. Responder 70mg vs 140mg
Conclusions:: Our real-life data confirm the efficacy and safety of erenumab in chronic migraine up to one year treatment with a significant improvement on quality of life. It is the first study that evaluate the effect of Erenumab on sleep: it could be attributed to an improvement in headache or to Erenumab action on CGRP, that is implicated in the mechanism underlying circadian rhythm.
ONABOTULINUMTOXINA REDUCE VISUAL CORTICAL EXCITABILITY IN CHRONIC MIGRAINE: PRELIMINARY RESULTS OF A STUDY WITH SOUND INDUCED FLASH ILLUSIONS

Salvatore Ferlisi1, Salvatore Di Marco1, Laura Pilati1, Angelo Torrente1, Serena Scardina1, Erika Di Marco1, Giuseppe La Bianca1, Giuseppe Cosentino2, Filippo Brighina1

1University of Palermo, Department Of Biomedicine, Neuroscience And Advanced Diagnostics,, Palermo, Italy, 2University of Pavia, Department Of Brain And Behavioral Sciences, Pavia, Italy

Background and Aims:: The number of sound-induced flash illusions (SIFI) perceived are related with the level of visual cortex (V1) excitability. In episodic migraineurs, in response to visual-acoustic illusions, V1 is hyperexcitable. The injection of botulinum toxin type A was approved as a therapy for chronic migraine (CM). Recent studies have correlated the action of botulinum toxin with the release of CGRP and cortical excitability. We used SIFI to evaluate the V1 excitability in CM at baseline and 3 months after treatment with botulinum toxin

Methods:: 15 CM candidated to onabotulinumtoxinA therapy and 12 control subjects in the same age range. CM were examined interictally. Visual and sound stimuli are presented with different combinations: multiple flash trials where a single beep causes the perception of less flashes (fusion illusion) and trial where multiple beeps with single flash, induce perception of more flashes (fission illusion). Each combination was randomly presented 10 times. At the end of each presentation the subject had to indicate the number of the flashes seen

Results:: First rmANOVA showed that healthy controls refer a higher number of flashes compared to chronic migraineurs, while the second analysis did not show significant changes in such scores before and after 3 months from the treatment, but planned comparisons showed a significant augmentation of scores in 1 flash 4 beeps combination.

Conclusions:: Data obtained suggest that chronic migraineurs manifest less fission illusions than healthy controls, consistently with previous studies. Furthermore, onabotulinumtoxinA restores, though partially, fission illusions and, consecutively, normalizes visual cortical excitability.
Background and Aims:: Lockdown measures have been introduced worldwide to contain the transmission of COVID-19. Italians were forced to stay at home changing their life-style. The aim of this study was to evaluate if remote working (RW) during first COVID-19 lockdown in Italy influenced chronic migraine (CM).

Methods:: The study was based on an e-mail survey addressed to CM patients of our headache center. Every patient in the study continued migraine therapy as appropriate during lockdown. We collected information about RW and variations of: migraine attack frequency, attack duration, pain intensity, drug efficacy between the previous month and first Italian COVID 19 lockdown.

Results:: A total of 92 patients completed the survey. Twenty patients switched to RW. Migraine attack frequency was stable in 37, increased in 31 and reduced in 24; migraine attack duration was stable in 51, increased in 22, reduced in 19. Migraine pain was stable or reduced in 60 and increased in 32. Migraine drug efficacy was stable in 68, reduced in 16 and increased in 8. Remote working was significant associated with reduced migraine attack duration (p<0.009) and increased drug efficacy (p<0.012).

Conclusions:: RW in our patients was associated with reduced migraine attack duration and increased drug efficacy. No data are present in literature concerning this point and we hypothesize that this improvement could be attributed to the distance from workplace and its stressor, and the possibility to manage time in a different manner.
DIFFERENT PERSONALITY PROFILES IN PATIENTS WITH CHRONIC CLUSTER HEADACHE: A DATA-DRIVEN APPROACH

Alessandra Telesca¹,², Alberto Proietti³, Monica Consonni¹, Sylvie Piacentini⁴, Emanuela Sansone³, Massimo Leone⁵, Susanna Usai³, Giuseppe Lauria⁶, Licia Grazzi³
¹IRCCS Carlo Besta Foundation, 3rd Neurology Unit And Motor Neuron Diseases Center, Milan, Italy, ²University of Milano-Bicocca, Department Of Medicine And Surgery, Milan, Italy, ³IRCCS Carlo Besta Foundation, Headache And Neuroalgology Unit, Neurological Institute “c. Besta” Irccs Foundation, Milan, Italy, ⁴IRCCS Carlo Besta Foundation, Headache And Neuroalgology Unit, Neurological Institute “c. Besta” Irccs Foundation, Milan, Italy, ⁵IRCCS Carlo Besta Foundation, 3rd Neurology Unit And Motor Neuron Diseases Center, Milan, Italy, ⁶Fondazione Istituto Neurologico Carlo Besta, Milano, Italy, Neurologia I, Milan, Italy, ⁷Fondazione IRCCS Istituto Neurologico Carlo Besta, Neuroalgology Unit, Milano, Italy, ⁸IRCCS Fondazione Istituto Neurologico Carlo Besta & University of Milan, Clinical Neurosciences, Milano, Italy

Background and Aims:: Chronic Cluster headache (CH) patients are usually comorbid to mood spectrum disorders, psychopathological symptoms and personality disorders, but the role of psychopathological aspects is still insufficiently explored. Our aim is to verify, by a data driven approach, if CH patients may be classified on the basis of personality trait disorders.

Methods:: We applied hierarchical cluster analysis (HCA) to classify 60 patients suffering from CH, based on values of the clinical personality pattern scales of the Millon Clinical Multiaxial Inventory-III (MCMI-III). Subgroup comparison on demographical data (age, sex, education) and clinical features (laterality, MCMI-III clinical scores) where subsequently performed.

Results:: The outcome of HCA revealed the existence of 3 groups of patients with different personality traits. Two groups had unique patterns. Group 1 (n = 20) had distinctive avoidant, borderline and schizotypal personality traits. Group 2 (n = 15) scored high on the obsessive-compulsive and histrionic personality traits. Group 3 (n = 25) did not show relevant patterns. Clinically, Group 2 had lower education level and higher level of post-traumatic stress symptoms and dysthymia than the other groups. CH hemispheric lateralization differed between groups with predominant right hemispheric manifestations for the Group 1.

Conclusions:: Our data-driven approach revealed different personality profiles in chronic CH patients with specific psychopathological features. Our findings also provided evidence on the role of individual factors, including cognitive reserve levels, on clinical manifestations. This might help to identify the most appropriate therapeutic strategies and predict the evolution of the disease.
HEADACHE AND SLEEP-RELATED BREATHING DISORDERS AMONG PATIENTS WITH SCLEROSTEOISIS AND DISEASE CARRIERS

Laura Rapisarda1, Monica Gagliardi2, Caterina Bombardieri3, Radha Procopio2, Giulio Demonte1, Federico Tosto1, Antonio Gambardella4, Grazia Annesi5, Francesco Bono1

1AOU Mater Domini, Magna Graecia University, Department Of Medical And Surgical Sciences, Institute Of Neurology, Catanzaro, Italy, 2National Research Council, Institute Of Molecular Bioimaging And Physiology, Catanzaro, Italy, 3AOU Mater Domini, Neuroradiology Unit, Catanzaro, Italy, 4AOU Mater Domini - Magna Graecia University, Department Of Medical And Surgical Sciences, Catanzaro, Italy, 5National Research Council, Institute For Biomedical Research And Innovation, Cosenza, Italy

Background and Aims: Headache and sleep-related breathing disorders among patients with sclerosteosis and disease carriers have been little studied. This study aimed to investigate the clinical characteristics and neuroimaging of a large Italian family affected by hyperostosis of the skull due to sclerosteosis.

Methods: Patients and gene carriers underwent careful neurological examination, cranial CT, brain MRI and MR-venography, CSF pressure monitoring and polysomnography to assess the presence of sleep apnea.

Results: In this Italian family with sclerosteosis, genetic tests detected the homozygous mutation p.Gln24X (c.70C>T) of the SOST gene in the proband, and a heterozygous mutation between 9 siblings. Severe hyperostosis of the skull caused chronic headache secondary to intracranial hypertension due to venous hypertension and obstructive sleep apnea syndrome in adult homozygotes. There was transosseous intracranial-extracranial occipital venous drainage which indicated a compensatory mechanism for intracranial venous hypertension, one of the causative factors of increased CSF pressure in sclerosteosis. While mild hyperostosis of the skull was associated with headache and snoring in heterozygotes.

Conclusions: Headache and sleep-related breathing disorders are common clinical manifestations among patients with sclerosteosis and disease carriers. Cerebral venous hypertension leading to intracranial hypertension and facial deformities are the causative factors of headache and sleep-related breathing disorders. These data suggest that venous stenting to accommodate cerebral venous drainage could be useful in the treatment of intracranial hypertension, and correction of facial deformities to relieve obstructive sleep apnea may play a role in the treatment of patients with sclerosteosis. The data highlight that it is reasonable to extend neurological evaluation and radiological study to gene carriers.
Background and Aims:: Compare maternal, fetal and infant outcomes among pregnant women with migraine exposed to galcanezumab to those exposed or not exposed to other migraine medications. There is a need to study utilization and safety of these medications before/during pregnancy since data on outcomes of pregnancies exposed to galcanezumab is limited.

Methods:: This multidrug pregnancy registry will enroll women with migraine exposed to galcanezumab up to 5 half-lives before/during pregnancy. Pregnant women with migraine (exposed or not exposed to other migraine medications) will be enrolled into comparator groups. Eligible women may enroll or be enrolled by their Health Care Provider by calling the phone number/visiting the website listed in the US Package Insert. Information on mother and fetus/infant (eg, demographics/medical history/exposures/outcomes) will be collected at multiple time points during pregnancy and to 1 year post delivery.

Results:: The primary outcome assessed in this pregnancy registry is major congenital malformations. Additional maternal, fetal and infant outcomes (to 1 year of age) will be evaluated.

Conclusions:: Real-world studies are needed to evaluate utilization and safety of new migraine medication exposures in pregnancy. This registry is part of a larger effort towards this goal. Sufficient enrollment of pregnant women will enable execution of two comparative safety studies using this registry.
BACKGROUND AND AIDS: Coronavirus Disease 2019 (COVID-19) caused by Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) is a contagious disease that causes the current pandemic. SARS-CoV-2 has been postulated to have a neuroinvasive potential. Headache as a very common non-respiratory symptom of COVID-19. The literature review is intended to explain about headache in patients with SARS-CoV-2 infection.

METHODS: The journals used in literature reviews obtained through databases include Google Scholar, PubMed, and Science Direct. The search found 26 articles from Google Scholar, 3 from PubMed, and 6 articles from Science Direct. Of all the articles, the selection was made based on the title and abstract, so that 35 articles were obtained. The literature used is not a thesis, dissertation, thesis, or other literature review. The articles used are only journals in full text. So that the number of articles used is 25 articles.

RESULTS: From the 25-literature reviewed, headache in COVID-19 patients appears in the prodromal phase and is followed by anosmia/hyposmia. Headache on COVID-19 patients in general were holocranial, hemicranial, or occipital, pressing, and worsens with physical activity or head movements. Pathogenesis of headache on COVID-19 patients still under debated. The mechanism of headache in SARS-CoV-2 is related to cytokine storm and cytokine release syndrome (CRS).

CONCLUSIONS: Headache is one of the most common neurological manifestations in patients infected with SARS-CoV-2. The characteristic of headache in patient COVID-19 is typically a headache of moderate to severe intensity with frontal predominance and oppressive quality.
FUNCTIONAL RESTORATION WITH REYVOW (FREE): A US-BASED CROSS-SECTIONAL SURVEY IN PATIENTS TAKING LASMIDITAN

Louise Lombard¹, Todd Schwedt², Erin Doty¹, Maurice Vincent¹, Kayla Mills¹, David Ayer¹, Demauri Mackie³, Marc Decongelio³, Paula Hauck¹, Carrie Dougherty⁴

¹Eli Lilly and Company, Neuroscience, Indianapolis, United States of America, ²Mayo Clinic, Neurology, Phoenix, United States of America, ³Kantar Health, Clinical Research, New York, United States of America, ⁴MedStar Georgetown University Hospital, Neurology, Washington DC, United States of America

Background and Aims:: Assess respondents’ ability to return to their usual activities and level of impairment of those activities after migraine acute treatment with lasmiditan.

Methods:: A 15-min web-based survey was conducted on adult respondents who had enrolled in the US patient support program, redeemed a savings card, and treated at least 1 migraine attack with lasmiditan within the prior month. Symptoms/outcomes/ability to engage in various activities after recent lasmiditan-treated migraine attack were assessed using descriptive statistics.

Results:: 78 respondents completed the survey (mean age 48 years/93.6% female/16.9 mean headache days/month). Untreated/unsuccessfully treated migraine attacks prior to ever taking lasmiditan resulted in inability/severely impaired ability to perform various activities (Table). At the time of lasmiditan dosing (most recent attack), 49% had severe and 45% had moderate pain. By 2-hours post-dose, 94% respondents had some/complete pain improvement. After lasmiditan treatment, 45-75% respondents returned to their current/planned activities, except for planned activities outside home (22%). Extent of ability to perform current/planned activities varied by activity (Table). 77% respondents were satisfied with lasmiditan; 62% were satisfied with its ability to return them to their usual activities.
**Conclusions:** With lasmiditan, majority respondents were satisfied and able to return to their usual activities with no/some degree of impairment.

| Past impact of untreated or unsuccessfully treated migraine attack (prior to ever taking lasmiditan), n (N), % | Usual activities |
|---|---|---|---|---|---|
| | Interacting with family, friends, and others who are close to you | Performing leisure time activities | Dealing with household chores | Dealing with activities outside the home | Performing work or school tasks |
| Completely unable to perform activity | 28 (78), 36 | 37 (78), 47 | 32 (78), 41 | 41 (78), 53 | 33 (78), 42 |
| Activity severely impaired | 34 (78), 44 | 23 (78), 30 | 28 (78), 36 | 24 (78), 31 | 28 (78), 36 |
| Activity impaired to some degree | 14 (78), 18 | 14 (78), 18 | 16 (78), 21 | 12 (78), 15 | 8 (78), 10 |
| Activity not impaired | 1 (78), 1 | 2 (78), 3 | 0 (78), 0 | 0 (78), 0 | 0 (78), 0 |
| Not Applicable | 1 (78), 1 | 2 (78), 3 | 2 (78), 3 | 1 (78), 1 | 9 (78), 12 |

**Activity engaged in at the time of taking lasmiditan, n (N), %**

| Ability to return to activity (among those who performed this activity) | Usual activities |
|---|---|---|---|---|---|
| | Interacting with family, friends, and others who are close to you | Performing leisure time activities | Dealing with household chores | Dealing with activities outside the home | Performing work or school tasks |
| Severe | 8 (14), 57 | 9 (12), 75 | 12 (16), 75 | 6 (9), 67 | 19 (29), 65 |
| Impaired to some degree | 5 (8), 63 | 6 (9), 67 | 8 (12), 67 | 3 (6), 50 | 11 (19), 58 |
ONABOTULINUMTOXIN-A DURING COVID-19 PANDEMIC: LONG-TERM EFFICACY IN CHRONIC MIGRAINE.

Martina Locatelli, Francesca Schiano Di Cola, Salvatore Caratozzolo, Paolo Liberini, Renata Rao, Alessandro Padovani
Brescia University, Department Of Clinical And Experimental Sciences, Neurology Clinic, Brescia, Italy

Background and Aims:: Current guidelines recommend regulare quarterly administration of Onabotulinumtoxin-A in chronic migraine patients. During the first Italian COVID-19 related quarantine period, as per national and international guidelines, Onabotulinumtoxin-A administrations were suspended, given its biological risk. Aim of the present study was to assess migraine outcome in patients in prophylaxis with Onabotulinumtoxin-A during COVID-19 related treatment suspension (March-May 2020).

Methods:: This is a retrospective observational study, conducted at the Headache Centre – ASST Spedali Civili Brescia. All patients scheduled for Onabotulinumtoxin-A treatment during March-May 2020, whose administration was suspended, were included.

Results:: Forty-two consecutive patients were enrolled. All patients had a diagnosis of chronic migraine and medication overuse. On average, patients were in their 4th treatment cycle (range 3-10), due to the COVID-19 treatment suspension, with a six months – instead of three – gap between administrations. Considering this cohort of patients, as of February 2020, 45.2% were non-responders, 19% were partial responders, and 35.7% were full responders. Post-COVID-19 suspension, up to 45.2% of patients were full responders and 26.2% partial-responders. Analysing single patients, seven patients remained non-responders and twelve remained full-responders, whereas nine worsened and fourteen improved compared to pre-COVID-19.

Conclusions:: Despite treatment delay, Onabotulinumtoxin-A still proved its efficacy in migraine prevention. The progressive increase in responders rates usually seen at subsequent treatments was still evident, regardless of the missing administration.
PROJECT FOR THE ESTABLISHMENT OF THE ITALIAN MIGRAINE REGISTRY (I-GRAINE-NEW)

Luisa Fofi¹, Lital Hollander², Cinzia Aurilia³, Gabriella Egeo¹, Giulia Fiorentini¹, Nicola Vanacore⁴, Stefano Bonassi⁵, Carlo Tomino⁶
¹IRCCS San Raffaele, Headache And Pain Unit, Rome, Italy, ²CD Pharma, Scientific Direction, Milan, Italy, ³IRCCS San Raffaele Pisana, Headache And Pain Unit, Rome, Italy, ⁴National Institute of Health, National Center For Disease Prevention And Health Promotion, Rome, Italy, ⁵IRCCS San Raffaele, Unit Of Clinical And Molecular Epidemiology, Rome, Italy, ⁶IRCCS San Raffaele, Scientific Direction, Rome, Italy

Background and Aims:: Migraine is the leading cause of disability in people under 50 but remains underdiagnosed and undertreated. A comprehensive appraisal of the full clinical, social and economic complexity of the disease is a fundamental prerequisite for its proper management. I-GRAINE-NEW aims to: provide information on migraine natural history, provide epidemiological, social and sanitary resource use data, identify the impact of patient management on prognosis.

Methods:: Data will be collected by 41 headache centers. I-GRAINE-NEW will enroll a representative sample of 10% of adult patients with migraine and will last at least 5 years. Patients will be evaluated by face-to-face interviews using a detailed semi-structured questionnaire. A subgroup of 6000 patients, referred for a first outpatient visit, will be considered for a retrospective-prospective sub-study.

Results:: I-GRAINE-NEW will include 10% of all the adult patients affected by episodic or chronic migraine visited at each center for at 5 years. Patients will be evaluated by face-to-face interviews using a detailed (~200 items), semi-structured questionnaire assessing socio-demographic factors, lifestyle, medical history, migraine characteristics and disability, patient’s journey and healthcare resource use. A subgroup of 6000 incident migraine patients referred for a first outpatient visit, will be considered for a retrospective-prospective cohort study - lasting 24 months - aimed of analysing more in-depth (~500 items questionnaire) clinical endophenotypes, treatments and the detailed history of migraine onset and evolution.

Conclusions:: The I-GRAINE registry is expected to shed light on migraine unmet needs, define the endophenotypes, and improve clinical management, resulting in increased disease awareness, better healthcare resource allocation, and reduced economic burden.
CGRP MONOCLONAL ANTIBODIES EARLY ONSET OF EFFICACY FOLLOWING FOUR WEEKS OF TREATMENT IN CHRONIC MIGRAINE

Francesca Schiano Di Cola¹, Salvatore Caratozzolo¹, Matteo Cortinovis¹, Paolo Liberini¹, Renata Rao¹, Alessandro Padovani²
¹Brescia University, Department Of Clinical And Experimental Sciences, Neurology Clinic, Brescia, Italy, ²University of Brescia, Dept. Clinical And Experimental Sciences, Brescia, Italy

Background and Aims:: Various studies have documented a rapid onset of efficacy in migraine prevention for monoclonal antibodies targeting CGRP. Aim of the present study was to assess migraine outcome following the first 4 weeks of treatment in patients treated with erenumab 70 mg or galcanezumab 240 mg (loading dose).

Methods:: This is a retrospective observational study, conducted at the Headache Centre – ASST Spedali Civili Brescia. All patients with a 4 weeks follow-up at March 2021 and a diagnosis of chronic migraine were included.

Results:: Seventy-four consecutive patients were enrolled, of whom 50 in treatment with erenumab and 24 with galcanezumab. All patients had a diagnosis of chronic migraine, of whom 64 also documented medication overuse. Following the first administration, a significant reduction in terms of migraine days (11.3±0.7 vs 20.9±0.9; p < 0.001), analgesics consumption (11.7±1.2 vs 24.1±1.9; p < 0.001) and pain intensity (6.3±0.2 vs 7.6±0.1; p < 0.001) compared to baseline, was found. At week 4, 58.9% of patient documented an overall significant clinical response (lost >50% migraine days compared to baseline). No significant differences were found between erenumab and galcanezumab both at baseline and week 4.

Conclusions:: The present study confirms monoclonal antibodies targeting CGRP rapid onset of efficacy, as early as from the very first administration, regardless of the type of monoclonal antibody.
FREMANEZUMAB IN THE PREVENTION OF HIGH-FREQUENCY EPISODIC AND CHRONIC MIGRAINE: FRIEND (FREMANEZUMAB IN REAL WORLD STUDY), THE FIRST ITALIAN MULTICENTER, PROSPECTIVE REAL-LIFE STUDY.

Background and Aims:: We assessed fremanezumab effectiveness, safety and tolerability in high-frequency EM (HFEM) and CM in a real-life population.

Methods:: This is a 24-week, multicenter (n=9), longitudinal, cohort, real life study performed from 28/01/2020 to 15/03/2021. We considered all consecutive patients with HFEM or CM aged 18-65 years. Change in monthly migraine days (MMD) at weeks 21-24 compared to baseline was the primary efficacy endpoint. Secondary endpoints encompassed variation in monthly analgesic intake and change in VAS, HIT-6 and MIDAS scores during the same time interval.

Results:: 47 patients received >1 fremanezumab dose (225 mg monthly, n=38; 625 mg quarterly, n=9). Thirty-one patients were treated for 24 weeks and considered for effectiveness analysis. From baseline to weeks 21-24, fremanezumab treatment induced a significant reduction in MMD (-8.9±5.3,p<0.001), analgesic intake (-12.7±9.8,p<0.001), and VAS (-3.0±2.6,p<0.001), HIT-6 (-13.8±9.5,p<0.001) and MIDAS scores (-69.7±57.5,p<0.001). 4 patients (8.5%) presented adverse events: injection site erythema (2), orticaroid reaction (2), abdominal colic (1). Only 1 patient discontinued for ineffectiveness.

Conclusions:: 24-week fremanezumab treatment provides effectiveness, safety and tolerability in real-life patients with HFEM or CM with >3 prior preventive treatment failures. Our data need to be confirmed in larger studies.
Background and Aims:: Recent studies have showed that in emergency department (ED) pediatric admissions for headache are increasing in the last years. However Covid-19 pandemic may have changed the use of health services for several reasons. Aim of this study is to analyze the rates of admission for pediatric headaches in ED before and during Covid-19 Pandemic.

Methods:: we have collected retrospectively the records of children (range of age 5-14) admitted on ED in 2012, 2019 and 2020. We selected the records including Headache and Headache associated to other symptoms (vomit, fever, dizziness, etc.), collecting further the use of computed tomography (CT) and neurological consultation.

Results:: In 2012, 2019 and 2020 the cephalaligic children admitted to ED were respectively 313/18806 (1.66%), 407/15605 (2.61%) and 234/9630 (2.43%). The admission rates for headaches shows highly significant differences between 2012 and biennial 2019/2020. There are no differences in use of CT and neurological consultations. The only difference in access was the initial drop in the first months of lockdown (2020/80% vs 2019/50%).

Conclusions:: Our data support the increase of admission for headache to the pediatric ED in the last ten years. However the Covid-19 pandemic has not increased the admission rate compared to 2019 neither the use of CT or neurological consultations. The fear of using EDs was no changed for headache compared to other pediatric alarm symptoms.
COST-EFFECTIVENESS ANALYSIS FOR PRIMARY HEADACHE IN SAMPLE SIZE, MONGOLIA

Davaasuren Bolortsetseg¹, L Otgonbayar², L Undram²
¹General Hospital for State Special Servants, Neurology, Ulaanbaatar, Mongolia, ²Mongolian National University of Medical Sciences, Neurology, Ulaanbaatar, Mongolia

Background and Aims:: Headache disorders are most prevalent public-health problem, affecting people in all countries. GBD2016 and GBD2017 established their high ranking among all causes of years lived with disability (YLDs). Evidence of the cost and effects of interventions for reducing the global burden of headache, usually chronic headache and migraine.

Methods:: In simple size, inpatient and outpatient headache suffers aged 18-65 were selected on ICHD-3. We assessed Headache-Attributed Lost Time (HALT) questionnaire. Individual and population-level disability attributed to migraine, TTH and chronic headache using disability weights (DWs) from GBD2017 for the ictal states of each. Enquire Indirect cost per patient and cost of Temporary loss of work ability

Results:: Disability level, estimated by applying the GBD2017 DW for the ictal state of migraine was 5.5%, chronic headache was 14.6% higher than TTH was 0.17%. People with headache on ≥15 days/month had markedly and significantly lower incomes than those headache on ≤15 days/month (p=0.004) HALT scores were higher in people with migraine than tension type headache (p=0.001). The average annual indirect cost per patient was USD4789, cost of temporary loss of work ability was USD2357.

Conclusions:: Headache disorders are not only common in Mongolia but also heavily burdensome, with a very similar picture to Nepal, Ethiopia and Russia. Individual disabilities attributable to all headache types make up a total disability of 1.7% among the entire population aged 18-65 years. It is important to recognize that this population is effectively the working population. This is enormous economic burden in a lower-middle-income country, likely to be reflected in national and gross domestic product.
HEADACHES AND SLEEP PROBLEMS AMONG THE MEDICAL STAFF

Selenge Enkhtuya¹, Saruultsetseg Byambadorj², Odonchimeg Dorjsuren³, Enkhtaivan Bataa³, Sarangerel Jambal¹
¹Reflex Neurological Clinic, Neurology, Ulaanbaatar, Mongolia, ²The First Central State Hospital, Neurology, Ulaanbaatar, Mongolia, ³The National Center for Mental Health, Psychiatry, Ulaanbaatar, Mongolia

Background and Aims:: This study was aimed to investigate the associations of sleep quality, symptoms and disorders with specific headache subtypes among the Mongolian medical staff.

Methods:: This cross-sectional survey consisting of semi-structured questionnaires was administered to 290 participants of medical staff from randomly selected state hospitals during the period from September to October 2019 in Ulaanbaatar, Mongolia. We used the Pittsburgh Sleep Quality Index (PSQI) and questionnaire of primary headache was based on the criteria of the International Classification of Headache Disorders-III.

Results:: We surveyed totally 290 participants; of them, 243 (83.8%) were females and 47 (16.2%) were males. The one-year prevalence of all types of headache was 235 (81.0%). The prevalence of migraine and tension-type headache was 36 (12.4%) and 43 (14.8%), respectively. Poor sleep quality was present in 187 (64.5%) of participants associated with sleep time (p=0.003), wake-up time (p=0.001), sleep latency (p<0.001), total hours slept (p<0.001), subjective sleep quality (p<0.001) and 1-year all headaches (p<0.001). There was no significant difference in sleep quality between participants with and without migraine or tension type headache. However, staff with 1-year all headaches reported significantly higher mean score of PSQI (p<0.001), less sleep duration (p=0.008), lower subjective sleep quality (p<0.001), higher day time sleepiness (p=0.032) and poor day time execution (p=0.018) than those without headache.

Conclusions:: Our study findings reveal that poor sleep quality and headaches are highly prevalent among the Mongolian medical staff. The short sleep duration and poor sleep quality index are associated with an increased 1-year headache symptoms.
CACNA1A-P.THR501MET MUTATION ASSOCIATED WITH FAMILIAL HEMIPLEGIC MIGRAINE: A FAMILY REPORT.

Marina Romozzi¹, Guido Primiano², Eleonora Rollo¹, Lorena Travaglini³, Serenella Servidei², Paolo Calabresi², Catello Vollono²
¹Università Cattolica del Sacro Cuore, Department Of Neurosciences, Rome, Italy, ²Università Cattolica del Sacro Cuore, Fondazione Policlinico Universitario A. Gemelli IRCCS, Department Of Neurosciences, Rome, Italy, ³Unit of Neuromuscular and Neurodegenerative Disorders, Laboratory of Molecular Medicine, Bambino Gesù Children's Hospital, IRCCS, Department Of Neurosciences, Rome, Italy

Background and Aims:: Hemiplegic migraine (HM) is a rare form of migraine characterized by the presence of motor and other types of aura. HM can be sporadic or familial. Familial hemiplegic migraine (FHM) is an autosomal dominant disorder, classified into 3 subtypes, based on the gene involved (CACNA1A in FHM1, ATP1A2 in FHM2 and SCN1A in FHM3). The clinical presentation is highly heterogeneous and some attacks may be severe. We report the clinical characteristics and genetic analysis of 12 patients belonging to a family with CACNA1A-p.Thr501Met gene mutation.

Methods:: We screened for mutations in CACNA1A gene 15 subjects belonging to the same family (Figure 1). The exonic sequences of CACNA1A were analyzed using a Tru-seq® Custom Amplicon (TSCA) (Illumina Inc., San Diego, CA) targeted capture and paired end library kit. Sanger sequencing was used to confirm CACNA1A variants and segregation analysis.

Results:: CACNA1A-p.Thr501Met mutation was found in 12 of the 15 patients screened, compatible with the diagnosis of FHM1 (Table 1). Attacks of HM² were reported by 10 of the 12 subjects (83.33%). Only one subject developed persistent cerebellar symptoms and none of the subjects developed cerebellar atrophy.
Conclusions:: The variant p.Thr501Met was described previously in association with episodic ataxia and rarely with FHM related to cerebellar symptoms. FHM1 has a broad clinical spectrum and about half of the families have cerebellar involvement. In our study, only one patient developed persistent cerebellar deficits. These data suggest that CACNA1A-p.Thr501Met mutation can occur prevalently as hemiplegic migraine.
CAN HEADACHE BE CONSIDERED AN ALTERED FUNCTION OF ATTENTIVE PROCESS?

Gioacchino Aiello¹, Merati Silvia², Rossini Michela², Toti Pia¹
¹PRIVATE OUT PATIENTS, Neuropsychophysiology, BERNAREGGIO, Italy, ²PRIVATE OUT PATIENTS, Neuropsychophysiology, MONZA E DELLA BRIANZA, Italy

Background and Aims:: In this study we want to analyse the role played by cognitive evoked potentials in individuals suffering from headache vs. non-cephalalgic subjects. Using as differential variables the amplitude and latency values of the visual and auditory P300 recorded in the FZ CZ PZ derivations,

Methods:: All enrolled subjects arrived at my outclinic for a neurological evaluation and as usual they underwent a series of evaluations to highlight whether the headache was attributable to some organic factor. 44 subjects with headache: 10 males and 34 females aged 18 to 65 years. The control group had no history of headache, 13 subjects: 4 males and 9 females. All subjects were subjected to a preliminary EEG with open eyes and closed eyes to highlight the presence of irritative phenomena. Registration of ERP, the paradigm used is ODDBALL.

Results:: The values of the amplitudes in the FZ CZ PZ derivations of the controls vs. headache group it is evident that in all 3 derivations the difference in amplitude is significantly different between normal and headache both for the visual P300 and for the auditory P300.

Conclusions:: The results obtained from this study, say that attention deficit is present in the subjects affected by headache and that could influence in a statistically significant matter their schooling and as a consequence their quality of life as well. Thus, the subjects with an attention deficit will have a bigger difficulty both in the performance and in the learning process too. This predisposes to anxiety disorders, depression.
Background and Aims:: Headache is the most common presentation in neurology and role of transcranial doppler (TCD) in headache disorders specially migraine and Idiopathic intracranial hypertension (IIH) has not been explored in the past. The present study was planned to decipher the role of TCD to assess the status of flow dynamics in the vessels, which may help in deciding appropriate therapeutic options in headache disorders.

Methods:: This prospective study was carried out at a tertiary care institute in North India and included 51 people with IIH (fulfilling Modified dandy criteria), 87 with migraine (diagnosed as per ICHD 3), and 101 healthy controls. All patients and controls were subjected for transcranial doppler study including vasomotor reactivity.

Results:: Mean age of patients in IIH was 33.41 years, in migraine was 34.6 years and in control group was 31.17 years. Vision loss was present in 66.67% patients of IIH. Neuroimaging was abnormal in 94.11% patients of IIH with mean CSF pressure of 31.27±5.32 cm. Mean VMR in IIH (1.11±0.32) was lower than mean VMR in migraine (1.34±0.43) and controls (1.49±0.46%) suggesting different pathophysiological mechanisms in them. Statistically significant difference between MCA mean flow velocity (MFV) and end diastolic velocity (EDV) was present when compared between IIH, migraine and controls. With increasing CSF pressure, pulsatility index showed a positive correlation (p value=0.045).

Conclusions:: TCD derived MCA flow velocities and indices differ considerably between IIH, migraine and controls and may be utilized in these patients to explain the pathogenetic mechanisms and clinical picture. More-over pulsatility index may be useful for non-invasive monitoring of raised ICP.
EFFECTS OF COVID-19 ON A MIGRAINOUS PATIENT TREATED WITH ERENUMAB: A CASE REPORT

Alberto Grassini, Andrea Marcinnò, Fausto Roveta, Erica Gallo, Innocenzo Rainero
University of Torino, Department Of Neurosciences, Headache Center, Torino, Italy

Background and Aims:: Headache is a frequent symptom of the novel coronavirus 19 disease (COVID-19). Two distinct headache phenotypes were observed in COVID-19 patients: one showing the features of migraine attacks while another characterized by symptoms of tension-type headache. We report the effects of SARS-CoV-2 infection on a chronic migraine patient treated with erenumab.

Methods:: A 47 years old patient suffering of chronic migraine started, in September 2020, an anti-CGRP receptor monoclonal antibody therapy with Erenumab, at the dosage of 70 mg per month. In a two-months period, headache frequency decreased from 16 to 5 attacks per month. On the third month the patient developed mild COVID-19 symptoms, like fatigue and hyposmia, with nasopharingeal swab-test resulting positive for SARS-CoV-2 RNA. A significant increase in migraine attacks (15 per months) was reported. Brain MRI and EEG were performed, resulting normal. Erenumab was increased to 140 mg/month.

Results:: After increase in anti-CGRP dosage, the frequency of migraine attacks progressively decreased to 3-4 per month and remained stable. All the headaches experienced by our patient during the infection fulfilled the criteria of the migraine attacks, without tensive like features.

Conclusions:: Our case report suggests that inflammatory processes induced by SARS-CoV-2 infection may increase the frequency of migraine attacks through an activation of the trigeminovascular system. Additional studies with anti-CGRP monoclonal antibodies in COVID-19 patients are needed.
TRANSCRANIAL DOPPLER ULTRASONOGRAPHY STUDY IN MIGRAINE PATIENTS TREATED WITH ERENUMAB

Luisa Vinciguerra¹, Valentina Puglisi¹, Elisa Pari¹, Chiara Costanzi¹, Alessia Giossi¹, Giuseppe Lanza², Rita Bella³, Bruno Censori¹
¹ASST Cremona, Department Of Neurology, Cremona, Italy, ²University of Catania, Department Of Surgery And Medical-surgery Specialties, Catania, Italy, ³University of Catania, Department Of Medical And Surgical Sciences And Advanced Technologies, Catania, Italy

Background and Aims:: Pathogenesis of migraine is believed to be neurogenic, with vascular changes having a role in the attack pathophysiology. Migraine patients have reported abnormalities in cerebral hemodynamics. Human monoclonal antibodies represent the new therapy of migraine, acting against the vasodilator effect of Calcitonin gene-related peptide. In this frame, the aim of the present study was to evaluate blood flow velocities in basal brain arteries and vasomotor reactivity of migraine patients using TCCD, before and after monoclonal antibody treatment with erenumab.

Methods:: 11 patients with migraine without aura treated with erenumab were age-matched with 11 healthy controls. Peak Systolic Blood Flow Velocity (PSV), End-Diastolic Blood Flow Velocity (EDV), Mean Blood Flow Velocity (MBFV), Pulsatility Index (PI), and Resistivity Index (RI) were recorded from the Middle Cerebral Artery (MCA) bilaterally and Basilar Artery (BA). Cerebrovascular reactivity to breath-holding was also evaluated. Patients were evaluated at baseline, after 6 months from the first erenumab injection and after one year of treatment.

Results:: A significant difference was observed in MBFV and PSV of the MCA in patients after one year of treatment with erenumab. In particular, patients exhibited a decrease in MBFV (p=0.009) and PSV (p=0.020) compared to controls.

Conclusions:: Cerebral hemodynamics are partially changed in migraine patients after a long period of treatment with erenumab.
RETROSPECTIVE ANALYSIS OF ADULT CHRONIC POST-TRAUMATIC HEADACHE WITH RESPECT TO THE INTRACRANIAL PRESSURE AND THE CHARACTERISTIC OF HEADACHE

Kiyoshi Takagi¹, Kazuyoshi Kato², Shuichiro Asano³, Ryosuke Takagi⁴, Takashi Kawahara⁵, Masamichi Atsuchi⁵
¹Abiko Seijinkai Hospital, Nph Center, xAbiko, Japan, ²Abiko Seijinkai Hospital, Department Of Surgery, Abiko, Japan, ³Kashiwatanaka Hospital, Department Of Neurosurgery, Kashiwa, Japan, ⁴Yokohama Minami Kyosai Hospital, Department Of Neurosurgery, Yokohama, Japan, ⁵Jifukai Atsuchi Neurosurgical Hospital, Nph Center, Kagoshima, Japan

Background and Aims:: Chronic post-traumatic headache (CPTH) is a life disturbing disorder with many symptoms (JAMA 2008; 300: 71-9) and yet the characteristic of the headache is still unclear. We have reported the possibility of increased intracranial pressure (ICP) in adult CPTH (Eur J Med Res 2007; 12: 246-54)). The main purpose of this study is to elucidate the intracranial pressure (ICP) and the characteristic of the headache.

Methods:: We retrospectively investigated 150 adult patients (≥20 years) with CPTH over 3 months. ICP was measured by lumbar spinal tap in all patients. Data were shown in mean (SD). Statistically significant level was set p<0.05.

Results:: Mean age was 42.1 (13.5) years (40.7 (11.1) years for male (n=58) and 43.0 (14.8) years for female (n=92), p=0.318). Mean ICP was 151.2(44.9) mmH₂O (167.1 (44.5) mmH₂O for male and 141.2 (42.6) mmH₂O for female p<0.001). Disease period was 68.1 (101) months. One hundred and thirty-two patients had headache with orthostatic nature and 116 patients complained deterioration of the headache by low atmospheric pressure. Thirty-one patients complained whole body pain similar to fibromyalgia. Removal of cerebrospinal fluid (CSF) was effective to relieve symptoms in 77 patients.

Conclusions:: Although many patients with CPTH complained headache with orthostatic nature suggesting low ICP, their ICP was normal or even high. Female ICP was significantly lower than male ICP. CSF removal was effective in many patients. The results of this study indicates the involvement of CSF abnormality in CPTH.
Background and Aims:: Neurocysticercosis is an infection caused by the larval stage of the tapeworm Taenia solium. The clinical manifestations depend on load, type, size, location, stage of development of the cysticerci, and the host's immune response against the parasite. An intraventricular cysticercus can produce Bruns syndrome, which can manifest as a thunderclap headache. Here we present an unusual case.

Methods:: The methodology is a case report.

Results:: 27-year-old male, industrial technician, from Barranquilla, Colombia, with no relevant pathological history. The patient pick up an object on the floor, tilting his head, later when changing from crouched to standing position, he triggered a thunderclap headache, followed by multiple emetic episodes and a feeling of dizziness. The intensity of the pain decreased during the following hours, yet returning or increasing when tilting the head. The biomarkers were within normal range, the cranial computed tomography evidenced multiple cortical calcifications, triventricular hydrocephalus without signs of activity (figure 1). The contrast cerebral magnetic resonance found a cystic mass in the third ventricle with a scolex, which corresponds to the vesicular phase of the cysticercus (figure 2). The patient received endoscopic surgical management with subsequent improvement. Figure 1.
Conclusions: The syndrome was first described in 1902 by Lugwig Bruns. Characterized by attacks of sudden severe headache, vomiting, and vertigo precipitated due to abrupt movements of the head due to presence of mobile deformable intraventricular lesion. Due to intermittent or positional obstruction resulting from ball-valve mechanism, causing episodic obstructive hydrocephalus. This case supports that neurocysticercosis can cause thunderclap headache.
CHRONIC MIGRAINE WITH MEDICATION OVERUSE HEADACHE: IS DETOXIFICATION STILL NECESSARY IN THE ERA OF NEW PROPHYLAXES?

Davide Mascarella¹, Eleonora Matteo², Umberto Pensato³, Gian Maria Asioli³, Valentina Favoni², Giorgia Andrini¹, Agnese Turrini¹, Giulia Pierangeli¹, Pietro Cortelli⁴, Sabina Cevoli⁵

¹IRCCS - Istituto delle Scienze Neurologiche di Bologna, Dibinem, Bologna, Italy, ²IRCCS Istituto delle Scienze Neurologiche di Bologna, Neurology, Bologna, Italy, ³University of Bologna, Department Of Biomedical And Neuromotor Sciences,, Bologna, Italy, ⁴IRCCS-Istituto di Scienze Neurologiche, Dibinem-University Of -bologna, Bologna, Italy, ⁵IRCCS Istituto delle Scienze Neurologiche, Headache Center, Bologna, Italy

Background and Aims:: Medication overuse headache (MOH) leads to high disability and poor quality of life; the debate on value and method of detoxification is still open, even more at the present time with new preventive treatments available. The aim of this study is to estimate the effectiveness of detoxification in multi-resistant chronic migraine (CM) with MOH patients who start prophylaxes Anti-CGRP monoclonal antibodies (mAb).

Methods:: Prospective analysis of all CM with MOH patients with at least 28 monthly headache days (MHD) who started a prophylaxis with Anti-CGRP, with or without detoxification at the beginning of treatment, at Bologna Headache Center between June 2019 and December 2020. We evaluated CM remission and MHD reduction (>50% response) at three months.

Results:: 39 patients were included; 26 started prophylaxis alone (PA), 13 started prophylaxis after detoxification (PAD). At 3-months we observed clinical conversion to episodic migraine in five of the 26 PA patients (19.2%) and in five (38.4%) (p 0.1) of the 13 PAD group. Mean MHD was 22.2 (± 8.1) in the PA group and 16.3 (± 10.2) in the PAD group (p 0.11); >50% responders were five of the 13 PAD patients (38.4%) and four of the 26 PA patients (19.2%) (p 0.1).

Conclusions:: Detoxification seems to maintain a key role in preventive treatment of CM with MOH patients, also in the era of new prophylaxes. Larger samples are warranted to obtain definitive results.
EVALUATION OF PREVALENCE AND SEVERITY OF OBSTRUCTIVE SLEEP APNEA USING OVERNIGHT - POLYSOMNOGRAPHY IN PATIENTS WITH IDIOPATHIC INTRACRANIAL HYPERTENSION

Vaishali Sharma1, Kamalesh Chakravarty2, Sucharita Ray3, Vivek Lal2, Aastha Takkar4, Parampreet Kharbanda5
1POSTGRADUATE INSTITUTE OF MEDICAL EDUCATION AND RESEARCH, Neurology, Chandigarh, India, 2Postgraduate Institute of Medical Education and Research (PGIMER), Neurology, Chandigarh, India, 3PGIMER, Chandigarh, Neurology, Chandigarh, India, 4PGIMER, Neurology, Chandigarh, India, 5PGIMER, Neurology, Chandigarh, India

Background and Aims:: Background: Patients with idiopathic intracranial hypertension (IIH) frequently have co-existent obstructive sleep apnea (OSA). It has been postulated that OSA, which causes apnea and hypopnea might be a contributing factor for the increased intracranial pressure, thereby contributing to IIH. We aimed to assess the prevalence of OSA among patients of IIH and evaluate its influence on the severity of IIH. Aims: To assess the prevalence of obstructive sleep apnea (OSA) among patients of Idiopathic Intracranial hypertension using overnight polysomnography (PSG) and evaluate its influence on the severity of IIH.

Methods:: In this case-control study, 18 cases of IIH and 12 controls were enrolled. Baseline clinical characteristics were noted. Assessment of different sleep abnormalities was done with different questionnaires e.g Berlin questionnaire for OSA, Pittsburgh Sleep Quality Index (PSQI) for overall sleep quality, Insomnia Severity Index (ISI) for Insomnia and RLS rating scale and PSG.

Results:: The mean age of IIH patients was 36.2 ± 10.9 years. 94.4% were female. The mean CSF pressure of cases was 33.25 ± 5.8mm H2O. A high risk of OSA was observed in 55.5% of cases and 33.3% of controls. Overnight PSG was conducted on 12 cases and 6 controls. 50% of cases had no OSA, 33.3% mild OSA, and 16.6% moderate OSA in comparison to 66.6%, 33.3%, and 0% in the control arm. IIH patients had poorer sleep quality (PSQI>5) and more RLS score in comparison to healthy controls.

Conclusions:: There was a higher prevalence of OSA in patients with IIH in comparison to healthy controls.
FEATURES OF A HEADACHE AFTER COVID-19 IN PATIENTS WITH PRIMARY HEADACHES

Nataliya Bozhenko, Myroslav Bozhenko
Danylo Halytsky Lviv National Medical University, Neurology, Lviv, Ukraine

Background and Aims:: The COVID-19 pandemic had a general adverse effect on patients with primary headaches. Both the COVID-19 and the psycho-emotional and social factors that accompany the pandemic affected the characteristics and course of primary headaches in many patients.

Methods:: Analysis of clinical cases of 38 patients with post-COVID syndrome and primary headache in anamnesis who were examined and treated by neurologists at the Delta Med medical center in 2020-2021.

Results:: During the acute phase of COVID-19, among the examined patients, 27 had a headache which was different from regular. 15 patients had a history of migraine, 23 had a history of tension-type headache before COVID-19. After COVID-19 most of the patients with migraine noted more frequent and intense attacks, 2 developed status migrainosus, in 46.7% of patients migraine transformed into chronic. Patients with TTH in most of the cases also noted an increase in both frequency and intensity of headache, but in addition, in some patients the headache pattern changed, there were signs of neuropathic component of pain, confirmed by Pain Detect. More frequent attacks led to excessive drug use. Out of 38 patients, 7(18.42%) were diagnosed with medication overuse headache in the structure of the post-COVID syndrome. 5 patients with migraine had small foci of gliosis on MRI.

Conclusions:: Most patients experience an increase in the frequency and severity of headache after COVID-19, and some patients show signs of neuropathic pain. Some of the patients engaged in self-medication and abused analgesics, which in combination with treatment of COVID-19 led to medication overuse headache.
FREMANEZUMAB IMPROVES QUALITY OF LIFE IN PATIENTS WITH HIGH- AND MODERATE-FREQUENCY EPISODIC MIGRAINE

Xiaoping Ning, Verena Ramirez Campos, Steve Barash, Joshua Cohen
Teva Branded Pharmaceutical Products R&D, Inc., Global Medical Affairs, West Chester, United States of America

Background and Aims:: Patients with migraine may experience increasing disease burden as migraine frequency increases. This pooled analysis evaluated quality-of-life and disability outcomes with fremanezumab, a fully-humanized monoclonal antibody (IgG2Δa) that selectively targets calcitonin gene-related peptide (CGRP), in patients with high-frequency episodic migraine (HFEM; 10-14 days/month) or moderate-frequency episodic migraine (MFEM; 4-9 days/month) from 2 double-blind phase 3 studies (HALO EM and FOCUS).

Methods:: In HALO EM and FOCUS (patients with inadequate response to 2-4 prior preventive treatment classes), patients were randomized 1:1:1 to quarterly fremanezumab, monthly fremanezumab, or placebo. Changes from baseline in Migraine-Specific Quality of Life (MSQoL) and Migraine Disability Assessment (MIDAS) scores were assessed in HFEM and MFEM subgroups during the 4 weeks after third study drug dose.

Results:: Analyses included 659 patients with MFEM and 515 with HFEM. Least-squares mean changes from baseline in MSQoL role-function restrictive scores were significantly greater with both fremanezumab dosing regimens versus placebo in MFEM (quarterly, 20.6; monthly, 21.7; placebo, 13.7; P<0.0001) and HFEM (quarterly, 17.2; monthly, 21.4; placebo, 13.1; P≤0.0343) subgroups, as were changes in role-function preventive (RFP) and emotional function (EF) scores for MFEM subgroup (both regimens; P≤0.0009) and changes in RFP (monthly dosing; P=0.0002) and EF scores (both regimens; P≤0.0498) for HFEM subgroup. Reductions from baseline in MIDAS scores were also greater with fremanezumab versus placebo (MFEM: quarterly, −23.5; monthly, −23.2; placebo, −16.0; P<0.0001; HFEM: quarterly, −23.3; monthly, −27.9; placebo, −16.7; P≤0.0150).

Conclusions:: Quality-of-life and disability were improved with fremanezumab versus placebo in patients with MFEM or HFEM.
LONG-TERM (>48 WEEKS) SAFETY AND TOLERABILITY OF ERENUMAB IN REAL-LIFE.

Mater Domini, Center For Headache And Intracranial Pressure Disorders, Neurology Unit, Catanzaro, Italy, 9Fondazione IRCCS Istituto Neurologico Carlo Besta, Neuroalgology Unit, Milan, Italy, 10Headache and Neurosonology Unit, Neurology Unit, Campus Bio-medico University Of Rome, Rome, Italy, 11ASST Santi Paolo Carlo, Headache Center, Milan, Italy, 12AOSG Moscati, Headache Center, Avellino, Italy, 13Cardinal Massaia Hospital, Headache Center, Asti, Italy, 14San Martino Hospital, Headache Center, Genova, Italy, 15San Camillo Hospital, Headache Center, Rome, Italy, 16San Carlo Hospital, Headache Center, Potenza, Italy

Background and Aims:: Background: Erenumab proved to be safe and well tolerated in a 5-year continuation of a 1-year double-blind, placebo-controlled study. Aim: to assess >48-week erenumab tolerability and safety in a real-world setting.

Methods:: In this long term (>48-week), multicenter (n=15), longitudinal cohort real life study, we monitored all the adverse events emerged in consecutive adult patients with high-frequency episodic migraine (HFEM) or chronic migraine (CM) treated with monthly erenumab 70 mg or 140 mg from 20 December 2018 to 15 December 2020.

Results:: 442 patients (HFEM: 115; CM: 327) were treated with erenumab for >48 weeks: 209 (47.3%) patients were treated for 49-60 weeks, 132 (29.9%) for 61-72 weeks; 73 (16.5%) for 73-84 weeks; 21 (4.7%) for 85-100 weeks. Overall, >1 treatment emergent adverse event (TEAE) was reported by 136 (30.8%) [HFEM: 43 (37.4%); CM: 93 (28.4%)]. Most common TEAE were constipation (n =66; 14.9 %), injection site erythema (n =15; 3.4%), and influenza (n =7; 1.6%). Serious adverse events (SAE) were reported by 8 patients (1.8%) and led to treatment discontinuation: severe constipation (n=3), abdominal pain (n=1), NSTEMI (n=3), Covid-19 infection (n=1). Only severe constipation was considered treatment-related SAE (0.45%).

Conclusions:: Conclusion: Erenumab is safe and well tolerated also in long-term treatment (>48 weeks) in real life.
THE RARE COEXISTENCE OF TRIGEMINAL AUTONOMIC CEPHALALGIA (TAC) WITH TRIGEMINAL NEURALGIA (TIC DOLOROUX) IN THE SAME PATIENT: TAC-TIC HEADACHES - A CASE SERIES

Pubudu Amarasena1, Mary Muthukumarasamy2, Amila Chandrakumara2, Bimsara Senanayake1
1National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka, 2National Hospital of Sri Lanka, Department Of Radiology, Colombo, Sri Lanka

Background and Aims:: The occurrence of Trigeminal Neuralgia, also known as tic-doloroux (Tic), and TAC headaches ipsilaterally in the same patient is rare. We describe a series of Sri Lankan patients with TAC-tics with an emphasis on clinical significance, pathophysiological conjectures and a literature review.

Methods:: Four patients having TAC-tic combination were evaluated using clinical history and brain MRI.

Results:: Two males had CH-tic and CPH-tic respectively whilst one female had CPH-tic & the other had probable CPH-tic. Male with CPH-tic initially had Tics involving all 3 branches of trigeminal nerve, followed by CPH 5 months later, whereas other 3 patients developed V1 Tics and TAC headaches simultaneously. CH-tic patient had Tics for about 3 days prior to a bout of CH, around the same time of the day as CH attacks, while others had both types of headaches occurring simultaneously as well as separately. MRI brain with CISS sequence demonstrated stretching of ipsilateral trigeminal nerve by vascular loops in all except CH-tic patient, who had a vascular loop near the trigeminal nerve without impingement. All patients had satisfactory response to combination treatment targeting both TACs and Tics.

Conclusions:: Strictly unilateral nature, overlapping clinical features, the combination of ipsilateral TACs and Tics in the same patient and the finding of trigeminal neuro-vascular conflict in our patients as well as in the available literature raises the possibility of a common structural aetiology for TACs and Tics. Further studies involving TACs, Tics and TAC-tic combinations with dedicated trigeminal nerve imaging would be beneficial to further evaluate this phenomenon.
SYMPTOMATIC CLUSTER-TIC SYNDROME DUE TO A MENINGIOMA

Pubudu Amarasena¹, Mary Muthukumarasamy², Amila Chandrakumara², Bimsara Senanayake¹
¹National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka, ²National Hospital of Sri Lanka, Department Of Radiology, Colombo, Sri Lanka

Background and Aims:: The combination of TAC headaches with trigeminal neuralgia (tic-doloroux) is a rare occurrence. Several cases have been reported, including from Sri Lanka. Some were symptomatic TAC-tics, whilst a definite cause was not identified in others.

Methods:: We report a case of a Sri Lankan female with cluster-tic attacks, occurring symptomatically due to a meningioma.

Results:: A 52-year-old female presented with right side-locked headaches for 6 years. She had 1-2 very severe attacks lasting about 20 minutes every day, associated with agitation and ipsilateral cranial autonomic symptoms. Acute attacks showed significant improvement with high-flow oxygen. She developed comparatively less severe, brief, shock-like, stabbing pain in the right periorbital region 8 months prior to presentation, occurring in bouts lasting about 15 minutes a day, without autonomic symptoms or cutaneous triggers. Two types of pains occurred simultaneously as well as sequentially. Different combinations of preventive medication failed to reduce the frequency of both types of attacks. Brain MRI with gadolinium enhancement showed a meningioma along the lateral wall of cavernous sinus with impingement of right trigeminal nerve. Patient underwent surgical excision of the meningioma, with significant improvement of symptoms.

Conclusions:: This patient had features of chronic cluster headache and right-sided probable trigeminal neuralgia, attributable to the meningioma. Available literature has descriptions of many cases with this combination, and some of these were due to structural causes such as pituitary adenoma, demyelination plaques, arachnoid cysts and vascular loops. An extensive search for an underlying structural lesion should be done in all patients with TAC-Tics and isolated TACs.
EFFICACY AND IMPROVEMENTS IN DISABILITY AND QUALITY-OF-LIFE WITH FREMANEZUMAB OVER 6 MONTHS IN MIGRAINE PATIENTS WITH INADEQUATE RESPONSE BY MULTIPLE PRIOR PREVENTIVE TREATMENT CLASSES

Carrie Dougherty¹, Jessica Ailani¹, Verena Ramirez Campos², Joshua Cohen², Steve Barash², Maja Galic², Xiaoping Ning², Rashmi Halker Singh³
¹Georgetown University Medical Center, Department Of Neurology, District of Columbia, United States of America, ²Teva Branded Pharmaceutical Products R&D, Inc., Global Medical Affairs, West Chester, United States of America, ³Mayo Clinic, Department Of Neurology, Phoenix, United States of America

Background and Aims:: Fremanezumab, a fully humanized monoclonal antibody (IgG2Δa) that selectively targets calcitonin gene-related peptide (CGRP), has demonstrated efficacy in patients with chronic and episodic migraine (CM and EM) and documented prior inadequate response by 2-4 classes of migraine preventive medication in the 12-week randomized, double-blind (DB), placebo-controlled period (DBP) of the phase 3b FOCUS study. Efficacy, disability, and health-related quality of life (HRQoL) were evaluated during the DBP and subsequent 12-week open-label extension (OLE) in patients reverting from CM (≥15 headache days [HD] before DBP) to EM (<15 HD at Months 1, 2, and 3 [DBP] or Months 4, 5, and 6 [OLE]).

Methods:: During the DBP, patients were randomized (1:1:1) to quarterly fremanezumab, monthly fremanezumab, or placebo. Patients completing the DBP entered the OLE, and all patients received 3 monthly doses of fremanezumab. Outcomes are summarized by DB randomization group.

Results:: Overall, 136 patients reverted from CM at baseline to EM during the DBP; 206 patients reverted during the OLE. Reductions from baseline in monthly migraine days, monthly headache days, and disability scores (6-item Headache Impact Test and Migraine Disability Assessment) achieved during the DBP were generally maintained or increased during the OLE, as were improvements in HRQoL, based on Migraine-specific Quality of Life domain scores (Table).

Conclusions:: Migraine patients with inadequate response by multiple prior migraine preventive medication classes who reverted from CM to EM achieved sustained, clinically meaningful reductions in migraine and headache days and improvements in disability and HRQoL over 6
Table. Efficacy, Disability, and HRQoL Outcomes in Patients Reverting from CM to EM

HEADACHE IN PATIENTS WITH COVID-19

Alexandr Barulin¹, Olga Kurushina², Anna Drushlyakova¹
¹Volgograd State Medical University, Neurology, Psychiatry, Manual Medicine And Medical Rehabilitation, Volgograd, Russian Federation, ²Volgograd State Medical University, Neurology, Neurosurgery, Medical Genetics, Volgograd, Russian Federation

Background and Aims: Aims: To study cephalic manifestations in individuals who have undergone COVID-19 to determine the frequency of occurrence and to assess the relationship of cephalgia with a new coronavirus infection.

Methods: There was developed a questionnaire that included points about the characteristics of cephalgia in this disease. Possible changes in the picture of headache during the pandemic, in people suffering from it earlier, were studied, as well as the characteristics of the newly identified headache and the alleged factors contributing to the development of headache.

Results: A total of 510 participants with a diagnosis of Covid-19 took part in the survey. Among the survey participants, 40.6% report headache as one of the main symptoms of Covid-19. 67.6% had a headache for the first time, 32.4% had it before. 33.8% – with a hypoxic state (a decrease in the level of saturation), 16.4% with taking medications, 5.4% believe that headaches occurred against the background of an asthenodepressive state in conditions of forced restrictions and self-isolation. The vast majority of patients with Covid-19- 72% reported that the headaches that occurred during the infection were different. The respondents rated the intensity of headache before COVID-19 on the VAS scale by 4.2±3.1 points, during the disease by 6.3±3.2. Among the survey participants, there were also those who had headaches during the exacerbation of Covid-19 that were identical to previously existing episodes.

Conclusions: During a new coronavirus infection, both the appearance of a newly identified headache and a change in the existing one are observed.
REAL LIFE EXPERIENCE OF ONE YEAR TREATMENT WITH GALCANEZUMAB IN CHRONIC MIGRAINE WITH AND WITHOUT MEDICATION OVERUSE HEADACHE

Gloria Vaghi¹,², Vito Bitetto¹,², Roberto De Icco¹,², Elena Guaschino¹, Marta Allena¹, Cristina Tassorelli¹,², Grazia Sances¹
¹IRCCS Mondino Foundation, Headache Science & Neurorehabilitation Center, Pavia, Italy, ²University of Pavia, Department Of Brain And Behavioral Sciences, Pavia, Italy

Background and Aims: To present real-life data regarding Galcanezumab in patients with chronic migraine (CM) and medication overuse headache (MOH) and to assess its one-year effectiveness.

Methods: We analyzed 26 patients (F22, M4, mean age: 53, migraine history: 38yrs) who failed at least 3 preventive therapies. Galcanezumab was administered monthly for 12 treatments (T1 through T12) with a loading dose of 240 mg and maintenance dose of 120mg. Two patients interrupted treatment for inefficacy at T7 and T9. We collected clinical data on headache features (diary), disability and allodynia (standardized questionnaires) at baseline and quarterly.

Results: Patients with a pattern reversal from chronic to episodic migraine (i.e.>50% responders) were 42% at T1, rising to 62% at T12. Super-responders (i.e.>75% responders) were 8% at T1, 21% at T12. All clinical parameters showed a significant improvement already at T1 and persisted over one-year treatment (Fig.1). An improvement in MIDAS and HIT-6 scores was detected from T3 (p<0.001), while allodynia intensity decreased significantly from T12 (p=0.03) (Fig.2). Only mild side effects were reported by 33% of patients (constipation, cutaneous reactions and fatigue).

Fig1 – Panel A Percentage of patients who experienced a pattern reversal from chronic to episodic (p <0.01 for all time points). Panel B Reduction in monthly total headache days and monthly acute medication doses and days of intake. Monthly headache days: T1-T3-T6-T9-T12 vs baseline p<0.01; monthly acute medication doses: T1-T3-T6-T9-T12 vs baseline p<0.02; monthly days of drug intake T1-T3-T6-T9-T12 vs baseline p<0.001. ANOVA for repeated measures and post-hoc test
Conclusions:: Galcanezumab is related to a high percentage of pattern reversal in difficult-to-treat patients, showing a significant improvement in clinical features already during the 1st month of treatment and in headache-related disability after a few months. Moreover, efficacy is maintained over the long-term showing a positive tolerability profile.
THE RELATIONSHIP BETWEEN DEPRESSION AND MIGRAINE IN PATIENTS TREATED AT THE NPZR

Elif Cindik-Herbrüggen, Rahman Demirkol
NPZR- Neuro-Psychiatric Center Riem (Neuro-Psychiatrisches Zentrum Riem),
Psychosomatik/psychotherapie, Munich, Germany

Background and Aims:: Data from a cross-sectional study revealed a higher prevalence of chronic headache as well as a very low utilization of adequate medical care in first-generation Turkish immigrants in Germany¹. Depending on the study the prevalence of migraine in Germany in women is reported between 15% and 23% and in men between 4% and 11%². Research shows a high correlation between migraine and psychiatric diseases. Especially the prevalence of depression (OR 2.2) is significantly higher³. A proper treatment of mental disorders is vital for a successful outcome of migraine therapies. The purpose of this research was to investigate the occurrence of depression among Turkish patients with migraine and to find a possible correlation between demographic characteristics.

Methods:: This study has determined the level of depression among Turkish patients with migraine (n=154, treated between 2015-2021).

Results:: The results show that severe depression was present in 75% of Turkish patients. Female patients showed higher rates of depression in comparison to male patients but there were no significant gender and severity of depression differences. Employment and income status were the significant factors in Turkish patients with migraine. Severe depression was more common among unemployed (p<.001) and low-income status (p<.001) migraine patients.

Conclusions:: The results of this ongoing research show no significant gender variation but differences in demographic characteristics such as income and employment status and disease severity, which could add more insight into the therapy of migraine. 1 (Kavuk, et al., 2006), 2 (RKI Headache Report 2020), 3 (Gaul & Hans, 2016).
PROGRESSIVE IMPROVEMENTS IN EFFICACY AND DISABILITY WITH FREMANEZUMAB IN PATIENTS WITH MEDICATION OVERUSE AND INADEQUATE RESPONSE TO MULTIPLE MIGRAINE PREVENTIVE MEDICATION CLASSES

Egilius Spierings¹, Verena Ramirez Campos², Steve Barash², Lynda Krasenbaum², Joshua Cohen²
¹Boston Headache Institute, Boston Paincare, Waltham, United States of America, ²Teva Branded Pharmaceutical Products R&D, Inc., Global Medical Affairs, West Chester, United States of America

Background and Aims:: Fremanezumab, a fully humanized monoclonal antibody (IgG2Δa) that selectively targets calcitonin gene-related peptide (CGRP), has demonstrated efficacy for migraine prevention in patients with episodic or chronic migraine (EM or CM) with documented inadequate response to 2–4 classes of prior preventive migraine medications in the phase 3b FOCUS study. This subgroup analysis evaluated the efficacy of fremanezumab in patients with baseline medication overuse (simple analgesics ≥15 days/month of triptans, ergots, barbiturate- or opioid-containing analgesics ≥10 days/month).

Methods:: In the double-blind (DB) period (DBP) of the FOCUS study, patients were randomized (1:1:1) to quarterly fremanezumab (675 mg subcutaneous [SC]), monthly fremanezumab (225 mg SC), or matched monthly placebo. For the open-label extension (OLE), all patients received monthly fremanezumab (225 mg SC). Results from the OLE were stratified by DB randomization group. Assessments included change from baseline in monthly average number of migraine days (MMDs), and disability scores (6-item Headache Impact Test [HIT-6] and Migraine Disability Assessment [MIDAS]).

Results:: During the DBP, for patients with medication overuse (427/838), fremanezumab treatment resulted in significant least-squares mean reductions in MMDs versus placebo (quarterly fremanezumab, −3.2; monthly fremanezumab, −4.4 vs placebo, −0.4; P≤0.0002), which increased during the OLE (mean: quarterly fremanezumab, −5.1; monthly fremanezumab, −6.0; placebo, −5.8). Significant improvements in HIT-6 and MIDAS scores versus placebo were also observed during the DBP (P≤0.0239); reductions increased through the OLE.

Conclusions:: Quarterly and monthly fremanezumab treatment demonstrated increasing efficacy and reductions in disability in patients with difficult-to-treat migraine and headache medication overuse.
REVERSION FROM MEDICATION OVERUSE WITH FREMANEZUMAB TREATMENT IN PATIENTS WITH INADEQUATE RESPONSE TO MULTIPLE MIGRAINE PREVENTIVE MEDICATION CLASSES

Sait Ashina¹, Verena Ramirez Campos², Joshua Cohen², Lindsay Janka², Lynda J. Krasenbaum²
¹Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States of America, ²Teva Branded Pharmaceutical Products R&D, Inc., Global Medical Affairs, West Chester, United States of America

Background and Aims:: Fremanezumab, a fully humanized monoclonal antibody (IgG2Δa) that selectively targets calcitonin gene-related peptide (CGRP), has demonstrated efficacy for migraine prevention in patients with documented inadequate response to 2–4 prior preventive medication classes in the phase 3b FOCUS study. The aim of this subgroup analysis was to evaluate reductions in acute medication use in patients treated with fremanezumab with baseline medication overuse (MO; any acute medication ≥15 days/month or triptans, ergots, or combination medications ≥10 days/month).

Methods:: In the double-blind (DB) period (DBP) of FOCUS, patients were randomized (1:1:1) to quarterly fremanezumab, monthly fremanezumab, or placebo. All patients completing the DBP entered the open-label extension (OLE) and received monthly fremanezumab; results from OLE are stratified by DB randomization group. Changes from baseline in monthly average days of acute medication use and proportions of patients reverting to no MO were evaluated.

Results:: Among patients with MO (427/838), significant reductions in acute medication use were observed with quarterly (least squares mean change, −3.8) or monthly (−4.7) fremanezumab during the DBP, compared to placebo (−0.7; P<0.0001); reductions increased in the OLE (quarterly fremanezumab, −6.1; monthly fremanezumab, −6.9; placebo, −5.0). A greater proportion of patients reverted to no MO with quarterly and monthly fremanezumab, respectively, during the DBP versus placebo (39% and 42% vs 13%); an even greater proportion reverted during the OLE (quarterly fremanezumab, 48%; monthly fremanezumab, 46%; placebo, 41%).

Conclusions:: For patients with prior inadequate response to multiple preventive migraine medication classes and MO, fremanezumab reduced acute headache MO.
EFFICACY AND TOLERABILITY OF FREMANEZUMAB FOR MIGRAINE PREVENTIVE TREATMENT IN KOREAN PATIENTS WITH CHRONIC OR EPISODIC MIGRAINE

Byung-Kun Kim1, Joshua Cohen2, Sukyung Kim3, Daeho Chang3, Xiaoping Ning2, Tamar Lengil4, Lindsay Janka2, Steve Barash2
1Nowon Eulji Medical Center, -, Seoul, Korea, Republic of, 2Teva Branded Pharmaceutical Products R&D, Inc., Global Medical Affairs, West Chester, United States of America, 3Teva-Handok Pharma Co, Ltd., -, Seoul, Korea, Republic of, 4Teva Pharmaceutical Industries Ltd, -, Petah Tikva, Israel

Background and Aims:: Fremanezumab, a fully humanized monoclonal antibody (IgG2Δa) that selectively targets calcitonin gene-related peptide (CGRP), has demonstrated efficacy in patients with chronic and episodic migraine (CM and EM). Efficacy and tolerability of fremanezumab for migraine preventive treatment in Korean patients with CM and EM have been evaluated in two randomized, double-blind, placebo-controlled phase 2b/3 clinical studies and compared with data from pivotal phase 3 HALO CM and HALO EM studies.

Methods:: The two phase 2b/3 studies had the same design as the pivotal HALO studies; patients were randomized (1:1:1) to quarterly or monthly fremanezumab or matched placebo for 12 weeks. For the CM and EM studies, respectively, primary efficacy endpoints were changes from baseline in monthly headache days of at least moderate severity (MHD) and monthly migraine days (MMD) during the 12-week treatment period.

Results:: For Korean CM (n=89) subgroup, least-squares mean reductions from baseline in MHD over 12 weeks with fremanezumab were comparable to those observed in the overall HALO CM study (Table). For Korean EM subgroup (n=54), least-squares mean reductions from baseline in MMD over 12 weeks with fremanezumab were also comparable to those observed in the overall HALO EM study (Table). Proportions of patients with ≥50% reduction in MHD or MMD was comparable in the Korean subgroups and pivotal studies (Table). No safety signals were identified in Korean subgroups.

Conclusions:: Although numbers of patients in Korean subgroups were small, there were trends in favor of fremanezumab for all endpoints analyzed, and fremanezumab was well tolerated.
ALTERED THALAMO CORTICAL CONNECTIVITY IN EPISODIC MIGRAINE: A RESTING STATE EXPLORATORY FMRI STUDY

Daniele Martinelli1, Gloria Castellazzi2, Roberto De Icco1, Vito Bitetto3, Marta Allena4, Lara Ahmad1, Alessia Putortì1, Maria Pocora1, Grazia Sances4, Anna Pichiecchio5, Cristina Tassorelli1

Of Brain And Behavioral Sciences, Pavia, Italy

Background and Aims:: Migraine is a heterogeneous disorder characterized by an altered sensory processing where the thalamus is known to play a leading role. To further investigate the extent of the specific role of the thalamus in migraine, we used resting-state functional MRI (rs-fMRI) to evaluate the functional connectivity (FC) of the thalamic subnuclei within the pain matrix network during the migraine inter-ictal phase.

Methods:: In this exploratory study we enrolled 10 patients with episodic migraine (EM, 8 female, 44.3±10.6 yrs of age, 11.7±12.0 migraine days/month, MIDAS score 44.4±31.5) and 5 healthy subjects (3 female, 36.2 ±8.7 yrs of age). All subjects underwent a rs-fMRI scan in a pain free condition. Individual pre-processed rs-fMRI data were analysed with a seed-based correlation approach (SCA). All the thalamic subnuclei were chosen as regions of interest. Functional connectivity (FC) was calculated between each seed region and the rest of the pain matrix network, involving the salience network and the brainstem. Resulting maps were statistically compared between groups using a non-parametric permutation test. A statistical threshold of p<0.05 was considered significant.

Results:: Compared to healthy subjects, EM showed reduced FC between the ventral posterior nuclei (VPN) and insula, dorsal pons, prefrontal cortex and posterior cerebellum. Moreover, EM presented increased FC between bilateral pulvinar and the dorsal pons, the prefrontal and the posterior cingulate cortex.
Conclusions: These results suggest that the VPN and pulvinar, which are part of the cerebral functional circuitries implicated in pain processing, are differently orchestrating brain activity between healthy subjects and migraineurs also during the inter-critical phase.
RELATIONSHIP BETWEEN SLEEP DISORDERS AND LIFE-STYLE IN PATIENTS WITH CHRONIC TENSION-TYPE HEADACHE.

Charos Rustamova, Marhamat Yakubova, Nargiza Qarshiboyeva
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: Many epidemiological studies have evaluated on this association in relation to nonspecific headache, whereas relatively few epidemiological studies have focused on the specific diagnosis of tension-type headache (TTH) which is associated with sleep disorders and bad quality of life. This study is aimed to assess the prevalence and impact of sleep disturbances and its associations with life-style including work, social functioning and well-being in TTH patients.

Methods:: We examined 80 patients (men-36, 45%; women - 44, 55%) aged from 20 to 58 years in TTH patients at the Tashkent Medical Academy in neurology department. The Pittsburgh questionnaire was used for determining the quality of sleep index (PSQI). Headache-related life-style was measured using the following scales: Medical Outcomes Study Short Form, Disability Days/Impairment Ratings, The Hassles Scale Short Form.

Results:: On the Pittsburgh scale, various sleep disorders were observed in 65 patients (81%) of cases from 1 to 5 times a week in relation to the duration of sleep, daytime dysfunction, and subjective sleep quality (p<0.005). Poor sleep quality (higher PSQI components 22-29 points) were observed in patients with TTH. Significant impairments in functioning and well-being were evident in chronic tension-type headache and were captured by each of the assessment devices. Headache-related disability days were reported by 84% of patients (p<0.0001), work or social functioning was severely impaired in 58% of patients (p<0.005). Concerning sleep quality, the greater sleep scores were the worse life-style would be.

Conclusions:: The presence of association of headache and sleep disorders was found and it impacts negatively on patient's life-style. A close attention to sleep problems among patients with headache may have implication for the choice of treatment and the prognosis, possibly preventing chronicification of headache disorder and worse quality of life.
FREMANEZUMAB IMPROVES QUALITY OF LIFE IN PATIENTS WITH HIGHER- AND LOWER-FREQUENCY CHRONIC MIGRAINE

Trupti Gokani¹, Xiaoping Ning², Verena Ramirez Campos², Steve Bara², Joshua Cohen², Patricia Pozo Rosich³
¹Zira Mind and Body Center, Glenview, United States of America, ²Teva Branded Pharmaceutical Products R&D, Inc., Global Medical Affairs, West Chester, United States of America, ³Headache Unit, Neurology Department, Vall d’Hebron University Hospital, Barcelona, and Headache and Neurological Pain Research Group, Vall d’Hebron Institute of Research (VHIR), Universitat Autònoma de Barcelona, -, Barcelona, Spain

Background and Aims:: Patients with migraine may experience increased disease burden as migraine frequency increases. Fremanezumab, a fully-humanized monoclonal antibody (IgG2Δa) that selectively targets calcitonin gene-related peptide (CGRP), has been shown to have significant effectiveness for migraine prevention. This pooled analysis assessed disability and quality-of-life (QoL) outcomes in patients with higher-frequency chronic migraine (HFCM; ≥19 monthly migraine days [MMDs]) or lower-frequency chronic migraine (LFCM; 15-18 MMDs) treated with fremanezumab from 2 double-blind phase 3 trials.

Methods:: In HALO CM and FOCUS, patients were randomized 1:1:1 to receive quarterly fremanezumab, monthly fremanezumab, or placebo. QoL and disability outcomes were assessed during the 4 weeks after the third dose of study drug by change from baseline in Migraine-Specific Quality of Life (MSQoL) domain scores and 6-Item Headache Impact Test (HIT-6) scores, respectively.

Results:: These analyses included 500 patients with HFCM and 511 with LFCM. Least-squares mean changes from baseline in MSQoL role-function restrictive scores were significantly greater with fremanezumab versus placebo in HFCM (quarterly, 16.2; monthly, 15.9; placebo, 8.1; $P\leq0.0006$) and LFCM (quarterly, 19.8; monthly, 20.6; placebo, 14.2; $P\leq0.0083$) subgroups, as were changes in role-function preventive (RFP) and emotional function scores for LFCM subgroup (both regimens; $P\leq0.0434$) and changes in RFP (both regimens; $P\leq0.0170$) for HFCM subgroup. Reductions from baseline in HIT-6 scores were significantly greater with fremanezumab (HFCM: quarterly, −4.5; monthly, −5.0; placebo, −3.3; monthly, $P=0.0169$; LFCM: quarterly, −5.6; monthly, −6.2; placebo, −3.8; both $P\leq0.0108$).

Conclusions:: QoL and disability were improved with fremanezumab versus placebo in patients with LFCM and HFCM.
Background and Aims:: White matter hyperintensity (WMH) in migraine could be related to inflammatory and antioxidant events. The aim is to verify whether migraine patients with WHM carry a genetic pro-inflammatory/pro-oxidative status.

Methods:: We compared lymphotoxin alpha (LTA) and superoxide dismutase1 (SOD1) and 2 (SOD2) gene polymorphisms (SNPs) in patients affected by episodic (EM) and chronic (CM) migraine and in unrelated healthy controls, and in migraine patients with (WMH+) and without WMH (WMH-) at brain magnetic resonance imaging (MRI).

Results:: We studied LTA, SOD1 and SOD2 polymorphisms in 370 consecutive patients (EM: 251; CM: 119) and in 100 controls. Brain MRIs were available in 183/370 patients (49.5%). Genotypes and allele frequencies did not differ between patients and controls. A strong linkage disequilibrium emerged between the two LTA (D'= 0.96, r= 0.29), but not among LTA and SOD1/SOD2 SNPs. The CAAC haplotype showed a significant trend toward a protective effect in migraine [OR= 0.49 (95% C.I.: 0.25–0.98), p=0.044]. No association was found between single SNPs or haplotypes and sex, migraine type, cardiovascular risk factors or disorders. The rs2071590T and the rs2234694C alleles were both associated with WMH (OR= 2.2; p=0.034; OR= 4.9; p=0.003). A four-loci haplotype (TGCT haplotype: rs2071590T/rs2844482G/rs2234694C/rs4880T) was significantly more frequent in WMH+ compared to WMH- (OR=8.7, p=0.009), being present in 7/38 (18.4%) WMH+ patients compared to 4/134 (3.0%) WMH- (p=0.003).

Conclusions:: A TGCT haplotype is independently associated with an increased WMH risk, suggesting that WMH could arise from an imbalance between migraine-related inflammatory/oxidative events and specific LTA and SOD1/SOD2 genotypes.
REAL-LIFE ASSESSMENT OF ERENUMAB DISCONTINUATION FOLLOWING ONE YEAR OF TREATMENT IN MIGRAINE PATIENTS

Eleonora Matteo, Davide Mascarella, Umberto Pensato, Agnese Turrini, Valentina Favoni, Giulia Pierangeli, Pietro Cortelli, Sabina Cevoli
IRCCS - Istituto delle Scienze Neurologiche di Bologna, Dibinem, Bologna, Italy

Background and Aims: Monoclonal antibodies (mAbs) against CGRP are first-in-class drugs for migraine prevention, yet studies on treatment discontinuation are currently lacking. Real-life data are warranted to create up-to-date guidelines on migraine prevention with mAbs.

Methods: We prospectively recruited migraine patients who stopped erenumab after completion of one-year treatment. We aimed to assess changes in monthly headache days (MHD) and monthly pain medication intake (MPMI) at the last month of therapy (LMT), and, thereafter, at one (M1) and two (M2) months following treatment discontinuation.

Results: Eighty-eight patients were included. At LMT, MHD decreased from 21±6.9 to 10±7.6 (p<0.001), while MPMI decreased from 29±23.6 to 11±6 (p<0.001). MHD and MPMI following erenumab discontinuation were persistently lower compared to baseline, yet higher than LMT (M1: MHD=13±7.6, MPMI=18±15; M2: MHD=14±8; MPMI=19±15.6. p<0.0001). Additionally, compared to LMT, 34% (n=30) and 39% (n=34) of the patients showed a ≥50% worsening of MHD at M1 and at M2, respectively. However, only 10% (n=9) at M1, and 24% (n=21) at M2, of the population study showed a significant MHD worsening compared to baseline.

Conclusions: Erenumab discontinuation following successful one-year treatment tends to worsen migraine frequency, yet without reaching pre-treatment levels. Nonetheless, a subgroup of patients showed scarce persistent benefit after treatment discontinuation. Further studies are needed to assess risk factors for migraine worsening after discontinuation.
EFFICACY OF FREMANEZUMAB IN PATIENTS WITH CHRONIC AND EPISODIC MIGRAINE STRATIFIED BY MIGRAINE FREQUENCY

Stephanie Nahas¹, Xiaoping Ning², Verena Ramirez Campos², Steve Barash², Joshua Cohen², Stephen Silberstein²
¹Thomas Jefferson University, Jefferson Headache Center, Department Of Neurology, Philadelphia, United States of America, ²Teva Branded Pharmaceutical Products R&D, Inc., Global Medical Affairs, West Chester, United States of America

Background and Aims:: Chronic and episodic migraine (CM/EM) can be characterized by frequency: low-frequency (LF), moderate-frequency (MF), or high-frequency (HF). This pooled analysis evaluated efficacy of fremanezumab, a fully humanized monoclonal antibody (IgG2Δα) that selectively targets the calcitonin gene-related peptide (CGRP) pathway, in patients with CM or EM by baseline migraine frequency.

Methods:: Patients from three phase 3 trials (HALO EM, HALO CM, and FOCUS) were randomized 1:1:1 to quarterly fremanezumab, monthly fremanezumab, or placebo for 12 weeks. Changes in monthly average migraine days (MMDs), headache days of at least moderate severity (MHDs), and percentage of patients with a shift down of ≥1 frequency category were evaluated by baseline frequency category.

Results:: At baseline, 659 patients had MFEM (4-9 MMDs); 515, HFEM (10-14 MMDs); 511, LFCM (15-18 MMDs); and 500, HFCM (≥19 MMDs). At 12 weeks, least-squares mean (SE) reductions from baseline in MMDs were significantly greater with fremanezumab versus placebo in patients with MFEM (quarterly, −3.5[0.22]; monthly, −3.4[0.22]; placebo, −1.5[0.21]; P<0.0001), HFEM (quarterly, −4.2[0.35]; monthly, −4.7[0.35]; placebo, −2.8[0.35]; P≤0.0009), LFCM (quarterly, −5.9[0.50]; monthly, −5.9[0.48]; placebo, −3.2[0.51]; P<0.0001), and HFCM (quarterly, −4.6[0.52]; monthly, −5.5[0.52]; placebo, −2.9[0.52]; P≤0.0078). Reductions in MHDs and proportions of patients with ≥50% reduction in MMDs were also significantly greater for fremanezumab versus placebo for all 4 subgroups (P≤0.0007 and P≤0.0464, respectively). Fremanezumab demonstrated increases in percentages of patients with ≥1-frequency category reduction versus placebo across all frequency category subgroups.

Conclusions:: Fremanezumab reduced MMDs, MHDs, and migraine attack frequency in patients with varied baseline migraine frequency.
IMPACT OF CALCITONIN GENE-RELATED PEPTIDE RECEPTOR ANTAGONIST ON QUALITY OF LIFE

Roberto Ferri¹, Marco Iudicello², Manuela Matta², Filippo De Mattei², Fabiana Colucci², Stefania Federica De Mercanti², Marinella Clerico²

¹Patologie Neurologiche Specialistiche, AOU San Luigi Gonzaga, Clinical And Neurological Sciences Department, Orbassano, Italy, ²S.S.D. Patologie Neurologiche Specialistiche, AOU San Luigi Gonzaga, Clinical And Neurological Sciences Department, University Of Torino, Orbassano, Italy

Background and Aims:: Migraine is a neurological condition that can interfere with every aspect of daily life. The calcitonin gene-related peptide receptor (CGRP) antagonists, such as Erenumab, bring a novel therapeutic approach to migraine management. This study aims to evaluate the Quality of Life (QoL) and mood in a sample of patients diagnosed with migraine and prophylactically treated with Erenumab.

Methods:: We offered Erenumab subcutaneously every 28 days to migraine patients, who referred unsatisfactory response to conventional prophylactic treatments. Patients were followed for nine months. Outcome measures, recorded at baseline (T0) and thereafter every 3 months (T1, T2, T3), included evaluation of the number of migraine episode/month, of disability through Migraine Disability Scale (MIDAS), of pain perception with the Visual Analogue Scale (VAS), of QoL with SF-36 questionnaire, and of mood with Back Inventory Depression (BDI) scale II.

Results:: We analyzed 27 patients (23 women), aged 45.33±9.72 years with a disease duration of 32.37±9.20 years. We observed a statistically significant difference from T0 to T3 regarding the number of migraine episodes (24.74±7.14 vs 8.52±8.03, p <0.01), the disability evaluated through MIDAS (32.78±17.32 vs 7.48±10.17, p <0.01), the QoL with SF-36 questionnaire (42.99±15.90 vs 63.11±20.26, p < 0.01) and the mood evaluated through BDI-II (16.04±10.09 vs 9.33±8.04, p <0.01). No significant differences occurred in the pain perception evaluation from T0 to T3 (8.61±0.78 vs 5.67±1.77, p >0.01).

Conclusions:: Erenumab is effective in patients with migraine refractory to conventional prophylactic treatments, as it reduces the frequency of migraine, and increase the QoL and the mood.
Quantitative EEG Recording of a Migraine Attack

Massimo Gangitano¹, Vincenzo Raieli², Antonio Marino³, Filippo Brighina¹
¹University of Palermo, Department Of Biomedicine, Neuroscience And Advanced Diagnostics (bi.n.d.), Palermo, Italy, ²University of Palermo, Child Neuropsychiatry School, Palermo, Italy, ³ARNAS CIVICO, Child Neuropsychiatry Unit -ismep, Palermo, Italy

Background and Aims:: Records of EEG during the post ictal period of migraine attack usually show electrical abnormalities of cortical activity mostly related to unspecific symptoms as drowsiness or hyperventilation. However, patients have abnormal EEG rhythms also during the visual aura with an overall slow activity and variation in power spectral values due to a decreased alpha activity in the posterior leads with an increased theta and delta power in the frontocentral regions mimicking some features of true epileptic patients.

Methods:: We address this issue by showing a case of a 15 years old girl that during an EEG recording, started to complain a visual and sensory aura followed by a severe unilateral pulsating pain. EEG trace was acquired and record was cut it in time blocks of 20 seconds each one and analyzed, block by block, by employing quantitative EEG (qEEG) technique. In each block spectrum frequencies for all cortical area were isolated and compared with a basal recording obtained from the same patient.

Results:: EEG traces were analyzed considering spectrum frequencies and delta, theta and alpha activities were isolated. QEEG showed an increase of slow rhythms during the aura in the posterior leads and a subsequent immediate recovery of fast rhythms in the pain phase recorded in the same locations. Fast rhythms are equally represented in both phases.

Conclusions:: This kind of EEG pattern seems to suggest further possible physiological connections between mechanism of spreading depression and electrical brain activity and may shed new light on pathophysiology of migraine.
SECONDARY EFFICACY OUTCOMES OF TOP-PRO STUDY: A RANDOMIZED DOUBLE-BLIND CONTROLLED TRIAL OF TOPIRAMATE VERSUS PROPRANOLOL FOR PREVENTION OF CHRONIC MIGRAINE

Luv Bansal¹, Debashish Chowdhury¹, Ashish Duggal¹, Debabrata Datta¹, Arun Koul¹, Ankit Mundra¹, Anand Krishnan², Anu Gupta³
¹G B Pant Institute of Postgraduate Medical Education and Research, Neurology, Delhi, India, ²AIIMS, Community Medicine, Delhi, India, ³All India Institute of Medical Sciences, Neurology, Delhi, India

Background and Aims:: We conducted TOP-PRO-study, a double-blind RCT, to know whether propranolol is as efficacious as topiramate for the prevention of CM. In this paper, we report the secondary efficacy outcomes. Primary efficacy outcome showing the non-inferiority of propranolol have been described in another paper.

Methods:: CM patients aged above 18 years and less than 65 years of age, not on any preventive treatment were randomly allocated to receive topiramate (100 mg/day) or propranolol (160 mg/day). Secondary outcomes were mean change per 28 days at the end of 24 weeks compared to baseline in headache days, acute migraine treatment (AMT) days, visual analog scale (VAS) scores, headache impact-6 (HIT-6) scores, migraine specific quality of life (MSQOL) score and achievement of more than 50% reduction in headache days.

Results:: COVID-19 pandemic and lockdown halted the recruitment before the trial reached the planned sample size of 244. Of the 175 randomized patients, 95 (topiramate 46 and propranolol 49) completed the trial. The two groups were matched in terms of age, sex and baseline headache parameters. At the end of 24 weeks, both groups showed similar mean improvements in headache days per 28 days (-7.7 vs -7.8; p=0.928), >50% responder rate (32.6% vs 34.7%), AMT days (-6.7 vs -7.0; p=0.835), VAS score (-1.7 vs -2.2; p=0.355), HIT-6 score (-5.2 vs -7.3; p=0.153), MSQOL score (-5.8 vs -9.3; p=0.098).

Conclusions:: Propranolol was as efficacious as topiramate for the prevention of CM as assessed by multiple secondary outcome parameters. (Academic study: Clinical Trials Registry-India CTRI/2019/05/018997)
ANXIETY-DEPRESSIVE DISORDERS IN WOMEN WITH MIGRAINE.

Nilufar Rashidova, Khanifa Khalimova, Gulnora Rakhmatullaeva, Bakhtigul Holmuratova
Tashkent medical academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: This research examines anxiety and depressive disorders in women with migraine.

Methods:: assessed the emotional sphere, the Spielberger test, the modification of Khanin, Beck Depression Scale Inventory.

Results:: 32 women with migraine were examined (2 groups: migraine without aura - 24 (75%) and migraine with aura - 8 (25%)). The control group consisted of 22 healthy women. Analysis of the emotional sphere showed that increased anxiety and decreased mood were found in 26 (81%) and 6 (19%) patients with migraine, respectively. The average score of reactive anxiety (RA) and personal anxiety (PA) in patients significantly exceeded the indicator of healthy subjects. Moderate or high anxiety was noted in 25 (82%) women, 7 (18%) had normal RA and PA. Depression was observed in 19 (59%) patients, of whom 8 (42%) were moderate and 11 (57%) were severe. It was investigated that in patients with wakefulness migraine at a relatively younger age, sleep disturbances and autonomic disturbances in the interictal period (IP) are less often observed. These patients have relatively low levels of anxiety (RA - 32, PA - 40), depression (14), and satisfactory health in the IP. Patients with sleep migraine are significantly older, characterized by a high frequency of autonomic disorders, the presence of persistent sleep disturbances in the IP, significantly higher (p = 0.02) levels of depression (24 points) and anxiety (RA - 36, PA - 50), which determines significant maladjustment of these patients in the IP.

Conclusions:: Women with migraine are characterized by a severe course of the attack, they are also characterized by a higher level of anxiety and depression.
INTERICTAL FRONTAL LOBE DYSFUNCTIONS IN EPISODIC MIGRAINE: A CLINIC BASED STUDY

Debabrata Datta, Debashish Chowdhury
G B Pant Institute of Post graduate Medical education and Research, Neurology, Delhi, India

Background and Aims:: Episodic migraine (EM) patients often complain of interictal cognitive difficulties. We aimed to study interictal frontal lobe functions in EM patients and compare them with healthy controls without headaches.

Methods:: Consecutive EM patients diagnosed by ICHD-3 were studied. Demographic variables and various headache related parameters were noted. Minimental state examination (MMSE) was used for cognitive screening and frontal assessment battery (FAB) for assessing frontal lobe functions in cases and controls.

Results:: 122 EM patients (mean age: 29.1±8.5 years; 27M: 95F; mean illness duration 57.6±54.3 months) and 122 healthy controls (mean age: 29.1±4.7 years, 28M: 94F) were studied. Mean migraine days were 5.4±2.7 days/month. Mean headache duration was 14.3±14.2 hours. Mean headache severity, headache impact score and headache disability score were 7.0±1.4, 60.3±5.8, 13.1±8.6 respectively. Psychiatry co-morbidities were seen in 48/122 (39.3%) patients and in 25/122 (20.5%) controls (p=0.0021). Mean Epworth Sleepiness score in patients and controls were 3.9±2.1 and 2.9±1.8 respectively (p<0.0001). Mean MMSE score in patients and controls were 27.5 and 27.7 respectively (p=0.53). FAB score was significantly low in EM (14.4±2.0) as compared to healthy controls (16.1±1.3) [p<0.0001]. Components of FAB showed significant differences in lexical fluency (p<0.0001), motor series programming (p=0.0119), conflict (p<0.0001) and go-no-go (p<0.0001). Presence of psychiatric co-morbidities did not have significant impact on FAB.

Conclusions:: EM patients had significant interictal frontal lobe dysfunctions especially involving mental flexibility, motor planning and inhibition & interference control. These deficits may increase their disability and can have a bearing in their quality of life.
GREATER OCCIPITAL NERVE INJECTION IN CLUSTER HEADACHE: WHICH PROTOCOL TO CHOOSE? A COMPARISON STUDY

Gian Maria Asioli1, Elena Merli2, Giacomo Urbinati1, Davide Mascarella1, Valentina Favoni3, Giulia Pierangeli1, Pietro Cortelli1, Sabina Cevoli3
1Alma Mater Studiorum, University of Bologna, Department Of Biomedical And Neuromotor Sciences, Bologna, Italy, 2IRCCS Istituto delle Scienze Neurologiche di Bologna, Neurology And Metropolitan Stroke Center, Bologna, Italy, 3IRCCS Istituto delle Scienze Neurologiche di Bologna, Uoc Clinica Neurologica Rete Metropolitana Neuromet, Bologna, Italy

Background and Aims:: Several Greater Occipital Nerve (GON) injections protocols are described for treatment of cluster headache (CH), and it is uncertain which leads to better results. Aim of this study is to compare two of most widely-accepted GON injections protocols: repeated suboccipital steroid injections and single GON anaesthetic blockade (GONB).

Methods:: We enrolled patients accessed for CH within 7 days from attacks-recrudescence. At first admission, patients received three repeated suboccipital injections (RSI) of slow-release methylprednisolone (srMP) 60mg on alternate-days. In the subsequent recrudescence-period and at least after 6 months, the same population received GONB with srMP 80 mg and lidocaine 40 mg. Primary outcome was the absence of CH-attacks at one-month. Secondary outcome was reduction of at least 50% of daily-attacks.

Results:: Fifteen patients were enrolled: 11 with episodic and 4 with chronic-CH. Nine patients (60%) were attacks free at one month after RSI, and 6 (40%) after GONB (p=0.27). Secondary outcome was reached in 12 patients (80%) after RSI and in 10 (67%) after GONB. Only mild adverse-events (AE) (stiffness/pain) were reported: more common with RSI (53%vs27%). Asked patient preference, 60% choose the RSI due to higher-rate and faster response.

Conclusions:: This is the first study comparing two GON injections protocols in the same CH population. RSI protocol showed a better response than GONB and was preferred by patients, even though the higher incidence of AE. However, no statistical superiority of one treatment was highlighted, and the choice must consider logistic, tolerability and patient preference. Further studies are needed to confirm these preliminary findings.
ASSESSMENT OF QUALITY OF SLEEP AND INSOMNIA IN MIGRAINE PATIENTS: A CLINIC BASED CASE CONTROL STUDY USING CLINICAL TOOLS

Murali Krishna P
GIPMER (GBPANT INSTITUTE OF POST GRADUATE MEDICAL EDUCATION AND RESEARCH), Neurology, NEWDELHI, India

Background and Aims: Migraine patients complain a wide spectrum of sleep disorders. We aimed to assess sleep quality and insomnia in migraine patients by using three clinical tools and compare the diagnostic yield of each.

Methods: Consecutive preventive drug-naive migraine patients diagnosed by ICHD-3 (aged >18 to <65 years) and age and sex-matched non-headache healthy controls were studied. We administered them a screening sleep questionnaire, a standardized 7-day sleep diary and Pittsburgh sleep quality index (PSQI) scale.

Results: Seventy migraine patients (mean age: 33.48 ±10.25 years; 9M: 61F; mean illness duration 64.18 ± 46.60 months) and 35 healthy controls (mean age: 34.14±9.41 years, 6M: 29F) were studied. Greater number of migraineurs demonstrated a poor quality of sleep as compared to healthy controls by the questionnaire method (82.9 % vs 25.7 %), by sleep dairy (62.8 % vs 14.2%) and by PSQI (abnormal global score >5 in 87.1 % vs 2.8 %). Insomnia was reported by 62.9% of migraineurs by the questionnaire method. Sleep dairy recorded 45.7% of migraineurs taking > 30 min of time to fall asleep & 57.4% having total sleep time <6 hours at night. The global PSQI score was significantly higher in migraineurs compared to controls [8.94± 4.00 vs 1.51 ±1.14 (p=<0.0001)]. The component scores of PSQI were also worse among the migraineurs.

Conclusions: Migraineurs had a greater magnitude of poor sleep quality and insomnia as compared to controls. For the detection of poor sleep quality and insomnia, all three instruments performed well; however, PSQI had the highest yield.
Background and Aims:: Estimations are that 60% of women who suffer from migraines experience attacks that are associated with menstruation. Menstrual migraines are typically more debilitating, more painful, and of longer duration. Menstrual migraines are mainly managed by the same pharmacological treatments as non-menstrual migraine, however these treatments are less effective for menstrual migraine attacks. Remote electrical neuromodulation (REN) is a non-pharmacological abortive treatment for migraine headache. The current analysis is the first to explore REN's effectiveness and tolerability in menstrual migraine. The current study evaluated the self-reported effectiveness and tolerability of REN for the acute treatment of menstrual migraine.

Methods:: This was a retrospective, observational survey study. Participants completed a short online survey assessing effectiveness, satisfaction, and tolerability outcomes.

Results:: Ninety-one participants qualified for the analysis, out of which 74.7% (68/91) reported that the treatment was at least moderately effective (moderately effective 37.4%, very effective 26.4%, extremely effective 11.0%). Additionally, 45.1% (41/91) reported satisfaction from remote electrical neuromodulation (slightly satisfied 33%, extremely satisfied 12.1%), while 34.1% were neutral and 20.9% (19/91) were not satisfied. Lastly, 100% of the participants reported that the treatment is at least moderately tolerable (moderately tolerable 8.8%, very tolerable 20.9%, extremely tolerable 70.3%), and 13.2% (12/91) reported mild short-term side effects.

Conclusions:: Remote electrical neuromodulation was reported as effective for menstrual migraine by most participants, and was very well tolerated. Remote electrical neuromodulation may thus provide a safe, non-pharmacological alternative for the acute treatment of menstrual migraine.
GENDER TYPES OF MIGRAINE

Bakhtigul Holmuratova, Nilufar Rashidova
Tashkent medical academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: Background: Migraine is considered mostly a woman’s complaint, even if it affects also men. The gender-related differences of migraine hold clinical relevance too. Differences between men and women in certain reactions, including responses to painful irritation, are largely due not only to the biological characteristics of men and women, but also to the varying degrees of their masculinity and femininity. Aim. The aim of this review was to study gender in patients with migraine and summarize recent findings on this matter.

Methods:: Materials and methods. The gender of 84 patients with migraine was determined using Sandra Bem survey; the clinical picture was assessed by headache diary

Results:: Results. The examined women were dominated by feminine types of gender: 34 people belonged to the androgynous type and 36 - to the feminine type. Among the masculine types of gender, the undifferentiated gender was found only in 10 patients, and masculine - only in 4. When assessing the percentage of gender types in patients with migraine men and women, the following gender characteristics were established: men were relatively more likely to belong to the gender of the undifferentiated type (21.9 %) and less often - androgynous (34.4%), in women the shares of these types were 5.8 and 44.2%, respectively.

Conclusions:: Conclusions. The most severe clinical course was typical for patients with undifferentiated gender characteristics. The most favorable clinical course was observed in the group of androgynous patients with migraine
THE ASSESSMENT OF THE SEVERITY OF HEADACHES CAUSED BY TEMPOROMANDIBULAR DISORDER. A DESCRIPTIVE ANALYSIS FROM THE MON-TIMELINE STUDY

Munkhtsetseg Otgonbayar¹, Puntsagdulam Byambajav¹, Oyuntugs Byambasukh², Tsolmon Jadamba³, Byambasuren Dagvajantsan¹
¹Mongolian National University of Medical Sciences, Department Of Neurology, Ulaanbaatar, Mongolia, ²Mongolian National University of Medical Sciences, Department Of Endocrinology, School Of Medicine, ulaanbaatar, Mongolia, ³Mongolian National University of Medical Sciences, Montime Research Center, ulaanbaatar, Mongolia

Background and Aims:: Temporomandibular disorders (TMD) are associated with various types of headaches; not only contributing to their development, also affecting their frequency and intensity. Headaches are one of the most common conditions affecting the general population. We studied the association between temporomandibular joint (TMJ) symptoms as the indication of TMD and headaches, in order to determine whether TMD are associated with headaches.

Methods:: This study is based on sub-samples of individuals residing in Ulaanbaatar from the Mon-TimeLine nationwide survey data. A total of 1087 participants, aged 13-65, were randomly selected. The temporomandibular characteristics were evaluated by professional orthodontists via a medical examination and a questionnaire. The headache assessment was undertaken by a neurologist via face-to-face interviews with the participants.

Results:: TMJ pain, TMJ sound, masticatory muscle pain (MMP), and difficulty during mouth opening (DDMO) were 13.7%, 28.4%, 11.8%, and 3.5%, respectively. In the sample population, the prevalence of headaches was 61.8% (n=672). Headache, whether defined as once a week or more or as moderate, severe, was significantly related to TMD pain. Severe headache showed stronger associations with TMD than between moderate and mild headache.

Conclusions:: In terms of headache characteristics, people with TMJ pain and MMP, the headaches were localized to the temporal region, and the pain level was stronger when compared to people without TMJ symptoms. In conclusion, headache appears to independently and highly associated with TMD pain in adults. Therefore, our study reveals the needs for further investigations, especially in people with TMD, to fully elucidate the problem of TMD management in Mongolia.
NEW DAILY PERSISTENT HEADACHE AFTER SARS-COV-2 INFECTION: A CASE SERIES

Stefano Consoli, Fedele Dono, Giacomo Evangelista, Dario Calisi, Matteo De Rosa, Laura Bonanni, Marco Onofrj
"G. D'Annunzio" University of Chieti-Pescara, Department Of Neuroscience, Imaging And Clinical Science, Chieti, Italy

Background and Aims:: The 2019 Coronavirus (SARS-CoV-2) is a novel respiratory virus which causes Coronavirus Disease 19 (COVID-19). Although the predominant clinical picture of COVID-19 is represented by respiratory symptoms, neurological manifestations are being increasingly recognized. Headache, in particular migraine-like and tension types, has been largely reported in patients suffering from COVID-19 both in the acute and the healing phase of the infection. New Daily Persistent Headache (NDPH) is a primary headache characterized by persistent and daily painful symptoms, with pain becoming continuous and non-remitting within 24 hours, and lasting more than 3 months. Even though an increasing number of reports describes patients who develop a persistent headache, diagnosis of NDPH has been rarely explored in the context of COVID-19.

Methods:: Two patients with persistent headache and Sars-CoV-2 infection were identified. Both underwent a full clinical and neuroradiological evaluation consisted on Computerized Tomography with angiography sequences and Magnetic Resonance of the brain. Blood sample with inflammatory biomarkers search was also performed.

Results:: According to International Classifications of Headache Disorders diagnosis of Probable New Daily Persistent Headache was made. The treatment with high doses of steroids was associated with relief of symptoms.

Conclusions:: Our report described two cases of probable NDPH due to SARS-CoV-2 infection. Clinical evaluation of COVID-19 patients presenting with persistent headache should take into consideration NDPH. Given the supposed major role for neuroinflammation in the genesis of Sars-CoV-2-driven NDPH, immunomodulatory therapy should be promptly started. In line with this hypothesis, we obtained a good therapeutic response to short-term high dose of corticosteroids.
PERIAQUEDUCTAL GRAY MATTER (PAG) IN MIGRAINE: TRANSCRANIAL SONOGRAPHY STUDY

Natascia Ghiotto¹, Elena Guaschino¹, Roberto De Icco², Eleonora Cecconi¹, Cristina Tassorelli², Grazia Sances¹
¹IRCCS Mondino Foundation, Headache Science And Neurorehabilitation Centre, Pavia, Italy, ²IRCCS Mondino Foundation - University of Pavia, Headache Science & Neurorehabilitation Center- Department Of Brain And Behavioral Sciences, Pavia, Italy

Background and Aims:: Periaqueductal gray (PAG) plays an important role in the modulation of descending pain control. Previous MRI studies showed that increased PAG iron levels in both episodic and chronic migraine patients correlated with disease duration. Transcranial sonography (TCS) is an imaging technique that allows visualization of heavy metals in the brain parenchyma as an area of hyperecogenicity. The PAG is the gray matter located around the cerebral aqueduct and usually ecographic signal of this region is indistinguishable from the adjacent parenchyma. Our aim was to investigate hyperechogenicity of PAG in migraine patients.

Methods:: TCS was performed with Esaote MyLab Twice ultrasound machine, applying the sonographic parameters according to international consensus guidelines used for Movement Disorders We investigated 13 patients with episodic migraine (EM), 15 with chronic migraine and medication overuse headache (CM+MOH) and 10 Healthy Controls (HCs). The area of PAG hyperechogenicity visualized through the transtemporal window was measured semiautomatically on each side and then calculated as a mean value.

Results:: PAG hyperechogenicity was visualized in 100% of the CM+MOH patients, 69% of EM patients and 44% of HCs (p <0.001). No significant difference was found in the hyperechogenic PAG area among the three groups (p=0.295). However PAG hyperechogenicity area correlated with disease duration (p<0.023), pain intensity (p<0.031) and scores of the HIT-6 scale (p<0.043).

Conclusions:: These preliminary data suggest that repeated migraine attacks may lead over time to increased oxidative stress and free radicals release, contributing to secondary damage, contextual hyperaemia, and iron deposit in the PAG.
Background and Aims:: Osmophobia, defined in medical dictionaries as a morbid fear of smells. Incidence based on the different diagnosis of headaches. Olfactory hypersensitivity, anxiety and pain share common neural pathways and area activation, a possible functional association and an interaction of one with the other might be argued, basing both on imaging data and on the clinical experience. The aim of this study was to investigate the relationship between osmophobia and clinical features in headache patients. It has been supposed that osmophobia play a role in the process of a central sensitization.

Methods:: This was an observational retrospective cohort study based on data collected in a headache center. We selected 1170 patients aged 18–65 years. Different clinical features were evaluated during the examination including: The migraine disability assessment (MIDAS), Allodynia Symptom Checklist, Self-rating Depression scale, Self-rating Anxiety scale, VAS, Fibromyalgia.

Results:: Osmophobia have a prognostic role during migraine chronicization. Significantly high is the correlation between osmophobia, pain intensity, allodynic migraineurs, length of headache history, anxiety and depression.

Conclusions:: The co-presence in patients of osmophobia and alldynia is one of the predictive indices to consider osmophobia as a central sensitization symptom. Osmophobic patients seems to have also more affective symptoms and that demonstrates that Osmophobia associated with sensory hyperactivity. All these aspects are linked to the migraine, seen as a process of cortical hyperactivity.
UNUSUAL ETIOLOGY OF CHRONIC HEADACHE

Assma Boudanga¹, Mohamed Chraa², Najib Kissani²
¹Mohammed VI University Hospital Center, Neurology, Marrakech, Morocco, ²Centre Hospitalier Universitaire Mohammed VI, Neurology, Marrakesh, Morocco

Background and Aims:: Introduction: Chronic headaches are one of the main causes of our patients’ consultation in neurology. This variety of headaches remains largely poorly recognized. However, it is a major problem of public health by its frequency and its socio-economic impact. Through this work, the authors report a case of pachymeningitis revealing a Sjogren’s syndrome whose clinical manifestation was a change in the character of a chronic headache.

Methods:: Clinical case: A 69-year-old woman, without past history, hospitalized at the Department of Neurology for etiological assessment of aggravation of chronic headaches, they became more intense and resistant to analgesic treatment. Clinical examination was without characteristics. Brain MRI objectified pachymeningitis of the cerebral falx, the cerebellar tentorium, and the clivus, with extension to the cervical spinal canal, associated with an enlargement of cerebral ventricles. History taking revealed the existence of xerostomia and xerophthalmia. The accessory salivary gland biopsy objectified Chisholm stage IV sialadenitis, the search for anti-SSA antibodies and anti-SSB antibodies was positive. The diagnosis of primary Sjogren’s syndrome was retained.

Results:: The patient improved with corticosteroid therapy.

Conclusions:: Through In this observation, we highlight the importance to look behind chronic headaches resisted to symptomatic treatment, or in front of an unexplained change in its characteristics. Even if the association of pachymeningitis and Sjögren’s syndrome is rare, it seems logical to rule it out.
MIGRAINE IN MENOPAUSE - A CROSS-SECTIONAL STUDY IN A HEADACHE CENTER IN RIO DE JANEIRO, BRAZIL.

Melina Da Silva Bernardes, Valéria Cavaco Barbosa, Gabriela Souza
Hospital Universitário Gaffrée e Guinle, Neurology, Rio de Janeiro, Brazil

Background and Aims:: Migraine mainly affects women in the reproductive years and the association between migraine and sex hormones, specifically estrogens, has induced the assumption that migraine would improve in menopause. However, while some studies found that migraine without aura would remit in menopause, others observed no changes in migraine activity after menopause. Here we aim to describe the characteristics of migraine in postmenopausal women.

Methods:: In August 2019, a headache center was inaugurated at our university hospital – Hospital Universitário Gaffrée e Guinle. All patients who subsequently attended this clinic were evaluated according to the diagnostic criteria from the International Classification of Headache Disorders, 3rd ed. Among the patients diagnosed with migraine, we have selected the women in perimenopause or menopause. Data were collected from medical records and further complimented with phone interviews. The cases were analyzed as to demographic and clinical variables, and as to putative risk factors.

Results:: Of 52 migraine patients, 12 (23.1%) were postmenopausal women. The mean age was 56.3 yrs (SD ± 4.0 yrs). Most of them (83.3%) had migraine without aura only. Ten patients (83.3%) had chronic headache. Medication overuse was observed in 50.0% of the cases. Half of them reported any mental disorder (predominantly mood disorders). Four patients (33.3%) had a past of smoking.

Conclusions:: Even migraine without aura might not subside in postmenopausal women. A tendency for chronic headache was also noted for this group, which could not be explained in half of the cases for medication overuse.
PATIENTS PRESENTED IN EMERGENCY DEPARTMENT OF SRD WITH HEADACHE AS SYMPTOM OF COVID-19

Edlira Harizi¹, Kledisa Shemsi², Ferid Domi³
¹Regional Hospital Durres, Neurology, Durres, Albania, ²Regional Hospital Durres, Emergency Practitioner Doctor, Durres, Albania, ³Regional Hospital Durres, Emergency, Durres, Albania

Background and Aims:: To see the patients presented in the Emergency Department of SRD with headache as a symptom of COVID-19.

Methods:: We have seen frequency and characteristic of headache in 180 patients in an emergency with a test of polymerase chain reaction positive.

Results:: These patients are presented in period 1 August 2020 until 31 December 2020 with the headache as the first symptom of COVID – 19. The most of cases was reported in man 56% (101 patients) and mid-age of cases were 52.5 years. The most of patients 62% (112 patients) had a very severe intensity of headache and it was diffuse or more in the frontal area (in 90% of these groups). 38 % of patients had moderate headache, and a part of all patients 22% (40 patients) had characteristics of migraine with hemicrania and nausea and vomitus and photophobia (this was seen more in patients that had experience migraine before, p < 0.05). In 25% of all patients (45) had continuous headaches without a period of free pain even after administration of analgesic therapy. A part of patients 34 % (61 patients) had anosmia as accompanied symptom. All cases had seen by a neurologist that did suggestions for all examinations that were necessary.

Conclusions:: In our Department of Emergency, we have seen a closed correlation of headaches with COVID-19. The most of patients had headache the only symptom in the first days of covid-19 and it was in general severe, diffuse, and in some patients as a migraine phenotype.
CT PERFUSION IN ACUTE CONFUSIONAL MIGRAINE

Veronica Iovene¹, Benedetta Piccardi², Francesco Arba², Francesca Pescini², Anna Poggesi³, Mariella Lamassa², Mascia Nesi², Cristina Sarti³, Patrizia Nencini², Vanessa Palumbo²
¹AOUC University of Florence, Neurofarba, Firenze, Italy, ²Careggi University Hospital AOUC, Stroke Unit, Firenze, Italy, ³AOUC University of Florence, Neurofarba, Firenze, Italy

Background and Aims:: Acute confusional migraine (ACM) is a rare migraine variant characterized by headache associated with altered mental status and speech difficulties. A 50-year-old headache-suffer male was admitted to our Hospital due to severe headache, vomiting, confusion, agitation, disinhibition and dysphasia. He performed brain CT, CTA and CTP which showed hypoperfusion in the left temporal lobe without an ischemic core. All these symptoms completely resolved the following day, with residual amnesia for the episode. Laboratory blood test and cerebrospinal fluid analysis were normal. Brain MRI showed a puntiform hyperintensity on DWI in left parietal lobe, not confirmed on follow-up MRI. Baseline EEG showed diffuse left-side dominant slow waves, with subsequent improvement. ACM is a rare migraine variant and often a challenge for clinicians to diagnose appropriately, also because there are no classification criteria. It is an exclusion diagnosis and some dangerous causes of confusion (e.g., epilepsy, ischemia, hemorrhage, neoplasm and encephalitis) should be ruled out. Data from previous published reports showed that ACM is characterized by decreased cerebral blood flow in the left splenium region and medial temporal lobe on SPECT scans. In our patient we found hypoperfusion on the left temporal lobe without an ischemic core on brain CTP. The more widespread use of brain CTP in an acute setting together with clinical course and blood and CSF results could help physicians to raise the doubt of this rare clinical entity avoiding misdiagnosis or excessive diagnostic testing.

Methods:: see B and A
Results:: see B and A
Conclusions:: see B and A
CT BRAIN IMAGING FINDINGS AMONG THE HEADACHE PATIENTS - A RETROSPECTIVE STUDY OF 220 CASES.

Abul Shoab1, Laila Rubaiat2, Saheen Wadud3
1Sylhet MAG Osmani Medical College, Neurology, Sylhet, Bangladesh, 2250 Bed Hospital, Moulvibazar, Radiology, Moulvibazar, Bangladesh, 3National Medical College, Neurology, Dhaka, Bangladesh

Background and Aims:: Headache is the most common complain of the patients presenting to Radiology department for the purpose of doing a CT scan of Brain.

Methods:: This retrospective study included all patients with the complaints of headache with or without other neurological symptoms and referred to Department of Radiology for CT scan of Brain from January to October 2018. Patients were divided into three groups based on CT scan findings: 1. Those with normal CT scan, 2. those with minor abnormality (not altering the patient management), 3. Those with clinically significant abnormality (altering the management protocol). Results were tabulated and analyzed from CT Brain imaging of patients with history of headache.

Results:: A total no of 220 patients were included from 668 patients in January to October 2018. Among them 128 had normal CT (58.18%) and 92 (41.82%) had abnormal CT findings of which major and minor abnormalities constitute 17.27% (eg. Acute cerebral infarction 14.08%) and 24.55% (eg. DCA 19.09%) respectively. Headache is common in both male (52.73%) and female (47.27%); most common age group affected is 41-60 years (35%).

Conclusions:: Abnormal CT in Headache patients is 41.82% at a district level hospital of Bangladesh indicates CT scan may play a vital role to rule out secondary cause of headache and help in further management.
THYROID STIMULATING HORMONE LEVEL IN MIGRAINE HEADACHE

Manabendra Bhattacharjee
Mymensingh Medical College, Neurology, Mymensingh, Bangladesh

Background and Aims::

Migraine is a primary headache disorder, the second commonest cause after Tension headache with a female preponderance. There is complex pathophysiology of migraine and migraine related disorders. Research is going on regarding potential association between migraine and thyroid function. The aim of this study was to investigate the association between Thyroid stimulating hormone level and migraine in adults and also to evaluate association of demographic and headache characteristics of migraine with thyroid function.

Methods:: This cross sectional comparative study was done to investigate the association between thyroid stimulating hormone level and thyroid abnormalities in adults migraine patients. The study was conducted in Mymensingh Medical College Hospital, a tertiary level hospital of Bangladesh. Study period was from November 2017 to April 2018. The study subjects consisted of 50 patients with migraine headache as case, compared with 50 patients of headache other than migraine as control, seen in Neurology out patient department (OPD). Thyroid function test was performed in both groups.

Results:: Mean age was 29.80±9.87 years in migraine group and 34.18±11.82 years in non migraine group. Male female ratio was 1:2.3 and 1:1.7 in two groups. Level of TSH was significantly higher in migraine patients (3.52±2.53 vs. 2.25±2.13) than other headache patients (p=0.008). Thyroid disorder especially subclinical hypothyroidism was significantly higher (28% vs. 08%) in migraineurs than non migraineurs (p=0.032). No significant relationship was found between thyroid hormone level and headache characteristics of migraine patients (p>0.05).

Conclusions:: Migraine headache is associated with low thyroid stimulating hormone and thyroid disorder can be considered as comorbidity of migraine headache.
TREATMENT OF PERSISTENT POST-TRAUMATIC HEADACHE WITH ONABOTULINUMTOXINA: RESPONSE RATES ACCORDING TO CLINICAL PHENOTYPE

John Rothrock, Allison Koutsandreas
George Washington University, Neurology, Washington, United States of America

Background and Aims:: Traumatic brain injury frequently is complicated by chronic headache which may have features of either chronic migraine (CM) or chronic tension-type headache (CTTH). We currently lack any evidence-based prophylactic therapy for persistent post-traumatic headache. In this study we assessed the efficacy, safety and tolerability of onabotulinumtoxinA in treating patients with persistent post-traumatic headache and stratified patients according to the clinical phenotype of their headache disorder (ie, CM vs CTTH)

Methods:: We randomized patients with persistent posttraumatic headache of at least 3 months duration to treatment with open-label onabotulinumtoxinA administered according to the PREEMPT dosing/injection paradigm. On the basis of the patient's history and using current ICHD-3 criteria, at baseline we assigned each patient a clinical phenotype for his/her headache disorder: CM or CTTH. We defined a positive treatment response as a 50% or greater decline in monthly headache frequency at month 8 of treatment relative to the pre-treatment baseline month.

Results:: Of 181 patients evaluated, 174 patients (96%) completed all 3 treatments. Clinical phenotype was CM in 116 (64%) and CTTH in 65 (36%). In the CM subgroup, significantly more patients (66/116: 57%) achieved the primary treatment endpoint than in the CTTH subgroup (14/65: 22%; p<.05).

Conclusions:: For patients with persistent post-traumatic headache, onabotulinumtoxinA appears to be more efficacious in those with a clinical phenotype of CM than in those with a phenotype of CTTH.
EVALUATION OF THE EFFECTS OF NON-PHARMACOLOGICAL INTERVENTIONS ON THE PSYCHOLOGICAL PROFILE IN ADOLESCENTS WITH TENSION-TYPE HEADACHE

Kostiantyn Stepanchenko, Vira Marchenko
Kharkiv Medical Academy of Postgraduate Education, Neurology And Neurosurgery, Kharkiv, Ukraine

Background and Aims:: Some evidence suggests that heart rate variability biofeedback-based training (HRV-BBT) might be an effective way to treat headaches and psychological symptoms. The aim to examine the effect of non-pharmacological therapy (HRV-BBT and complex isometric exercises (IE)) on anxiety and depression in adolescents with tension-type headache (TTH).

Methods:: 118 adolescents (ages 13-18) were examined. We formed four groups of adolescents with episodic (ETTH) and chronic TTH (CTTH) who received only drug therapy and only non-drug therapy and 5th group – adolescents with CTTH who received a combination of drug and non-drug therapy. The intensity of the pain (VAS); the level of reactive and personal anxiety (self-esteem scale Spielberger-Hanin); the level of depression (scale of V.A. Zhmurova) were performed. Adolescents received conventional pharmacotherapy for 1 month. Non-drug therapy was in the form of HRV-BBT (10-12 sessions) and a complex of isometric exercises (IE).

Results:: We observed a decrease in the level of anxiety in adolescents with TTH after HRV-BBT. However, only the reduction in reactive anxiety was significant (ETTH: before/after treatment – 42,6±7,5/33,5±5,4, p<0,05; CTTH: 37,7±6,8/29,2±6,8, p<0,05). The level of depression was significantly reduced after HRV-BBT in adolescents of all groups (ETTH: before/after treatment – 20,2±4,7/14,4±3,9, p<0,05; CTTH: 24,9±5,3/9,4±3,8, p<0,05), and the use of pharmacotherapy had a positive effect (before/after treatment – 25,1±5,2/11,7±4,8, p<0,05) only in the group with CTTH (who more often received amitriptyline).

Conclusions:: Our findings support the beneficial impact of non-drug therapy (HRV-BBT and IE) on anxiety and depression for adolescents with TTH (with higher effectiveness in adolescents with episodic forms).
IMPACT OF RAMADAN FASTING ON MIGRAINE HEADACHE

Samar Farouk Ahmed¹,², Fathi Abokalawa¹, Raneem Toma³, Amani Algubari³, Jasem Al Hashel¹,³
¹Ibn Sina Hospital, Kuwait, Neurology, Kuwait City, Kuwait, ²Minia University, Neuropsychiatry, Minia, Egypt, ³Kuwait University, Medicine, Kuwait, Kuwait

Background and Aims:: Fasting is known as a migraine trigger for migraine. We aimed to study the impact of fasting of The Holy month of Ramadan on episodic migraine.

Methods:: This retrospective study included patients diagnosed as migraine according to The International Classification of Headache Disorders, 3rd edition (ICDH-3). Both genders, aged between 18 and 65 years were included. Frequency, severity of migraine attacks and number of analgesic days during Ramadan were compared to those during Shaban, the Immediate previous month to Ramadan. Number of breaking fasting due to migraine was reported.

Results:: This study identified 293 with migraine with mean age and mean disease duration 37.09 ±9.36, 12.34±9.27 years respectively. Most of them were females(89.1%). During Ramadan, the patient had significant increase in migraine days 10.42±7.98 compared with 6.90±6.55 migraine days during the previous month (p < 0.001). Days of analgesic use (11.32±10.46 versus 6.11±6.69;P<0,001) and migraine severity (7.46±2.39 versus 6.84±2.25; P<0,001) were significantly increased during Ramadan compared to Shaban. A minority (1.7) of the patients could not tolerate fasting whole Ramadan and 36.5% broke their fasting for some days during Ramadan. Some patients changed previous prophylactic therapy before fasting to reduce the impact of fasting on migraine headache. Most of cohort (82.3%) continue on the same management plan for migraine during Ramadan. Majority of cohort (75.4%) reported that migraine interfered with their daily activities due to fasting during Ramadan.

Conclusions:: Ramadan fasting has negative impact on migraine patients. Physicians should educate migraine patients how to manage their headache and habits before starting fasting.
TRIGGERS OF MIGRAINE DURING COVID-19 PANDEMIC LOCKDOWN

Samar Farouk Ahmed¹,², Fathi Abokalawa¹, Jasem Al Hashel¹,³
¹Ibn Sina Hospital, Kuwait, Neurology, Kuwait City, Kuwait, ²Minia University, Neuropsychiatry, Minia, Egypt, ³Kuwait University, Medicine, Kuwait, Kuwait

Background and Aims:: Lock down caused lifestyle changes and represented an impact on human health. Environmental factors can trigger migraine headache. We aimed to report the triggers of migraine attacks due to lifestyle changes during coronavirus disease 2019 (COVID-19) pandemic lockdown.

Methods:: This cross-sectional survey included patients diagnosed as migraine according to The International Classification of Headache Disorders, 3rd edition (ICDH-3). During the lockdown, we submitted an online self-reported web-based questionnaire to patients already diagnosed with migraine and attends headache clinic at Ibn Sina Hospital in Kuwait. Questions explored triggers of migraine headache attacks during COVID-19 Pandemic lockdown. Answers were transformed into data for statistical analysis.

Results:: A total of 340 migraine patients responded to questionnaire. The mean age of them is 34.65 years. Females were predominant 79.1%. Majority of the cohort 85 % has more than one trigger of migraine attack. The commonest triggers were smell of strong odors in 214 (62.9%), followed by certain food in 175 (51.8%), sleep disturbance in 120 (35.3%), Emotional or mental stress in 80 (23.6%), caffeine in 80 (23.6%), flickers of Light in 78 (22.9), weather changes in 68(20%), smoking in 65 (19.12), noise in 56 (16.5), sun light exposure in 41 (12.1), Fasting/ Hypoglycemia in 40 (11.7), hormonal changes in 37 (10.6%), physical excretion/fatigue in 24 (7.1), screen exposure in 20 (5.9%), and dehydration in 14 (4.1%).

Conclusions:: Lifestyle changes during lock down may negatively impact migraine through patients exposure to many triggers. Strong odors, food, sleep disturbance and stress were the most migraine triggers during COVID-19 lockdown.
OXYGEN THERAPY IN HEADACHE DISORDERS: WHAT IS KNOWN?

Tiziana Ciarambino¹, Gennaro Sansone², Giovanni Menna¹, Mauro Giordano²
¹Hospital of Marcianise, Internal Medicine, Caserta, Italy, ²University of Campania, Internal Medicine, Naples, Italy

Background and Aims:: The global active prevalence of migraines is approximately 14.7%. Oxygen therapy may reduce the use of Nonsteroidal anti-inflammatory drugs (NSAIDs) which often have various negative side effects. The purpose of this systematic review is to analyze the literature on the efficacy of high flow oxygen for the management of headache disorders, compared to placebo treatment.

Methods:: Studies were identified by PubMed, Web of Science and Scopus database from 1980 to the 30th of October 2020. The search included the following terms: “oxygen therapy” and “headache” and “migraine.” Studies were included if high flow oxygen was used in the treatment of headache disorders All selected studies were qualitatively analyzed.

Results:: Our literature search identified 71 studies, of which 65 were discarded and 6 were included in the meta-analysis. The random effect model did not show a pooled significant resolution of headache disorders (OR 2.08 (95% CI 0.92–4.70), p < 0.0001) in the oxygen therapy group compared to the placebo group.

Conclusions:: In our systematic review of six studies, there were no significant differences between high flow oxygen and placebo treatment groups.
CEREBRAL FAT EMBOLISM SYNDROME PRESENTING WITH A MIGRAINE ATTACK

Marco Simonetto^1, Carlo Rettore^2, Sofia Zywicki^1, Cristina Vilotti^1, Giampietro Ruzza^1, Viviana Lunardelli^1, Emma Frasson^1, Licia Finamore^1, Giorgio Caneve^1
^1AULSS6 EUGANEA, Neurology, Cittadella, Italy, ^2AULSS6 EUGANEA, Radiology, Cittadella, Italy

Background and Aims:: Fat embolism syndrome (FES) is characterized by cerebral, respiratory, and cutaneous manifestations following orthopedic trauma. Cerebral fat embolism (CFE) is a subtype of FES. We report a case of subarachnoidal fat embolism due to a sacral trauma presenting with a migraine attack.

Methods:: A 39-year-old Caucasian man (BMI 22) fell down accidentally with acute low back pain and progressive severe pulsatile headache. Admitted to the hospital, a brain CT showed multiple hypodense areas into the subarachnoid space. Hounsfield unit analysis demonstrated numbers compatible with fat. A brain MRI confirmed the presence of subarachnoid fat droplets. The sacral-coccygeal MRI showed a displaced fracture of the 5th sacral vertebra and inflammation of epidural fat. After three days he went home with symptomatic therapy.

Results:: To our knowledge it is the first case of subarachnoidal fat embolism presenting with a migraine attack.

Conclusions:: Migraine is a multifactorial disorder, which could be triggered by a specific injury. Typically CFE imaging is a “starfield” pattern on diffusion-weighted MRI due to the involvement of multiple small arteries. Fat present in the subarachnoid space is less common. Patient’s trauma caused the vertebral fracture, and probably allowed the epidural fat to enter into the subarachnoid space giving evidence of multiple subarachnoid fat droplets in the brain.
FAMILIAR HEMIPLEGIC MIGRAINE: A PRELIMINARY CLINICAL AND FOLLOW-UP STUDY IN A PEDIATRIC SAMPLE.

Mariarita Capizzi¹, Giuseppe Quatrosi¹, Giovanna Martina Nocera¹, Fulvio Guccione¹, Luigi Vetri², Rosaria Nardello¹, Andrea Santangelo³, Maurizio Elia², Salvatore Mangano¹, Filippo Brighina⁴, Giuseppe Santangelo⁵, Vincenzo Raieli⁵

¹University of Palermo, Italy, Child Neuropsychiatry Unit Department Pro.m.i.s.e. “g D’alessandro”, PALERMO, Italy, ²Oasi Research Institute-IRCCS, Troina, Child Neuropsychiatric, Troina, Italy, ³Pediatric Clinic, University of Pisa, Dept. Of Clinical And Experimental Medicine, Pisa, Italy, ⁴University of Palermo, Department Of Experimental Biomedicine And Clinical Neurosciences, Palermo, Italy, ⁵ARNAS Civico Palermo, P.o. Di Cristina - Child Neuropsychiatry Dept, Palermo, Italy

Background and Aims:: Familial Hemiplegic Migraine (FHM) is a rare clinical condition characterised by headache and motor weakness often unilateral. Follow-up studies are even rarer and there is the need to increase the observations of pediatric population affected by FHM to better clarify the prognosis and possible treatment. Aim of our study was to carry out a follow-up activity in a group of 7 children affected by FHM.

Methods:: A multi-center study was conducted retrospectively to select all genetically proven cases of FHM, collecting data based on clinical and genetic documentation. The selected subjects were interviewed on clinical course of hemiplegic migraine, possible other types of headache and clinical disorders.

Results:: Our children were 5 males and 2 females (age media onset: 7ys 8m, range age 3,3-15,2; age media follow-up 13 ys 6 m; follow-up duration 5 ys 9 m., range 3ys4m -9ys). We found a CACNA1A mutation in 3 children and a ATP1A2 in 4. At the follow-up time they had complained 1.86 attacks for year. Moreover clinically 57% presented speech disorders, 28,57% sensory disorders, 14,28% visual disorders and 57,14% an impairment of consciousness. Otherwise only 1 child presented a diagnosis of epilepsy and intellectual disability. 3 children showed recurrent attacks of migraine with and without aura.

Conclusions:: Our data supports the recent data of other Italian multicentric studies on 14 subjects showing a low frequency of hemiplegic attacks. Further our cases were rarely associated to other disorders and had a good prognosis to short-term follow-up.
SEROTONERGIC DYSREGULATION: NEW INSIGHTS OF REVERSIBLE CEREBRAL VASOCONESTRICTION SYNDROME PATHOPHYSIOLOGY.

Giada Giuliani\textsuperscript{1}, Marta Puma\textsuperscript{1}, Ilaria Maestrini\textsuperscript{1}, Edoardo Vincenzini\textsuperscript{1}, Vittorio Di Piero\textsuperscript{1,2}
\textsuperscript{1}Sapienza University of Rome, Department Of Human Neurosciences, Rome, Italy, \textsuperscript{2}Headache Science Center, Consortium For Adaptive Disorders And Head Pain, Ucadh, Pavia, Italy

Background and Aims:: The pathophysiology of RCVS is not yet fully understood. Several precipitating factors, such as serotonergic hyperactivity, have been associated to this transient disturbance in cerebrovascular tone control. We present two atypical cases that offer new insights on the etiological role of serotonergic regulation in RCVS.

Methods:: In the first case, a 38-year-old woman presented a postpartum, new onset, severe and excruciating headache followed by a mild and continuous daily headache. Transcranial Doppler showed mean increased velocities in left middle (Vmean 140 cm/s) and anterior (Vmean 120 cm/s) cerebral arteries that normalized after nimodipine treatment. Headache improved with amitriptyline preventive treatment. In the second case, a 52-year-old migraineur woman presented an unusual thunderclap headache, followed by sudden onset of aphasia and clumsiness of the right hand. Colour cervical Doppler showed an increased peak systolic velocity in the left distal internal carotid artery (VPS 140 cm/s) and carotid syphon (VPS 110 cm/s), which normalized after nimodipine. She suffered from tryptophan deficiency, the amino acid precursor of serotonin.
**Results:** Although amitriptyline primarily inhibits serotonin and norepinephrine reuptake, it allows in the first patient a progressive pain relief without worsening vasospasm, possibly due to its complex pharmacodynamic profile. Secondly, no other cases of RCVS associated with tryptophan deficiency are currently reported: its low levels, unlike an excess of serotonin, could promote endothelial dysfunction. 

**Conclusions:** RCVS may not be due to a merely increase in serotonergic tone, but more likely, to a dysregulation of serotonergic neurotransmission, leading to an abnormal brain vasoreactivity.
TREATMENT RESPONSES TO ERENUMAB IN ONABOTULINUMTOXINA-REFRACTORY CHRONIC MIGRAINE: LONG-TERM REAL-WORLD EXPERIENCE FROM A SPECIALIST HEADACHE CENTRE

Fan Cheng¹², Ker Tang¹, Shunwei Wan², Weihai Hu²
¹Hull University Teaching Hospitals NHS Trust, Department Of Neurology, Kingston upon Hull, United Kingdom, ²Peking Union Medical College Hospital, Department Of Neurology, Beijing, China

Background and Aims:: Erenumab is a novel humanised anti-calcitonin gene-related peptide (CGRP) receptor monoclonal antibody efficacious in chronic migraine (CM) prophylaxis. We investigate long-term real-world erenumab efficacy in converting OnabotulinumtoxinA-refractory CM to episodic migraine (EM).

Methods:: We measured monthly headache-days (MHD) and monthly migraine-days (MMD) in a real-world prospective study of 186 OnabotulinumtoxinA-refractory CM patients treated with erenumab for 23 months in a Chinese specialist headache centre. Mean MHD<15 and mean MMD<8 days/month responses assessed conversion to EM.

Results:: Mean baseline MHD and MMD were 26.2 and 18.6 days. 115 (61.8%) patients experienced no baseline headache-freedom. At Month 23, mean MHD and MMD reductions were 12.8 and 13.4 days (p<0.001). At Month 23, 79 (42.6%), 111 (59.7%) and 89 (47.8%) patients achieved mean MHD<15, mean MMD<8, and both outcomes; 50 (26.9%) and 41 (22.0%) patients achieved mean MHD<15 and MMD<8 between 6–19 months; whilst 152 (81.7%), 124 (66.7%) and 42 (22.6%) patients achieved >30%, >50% and >75% baseline MMD reduction. 45 (24.2%) achieved >30% response after >3 months. More patients with baseline headache-freedom achieved mean MHD<15 responses at Months 12 and 23 (Month 12: 76.1% vs 7.8%, 68.3% difference, p<0.0001; Month 23: 77.5% vs 20.9%, 56.6% difference, p<0.0001), and >50% baseline MMD reduction responses at Months 12 and 23 (Month 12: 95.8% vs 53.0%, 42.8% difference, p<0.0001; Month 23: 93.0% vs 50.4%, 42.6% difference, p<0.0001), than those without.

Conclusions:: Erenumab converts onabotulinumtoxinA-refractory CM to EM in the real-world over 23 months, with some delayed responders. Baseline headache-freedom heralded superior treatment responses.
ASSOCIATION STUDY BETWEEN HEADACHE AND DIZZINESS ACCORDING TO AGE SPECTRUM FOR PATIENTS

Jongyoon Lee
HimChan hospital, Neurology, Seoul, Korea, Republic of

**Background and Aims:** Patients with headache often experience various types of vertigo. And several studies have suggested an epidemiologic and physiologic association of headache and vertigo. Researchers have investigated the association between headache and vertigo. We investigate whether vertigo (peripheral vertigo or central vertigo) is correlated with clinical relevance in headache patients according to age spectrum.

**Methods:** From May 2020 to February 2021, 925 patients, aged ≥7 years and participants who met the inclusion criteria were enrolled from the neurology clinics. We re-analyzed patients who experience headache with/without vertigo symptoms and two groups were studied according to the patient’s age. Logistic regression analysis was used to evaluate the association between headache and vertigo. First, we reviewed vertigo with diagnosed 281 and 570 headache patients, and 31 vertiginous headache. Second, common types of primary headache patients were included. Third, the vertigo was classified into 2 groups: peripheral or central types.

**Results:** Of the 925 outpatient, headache of 570 (61.6%) and vertigo of 281 (30.3%) were reported. The frequency of vertigo in headache patients was significant relationship with ageing. Total 31 headache related vertigo patients were divided into two groups (peripheral (n=27), central (n=4)) and proportion of peripheral vertigo has a positive relevance with headache.

**Conclusions:** The clinical relevance of vertigo in headache patients is associated with increasing age spectrum. The proportion of peripheral vertigo was correlated with vertiginous headache groups. The findings of our study may provide direction for potentially useful diagnostic and therapeutic approach to the attack of vertigo such problem in vertiginous headache patients.
SURGICAL TREATMENT FOR PAIN ATTRIBUTED TO A LESION OR DISEASE OF THE TRIGEMINAL NERVE – A SINGLE-CENTER EXPERIENCE

Miguel Miranda1, Sofia Delgado2, Marta Magriço3, Pedro Da Cunha4, Luis Marques4, Carla Reizinho4, Sérgio Figueiredo4, José Cabral4

1Hospital de Cascais Dr. José de Almeida, Department Of Neurology, Alcabideche, Portugal, 2Hospital Professor Doutor Fernando Fonseca, Department Of Neurology, Amadora, Portugal, 3Centro Hospitalar Lisboa Ocidental, Department Of Neurology, Lisbon, Portugal, 4Centro Hospitalar Lisboa Oci
dental, Department Of Neurosurgery, Lisbon, Portugal

Background and Aims:: According to ICHD-3, “Pain attributed to a lesion or disease of the trigeminal nerve” (PLDTN) includes both trigeminal neuralgia (TN) and painful trigeminal neuropathy. Despite initial preference for medical management, patients with refractory pain or intolerant to drug therapy side effects are candidates for surgical therapy. We aimed to characterize a single-center population of patients selected for surgical management of PLDTN, accessing surgery effectiveness and patient satisfaction.

Methods:: Clinical information from patients undergoing surgery for PLDTN between January 2010 and March 2021 at CHLO was reviewed retrospectively. Surgery effectiveness and patient satisfaction was evaluated resorting to the Penn Facial Pain Scale-Revised (PFPSR) and the Patient's Global Impression of Change Scale (PGICS), applied by the telephone.

Results:: Twenty-three patients underwent surgical therapy, with a time from symptom onset to first neurosurgery appointment of 6.43±5.44 years (mean±standard deviation). By the first appointment, patients were medicated with 3±2 drugs for pain control. Most patients had classical TN (73.9%), followed by secondary (8.7%), idiopathic TN (8.7%) and painful post-traumatic trigeminal neuropathy (8.7%). Microvascular decompression (MD) was performed in 65.2%, Gasserian ganglion radiofrequency in 17.4%, partial rhizotomy (PR) in 4.3% and MD+PR in 13.0% of cases respectively. Thirteen patients (56.5%) answered to the telephone survey with an average surgery satisfaction score (PGICS) of 5.77 (1 to 7). Half of these patients became medication free after surgery.

Conclusions:: Surgery for PLDTN is an effective management option that prevents polymedication and pain persistence over the years if earlier referral to Neurosurgery outpatient clinic.
CASE REPORT: ATYPICAL MIGRAINE AS A SENTINEL SYMPTOM FOR SARS-COV2 INFECTION.

Ennio Pucci¹, Marco Quintilio Falvo², Valentina Nava¹, Marta Lagorio¹
¹IDR Santa Margherita, Alzheimer's Nucleus Asp, Pavia, Italy, ²University of Pavia, Graduate School Of Geriatrics And Gerontology, Pavia, Italy

Background and Aims:: Migraine without aura is the most frequent of the forms of migraines (about 60% - 80% of all forms of migraines). There are many causes that can trigger migraines, including infections (IHS ICDH-3).

Methods:: 69 year old woman. Professional nurse. Family history of migraine (maternal line). Arising in school age. Diagnosis made according to the IHS ICDH-3 criteria. The patient presented 2-3 crises / month with pulsating pain in the bilateral frontotemporal region, medium-strong intensity, associated with photo-phonophobia, nausea, sometimes vomiting. Duration 24-36 hours. Triggering factors: menstruation and psychophysical stress. After menopause (49 years) reduction of intensity, duration and frequency with 1-2 crises / month related stress lasting 12-24 hours and responsive to NSAID intake. No preventive therapy performed.

Results:: On 29.11.2020 episode of atypical headache (described as different from other episodes) with very strong, throbbing, stabbing, burning pain in the bilateral frontotemporal region, unresponsive to the intake of NSAIDs. Duration 24 hours. No other symptoms reported, afebrile. 30.11.2020: TNF fast: +. Molecular TNF: positive for SARS COV 2. During the period of infection headache present whenever the patient had fever and was unresponsive to paracetamol.

Conclusions:: In our case report, atypical migraine can be considered a sentinel symptom of an initial infection. The patient works as a professional nurse in the ward which had become Covid on 3.11.2020.
PRIMARY HEADACHES IN A GROUP OF HOSPITAL WORKERS DURING SARS-COV2 INFECTION: AN OBSERVATIONAL STUDY.

Ennio Pucci, Marco Quintilio Falvo, Valentina Nava, Marta Lagorio
University of Pavia, Department Of Brain And Behavioral Sciences, Pavia, Italy

Background and Aims:: Headaches represent at the same time the symptom and the disease, while the secondary ones are the expression of an ongoing pathology that can be systemic, locoregional or distant. The aim of this study is to determine the prevalence rate in the workplace in a ward (Nucleo Alzheimer) during the period of Sars-COV2 infection. This survey was carried out using 2 questionnaires: 1 (work activity sheet), 2 (headache sheet according to IHS criteria).

Methods:: All health personnel belonging to the Alzheimer Nucleus of the IDR S. Margherita di Pavia were subjected to compilation of questionnaires during the Sars-COV2 infection period.

Results:: From the analysis of the questionnaires administered, it was found that out of 15 workers, 10 were women and 5 were men. 4 (all women had migraines without aura) and 7 tension-type headaches (5 women and 2 men). Before the Sars-COV2 period, only 2 workers had migraine without aura and 2 tension-type headaches (all women). All 11 workers reported stress, insomnia, and concern for family members and their own health. None of the workers at the time of testing had been vaccinated.

Conclusions:: Factors related to the work environment are able to increase the frequency and / or intensity of pre-existing headaches. It is also likely that particular situations can give rise to or cause some forms of headache under certain working conditions. Excessive responsibility or, on the contrary, disaffection and incongruous work rhythms should be considered among the occupational risk factors.
FEATURES OF THE CLINICAL PICTURE OF CERVICOGENIC HEADACHE DEPENDING ON THE LEVEL OF THE VERTEBRAL DAMAGE

Dina Khaibullina, Farida Devlikamova, Yury Maximov, Bulat Gubeev, Daniyar Mansurov, Asya Khaibullina, Yuliya Karpukhina

Background and Aims:: Relevance. About 70% of patients with neck pain simultaneously experience a headache, only in 18% of cases the headache is considered as a consequence of neck pain. Objective: To identify the features of the cervicogenic headache clinic depending on the level of neck damage.

Methods:: 110 patients with complaints of neck pain radiating to the head (mean age 38.7±2.3 years; 68 (61.8%) women and 42 (38.2%) men; symptoms from 20 days till 11 years), were included in the study. The diagnosis of cervicogenic headache was verified according to diagnostic criteria (ICHD-3, 2018).

Results:: 100% of patients had neck pain. Crunching sound which occurs during movement was observed in 28.1%, neck movement limitation – 51.8%, visual disturbances – 60.0%, unilateral noise in the ear-14.5%. Cervicogenic headache associated with changes in C0-Ci-CII was detected in 49 (44.5%) cases and was characterized by unilateral pain (82.7%), visual disturbances, non-systemic vertigo associated with the neck position. Changes in CIII-CIV – in 27 (24.5%) cases were manifested by intense unilateral, throbbing headache with autonomic symptoms. Palpation of CIII-CIV from the headache localization led to clinical manifestations increase. The simultaneous lesion of C0-Ci-CII and CIII-CIV was characterized by unilateral occipital-parietal headache with irradiation to the frontotemporal and ocular region, which had an autonomic disorder, was accompanied by vertigo, nausea, simulating a migraine. CV-CVII do not play a significant role in the cervicogenic headache.

Conclusions:: Thus, the level of localization of cervical spine dysfunction affects the clinical features of cervicogenic headache.
COVID-19 AND HEADACHE: IMPACT ON PRE-EXISTING AND CHARACTERISTICS OF DE NOVO: A CROSS-SECTIONAL STUDY

Samar Farouk Ahmed1,2, Fathi Abokalawa1, Maram Alenzi3, Raed Alroughani4, Jasem Al Hashel1,5
1Ibn Sina Hospital, Neurology, Kuwait, Kuwait, 2Minia University, Neuropsychiatry, Minia, Egypt, 3Farwaniyah hospital, Internal Medicine, Farwaniyah, Kuwait, 4Amiri Hospital, Neurology Division, Kuwait, Kuwait, 5Kuwait university, Neurology, Kuwait, Kuwait

Background and Aims:: Background: Headache is a common symptom during and after acute respiratory syndrome coronavirus 2 (SARS-COV-2). Objective: To study headache character in relation to SARS-COV-2 infection.

Methods:: This was a cross-sectional study. Patients who had SARS-COV-2 and presented to the headache clinic within 3 months after the onset of infections were identified to the study. Participants were grouped into categories according to having previous or de novo headache.

Results:: A total of 121 patients were included in this study. Their mean age was 35.29 ±9.54 and most of them were females (83.5%). Prior to SARS-COV-2 infections, 85 (70.2%) had migraine and 18(14.9%) experienced a tension-type headache while 18 (14.9) reported de novo headache post SARS-COV-2. Post SARS-COV-2, the patient had significant increase in headache days 11.09±8.45 compared with 8.66±7.49 headache days before SARS-COV-2 infection (p< 0.006). Post SARS-COV-2 infection, the usage of analgesic increased significantly by the patient with migraine (2.31±1.65 vs 3.05±2.09, p= 0.002) while the patient with tension type headache had statistically significant increase in severity (5.556±1.86 vs 7±2.25, p= 0.033) and frequency (7±6.29 vs 12.72±7.96, p=0.006) of headache attacks.. Patients younger than 40 years had longer duration of the headache attack (18.50±16.44 vs 5.5± 9.07, p=0.045). Male patients compared to females (8.66±1.15 versus 5.93±2.01 p=0.04) had more severe headache.

Conclusions:: Primary headache get worse after SARS-COV-2 infection. De novo primary headache is frequent post SARS-COV-2 infection. Young male patients with SARS-COV-2 infection tend to have worse headache. These features may be helpful in diagnosing the headache related to SARS-COV-2.
USE OF TRADITIONAL MEDICINE IN TREATMENT OF MIGRAINE DURING CORONAVIRUS DISEASE 2019 (COVID-19) PANDEMIC- AN ONLINE SURVEY

Ismail Ismail, Jasem Al Hashel
Ibn Sina Hospital, Neurology Department, Kuwait city, Kuwait

Background and Aims:: Since the emergence of COVID-19 pandemic, patients with migraine were specifically vulnerable to worsening of their headaches, in addition to inadequate quality of medical care and overall psychosocial stressors. Traditional medicine (TM) has been used for centuries to treat headache disorders, and around 2/3 of migraine patients reported seeking TM in literature.

Methods:: We conducted an internet-based, cross-sectional study, to assess the use of TM in treatment of migraine amid COVID-19 pandemic. A self-administered questionnaire was distributed to patients with migraine from the headache clinic in the largest neurology center in Kuwait, and was also posted on several medical social-media accounts.

Results:: A total of 1018 patients completed the survey. TM was used by 406 (39.9%) respondents; 353 (86.9%) females, with mean age of 34 ± 9.5 years, and mean disease-duration of 9.8 ± 8.3 years. The most common reported TM methods were; head-massage by 52.3%, head-banding by 47.9%, herbal-drinks by 45.8%, and essential-oil aromatherapy by 37.2% respondents. Hijama and Farry were reported by 1.1%, and 0.5%, respectively. Higher migraine frequency (p <0.001) and migraine severity (p=0.002), older age (p =0.04), longer disease duration (p =0.005), non-compliance to treatments (p<0.02), and less communication with physicians were associated with higher TM use.

Conclusions:: Worsening of migraine, in addition to the overall negative impact of COVID-19 pandemic, has forced the patients to self-treat themselves by using TM, despite being compliant to their conventional treatments. Neurologists should prepare their patients with "rescue" strategies for headache management, and new means of communication, to face these "new normal" challenges.
IMPACT OF COVID-19 PANDEMIC ON THE CARE OF PATIENTS WITH MIGRAINE

Cristiana Silva, Carolina Fernandes, Isabel Luzeiro
Centro Hospitalar de Coimbra, Neurology, Coimbra, Portugal

Background and Aims:: Migraine is one of the most prevalent chronic diseases. The COVID-19 pandemic and the consequent deep remodeling of health care may have contributed to the worsening of migraine. We aim to study the impact of COVID-19 pandemic on the care of patients with migraine.

Methods:: Cross-sectional study with patients with migraine followed in a Neurology outpatient clinic. Patients completed an online survey that included variables related to migraine, treatment and healthcare approachability.

Results:: A total of 97 patients completed the survey, mostly female (92.8%), with a mean age of 43.3 years old, in a full-time job (60.8%), 14.4% changed to teleworking. There was an increasing of anxiety (87.6%) and TV watching (63.9%) and a decrease of exercise (52.6%) and quality of sleep (56.7%). There was a worsening of pain severity in 54.6% patients, with greater need of analgesia (56.7%), 26.8% reported difficulty in getting their medication, botox injections treatment was mostly delayed (82.0%) and 20.6% had to go to emergency ward. Only 11.3% had COVID-19, of those 60.0% had worsening of symptoms. The majority had teleconsultation (55.6%), 42.2% reported that frequency of consultations was not appropriate, and that care was different from presential appointments.

Conclusions:: The COVID-19 pandemic had a negative impact in patients with migraine, there were profound changes in habits and, overall, there was an insufficient health care response to these patients. It is urgent to reorganize health care in order to enhance teleconsultation and promote accessibility to health care.
THE MIGRAINE POSTDROME: THE MISUNDERSTOOD PHASE WITH A SIGNIFICANT IMPACT IN QUALITY OF LIFE

Inês Carvalho, Diogo Damas, Catarina Fernandes, Helena Gens, Isabel Luzeiro
Centro Hospitalar e Universitário de Coimbra, Neurology, Coimbra, Portugal

Background and Aims:: The postdromic phase consists in a set of symptoms occurring once the acute headache has resolved. Its duration varies between several hours and one or more days and it occurs in around 2/3 of the patients. Although it is very common and disabling, the postdromic phase is the least studied and understood phase of the migraine attack. We aimed to determine the prevalence, characterize the clinical presentation and assess the impact of the postdromic phase on daily activities, work activity and quality of life.

Methods:: Sequential patients with migraine according to ICHD-3 were screened about the occurrence of postdromic symptoms and its characteristics using a self-fulfilled questionnaire.

Results:: Of 70 evaluable patients, 94,3% reported at least one nonheadache symptom in the postdromic phase. Postdrome symptoms, in order of frequency, included feeling tired (71,2%), photophobia (62,1%) and having difficulty concentrating (57,6%). 58,5% reported an impact on daily activities and 78,8% in quality of life. Migraine relief medication influenced positively the duration of postdromic phase in 83,1%. The headache frequency was not correlated with the frequency (p=0,83) or duration (p=0,06) of the postdromic phase.

Conclusions:: Nonheadache symptoms are common in the postdromic phase, which contributes significantly to overall disability. Migraine medication positively influences the postdromic phase. In contrast, the frequency of attacks does not influence the occurrence or duration of the postdromic period. Understanding migraine postdrome will improve our knowledge in migraine pathophysiology as well as upgrade our therapeutic approaches.
POOLED ANALYSIS OF SAFETY AND EFFICACY OF FREMANEZUMAB IN DIFFERENT RACIAL AND ETHNIC SUBGROUPS OF PATIENTS WITH MIGRAINE

Larry Charleston Iv1, Joshua Cohen2, Xiaoping Ning2, Verena Ramirez Campos2, Steve Barash2, Tamar Lengil3, Byungkun Kim4

1Michigan State University College of Human Medicine, Department Of Neurology, East Lansing, United States of America, 2Teva Branded Pharmaceutical Products R&D, Inc., Global Medical Affairs, West Chester, United States of America, 3Teva Pharmaceutical Industries Ltd, Global Medical Affairs, Petah Tikva, Israel, 4Nowon Eulji Medical Center, Eulji University School of Medicine, Department Of Neurology, Seoul, Korea, Democratic People’s Republic of

Background and Aims:: Fremanezumab, a fully humanized monoclonal antibody (IgG2Δa) that selectively targets calcitonin gene-related peptide (CGRP), has proven efficacy for migraine prevention in adults. These pooled analyses evaluated the safety and efficacy of fremanezumab in racial/ethnic subgroups.

Methods:: These pooled analyses included data from 3 clinical trials (HALO episodic migraine [EM], HALO chronic migraine [CM], and FOCUS [EM/CM with inadequate response to 2-4 prior preventive classes]), in which patients were randomized to 12 weeks of double-blind treatment with quarterly fremanezumab, monthly fremanezumab, or placebo. These pooled analyses assessed changes from baseline in monthly migraine days (MMD), proportion of patients with 50% or greater reduction in MMD from baseline, and adverse events (AEs) based on patients’ racial/ethnic groups.

Results:: This pooled population included 2,842 patients. Quarterly and monthly fremanezumab provided reductions in MMD and increases in the proportion of patients with 50% or greater reduction in MMD from baseline during 12 weeks versus placebo across White and Non-white racial/ethnic groups (Table). In the quarterly fremanezumab, monthly fremanezumab, and placebo groups, respectively, at least 1 AE was reported by 64%, 62%, and 59% of White patients and 66%, 61%, and 53% of Non-white patients (Black/African American patients, 60%, 58%, and 54%; Asian patients, 64%, 62%, and 44%; Other, 85%, 68%, and 81%). The most commonly-reported AEs across all racial/ethnic groups were injection-site erythema, induration, and pain.

Conclusions:: Treatment with fremanezumab was safe and effective, based on reductions in MMD and increases in ≥50% response rates versus placebo, across White and Non-white racial/ethnic groups, including the Asian subgroup.

ATYPICAL HORTON’S ARTERITIS WITH OCULOMOTOR NERVES INVOLVEMENT AND ACUTE BRAIN ISCHEMIC LESION: A CASE REPORT

Alessandro Miscioscia, Paola Decet, Tommaso Carrer, Valentina Carlucci, Silvia Favaretto, Federica Garri, Annachiara Cagnin
Padova University Hospital, Department Of Neuroscience, Padova, Italy

Background and Aims:: Background: Oculomotor nerves palsy is a less common complication of giant cell arteritis (GCA) than ischemic optic neuritis, nevertheless it occurs in at least 10% of cases. Other rare complications are cerebrovascular ischemic events, which occur in about 7% of cases. The latter can underlie intra-extracranial vessel stenosis or occlusion, mainly in vertebro-basilar territory, but also an arterial-embolic stroke is possible. Aims: We first report a case of histologically proven GCA in which occurred two rare clinical manifestations, both peripheral oculomotor nerves palsy and acute cerebral ischemic stroke. Besides, PET-MRI compatible with aortitis was found, and arterial-embolic etiology of the stroke was hypothesized.

Methods:: Not applicable

Results:: Case report: A 75-year-old woman presented with headache, horizontal diplopia, and ptosis resulted in bilateral sixth nerve palsy and extrinsic right third nerve deficit. Her blood inflammation markers were moderately high, and brain MRI detected a small right frontal spot with DWI restriction, compatible with acute ischemic lesion, in the absence of other causes. Total-body PET MRI showed high hypermetabolism of the thoracic ascending and descending aorta, consistent with aortic inflammation. Left-temporal artery biopsy was performed, showing a severe inflammatory lympho-monocyte infiltrating pattern, with giant cells and necrosis in the artery wall. High dose of intravenous steroid therapy was started with complete recovery.

Conclusions:: Peripheric oculomotor nerves palsy and ischemic stroke are rare complications of GCA. In the case of increased levels of ESR and CRP and oculomotor abnormalities, Horton arteritis is one of the differential diagnoses to be considered.
IDIOPATHIC HYPERTROPHIC PACHYMENINGITIS, A CASE REPORT.

Daniel Rebolledo García¹, José Antonio Serna Higareda¹, David Eduardo Prestegui Muñoz¹, Rosa Xel Ha Dominguez Vega²
¹Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Departamento De Neurología Y Psiquiatría, Mexico City, Mexico, ²Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Laboratorio De Fibra Nerviosa Delgada, Mexico City, Mexico

Background and Aims:: Idiopathic hypertrophic cranial pachymeningitis (ICHP) is a rare entity characterized by chronic inflammation resulting in the thickening of the dura mater. The first cases of IICHP were related to tuberculosis or syphilis. Other causes are rheumatologic diseases, solid neoplasms or lymphoproliferative processes. After extensive evaluation by neuroimaging, lumbar puncture and serum markers (immunological-infectious-granulomatous) and no cause is founded, it is considered idiopathic in origin. Due to the lack of pathophysiological knowledge (whose hypotésis is possibly inflammatory), the appropriate therapeutic management is still a matter of debate. We describe a case of ICHP and its response to treatment with weekly subcutaneous MTX as described in Ruiz-Sandoval's cases.

Methods:: A 33-year-old man with a history of Gilbert's syndrome. In January 2021, he presented an oppressive headache in the cervical and occipital region that worsens with physical activity, intensity 8/10, extending to the frontal region and back, accompanied by dizziness. Neurological examination was positive for bilateral six cranial nerve palsy and meningismus. the rest was unremarkable. Lumbar punctions are shown in table 1.

Initial study ---> Steroids treatment ---> MTX SC

Converted angiotensin en CSF (ACE) | Negative
Serum levels of IgG4 | Negative
Serum levels IgG anti-PR3, IgG anti-MPO | Negative
Antinuclear - Antibodies - Immunofluorescence | 1:80 --negative

Results:: Cranial MRI scans were made as follows: -26.06.21
Conclusions:: Patient improvements headache and horizontal diplopia; continues MTX subcutaneous /weekly.
Background and Aims:: Available literature on migraine treatment have shown low persistence to preventive medication. The aim of this study is to describe the persistence of oral preventive treatments in subjects with migraine in Spain and its relationship with healthcare resource use (HRU) and associated costs.

Methods:: Data for this observational retrospective study come from electronic medical records in the BIG-PAC® database (Real Life Data) and include migraine patients ≥18 years who started their first oral preventive medication between 01/01/2016 and 30/06/2018. Patients were followed-up for one year and divided in two groups based on their one-year persistence. Differences between groups in HRU and costs (direct and indirect) were compared using 95% confidence intervals (CI).

Results:: A total of 7,866 migraine patients were analyzed: 80.4% women; mean age 48.2 years (SD=14.8); mean time since diagnosis 3.6 years (SD=1.9) and most frequent comorbidities anxiety (35.9%) and dyslipemia (27.0%). First-administered preventive treatments were antidepressants (46.3%) and antiepileptics (22.1%); median time in first-line treatment was 162 days. The persistent and non-persistent groups included respectively 2,390 (30.4%) and 5,414 (69.4%) patients. In the non-persistent group, the average number of medical visits and days of sick leaves increased by 3 (95% CI: 2.56-3.41) and 2.7 (95% CI: 0.84-4.54) days, compared to persistent patients, what raised total annual cost per patient by 622.1€ (95% CI: 414.9-829.2).

Conclusions:: One-year persistence in patients who initiated oral preventive migraine treatments was low. Persistent patients required a lower use of HRU and sick leaves resulting in reduced annual cost per patient.
VITAMIN PRESCRIPTION PATTERN IN SUDAN: AN EVIDENCE OF SUPPLY INDUCED DEMAND

Maisa Elfadul¹, Tahir Obeid², Omnia Ali³
¹University Of Medical sciences and Technology, Public And Tropical Health, Khartoum, Sudan, ²University Of Medical sciences and Technology, Medicine, Khartoum, Sudan, ³University Of Medical sciences and Technology, Medicine, Khartoum, Sudan

Background and Aims:: A growing trend of using vitamins has been documented, yet prescription pattern and reasons for use were not studied. The vitamins industry claims benefit in treating several neurological disorders in the absence of supportive evidence. The aim of this study was to explore the prescription pattern among patients attending neurology clinic.

Methods:: A cross-sectional survey was carried out in Alzaytuna Specialized Hospital, Neurology Department, May 2015 – July 2017. All patients had been assessed and investigated. EMG and Nerve conduction studies were performed to confirm diagnosis of some disorders. Structured assessment tool was used that included: information related to demographic, prescribed vitamin drug name and components, referring doctor’s specialty and the diagnosis.

Results:: A total of 335 patients were included, of which 143 are females. Main prescribers were neurologist (33.4%), Internist (22.7%) and the least were ENT, neurosurgeon and rheumatologist. Half of prescriptions were combinations of “B1, B6, B12” (51%) followed by B12 (23.3%). Vitamins were prescribed for variety of conditions including neurological, orthopedic and systemic disease. The Demyelinating diseases and Stroke/ TIA is accounted for (33%) among neurological conditions, where disc radiculopathy (63%) was the major condition across orthopedic condition. No significant differences were shown when testing association between types of vitamins and referred doctors or conditions.

Conclusions:: Neurologists and orthopedic surgeons induce supply for vitamins without any supportive evidence for cost effectiveness. The practice would increase risk of vitamins toxicity as well as risk opportunities of misdiagnosis. Continuous professional development programs should be designed to address misuse and improve evidence base practice and prescription pattern.
Background and Aims:: Transthyretin amyloidosis (ATTR) is a progressive, systemic, and potentially fatal condition in which misfolded transthyretin proteins form amyloid deposits in muscle and organ tissue. Currently available disease modifying ATTR-related pharmacotherapies generally slow or stop the progression of disease and the benefit of early initiation of treatment has been demonstrated. These analyses examine the relationship between time-to-treatment following symptom onset and long-term patient-reported outcomes (PROs) in patients with ATTR.

Methods:: Several PROs, including Composite Autonomic Symptom Scale, Norfolk Quality of Life—Diabetic Neuropathy questionnaire, and SF-36v2 Health Survey, were administered to 34 patients with ATTR (26 with nervous system involvement) at initial and 12-month assessments in a longitudinal, observational, online survey study. Time-to-treatment was calculated as years between self-reported symptom onset and initiation of ATTR-related pharmacotherapy. The associations between time-to-treatment and PROs at 12 months were examined using correlations, effect sizes for mean differences at yearly cut-points, and linear regression.

Results:: Longer time-to-treatment was at least moderately correlated with autonomic dysfunction including orthostatic hypotension and vasomotor dysfunction, large fiber neuropathy, role limitations due to health problems, and poor health perception (all r>|0.40|). Among the 24 PRO scores examined, effect sizes were at least moderate (all d>0.5) for 17 scores at the 5-year time-to-treatment cut-point. Results from regression models were consistent. Similar patterns were observed when examining only patients with nervous system involvement.

Conclusions:: This analysis provides further support for early initiation of pharmacotherapy for patients with ATTR as vital for preserving health and quality of life.
Background and Aims:: Hereditary transthyretin amyloidosis (hATTR) is a rare, progressive, systemic, fatal condition in which misfolded transthyretin proteins form amyloid in tissues and organs, often manifesting in polyneuropathy (hATTR-PN). The FDA has approved 2 gene-silencing pharmacotherapies for hATTR-PN: inotersen, administered subcutaneously; and patisiran, administered intravenously. Patient satisfaction for each treatment was examined during a period overlapping with the COVID-19 pandemic.

Methods:: Patients with hATTR-PN (with and without accompanying cardiomyopathy) in the United States participated in an observational, online survey between January 1 and October 25, 2020. The Treatment Satisfaction Questionnaire for Medication, version II (TSQMvII), was administered to 29 patients currently being treated with inotersen (n=11) or patisiran (n=18). TSQMvII produces 4 scale scores—Effectiveness, Side Effects, Convenience, and Global Satisfaction—ranging from 0 to 100. Higher scores indicate greater satisfaction. TSQMvII scores were descriptively compared between treatment groups.

Results:: Patients receiving inotersen indicated greater satisfaction with convenience than patients receiving patisiran (mean, 76.3 [SD=19.4] vs 58.6 [15.3], respectively), and less dissatisfaction with treatment side effects (86.1 [16.4] vs 68.3 [19.0]). Ratings were comparable between treatments with respect to effectiveness (72.0 [21.5] vs 67.1 [19.7]) and global satisfaction (78.0 [20.0] vs 74.5 [21.7]).

Conclusions:: While inotersen and patisiran were rated similarly in effectiveness and overall treatment satisfaction, inotersen was associated with less dissatisfaction with side effects and greater convenience, with the latter possibly reflecting differences in mode of administration (ie, at home vs visit to a clinical site), which may be particularly important during a pandemic.
FACTORS ASSOCIATED WITH GREATER HEALTH-RELATED QUALITY OF LIFE BENEFITS IN PEOPLE WITH HATTR AMYLOIDOSIS WITH POLYNEUROPATHY TREATED WITH INOTERSEN

Duncan Brown¹, Montserrat Llonch¹, Chafic Karam², Min Yang³, Nicolae Done³, Ibou Dieye³, Ana Bozas⁴, James Signorovitch⁵

¹Akcea Therapeutics, Global Health Economics & Outcomes Research, Boston, United States of America, ²University of Pennsylvania School of Medicine, Department Of Neurology, Philadelphia, United States of America, ³Analysis Group, Inc., Health Economics & Outcomes Research, Boston, United States of America, ⁴Akcea Therapeutics, Global Medical Communications, Boston, United States of America, ⁵Analysis Group, Inc., Data Analytics, Boston, United States of America

Background and Aims:: Hereditary transthyretin-mediated amyloidosis with polyneuropathy (hATTR-PN) is a genetic condition that shortens lifespan and carries significant morbidity. We aimed to identify factors associated with greater benefits from inotersen, measured by changes in Norfolk QOL–DN total score (TQOL, score range −4 to 136, higher scores indicating poorer QOL).

Methods:: We used data from the inotersen randomized, double-blind, placebo-controlled phase 2/3 trial for hATTR-PN, NEURO-TTR (NCT01737398, 66 weeks). LASSO regression models predicted TQOL change scores from baseline in the inotersen and placebo arms. Individualized response scores were calculated as differences between predicted change scores had patients received inotersen versus placebo. Patients were ranked by response scores from largest to smallest to define the subpopulation with greatest benefit (top 50%). Unadjusted TQOL change scores of inotersen-treated versus placebo-treated patients were compared within the greatest-benefit subpopulation.

Results:: The overall mean±SD TQOL change was −0.20±19.13 for inotersen (indicating no/minimal change) and 10.77±21.13 for placebo (indicating deterioration). Within people who benefited the most, the mean TQOL change was −11.03±17.06 (improvement) for inotersen and 11.24±22.97 (deterioration) for placebo (P<0.001). Compared with the overall population, patients in the greatest-benefit subpopulation were younger, more likely to have PND scores 1 or 2, less likely to have previous treatment and Thr60Ala, Leu58His, or Ser77Tyr mutations, and a higher (worse) baseline TQOL.

Conclusions:: People with hATTR-PN who were younger and/or at earlier polyneuropathy stages experienced greater HR-QOL benefits from inotersen over 66 weeks. These findings underscore the need for early diagnosis and treatment initiation in hATTR-PN.
HOSPITAL DIRECT COST OF STROKE IN SUB SAHARAN AFRICA: THE CASE OF SENEGAL.

Japhari Nyassinde¹, Kamadore Toure², Daniel Gams Massi³, Moustapha Ndiaye², Cissé Abass⁴, Ibrahima Camara¹, Amadou Diop²
¹Lannion-Trestel Hospital Center, Neurology, Lannion, France, ²University cheikh anta diop, Neurology, Dakar, Senegal, ³Faculty of Health Sciences/ Douala General Hospital, Internal Medicine And Paediatrics, Douala, Cameroon, ⁴Ignace Deen Teaching Hospital, Neurology, Conakry, Guinea

Background and Aims:: Stroke is a major public health problem because of its frequency, severity and cost. The aim of this study was to estimate the direct cost of care for stroke in hospital for clinical neuroscience of Fann Hospital in Dakar and to identify associated factors.

Methods:: We conducted a prospective economic study based on prevalence, descriptive and analytical. Patients were enrolled from June 1, 2016 to May 31, 2017. Our study population consisted of all patients hospitalized for stroke during the study period.

Results:: A total of 291 patients were included. The average cost was 450717 XOF ± 405214(825$ ± 742). The mean cost of intracerebral hemorrhage was higher 552420 XOF ± 591391(1012$ ± 1083) than that of cerebral infarct 390695 XOF ± 220978 (715$ ± 405) p = 0.07. Paraclinical investigations and hospitalization were the main expense items. The main predictors of cost were the duration of hospitalization (p <0.000001), intensive care unit and NIHSS score (p = 0.00021).

Conclusions:: The cost of stroke is high in Senegal and it is largely supported by patients. Duration of hospitalization and clinical severity are the main factors associated with total cost. Primary prevention must be a priority in our health policy.
SWITCHING MEDICATION WITHIN 12 MONTHS OF INITIATING CALCITONIN GENE-RELATED PEPTIDE MONOCLONAL ANTIBODIES VERSUS OTHER PREVENTIVE TREATMENTS FOR MIGRAINE

Oralee Varnado¹, Janna Manjelievskiaia², Janet Ford¹, Wenyu Ye¹, Allison Perry², Kory Schuh¹, Richard Wenzel¹
¹Eli Lilly and Company, Health Outcomes And Real-world Evidence, Indianapolis, United States of America, ²IBM Watson Health, Outcomes Research, Life Sciences, Cambridge, United States of America

Background and Aims:: Monoclonal antibodies targeting calcitonin gene-related peptide pathway (CGRP mAb) for migraine prevention are FDA-approved. This study assessed 12-month real-world switching patterns for patients initiating CGRP mAb versus other preventive migraine (non-CGRP) treatments.

Methods:: This retrospective, observational study was performed using IBM® MarketScan® Databases. Adults with ≥1 claim (first claim=index) for CGRP mAb (erenumab, fremanezumab, or galcanezumab) or non-CGRP treatments (e.g., antiepileptics, antidepressants, beta-blockers) between 1 May 2018 and 30 June 2019 with continuous enrollment for 12 months pre- and post-index (follow-up) were included. First switch occurred when patients discontinued index treatment (≥60-day gap) and started any other non-index CGRP mAb or non-CGRP treatment(s). Time to switch was calculated as days from index to first switch during follow-up. Descriptive, Chi-square (categorical variables), and Student’s t-test (continuous variables) analyses were conducted.

Results:: Eligible patients on CGRP mAb (N=4,528; female:86.2%) were older than patients on non-CGRP treatments (N=10,897; female:85.1%); mean age was 45.1 versus 41.3 years, respectively (P<.001). Over 12-month follow-up, 59.0% of CGRP mAb and 76.4% of non-CGRP initiators discontinued therapy (P<.001). Of these, 61.9% of CGRP mAb and 27.1% of non-CGRP initiators switched to another non-index CGRP mAb or non-CGRP treatment(s). Time to switch was similar (CGRP mAb: 180.7 days vs. non-CGRP treatments: 177.6 days; P=.15).

Conclusions:: CGRP mAb initiators were less likely to discontinue therapy over the 12-month follow-up period versus non-CGRP initiators. However, of those who discontinued index treatment, CGRP mAb initiators were more likely to switch to another preventive compared with those on non-CGRP treatments.
PATTERN AND OUTCOME OF NEUROCRITICAL DISORDERS IN MULTICENTER HOSPITALS IN KHARTOUM STATE, SUDAN. OCTOBER 2020-JANUARY 2021.

Khalid Mohammed¹, Mahmoud Daoud², Ammar Ahmed³
¹Gadarif University/Faculty of Medicine, Internal Medicine, Khartoum, Sudan, ²University of Gezira/Faculty of Medicine, Internal Medicine, Khartoum, Sudan, ³University of Khartoum/Faculty of Medicine, Neurophysiology, Khartoum, Sudan

Background and Aims:: Background Neurocritical care is a growing subspecialty. It concerns with the management of life-threatening neurological disorders. There is limited information regarding epidemiological data, disease characteristics, variability of clinical care, and in-hospital mortality of neurocritical patients worldwide. Objectives To study the pattern and outcome of neurocritical disorders as well as to highlight on neurological consultation in intensive care unit.

Methods:: Methodology This is a prospective observational study which was conducted in neurocritical patients who admitted in four intensive care units of major hospitals in Khartoum state during the period from October 2020 to January 2021.

Results:: Results Seventy two neurocritical patients were included in this study, 40(55.6%) were males and 32(44.4%) were females. 23(31.9%) patients with stroke, 12 (16.7%), with encephalitis, 9 (12.5%) with status epilepticus,6 (8.3%) with Guillain Barre syndrome, 4(5.6%) with MG and 16(22.2%) patients were consulted for neurological manifestation developed within the intensive care unit stay. 23 patients (39.9%) needed MV which was the major indication for intensive care unit admission.21 (29.2%) patients fully recovered,35 (48.6%) partially recovered and 16 (22.2%) died

Conclusions:: Conclusion & Recommendation Stroke was the dominant diagnostic pattern requiring intensive care unit admission. The majority of patients partially recovered. Establishing specialized neurocritical intensive care units with effective collaborations between neurologists, neurosurgeons and intensivists will improve the practice and outcome in this hot field.
THE NEUROLOGICAL EMERGENCIES ADMITTED TO ICU: FREQUENCY, ETIOLOGY AND OUTCOME AT KHARTOUM STATE HOSPITALS IN THE PERIOD FROM OCTOBER 2019 TO APRIL 2020

Sara Ismail¹,², Mahmoud Daoud², Hussam Ali³
¹Fedail Hospital, Internal Medicine, Khartoum, Sudan, ²University of Gezira/ Faculty of Medicine, Internal Medicine, Khartoum, Sudan, ³Fedail Hospital, Neurology, Khartoum, Sudan

Background and Aims: Neurological emergencies are frequent presentations and often times with devastating short and long term consequences. Neurological disorders are increasingly prevalent in Sub-Saharan Africa with paucity of data on adult neurological emergencies in our context. Objective: To study etiologies, patterns of clinical presentation, and outcomes of neurological emergencies patients admitted to ICU

Methods: A Prospective study enrolled 103 patients with neurological emergencies admitted to ICU Khartoum state intensive care departments during the period from October 2019 to April 2020. Data regarding demographics, presentations, clinical examinations, laboratory investigations, indications of ICU admission, diagnosis of neurological conditions, length of ICU stay, patterns of medications and outcomes were collected. Data was analyzed by using SPSS v. 21.0

Results: Among 103 patients, 58(56%) were males and 45(44%) were females, and their mean age was 56.4±16.8 years. Meningitis (n=28; 27.2%), encephalitis (n=28; 27.2%), ischemic stroke (n=19; 18.4%) and hemorrhagic stroke (n=13; 12.6%) were the common diagnosis. Altered mental status was the predominant complain in 66(64.1%) patients. A decreased level of consciousness was the major indication of ICU admission in 77(74.8%) patients. 45(44%) patients improved and discharged, 42(41%) and 16(15%) died ; most due to aspiration pneumonia (n=25; 24.3%).

Conclusions: Sudanese patients with neurological emergencies admitted to ICU were older and mostly males. Meningitis, encephalitis and stroke were the main diagnoses. Patients commonly presented with altered mental status. Half of the patients were improved and aspiration pneumonia observed in a quarter of the patients.
REAL-WORLD IMPACT OF PERAMPanEL USE AMONG PATIENTS DIAGNOSED WITH EPILEPSY IN THE UNITED STATES

Brian Moseley¹, Jonathon Wright², Shaloo Gupta², Victoria Barghout³, Nate Way², John Rowland², Craig Plauschinat⁴, Feride Frech⁴

¹University of Cincinnati College of Medicine, Department Of Neurology And Rehabilitation Medicine, Cincinnati, United States of America, ²Kantar Health, Health Division, New York, United States of America, ³VEB Healthcare, LLC, Health, Morristown, United States of America, ⁴Eisai Inc., Us Heor & Rwe, Woodcliff Lake, United States of America

Background and Aims:: Real-world experience with antiepileptic drugs (AEDs) has important repercussions on outcomes and quality of care. Our aim was to evaluate patient experience with perampanel in the USA.

Methods:: A multi-center survey was completed by patients who were ≥18 years old, had a physician confirmed epilepsy diagnosis, used perampanel for ≥4 months, and provided informed consent. Patients provided sociodemographics, treatment history, experiences before perampanel and currently, treatment satisfaction (0-100), medication adherence, quality of life (QoL) and healthcare resource utilization. Statistical analyses were performed using SAS Software, Version 9.4.

Results:: Patients (N=61) were mean age 42.8 years, 63.9% female, 75.4% white and 96.7% had health insurance. Patients had focal onset (62.3%) and primary generalized seizures (45.9%). Mean perampanel exposure was 2.5 years and 62.3% were adherent; 55.7% were taking sodium-channel blockers concomitantly. Patients reported 20.4 (SD=60.0) versus 5.5 (SD=13.2) seizures/month before perampanel and currently, respectively. Compared to prior AEDs, patients “strongly agreed” that perampanel allowed them to live a more normal life (36.1% versus 27.5%) and worked as intended if they missed a dose (16.4% versus 7.8%). Satisfaction scores for perampanel were, 71.8 for effectiveness, 84.0 for convenience and 71.9 for global satisfaction. Perampanel use was associated with improvements in QoL and fewer symptoms of depression and anxiety. Patients had fewer epilepsy-related office (1.8 versus 2.7) and emergency room visits (0.7 versus 2.2) compared to 6 months prior to perampanel initiation.

Conclusions:: Epilepsy patients taking perampanel reported reduced number of seizures, better QoL, lower healthcare resource use and high patient satisfaction in the real-world setting.
Background and Aims:: In June 2019, the Institute celebrated its centenary. The history of scientific activity of the Laboratory of Neuro-Orthopedics and Pain Problems is interesting.

Methods:: The archival materials of the institution were studied.

Results:: In August 1990, 4 scientific associates and 2 doctors from the Kyiv branch of the Kharkiv Research and Scientific Institute of Neurology and Psychiatry were transferred to the Kyiv Research and Scientific Institute of Orthopedics. In May 2006, they established an independent neuro-orthopedic laboratory. Today the Laboratory is expanded and conducts scientific researches in the Institute clinics. Criteria for neurotrophic disorders in patients with chronic hematogenous, traumatic osteomyelitis were developed. A number of degenerative, dystrophic injuries of extremities joints of vertebrogenic origin were revealed. The role of peripheral autonomic nerve structures and spinal cord in pathology formation was established in children with congenital malformations of extremities major joints, both at regional level and in body as a whole. Criteria for diagnostics of pain in vertebral body fractures on background of systemic osteoporosis under deformable spondylosis were revealed. Special features of nervous system disorder in persons with funnel chest deformation were established. The original classification of neuro-orthopedic pain syndromes and neurological complications in patients with amputated extremity parts was developed. The neurological examinations of servicemen of the Armed Forces of Ukraine having received a combat extremity injury within War in Donbass are conducted with further surgical treatment in the Institute clinics.

Conclusions:: The Laboratory of Neuro-Orthopedics and Pain Problems has prospects for further development, working closely with orthopedists, neurologists in Ukraine and abroad.
ATYPICAL MANIFESTATION OF PANCOAST TUMOR WITH NEUROPSYCHOLOGICAL DISORDERS

Andriana Mavriki, Apostolos Manolopoulos, Teresa Acquaviva
Thriasio Hospital, Neurology, Elefsina, Greece

Background and Aims: Introduction: Horner’s syndrome was named after Swiss ophthalmologist Johann-Friedrich Horner (1831–1886), who first described it in 1869. The French physiologist Claude Bernard (1813–1878) also took part in the discovery of this particular syndrome, therefore it is also sometimes referred to as Bernhard-Horner Syndrome. It is one of the most known and rare neurological syndromes that can cause a rare clinical manifestation of the also rare Pancoast-type lung cancer. The Pancoast tumor, first described by the British surgeon Edward Selleck Hare (1812–1838) and afterwards by the Italian physician Publio Ciuffini (18??–19??) in 1911, was finally named after the American radiologist Henry Pancoast (1875–1939), and it is a rare and rapidly spreading peripheral tumor of the pulmonary apex.

Methods: Case report: 72-year old patient examined at the Emergency Department due to memory impairment 7 days before.

Results: The results show Horner’s syndrome with pupil contraction, blepharoptosis and left eye enophthalmos, along with impairment of memory abilities, bradypsychia and slowness of movement (bradykinesia). The patient was subjected to chest x-ray and cerebral CT scan, which revealed a tumor at the pulmonary apex and brain metastases respective.

Conclusions: Conclusion: The past discovery of two major syndromes was a case of international collaboration. We must all never omit to show our respect and cite the masters of Medicine, past and contemporary alike. In the context of the Emergency Department, the atypical manifestation of Pancoast tumors with neuropsychological disorders may mislead physicians and result in patients being referred to in outpatient clinics. According to literature, the scientific interest for both these eponymous syndromes remains unchanged throughout the century, with reports published as recent as in 2020.
Background and Aims:: The year 2021 marks the 700th anniversary of medieval poet and philosopher Dante Alighieri death. Dante a giant of Italian literature and credited as “father of the Italian language”, died in 1321 in Ravenna. He had a sound level of medical knowledge, as demonstrated by his description of mental disorders and attended courses at the University of Bologna and at the Sorbonne of Paris, where he may have also studied human anatomy and physiology reading ancient medical writings by Greek, Roman and Arab physicians.

Methods:: Notions of neuroanatomy and neurophysiology (the connection between brain and spinal cord, function of optic nerve and peripheral nerves, knowledge of vegetative nervous system) and descriptions of epileptic seizures and narcolepsy may be found in the Inferno.

Results:: Purgatorio and Paradise demonstrated his imaginative and allegorical travel through all human emotions from Limbic System (Amygdala and hippocampus) to Beatrice smile . “And I, who to the end of all desires/ Was now approaching, even as I ought/The ardour of desire within me ended” (Par. XXXIII, 46-48). The figure of Dante, prophet of hope and witness to the human desire for happiness, can still provide us with words and examples that encourage us on our journey.

Conclusions:: The analysis of neuro-expressionism and Limbic System in Dante’s works confirms that literature and art may be an important source of information and inspiration for neurologists and for history of neurology. Does neurology express art or art express neurology?
ROLE OF THE ALL-UNION INSTITUTE OF EXPERIMENTAL MEDICINE IN THE DEVELOPMENT OF NEUROLOGY IN THE SOVIET RUSSIA

Dmitriy Labunskiy, Svetlana Kiryukhina, Vyacheslav Podsevatkin
Ogarev Mordovia State University, Neurology And Psychiatry, Saransk, Russian Federation

Background and Aims:: Since 1930, on the initiative of the writer Maxim Gorky, idea of the director of the Leningrad L.N.Fyodorov was being worked out on organization of All-Union Institute for comprehensive study of man. By decree of Council of People's Commissars of the USSR dated October 15, 1932 "On the All-Union Institute of Experimental Medicine in Moscow."

Methods:: We studied Institute's archives and spoke with witnesses and participants of Institute's formation.

Results:: When VIEM was transferred to Moscow, Bach Biochemical Institute formed the VIEM chemistry sector. After the VIEM moved to Moscow, there departments of human physiology (Razenkov), physiology and pathology of sense organs (Stern and Kaplansky), human morphology (Lavrent'ev), biological physical chemistry Rubenstein), organic chemistry (Zelinsky), parasitology E. N. Pavlovsky), viruses (Smorodintsev). At the beginning of 1940s, 3000 people worked at institute, of which 500 were famous scientists and researchers. Institute's annual budget reached 30 million rubles. As of January 1943, structure of Institute consisted of following divisions: Department of Nervous System Physiology (Head - Anokhin) - since 1944 the Institute of Physiology of Soviet Academy of Medical Sciences, laboratory of electrophysiology; laboratory of higher nervous activity; laboratory of neurophysiology; morphological laboratory; Department of General Pathology (Speransky) laboratory of histology, head. - prof. Borovsky; laboratory of experimental pathology, head. - Lebedinskaya; laboratory of infection and immunity, head. - Ostry; laboratory of age physiology and pathology, head. - Arshavsky; chemical laboratory, head. - Saltykov.

Conclusions:: An integrated strategic approach helped organization of fundamental research in neuroscience in Soviet Russia.
NEURO-EXPRESSIONISM IN MICHELANGELO

Ana Isabel Fumagalli
Sanatorio Parque, Neurology, Rosario, Argentina

Background and Aims:: In addition to being an artistic genius, the Florentine painter, sculptor, and architect Michelangelo Buonarroti (1475–1564) was a master anatomist. He acquired his vast understanding of human anatomy by performing cadaver dissections independently and in an unstructured fashion. Meshberger's assertion that Michelangelo incorporated a view of the brain in the Creation of Adam is compelling and appears to be gaining support among art historians.

Methods:: Michelangelo probably explored gross neuroanatomy.

Results:: He developed an understanding of the human emotions from Limbic System (Amygdala and hippocampus) to Moises Terribilità, pain and maternal love in The Pietà and sublime and beautiful David being regarded as a virtuous fighter for freedom. According to Prof. Semir Zeki the neural activity that correlates with experience of the beautiful is very different from that which correlates with experience of the sublime.

Conclusions:: The analysis of neuro-expressionism and Limbic System in his magnificent beautiful and sublime creations confirms that art may be an important source of inspiration for neurologists.
Background and Aims:: Coronavirus 2019 (COVID-19), with more than 3 million deaths worldwide, is one of the deadliest pandemics in history. Patients with primary mitochondrial diseases (PMDs) are considered at high risk of complications. However, little is known about how COVID-19 affects this group. The aim of our study was to: (1) identify risk factors associated with hospitalisation; and (2) determine outcomes and long-term sequelae of COVID-19 in people with PMDs.

Methods:: Inclusion criteria included: (1) clinico-pathological and/or genetically confirmed PMDs at any age; and (2) COVID-19 infection with compatible symptoms and/or positive PCR testing. Data concerning the underlying diagnosis and COVID-19 infection were anonymously collated by physicians worldwide. The primary outcome was hospitalisation due to COVID-19. Univariable analysis and multivariable-adjusted logistic regression were subsequently applied to data.

Results:: Seventy-two subjects with PMDs from nine countries were included in the study (mean age 41.3 ± 18.2 years); 22 (30.6%) were hospitalised; 43 (59.7%) recovered fully; 25 (34.7%) resolved with sequelae (global deterioration of PMD in six cases, long-COVID-19 in 19 cases); and three (4.2%) died. Statistically significant differences in hospitalisation status were observed for: (1) age (p=0.005); (2) Newcastle Mitochondrial Disease Adult Scale score (p=0.003); (3) modified Rankin scale before COVID-19 (p=0.03); (4) respiratory (p<0.001) and skeletal muscle weakness (p=0.004); (5) wheelchair dependence (p=0.005); and (6) gastrointestinal dysmotility (p=0.002).

Conclusions:: Our study confirms the PMD patients most vulnerable to COVID-19 related hospitalisation, thus helping stratify risk and appropriate management. Long-term sequelae, including worsening of the pre-existing PMD and “long COVID-19 symptoms”, were a frequent finding in our cohort.
NADPH OXIDASE 5: A NEW PLAYER IN PERIPHERAL NEUROPATHY

Stephanie Eid, Faye Mendelson, John Hayes, Crystal Pacut, Kai Guo, Junguk Hur, Eva Feldman

1University of Michigan, Neurology, Ann Arbor, United States of America, 2University of North Dakota, Biomedical Sciences, Grand Forks, United States of America

Background and Aims:: Peripheral neuropathy (PN) is a debilitating complication affecting over 30% of prediabetic and 60% of type 2 diabetic (T2D) patients. Dyslipidemia has emerged as an independent risk factor for PN. However, the mechanisms by which dyslipidemia leads to nerve injury are not fully defined. While dyslipidemia is associated with systemic and tissue-specific oxidative stress, how it intersects with reactive oxygen species (ROS) sources to contribute to nerve damage is unknown. NADPH oxidase (Nox) enzymes are specialized for ROS production, and of the 7 members, the Nox5 isoform is only expressed in humans. In this study, we examined the role of Nox5 in human nerves and in culture models of PN.

Methods:: Nox5 methylation status, gene and protein expression were assessed in sural nerve biopsies from PN patients. In vitro, human Schwann cell (SC) and neuronal cultures were exposed to the saturated fatty acid palmitate to evaluate Nox5-derived ROS, apoptosis, and Nox4-Nox5 interaction.

Results:: Nox5 promoter was hypomethylated in the sural nerve of patients with worse PN that was associated with increased Nox5 expression. In vitro, palmitate increased Nox5-derived ROS in cultured neurons. Although Nrf2 nuclear translocation was increased after 24 h of palmitate exposure, this effect was not sufficient to reduce upregulated caspase 3 protein expression at early and late time points. Similar results were observed in SCs, with preliminary data of a potential Nox4-Nox5 interaction in palmitate-treated SCs.

Conclusions:: We highlight a role of Nox5 as a target for dyslipidemic oxidative stress that may injure PN-relevant cell types and contribute to PN.
ELECTROMYOGRAPHIC FINDINGS IN PATIENTS WITH LATE-ONSET POMPE DISEASE

Olimpia Musumeci¹, Carmen Terranova², Alessia Pugliese¹, Vincenzo Rizzo², Paolo Girlanda², Antonio Toscano¹
¹University of Messina, Unit Of Neurology And Neuromuscular Disorders, Department Of Clinical And Experimental Medicine, Messina, Italy, ²University of Messina, Department Of Clinical And Experimental Medicine, Messina, Italy

Background and Aims:: Background Pompe disease is an autosomal recessive disorder caused by mutations in the GAA gene encoding the enzyme acid alpha-glucosidase. The late-onset form (LOPD) is characterized by most prominent proximal muscles involvement at four limbs. Electrophysiological study is a diagnostic tool still applied in the diagnostic work up of patients with suspected LOPD. Aim of the study is to evaluate EMG findings including the distribution of involved muscles looking for distal muscle involvement, in a cohort of LOPD patients.

Methods:: 30 LOPD patients (16 M– 14 F) underwent electromyographic evaluation looking at spontaneous activity, MUP analysis and firing rate and recruitment of MUPs in proximal and distal muscles. Moreover electroneurography was performed.

Results:: EMG evidenced the presence of myotonic discharges (MD) in paraspinal muscles in 15/30 patients (50%) but also in distal limb muscles in 5/30 patients (15%). Fibrillation potentials occurred in all muscles where MD were found. Short duration, polyphasic motor unit potentials (MUPs) were found in the paraspinal (35%), proximal (35%) and distal limb muscles (17%) of patients studied. Nerve conduction studies were normal in all patients.

Conclusions:: Conclusion Our results confirmed that myopathic EMG pattern is usually observed in proximal muscles, but we also found a similar pattern in distal muscles revealing a subclinical involvement. Moreover myotonic discharges and denervation activity are present in both paraspinal and distal muscles. We can conclude that it is useful to extend the EMG study also to distal muscles even if not clinically involved.
METFORMIN IMPROVES BIOENERGETICS STATE AND MITOCHONDRIAL DYNAMICS OF DIFFERENT BRAIN REGIONS IN RESTRAINT STRESSED RATS

Shima Zare Shahamati¹, Fariba Khodagholi²
¹Shahid Beheshti University of Medical Sciences, Neurology Department, Imam Hossein Hospital, Tehran, Iran, ²Shahid Beheshti University of Medical Sciences, Neurobiology Research Center, Tehran, Iran

Background and Aims:: Mitochondrial dysfunction contribute to ageing and neurodegenerative disorders by producing reactive oxygen species (ROS). Restraint stress as a physical and psychological stressor results in increased generation of ROS, selectively affects the hippocampal neurons that associated with an impairment in spatial learning and memory tasks. Metformin activates AMP-activated protein kinase (AMPK) that presents anti-inflammatory and anti-oxidative properties on the human brain metabolism. Here, we aimed to investigate the adverse effects of restraint stress on the mitochondrial functions of central nervous system which would be attenuated by metformin.

Methods:: Twenty-four male Wistar rats, were randomized into four groups (n = 6), metformin, stress, metformin and stress, and control. Metformin dissolved in distilled water and gavaged once in a day for 14 days. In stress groups rats were immobilized as an acute stress for 6 hours. Rats were then euthanized by decapitation and tricarboxylic acid (TCA) cycle enzyme activity, antioxidant levels, and mitochondrial biogenesis factors were assessed in the frontal, hippocampus, parietal and temporal regions using spectrophotometer and western blot technique.

Results:: Metformin reduced anxiety like behavior, evaluated by elevated plus maze test, caused by restraint stress. There was an increase in activity of TCA cycle enzymes in stress and metformin-stress groups, along with an increase in antioxidant agents, mitochondrial biogenesis factors and dynamic markers.

Conclusions:: Our data suggest mentioned mitochondrial factors increased in the frontal and parietal lobes with metformin pretreatment. Accordingly, metformin can be used as a prophylactic approach against bioenergetics and mitochondrial dysfunction.
MODULATORY POTENTIALS OF VOGLIBOSE ALONG WITH PROBIOTIC IN DIABETIC RATS

Akashdeep Singh, Nitin Kumar, Gurfateh Singh
UNIVERSITY SCHOOL OF PHARMACEUTICAL SCIENCES, RAYAT-BAHRA UNIVERSITY, SAS NAGAR, PUNAB, INDIA 140104, Pharmacology, KHARAR-SAS NAGAR (MOHALI), India

Background and Aims:: Diabetes mellitus regarded as a chronic metabolic disorder characterized by hyperglycemia is prevailing rapidly all over the world and accompanied with various micro and macro vascular complications. The purpose of present study was to examine the modulatory effect of probiotics on different doses of Voglibose in the type 2 diabetic (T2D) rat model.

Methods:: Sprague–Dawley rats (180-250gm) were subjected to high Fat Diet (HFD) for a period of 2 weeks followed by Streptozotocin (STZ) (35mg/kg i.p.) till 21th day of experimental protocol. Then, diabetic rats were treated with Probiotics (75 mg/kg, oral gavage), Voglibose (0.1 mg/kg or 0.3 mg/kg, oral gavage) and combination of different doses of voglibose and probiotics. Serum Lipid parameters such as Total Cholesterol Estimation, Triglyceride estimation and estimation of blood glucose level was done on 0, 14th, 21th and 42th day of the experimental protocol.

Results:: Treatment with Voglibose (0.3mg/kg) and probiotics (75mg/kg) significantly attenuates the body weight (BW) in a dose dependent manner when compared with normal animals. Further, when drugs are given in combination i.e. Voglibose (0.3mg/kg) and probiotics (75mg/kg), significantly decreased the blood glucose level, total cholesterol level in comparison to diabetic group treated with Voglibose (0.3mg/kg). In addition, there is marked increase in the level of high density lipoprotein (HDL) with significant decrease in the level of Low Density lipoprotein (LDL) and very low density lipoprotein (VLDL) level in comparison to diabetic control.

Conclusions:: Thus, it may be concluded that synergistic protective effect on T2D rats may be due to combination of Probiotics and Voglibose.
A YOUNG MALE WITH WALKING DIFFICULTIES AND SUBACUTE BRAINSTEM DYSFUNCTION: ADULT-ONSET LEIGH SYNDROME.

Elia Cipriano¹, Domizia Vecchio², Letizia Mazzini³, Gionata Strigaro³, Roberto Cantello³, Gionata Strigaro³, Gionata Strigaro³, Giacomo Pietro Comi⁵, Daniela Piga⁵, Monica Sciacco⁵, Egidio Genovese⁶

Background and Aims:: Leigh syndrome (LS) or subacute necrotizing encephalomyelopathy is a progressive, lethal, mitochondrial disease mostly presenting in the childhood.

Methods:: We report a 36 year-old male born in Ivory Coast and living in Italy for the last 20 years. He presented to the Urgency Department after falling over with a 6-month history of progressive dysarthria. When repeatedly asked, he revealed walking difficulties since he was 25 (not investigated) with mute family history. Neurological examination showed: dysarthria, oculomotor limitations for downgaze and convergence, mild right-side paresis with Babinski sign with no reflexes to the lower limbs. A brain magnetic resonance (MRI) showed diffuse white matter lesions restricted to diffusion-weight sequences with no enhancement, localized: around the third ventricle, to the medulla oblongata, and bilaterally at caudate nuclei and putamen. Spectroscopy documented a peak of choline and creatine, increased lactate and reduced n-acetyl-aspartate. Blood and cerebral spinal fluid analyses excluded any autoimmune/demyelinating/infective/paraneoplastic encephalopathy. A quadriceps muscle biopsy showed mild myopathic changes. Mitochondrial genes polymerase-chain-reaction amplification followed by direct sequencing found a 10191T>C variant that is related to LS. Meanwhile the patient worsened his respiratory function and needed a tracheostomy with not-invasive ventilation. He then stabilized in the respiratory rehabilitation, still alive 7 months after diagnosis. Maintenance therapy included: acetylcarnitine 1500 mg, ubidecarenone 50 mg.

Results:: Our patient presented a prolonged history of mild walking difficulties with a subacute onset of brainstem dysfunction that finally resulted LS.

Conclusions:: Only other 9 late-onset cases share the same pathogenic variant 10191T>C
Background and Aims:: Leucoencephalopathies include a broad spectrum of inherited neurodegenerative disorders mainly due to lysosomal or peroxisomal diseases. The involvement of white matter is currently recognized as a common feature of mitochondrial disease. We aimed to determine the clinic-radiological characteristics of mitochondrial leucoencephalopathy (ML) over other types of leucodystrophy.

Methods:: A retrospective study was conducted between 2008 and 2019 including pediatric patients with ML. Detailed analysis of the clinical course and imaging findings was performed. The diagnosis of ML was confirmed through clinical, radiological, biochemical features and sometimes using genetic testing.

Results:: We included 17 patients with ML (M/F = 12/5, mean age: 89.2 ± 49 months). All patients had a disease onset before the age of 2 years (mean age: 12.6 ± 7 months) and most of them had a progressive disease course (76%). Clinical features commonly included encephalopathy (70%), spasticity (70%), gaze abnormalities (53%), and peripheral neuropathy (47%), while epilepsy (23%) and movement disorders (11%) were rarely described. Half of the patients had hyperlactatemia and only 15% had high CSF lactate rate. Brain MRI frequently revealed hypomyelinating leucodystrophy (47%). Other radiological characteristics were white matter cysts (18%), corpus callosum involvement (18%), diffusion restriction (6%), contrast enhancement (6%), basal ganglia and/or brainstem involvement (41%), and lactate peak on spectroscopy (35%). The molecular analysis confirmed a SURF1 mutation in 3 patients and an FBXL4 mutation in one.

Conclusions:: The diagnosis of ML is quite difficult without genetic testing, as clinical presentation often mimics other types of leucodystrophy and biochemical testing does not always help. However, it can be guided through MRI and spectroscopy.
PERIPHERAL NEUROPATHY DUE TO MITOCHONDRIAL DISORDERS IN PEDIATRIC PATIENTS

Rania Zouari¹, Chahnez Triki², Wafa Bouchaala², Sihem Ben Nsir², Fatma Kamoun²
¹Hedi Chaker Hospital, Child Neurology Department, Sfax, Tunisia, ²Sfax university, Search Unit « Neuropédiatrie » Ur12es16, Sfax, Tunisia

Background and Aims:: mitochondrial diseases (MD) constitute a heterogeneous group of disorders that preferentially affect high energy-demanding tissues, as the peripheral nervous system (PNS). The PNS is frequently involved in MD with variable degrees of severity. We aimed to describe the clinical-electric characteristics of peripheral neuropathy (PN) in children with MD.

Methods:: we retrospectively assessed the medical records (clinical and EMG data) of patients diagnosed with MD in our department of child neurology over 11 years. Then, we focused on PN as a clinical feature of MD. In most patients, PN was clinically suspected then confirmed later through EMG. In each patient, we determined the type, severity, and distribution of PN along with the associated signs.

Results:: among the 92 patients with MD, we selected 17 patients (M/F=12/5) having PN (18%). At the onset, the mean age was 24.6±25 months and most patients (47%) had encephalopathy and generalized hypotonia, while 35% had gait abnormalities and 11% had a muscular weakness. At follow-up, besides PN, 82% had a complex neurological presentation, including encephalopathy (85%), hypotonia (85%), spasticity (43%), movement disorders (43%), epilepsy (35%) and ophthalmoplegia (23%). On EMG, 11 patients had a demyelinating polyneuropathy whom genetic study showed a SURF1 and FBXL4 mutation in 2 patients, while only 5 had an axonal polyneuropathy. PN was sensory-motor in 10 patients and pure motor in 5.

Conclusions:: PN is a common feature in MD. Although suspecting the presence of PN in a child with a complex multi-system presentation is challenging, the type of PN can guide the molecular analysis.
CENTRAL PONTINE MYELINOLYSIS IN ACUTE MALNUTRITION: CASE REPORT

Maria Isabel Correa Naranjo1,2, Maria Isabel Raad Sarabia2, Edgard Eliud Castillo Támara1,2
1University of Sinú, Neurology, MEDELLIN, Colombia, 2University of Sinú, Neurology, medellin, Colombia

Background and Aims:: Central pontine myelinolysis (CPM) is a rare non-inflammatory neurologic condition most frequently caused by the rapid correction of metabolic disturbances as part of osmotic demyelination syndrome (ODS). It is characterized by damage to regions of the brain, most commonly pontine white matter tracts. Clinical manifestations can appear within several days and can range from encephalopathy to coma and death. CPM has been reported in cases of patients with alcohol use disorder, severe burns, liver transplantation, anorexia nervosa, hyperemesis gravidarum and hyperglycemic or hyponatremic states followed by a rapid correction.

Methods:: We report a 30 year old male patient with 2 week course of progressive weakness that begins in the lower extremities and subsequently involves upper extremities, with subsequent onset of diplopia, dysphagia and dysphonia in whom hydroelectrolyte, glycemic, infectious disorders and chronic alcohol consumption were ruled out. The only related triggering factor is the decrease in protein-calorie intake, marked decrease in weight and BMI 16 in the last few months as a consequence of the current pandemic economic crisis.

Results::
MAGE 1. Brain Magnetic Resonance (T2, T2 FLAIR, Diffusion-weighted imaging/DWI)

**Conclusions:** There are few published cases relating ODS and malnutrition, however it is one of the mechanisms that decrease serum tonicity. Nutrition disorders may be a cause of demyelination of white matter after rapid correction and it is important to keep in mind the possibility of progression to CPM.
A NOVEL MUTATION OF PORPHYRIA VARIEGATE WITH PREDOMINANT PAINFUL SENSORIMOTOR PERIPHERAL NEUROPATHY DISCLOSED BY POST GASTRIC BY-PASS COMPLICATIONS: A CASE REPORT

Edwige Collaud¹, Luis Wittwer², Joelle Chabwine³, Jean-Marie Annoni³, Anna-Elisabeth Minder⁴, Elisabeth I Minder⁴
¹Fribourg Hospital, Medicine, Villars-sur-Glâne, Switzerland, ²Emmental Hospital, Medicine, Burgdorf, Switzerland, ³University of Fribourg, Neurosciences, Fribourg, Switzerland, ⁴Triemli Hospital, Endocrinology, Zurich, Switzerland

Background and Aims:: Porphyrias are a group of rare genetic diseases due to various mostly autosomal dominant mutations causing enzymatic deficiency in heme biosynthesis. As a result, neurotoxic porphyrin precursors and light-sensitizing porphyrins accumulate, while their targets determine the disease symptoms. Porphyria variegate (VP), one of the acute hepatic porphyrias, is caused by a PPOX mutation. During acute crisis triggered by drugs, stressors or fasting, an increase of porphobilinogen (PBG), aminolaevulinic acid (ALA) and porphyrins in urine and stool occur, damaging the autonomous, peripheral and central nervous system. Elimination of precipitating factors, heme-infusions, symptomatic treatment of acute symptoms, sufficient carbohydrate supply constitute the key management. Frequently, the disease remains latent life-long, or minimal symptoms are ignored.

Methods:: This 46-year-old woman presented, some days after a gastric by-bass surgery (RYGB), with severe flaccid tetraparesis and neuropathic pain, initially misdiagnosed to be functional.

Results:: The severe sensorimotor polyneuropathy led to further investigations, disclosing high urinary PBG, ALA and porphyrin levels due to a new PPOX mutation. Retrospectively, the patient had had symptoms typical for VP (especially fragile skin, dark urines) for years prior to surgery. With carbohydrate load, rehabilitation and analgesics, she slowly recovered to full mobility, partial autonomy in her daily life activities, but pain persisted.

Conclusions:: This case documents an exceptional complication after RYGB, but suggests also that a screening for porphyria in patients with cardinal symptoms or a family history of acute porphyria prior to any treatment influencing the diet could prevent porphyria crises and their irreversible adverse consequences.
MELAS SYNDROME, CASE REPORT

Serla Grabova¹, Gleni Halili², Jera Kruja²
¹UHC Mother Teresa, Neurophysiology, Tirana, Albania, ²Faculty of Medicine, UMT, Neurology, Tirana, Albania

Background and Aims:: MELAS syndrome is a mitochondrial cytopathy, which is characterized by encephalomyopathy, lactic acidosis and ‘stroke like’ episodes, and it is caused by mutations in the mitochondrial DNA. It constitutes a rare multisystemic progressive disorder, with major influence in the muscular and nervous system. Clinical signs and symptoms appear mainly in childhood and adolescence (typically < 40 years old), but can appear at any age.

Methods:: This is a case report of a patient hospitalised in Neurology dept, UHC Mother Teresa.

Results:: The patient E.D is 16 years old when he comes to our attention for an evaluation after some episodes of acute headache, photophobia, decreased vision, and difficulty speaking and repeated seizures. In his medical history it is noted a palatoschisis intervention at the age of 2 and behavioral problems since he was a little child, with mild cognitive impairment. His MRI reveals a left edematous fronto-insular lesion and bilateral occipital lesions, of a similar nature. The patients undergo a biochemistry laboratory analysis and also a muscle biopsy, with conclusive evidence of mitochondriopathy.

Conclusions:: MELAS syndrome is a rare genetic and metabolic disorder, which should have a special diagnostic consideration by clinicians when neuroimaging shows cerebral cortical lesions, which do not follow vascular territories. This case is a classic example of the progression of the disease, with clinical relapses and fluctuant lesions similar to ischemia, in neuroimaging. There isn’t yet a clearly defined consensus for treating patients with MELAS syndrome, but there are recommendations towards a symptomatic approach of treatment.
Background and Aims:: Acute intermittent porphyria (AIP) is a rare and challenging hereditary neurovisceral disease. Peripheral neuropathy is considered the most common neurological manifestation of AIP. Posterior reversible encephalopathy syndrome (PRES) is a clinical and radiological syndrome with bilateral reversible lesions, mostly in parieto-occipital gyri, that is associated with many different conditions, especially severe hypertension. seizures in an acute attack of AIP have been reported, especially if associated with abdominal pain.

Methods:: 17-years old female patient, previously known well, presented with acute onset recurrent attacks of tonic-clonic seizures and high blood pressure. Magnetic resonance imaging (MRI) brain showed a picture of PRES (Figure 1). Three attacks of abdominal pain and vomiting occurred before the onset of seizures over six weeks, with no abnormality detected except mild hypokalemia. Antiepileptic medications and dexamethasone started, CSF analysis was unremarkable. Two weeks later, the patient started to be quadriparetic, hypoventilated with autonomic instability, and mechanically ventilated.
Results:: AIP was suspected, and Watson–Schwartz test was positive (figure 2). Porphobilinogen (PBG) and delta-aminolevulinic acid (ALA) in urine sent out. Her medications were revised and all unsafe medications, especially antiepileptics, were stopped. Moreover, she started on a high carbohydrate diet and other supportive measurements with mild improvement. After high levels of PBG and ALA detections, she started on Hematin, with marked improvement and discharged from ICU.
Conclusions:: AIP should also be considered when seizures and PRES are associated with unexplained abdominal pain. A good prognosis could be achieved when early recognition, supportive and hematin therapy, and withdrawal of precipitating factors, including some antiepileptic drugs.
NEUROLOGICAL DISORDERS DUE TO VITAMIN B12 DEFICIENCY

Nadia Bouattour, Sameh Triki, Salma Sakka, Nouha Farhat, Olfa Hdiji, Khadija Sonda Moalla, Sawsan Daoud, Mariem Damak, Chokri Mhiri
Habib Bourguiba University Hospital, Neurology, Sfax, Tunisia

Background and Aims:: Cobalmins and folate are two vitamins essential for the integrity of the nervous system. Neuropsychiatric disorders are also classic even in the absence of anemia or macrocytosis. The objective of our study is to describe clinical, and evolutionary profile of patients with neurological disorders due to vitamin B12 deficiency.

Methods:: We conducted a retrospective study at neurology department in Sfax over a period of 15 years [2005 - 2020]. We included all patients with neurological manifestations suggestive of vitamin B12 deficiency. We excluded those for whom another associated cause could explain the neurological symptoms.

Results:: We recruited 51 patients (30 men, 21 women). The mean age of onset of the disorder was 53.3 years. The clinical signs of onset were dominated by paresthesias and gait disturbances. Neurological examination showed a posterior cord syndrome in 84.31% associated with pyramidal syndrome in 62.8%. Cerebellar syndrome was found in 21.56%, sphincter disorders 37.25% and polyneuropathy were also found in 62.74% of our patients. Biologically, anemia was observed in 80.3% patients. Macrocytosis was noted in 82.35%. The serum vitamin B12 level was most often decreased. The spinal cord MRI showed a T2 hyperintensities localized in the dorsal region in 9.8%. Brain MRI was normal in the majority of patients. All patients were receiving vitamin B12 treatment. Clinical and biological improvement was noted in most of our patients.

Conclusions:: Vitamin B12 deficiency should kept in mind face of any unexplained progressive neurological symptoms. Early diagnosis and rapid supplementation prevent irreversible damage.
MITOCHONDRIAL NEURO-GASTRO-INTESTINAL ENCEPHALOMYOPATHY: A CASE REPORT

Guglielmo Capaldo¹, Chiara Pelosi², Antonio Corbo³, Patrizia Fiori³, Marco Massarelli³, Lia Allegorico², Francesco Aruta⁴, Paolo Romano⁵, Rita Rinaldi⁶, Antonio Monaco³, Filippo Maria Santorelli⁷, Annamaria Bellizzi⁸, Lucia Ruggiero⁴

¹S. Ottone Frangipane Hospital, Neurology - Stroke Unit, Ariano Irpino (Avellino), Italy, ²S. Ottone Frangipane Hospital, Internal Medicine, Ariano Irpino (Avellino), Italy, ³S. Ottone Frangipane Hospital, Neurology, Ariano Irpino (Avellino), Italy, ⁴University of Naples Federico II, Department Of Neuroscience And Reproductive And Odontostomatological Sciences, Napoli, Italy, ⁵Gabriele Criscuoli Hospital, Radiology, S. Angelo dei Lombardi (Avellino), Italy, ⁶S. Orsola Malpighi Hospital, Neurology, Bologna, Italy, ⁷Fondazione Stella Maris, Molecular Medicine, Pisa, Italy, ⁸S. Ottone Frangipane Hospital, Internal Medicine, Ariano Irpino (AV), Italy

Background and Aims:: The gastrointestinal symptoms are possible complication in neurological diseases and sometimes the first manifestation of rare genetic diseases as mitochondrial neurogastrointestinal encephalopathy (MNGIE). This association is misdiagnosed by physician without an expertise in rare diseases.

Methods:: A Thirty-two years old woman was evaluated from the juvenile age exclusively in several Gastroenterology Divisions for a severe weight loss due to unexplained malabsorption syndrome. The various histological and endoscopic investigations had never given contributory results. The patient was even diagnosed with Anorexia Nervosa. Furthermore, due to several vomiting episodes, she developed recurrent aspiration pneumonia and she needed intensive care. However her clinical picture was characterized by some neurological signs that had been neglected.

Results:: Neurological examination showed waddling gait, bilateral ptosis with ophthalmoplegia, dysphagia for liquids, proximal weakness of the lower limbs and diffuse muscle atrophy. Brain MRI showed severe bilateral confluent leukoencephalopathy with cortical and subcortical white matter alterations (Fig.1). Electrophysiological study identified an axonal sensory polyneuropathy with normal electromyography (Fig.2). Muscle biopsy showed several fibers with oxidative metabolism deficiency (Fig.3). Considering the combination of neurological features, mitochondrial alterations on muscle biopsy and gastrointestinal impairment, we suspected the mitochondrial neurogastrointestinal encephalopathy (MNGIE). Finally genetic analysis identified the homozygous c.1160-1G>A mutation on the TYMP gene. A few months later, the patient received a liver transplantation but she died as a result of post-surgical complications.
Conclusions:: Neurogenetic diseases are often multisystemic and however misdiagnosed. Our case demonstrates the fundamental role of the multidisciplinary approach to avoid dangerous diagnostic delays.

VALIDATION OF DIRECT AMP KINASE (AMPK) ACTIVATION FOR TREATMENT OF X-LINKED ADRENOLEUKODYSTROPHY

Pierre-Axel Monternier, Jaspreet Singh, Pascale Gluais, David Moller, Sophie Bozec
1Poxel SA, Pharmacology, Lyon, France, 2Henry Ford Health System, Department Of Neurology, Detroit, United States of America

Background and Aims:: X-linked Adrenoleukodystrophy (ALD and adrenomyeloneuropathy - AMN) is a neurologic peroxisomal disorder, caused by ABCD1-gene mutations, leading to Very Long Chain Fatty Acid (VLCFA; C26:0) accumulation, AMPK downregulation, inflammation, mitochondrial impairment and demyelination. We investigated PXL770, a clinical-stage new direct AMPK activator, in AMN/ALD models.

Methods:: AMN/ALD patient-derived fibroblasts/lymphocytes and ABCD1-KO mouse glial cells were exposed to PXL770 for 7 days. Phospho-AMPK was measured by Western-blot, VLCFA content by LC-MS, selected gene expression by RT-qPCR and oxygen consumption with a Seahorse Analyzer. PXL770 (oral 75mg/kg, BID, 12 weeks) was administered to ABCD1-KO mice. VLCFA content was measured by LC-MS, sciatic nerve axonal morphology by electronic microscopy, and locomotor function by beam balance test.

Results:: In AMN fibroblasts PXL770 reduced C26:0 levels (-90%, p=0.0001), increased compensatory ABCD2 mRNA levels (9-fold), and improved mitochondrial function by increasing basal and ATP-linked respiration (14% and 112%, respectively) and decreasing proton leak (-25%). Similar profile was achieved in ALD fibroblasts, ALD/AMN lymphocytes and ABCD1-KO mice glial cells. In ALD lymphocytes, PXL770 decreased mRNAs encoding pro-inflammatory proteins including NF-κB, iNOS and CCR3 (2.9-fold, 8.2-fold, 5.9-fold, respectively). In ABCD1-KO mice treated with PXL770, C26:0 levels were decreased in the spinal cord by 29% (greater VLCFA decrease was also observed in brain/plasma). Sciatic nerve axons showed less myelin invaginations (-61%) and neurologic function was improved compared to untreated mice.

Conclusions:: We established preclinical validation for the potential utility of direct AMPK activators as a treatment for X-ALD, supporting further development of PXL770 for this debilitating neurometabolic disease.
MOTOR NEURON DISEASE AS AN OUTCOME OF NEURODEGENERATION, NEUROINFLAMMATION OR MERCURY POISONING?

Dmitriy Labunskiy, Galina Kukina, Natalia Kolmykova, Svetlana Kiryukhina, Eugenia Yurasova
Ogarev Mordovia State University, Neurology And Psychiatry, Saransk, Russian Federation

Background and Aims:: Amyotrophic lateral sclerosis (ALS) is the main disease in the group of motor neuron diseases. It is fatal disease that affects lateral columns of spinal cord, leads to generalized muscular atrophy. Most severe damage to respiratory muscles resulting from degeneration of motor neurons ultimately leads to certain death approximately 5 months after first symptoms onset. Mercury intoxication (MI) in some cases makes significant contribution to neurodegenerative processes or aggravates existing symptoms of ALS and simultaneously immune deficience.

Methods:: We studied immune status in 29 ALS patients, both genders from 45 to 67 years old and in 139 healthy donors by the same ages, including determination of number of indicators of cellular and humoral immunity, including calculation of immunocompetent cells of T and B-lymphocytes, indicators of phagocytosis of latex particles by leukocytes, pro-inflammatory cytokines IL-2 and IL-6 and immunoglobulins A, M and G. Neurodegenerative changes in brain were studied in transgenic mice with superoxide dismutase defect. Effect of mercury vapor on course of neurodegenerative processes was studied using this experimental model, which also showed signs of severe immunodeficiency.

Results:: We found that 67% of patients with ALS in region of Republic of Mordovia had occupational MI for long period, demonstrated a profound immunodeficiency: decrease of T and B-cells, Ig G and IgA, increase of IgM, IL-2 and IL-6. Revealed deficit of DNA-binding protein of TDP-4 in brains of experimental models. Mice exposed to MI demonstrated more considerable neurodegenerative changes.

Conclusions:: It is difficult to establish which role is primary: neuroinflammation or MI in ALS neurobiology.
BRADYKINESIA IN AMYOTROPHIC LATERAL SCLEROSIS

Giulia Paparella1, Marco Ceccanti2, Donato Colella2, Antonio Cannavacciuolo2, Andrea Guerra1, Maurizio Inghilleri2, Alfredo Berardelli1,2, Matteo Bologna1,2
1IRCCS Neuromed, Ircs Neuromed, Pozzilli, Italy, 2Sapienza University of Rome, Department Of Human Neurosciences, Rome, Italy

Background and Aims:: Amyotrophic lateral sclerosis is primarily characterized by the degeneration of motor neurons, leading to muscle weakness and motor impairment. There are some clinical reports of bradykinesia in this condition, but no studies have objectively assessed voluntary movements in these patients. The relationship between motor neurons involvement and movement abnormalities is also unknown. We here kinematically assessed repetitive finger movements in patients with amyotrophic lateral sclerosis as compared to healthy controls. We investigated possible relationships between altered movement kinematics and neurophysiological measures of motor neurons involvement in patients.

Methods:: Fourteen amyotrophic lateral sclerosis patients and seventy-nine healthy controls were enrolled. Finger tapping was assessed by a motion analysis system. Patients also underwent a motor nerve conduction study, a central motor conduction time assessment, and a needle electromyography. Kinematic data from the two groups were compared by non-parametric tests. Possible relationships between clinical, kinematic and neurophysiological data were assessed in patients.

Results:: Patients performed repetitive finger movements slower than healthy controls. Patients also showed altered movement rhythm during the motor task. Notably, movement slowness in patients correlated with muscle strength, as well as with the amplitude of the compound muscle action potential recorded after nerve stimulation of the muscles involved in the task. Finally, movement slowness correlated with denervation activity. No correlations were found between movement slowness, measures of upper motoneuron involvement, and other clinical and neurophysiological data.

Conclusions:: This study provides a demonstration of movement abnormalities in patients with amyotrophic lateral sclerosis and highlights the pathophysiological role of motoneurons in generating bradykinesia in this condition.
DUX4 EXPRESSION IS INCREASED IN LYMPHOMONOCYTES OF PATIENTS WITH AMYOTROPHIC LATERAL SCLEROSIS: POSSIBLE INVOLVEMENT IN TDP-43 AGGREGATION?

Elisa Duranti¹, Gessica Sala¹, Cristina D’Orlando¹, Francesca Gerardi², Nilo Riva², Christian Lunetta², Riccardo Sirtori¹, Raffaella Meneveri¹, Lucio Tremolizzo¹, Carlo Ferrarese¹
¹University of Milano-Bicocca, School Of Medicine And Surgery, Monza, Italy, ²Centro Clinico NEMO, Fondazione Serena Onlus, Milano, Italy

Background and Aims:: TAR DNA binding protein-43 (TDP-43) is the main component of cytoplasmic aggregates in motor neurons of Amyotrophic Lateral Sclerosis (ALS) patients. TDP-43 aggregates have also been found in muscle cells of patients with Facioscapulohumeral dystrophy (FSHD), a disease caused by the aberrant expression of DUX4 protein. Interestingly, the expression of DUX4 has been demonstrated to induce TDP-43 aggregation in human FSHD myoblasts and healthy cells transfected with DUX4. Based on these premises, we decided to verify if DUX4 is expressed in cells of ALS patients and, if expressed, its possible involvement in TDP-43 aggregation.

Methods:: Gene and protein expression of DUX4 was assessed by qRT-PCR, Western blot and immunofluorescence in peripheral blood mononuclear cells (PBMCs) obtained from 58 ALS patients and 39 healthy controls.

Results:: While a mild DUX4 protein expression was detected in control PBMCs, a 3-fold increase (p<0.0001) of DUX4 protein levels and a mis-localization in the perinuclear area were observed in ALS PBMCs. Similar results were obtained for DUX4 mRNA levels, measured in a subgroup of subjects. We also confirmed an increased TDP-43 protein expression in ALS PBMCs and identified a positive correlation with DUX4 (r=0.6, p<0.0001). A DUX4/TDP-43 co-localization in the perinuclear region and a tendency to aggregate emerged in a subset of ALS PBMCs underwent immunofluorescence analyses. Finally we demonstrated in an in vitro model that DUX4 upregulation induced an increase of TDP-43 insoluble fraction.

Conclusions:: These results suggest a possible role of DUX4 in TDP-43 aggregation, although further studies are needed.
IMPAIRED RECOGNITION OF DISGUST IN AMYOTROPHIC LATERAL SCLEROSIS IS RELATED TO BASAL GANGLIA INVOLVEMENT

Veronica Castelnovo¹, Eliisa Canu¹, Maria Magno¹, Nilo Riva³, Barbara Poletti⁴, Vincento Silani⁵, Massimo Filippi¹,²,⁶, Federica Agosta¹,²,³

Background and Aims:: To investigate emotion recognition in amyotrophic lateral sclerosis (ALS) patients without cognitive/behavioural deficits and its relationship with the integrity of basal ganglia, hippocampus and amygdala.

Methods:: Twenty ALS patients without cognitive/behavioural deficits and 52 matched healthy controls performed a neuropsychological assessment including the Comprehensive Affect Testing System (CATS) investigating emotion recognition. All participants underwent also a 3T brain MRI. Volumes of the caudate nucleus, putamen, pallidum, nucleus accumbens, thalamus, amygdala and hippocampus bilaterally were obtained using FIRST in FSL. Sociodemographic, cognitive and MRI data were compared between groups. In ALS patients, correlations between CATS significant findings, brain volumes, cognition, mood and behaviour were explored.

Results:: ALS patients showed altered performances at the CATS total score and at the CATS affect selection and affect matching subtests compared with healthy controls. Among the investigated emotions, patients were significantly less able to recognize disgust compared with controls. No brain volumetric differences were observed between groups. In ALS patients, a lower performance in disgust recognition was related with a lower performance on the Edinburgh Cognitive and Behavioural ALS Screen (ECAS) and reduced volume of the left pallidum.

Conclusions:: Cognitively and behaviourally unimpaired ALS patients showed impaired disgust recognition, which was associated with the degree of basal ganglia pathology. The association with cognitive alterations may suggest impaired disgust recognition as an early marker of cognitive decline. Funding: Italian Ministry of Health (GR-2013-02357415); European Research Council (StG-2016_714388_NeuroTRACK).
CLINICAL AND HORMONAL CHARACTERISTICS OF SPINAL AND BULBAR MUSCULAR ATROPHY (SBMA): A NATION-WIDE STUDY OF 82 KOREAN PATIENTS

Hee-Jin Cho, Jin-Sung Park
Kyungpook National University Chilgok Hospital, Department Of Neurology, Daegu, Korea, Republic of

Background and Aims:: Spinal and bulbar muscular atrophy (SBMA) is an X-linked motor neuron disease caused by the expansion of a CAG repeat in the androgen receptor (AR) gene. The aim of this study was to characterize the clinical and genetic features of SBMA in South Korea.

Methods:: 82 genetically confirmed SBMA patients were enrolled. The clinical parameters included were age of onset, disease duration, initial symptom at onset, amyotrophic lateral sclerosis functional rating scale, revised (ALSFRS-R), 6 minute walk test and medical research council sum score (MRCSS) were assessed. The laboratory parameters included were testosterone, luteining hormone, follicle stimulating hormone and creatine kinase.

Results:: A total of 82 patients with SBMA were included in this study. The mean age was 54.87 ± 10.16 years. The mean age of initial symptom was 44.38 ± 9.92 years. The mean number of CAG repeats in the AR gene was 46.4 ± 4.38. Average creatinine kinase level was 967.63 IU/L. 60 out of 81 patients (73.2%) were of lower limb onset. There was a statistically significant correlation between the number of CAG repeats and the age at onset. Interestingly, testosterone levels showed positive correlation with ALSFRS-R score (r=0.273, p=0.014).

Conclusions:: Thw novelty of this study is that we identified clinical features with hormonal levels in characterizing Korean SBMA patients. Longitudinal studies are warranted to understand the natural history of Korean SBMA leading to a better understanding of the disease.
TEMPORAL MUSCLE THICKNESS AS PREDICTOR OF SURVIVAL IN PATIENTS WITH AMYOTROPHIC LATERAL SCLEROSIS.

Claudia Vinciguerra1, Antonella Toriello2, Valerio Nardone3, Filomena Abate2, Annamaria Landolfi2, Daniele Giuseppe Romano4, Salvatore Tartaglione4, Paolo Barone2

Background and Aims:: Temporal muscle thickness (TMT), is a new potential Magnetic Resonance Imaging (MRI) biomarker which has shown prognostic relevance in patients with brain metastasis and in some neurological disorders. We aim to investigate the potential clinical value of TMT in patients with Amyotrophic Lateral Sclerosis (ALS)

Methods:: We retrospectively enrolled ALS patients whose clinical, MRI and Electrodiagnostic (EDX) data were available. TMT was calculated on T1-weighted MR images and patients were divided in two cohorts according the median value of TMT. A survival analysis among the two groups was calculated with Kaplan Meier method. The differences of clinical characteristics and EDX parameters between the two groups were calculated with T-Student test for continuous parameters and Chi-Square test for nominal parameters.

Results:: A total of 40 patients were included for the analysis: twenty-six males (65%) and fourteen females (35%) (median age 62 +/- 13y-o, median duration disease 50 +/- 10 months), 11 with upper motor neuron predominance (UMNP) 20 with lower motor neuron predominance (LMNP), 9 with non clinical defined predominance (NCDP). Median TMT value was equal to 6,8 mm. The only parameter that resulted significantly different in the two cohort was the compound motor action potential (CAMP) (p-value: 0,036). TMT, finally, was significantly correlated with overall survival (OS) (lower TMT: median OS 35 +/- 8,0 months, versus higher TMT: median OS 65 +/- 5,1 months, p-value: 0,033).

Conclusions:: This novel and simply MRI marker seems to be a promising surrogate biomarker of sarcopenia and survival in ALS. Our study deserves further investigations in multicenter and prospective trials.
"MENTAL" COMPONENT OF FATIGUE CORRELATES WITH COGNITIVE AND BEHAVIORAL IMPAIRMENT IN AMYOTROPHIC LATERAL SCLEROSIS

Fabrizio Canale, Francesca Trojsi, Federica Di Nardo, Mattia Siciliano, Giulia D'Alvano, Carla Passaniti, Fabrizio Esposito, Gioacchino Tedeschi
Università degli Studi della Campania, Advanced Medical And Surgical Science, Napoli, Italy

Background and Aims:: Amyotrophic lateral sclerosis (ALS) is increasingly recognized as a multisystem neurogenerative disease, mainly affecting motor neurons, although also characterized by cognitive and behavioral impairment. Fatigue is a symptom of exhaustion unexplained by drug effects, or psychiatric disorders, associated with other fatigue-related symptoms, such as reversible motor weakness and whole-body tiredness, which are only partially relieved by rest. We aim at investigating the clinical correlations between both “physical” and “mental” components of fatigue, measured by the Multidimensional Fatigue Inventory (MFI) scale, and motor and cognitive/behavioral disability in ALS. Moreover, we investigated the correlations between these symptoms and brain resting state functional magnetic resonance imaging (RS-fMRI) alterations in a cohort of patients with ALS.

Methods:: 130 ALS patients were assessed for: motor disability (ALS Functional Rating Scale-Revised, ALFRS-R); cognitive and behavioral dysfunctions (Edinburgh Cognitive and Behavioral ALS Screen, ECAS); fatigue (MFI); anxiety; apathy and daytime sleepiness. Moreover, the collected clinical parameters were correlated with RS-fMRI connectivity changes in 30 ALS patients who underwent MRI.

Results:: Multivariate correlation analysis revealed that “mental” fatigue was positively related to memory and executive dysfunctions. RS-fMRI analysis showed inverse correlations between functional connectivity in the right and left insula (“salience” network) and in the left middle temporal gyrus (Default Mode Network) and mental fatigue.

Conclusions:: Although the “physical” component of fatigue may be influenced by the disease itself, in ALS the “mental” component of fatigue correlates with cognitive and behavioral impairment, as well as with alterations of functional connectivity in extra-motor areas.
RESTING STATE FMRI CORRELATES OF PSEUDOBULBAR SYNDROME IN AMYOTROPHIC LATERAL SCLEROSIS (ALS)

Giulia D'Alvano1, Francesca Trojsi2, Federica Di Nardo1, Carla Passaniti1, Mattia Siciliano3,4, Giusy Caiazzo1, Antonietta Canna1, Fabrizio Esposito5,5, Gioacchino Tedeschi1

1Università degli studi della Campania "Luigi Vanvitelli", Department Of Advanced Medical And Surgical Sciences, Napoli, Italy, 2University of Campania Luigi Vanvitelli, Department Of Advanced Medical And Surgical Sciences, Napoli, Italy, 3University of Campania "Luigi Vanvitelli, I Division Of Neurology, Department Of Advanced Medical And Surgical Sciences, Mri Research Center Vanvitelli-fism, Naples, Italy, 4University of Campania "Luigi Vanvitelli, I Division Of Neurology, Naples, Italy, 5Università degli Studi della Campania, Advanced Medical And Surgical Science, Napoli, Italy

Background and Aims:: Pseudobulbar syndrome (PBS), referring to exaggerated or inappropriate episodes of laughing and/or crying without an apparent motivating stimulus, has been mainly attributed to bilateral degeneration of corticobulbar tracts. Our objective was to explore brain functional connectivity (FC) correlates of PBS in patients with amyotrophic lateral sclerosis (ALS), the most common motor neuron disease frequently associated to PBS, assessed by Center for Neurologic Study Lability Scale.

Methods:: Resting state functional MRI (RS-fMRI), and voxel-based morphometry (VBM) analyses were performed in 27 ALS patients (13 with PBS; 14 without PBS) and 26 healthy controls (HCs), for investigating functional and structural abnormalities in ALS patients compared to HCs and in patients with PBS compared to patients without PBS.

Results:: Between-patients analysis revealed: decreased FC in the right middle temporal gyrus (MTG), right precuneus and posterior cingulate cortex and an increased FC in the left MTG (default mode network); increased FC in bilateral precuneus (frontoparietal network), right precentral gyrus (sensory-motor network), right insula (salience network); and no significant differences in gray matter atrophy in patients with PBS compared to patients without PBS. Pseudobulbar index was inversely related to FC in the right MTG and positively related to FC in bilateral precuneus, right postcentral gyrus, right insula and anterior cingulate cortex.

Conclusions:: Our findings suggested that alterations of fronto-temporal circuits may be related to PBS in ALS. In particular, decreased FC in the right MTG and increased FC in bilateral precuneus and in right fronto-temporo-parietal areas may underlay PBS in patients with ALS.
LONELINESS IS A THREAT TO NEUROBEHAVIORAL FUNCTIONING IN AMYOTROPHIC LATERAL SCLEROSIS

³University of Milano-Bicocca, Department Of Medicine And Surgery, Milan, Italy,
⁴IRCCS Fondazione Istituto Neurologico Carlo Besta & University of Milan, Clinical Neurosciences, Milano, Italy

Background and Aims:: Perceived social isolation, also termed loneliness, impacts on neurobiological architecture, ensuing significant consequences on mental and physical health. In this framework, we look for a possible negative backlash of loneliness in amyotrophic lateral sclerosis (ALS), a neurodegenerative disease that primarily affects the motor system, but also cognition and behaviour.

Methods:: Cognitive performances, mood, alexithymia, behavioural change and quality of life (QoL) were assessed in 139 consecutive ALS patients. Perceived social isolation was esteemed with the revised UCLA 3-items loneliness scale. Spearman rho correlations (Bonferroni correction, p≤0.003) and the Kruskal-Wallis H tests examined factors associated with UCLA scores. Loneliness, age and disease stage were used as dependent variables in logistic regression, with bootstrap validation, to predict the occurrence of behavioural impairment, mood disorder, and alexithymia.

Results:: The UCLA scores were significantly associated with behavioural changes, mood, alexithymia and QoL, and not with motor functional status, disease duration or cognitive abilities. Having feeling of loneliness (UCLA scores ≥ 4) significantly increased the odds of behavioural impairment, depression and alexithymia by 3, 7 and 5 times respectively.

Conclusions:: In our cohort of ALS patients, the satisfaction of social environment is associated with a sense of life well-being that is not limited to the functional motor status. Our findings indicate that loneliness acts as a threat to neurobehavioral functioning in ALS, as other risk factors do (e.g. advanced disease stages), with potential great impact on patients’ care and clinical trial design.
SERUM CHI3L1 IN AMYOTROPHIC LATERAL SCLEROSIS: A USEFUL TOOL FOR PROGNOSTIC DEFINITION?

Ilaria Martinelli1,2, Cecilia Simonini3, Elisabetta Zucchi3, Giulia Gianferrari3, Roberta Bedin2, Serena Carra1, Jessica Mandrioli2

1University of Modena and Reggio Emilia, Clinical And Experimental Medicine Phd Program, Modena, Italy, 2Azienda Ospedaliero Universitaria di Modena, Neurology Unit, Department Of Neuroscience, Modena, Italy, 3University of Modena and Reggio Emilia, Department Of Biomedical, Metablic And Neural Sciences, Modena, Italy, 4University of Modena and Reggio Emilia, Italy., Department Of Biomedical, Centre For Neuroscience And Nanotechnology Metabolic And Neural Sciences., Modena, Italy

Background and Aims: Neuroinflammation is a key pathophysiological hallmark in amyotrophic lateral sclerosis (ALS), which seems to be linked to the disease progression. Cerebrospinal fluid (CSF) chitinase-3-like protein 1 (CHI3L1), a marker of glial activation, is a recent candidate biomarker of ALS, but less is clear about its value in the serum. In this study, we explore if serum CHI3L1 could add prognostic value as biomarker of ALS.

Methods: CHI3L1 levels were measured by immunoassay kit (Protein SimpleTM) in CSF and serum of ALS patients (n=64) and healthy controls (HC) (n=10). CSF and serum levels were correlated with several clinical parameters, classifying slow and fast ALS progressors according with ALSFRSr slope (lower than the 25th percentile and higher than the 75th percentile, respectively, in our reference population). Between-group comparisons were drawn by Mann-Whitney test and ROC analysis was performed to assess diagnostic performance.

Results:

In CSF CHI3L1 levels were similar in ALS and HC (p=0.97, p=0.98), while in serum CHI3L1 levels were
not significantly different (p=0.43, p=0.45, respectively). Serum CHIT3L1 levels strongly correlated with the disease progression rate (p=0.01, p=0.0085) while no significance was found for CSF (p=0.26, p=0.30). ROC analysis showed that serum CHI3L1 could discriminate between fast and slow ALS progressors (AUC=0.86), while CSF had worse performance (AUC=0.72).

**Conclusions:** Serum CHIT3L1 is significantly elevated in ALS fast progressors, with discriminatory power towards a slower phenotype. Its prognostic role is not confirmed for CSF levels. Our data encourage the research on neuroinflammatory markers in patient stratification as surrogate markers of ALS progression.
Background and Aims:: Mutations in the tropomyosin-receptor kinase fused gene (TFG) are prominently described in Asian countries in association with hereditary motor sensory neuropathy with proximal involvement (HMSN-P), Charcot–Marie–Tooth disease type 2 (CMT2) and hereditary spastic paraplegia type 57 (SPG57). HMSN-P is a rare autosomal dominant motor and sensory neuropathy starting with fasciculations and proximal weakness and progressing slowly with a pattern similar to Amyotrophic Lateral Sclerosis (ALS).

Methods:: Review of the patient's and her relatives' medical history.

Results:: An Italian 30-year-old woman presented with isolated fasciculations, followed four years later by cramps and slowly progressive proximal lower limbs weakness. She had a family history of atypical slowly progressive motor neuron disease in the three previous generations. Neurophysiological studies showed a sensitive axonal neuropathy with diffuse chronic neurogenic sufferance in absence of active denervation except for mild fasciculations. An extensive next-generation sequencing (NGS) panel, including genes associated with diseases affecting the motor neurons, displayed the heterozygous TFG p.Pro285Leu variant, currently described in HMSN-P cases confined to the Far and Middle East. Thus, we considered the mutation found could explain our patient's and her relatives' symptoms, indeed suggestive for HMSN-P, and the pattern of transmission. To the best of our knowledge, this case is the first report of HMSN-P associated with the p.Pro285Leu substitution in a Caucasian patient.

Conclusions:: Inclusion of TFG in worldwide NGS panels could help define atypical familial cases of motor neuron diseases or neuropathies and plan follow-up according to the expected disease course.
VALIDATION OF THE ITALIAN VERSION OF THE RASCH-BUILT OVERALL AMYOTROPHIC LATERAL SCLEROSIS DISABILITY SCALE (ROADS).

Luca Solero¹, Antonio Canosa², Rosario Vasta¹, Alessandro Bombaci¹, Maurizio Grassano¹, Francesca Palumbo¹, Maria Claudia Torrieri¹, Cristina Moglia², Andrea Calvo², Adriano Chio², Umberto Manera¹
¹Turin University, Als Centre, “rita Levi Montalcini” Department Of Neuroscience, Turin, Italy, ²AOU Città della Salute e della Scienza of Turin, Als Centre, Neurology 1, Turin, Italy

Background and Aims:: The ALS functional rating scale – revised (ALSFRS-R) is widely used for the assessment of ALS patients. Despite its usefulness as a multidimensional scale, the combined score derived from different domains is not linearly related to symptom severity. The Rasch-Built Overall ALS Disability Scale (ROADS), which is linearly weighted and unidimensional, was developed to overcome some of these limitations. Our objectives are to validate the Italian version of the ROADS scale and assess the reliability of its administration to patients versus their caregivers and the correlation to ALSFRS-R.

Methods:: The ROADS questionnaire was administered with the ALSFRS-R to 55 ALS patients and their caregivers during assessments in the Turin ALS Centre. Correlation analysis was performed using Spearman's rho, Bland-Altman difference plots, Cronbach's alpha coefficient and Intraclass Correlation Coefficient; a value of p <0.05 (two-tailed) was considered significant.

Results:: The median normalized ROADS values did not differ significantly between patients and caregivers (73.0, IQR 60.0-86.0 vs 70.0, IQR 57.0-82.0, p=0.524). Their correlation coefficient was high (ICC 0.95, p<0.00; Cronbach’s alpha coefficient 0.94) and the total score agreement based on Bland-Altman showed no systematic directional bias (mean difference: 0.82, 95% limits of agreement: -15.9-17.6). High ICC values were observed when stratifying for sex, age classes and caregiver type. A high correlation was found between ROADS and ALSFRS-R total score (patients’ and caregivers’ correlation coefficients respectively 0.88 and 0.87).

Conclusions:: The ROADS scale is a valid and reliable tool to monitor disease burden, showing a high level of agreement between patients’ and caregivers’ responses.
6MWT AS MEASURE OF MOTOR FUNCTION AND ENDURANCE IN SMA TYPE 3 PATIENTS TREATED WITH NUSINERSEN

Background and Aims:: Spinal muscular atrophy (SMA) is an autosomal-recessive motor neuron disease causing progressive muscular atrophy and weakness. Nusinersen, an antisense oligonucleotide able to increase functional SMN protein modifying the SMN2 pre-mRNA splicing, is proved to be able to significantly modify the natural course SMA type 1 (the severe phenotype) in infants. Data of efficacy in adults are limited. We aim to investigate the impact of nusinersen therapy in walking resistance in SMA 3 patients since abnormal muscle fatigability represents an additional dimension of attenuated motor function in SMA.

Methods:: From a large Italian cohort of patients we selected 58 ambulant adult SMA3 patients being treated with nusinersen and we analyzed data on 6 minute walking test (6MWT) since baseline (beginning of treatment) to 14 months.

Results:: The 58 patients started therapy at an average age of 40,7 years (18-65 years) and reached
different time points follow up: 25 patients 14 months, 13 patients 10 months, 13 patients 6 months and 7 patients the baseline. Of 46 subjects, the meters walked every single minute during the 6MWT were also collected. We found that there is an increase in the meters walked, cumulative over time which is, compared to the baseline, respectively of 13,2 ± 28 m after 6 months, 20,7±34 m after 10 months and 35 ± 56,8 m after 14 months. 
**Conclusions:** Our data broaden the evidence of nusinersen efficacy in adult ambulant SMA patients. Furthermore, the 6MWT data provide an estimate not only of motor ability, but also of resistance to physical exercise.
E-HEALTH SOLUTIONS FOR AMYOTROPHIC LATERAL SCLEROSIS PATIENTS: A CHATBOT FOR DIETARY MONITORING

Fabiola De Marchi, Ilaria Angela Amantea, Marcella Serioli, Emilio Sulis, Guido Boella, Francesca Aliotti, Andrea Bolioli, Sergio Riso, Roberto Cantello, Letizia Mazzini

1Department of Translational Medicine, University of Piemonte Orientale, and Azienda Ospedaliero-Universitaria “Maggiore della Carità”, Neurology Unit, Novara, Italy, 2University of Torino, Computer Science Department, Torino, Italy, 3University of Piemonte Orientale, Azienda Ospedaliero-Universitaria "Maggiore della Carità", Department Dietetic And Clinical Nutrition, Novara, Italy, 4CELI, Language Technology, Torino, Italy

Background and Aims:: Nutritional status is one of the most relevant prognostic factors in Amyotrophic Lateral Sclerosis (ALS), and close monitoring can help avoid severe weight loss over the disease course. We aimed to describe the impact of a technological chatbot on improving the communications between healthcare providers and patients and caregivers for dietary monitoring.

Methods:: We developed a chatbot that provides patients a tool to register their meals through a simple and carefully designed conversational interface. Patients recorded dietary intake three times a week, and they received a nutrition recommendation biweekly. Of these, we monitored body mass index (BMI), caloric intake, need for artificial supplementation and/or thickeners, and ALSFRS-R.

Results:: A total of 26 patients were enrolled and monitored for six months, for a total of 554 fillings (mean of 21/patient). From the recorded data, it appears that patients, on average, ate ¾ of recommended portion, and 66% maintained the caloric intake during the six-month follow-up. The mean BMI at chatbot onset was 24.00 (SD: 3.82) which remained stable over time (BMI 23.67 (SD: 2.87)). During chatbot monitoring, 45% of patients required artificial supplementation, 11.5% had a gastrostomy tube placed.

Conclusions:: A positive evaluation was obtained both on patient well-being and physicians’ perspective. Also, following these patients with frequent monitoring turned out to help prevent further weight loss due to integrating caloric needs and dietary changes. The solution discussed in this work also provided a significant impact during the COVID-19 emergency.
CHALLENGING DIAGNOSIS OF JUVENILE AMYOTROPHIC LATERAL SCLEROSIS FUS-RELATED DURING COVID-19 PANDEMIC

Giorgia Bruno¹, Francesco Barbato¹, Giovanni Colacicco¹, Domenico Ippolito¹,², Antonio Di Masi¹, Maria Francesca Siani¹, Marcello Silvestro², Antonio Russo², Mario Sabatelli³, Vincenzo Pota¹,⁴
¹NeuroMuscular Omnicentre (NeMO), Fondazione Serena Onlus, Neurorehabilitation Unit, Naples, Italy, ²University of Campania Luigi Vanvitelli, I Division Of Neurology, Department Of Advanced Medical And Surgical Sciences, Naples, Italy, ³Fondazione Policlinico A. Gemelli IRCCS, Neurology, Roma, Italy, ⁴University of Campania “Luigi Vanvitelli”, Department Of Woman, Child, General And Specialty Surgery, Naples, Italy

Background and Aims:: Juvenile amyotrophic lateral sclerosis (JALS) is a rare motor neuron disease (MND) characterized by progressive degeneration of upper and lower motor neurons. Symptoms of JALS typically begin before age 25, but often in early childhood. We present the case of an apparently sporadic ALS patient carrying a missense mutation in FUS gene where previous infection of SARS-CoV-2 misled clinical investigations.

Methods:: The patient was a 16-year-old boy with mild intellectual disability whose complained progressive hypotonia of the left lower limb.

Results:: At the admission RT-PCR nasopharyngeal swab was positive for SARS-CoV-2 without symptoms. Lumbar puncture was carried out, showing albumin-cytological dissociation and oligoclonal bands. Laboratories revealed high level of inflammatory markers along with monoclonal IgG Kappa component. Neurophysiologic studies showed multi-metamer axonal neurogenic suffering without clear demyelinating alterations. Brain and medulla MRI were normal. Plasma exchange and intravenous immunoglobulins were performed without benefit. Genetic analysis revealed a rare mutation in FUS gene. After five months flaccid tetraparesis with pyramidal signs were evident. He began total dependent of non-invasive ventilation until he died for acute respiratory insufficiency.

Conclusions:: The variability in clinical findings early in the spectrum of MNDs and the lack of any biological diagnostic marker make absolute diagnosis difficult, even more in JALS. The lesson learned in this outbreak of SARS-CoV-2 is that the neurological manifestations attributable to COVID-19 are not so uncommon. In our case laboratory findings were confusing, maybe influenced by the recent SARS-CoV-2 infection, but clinical and neurophysiologic assessment guided us to the correct diagnosis.
NATURAL HISTORY STUDY OF SPINAL MUSCULAR ATROPHY WITH RESPIRATORY DISTRESS TYPE 1 (SMARD1) IN A COHORT OF EUROPEAN PATIENTS

Background and Aims:: Spinal muscular atrophy with respiratory distress type 1 (SMARD1) is a rare childhood autosomal recessive motor neuron disease, caused by IGHMBP2 gene mutations. The main hallmarks of the disease are diaphragmatic palsy and progressive distal muscular atrophy and paralysis. Currently, there is no treatment and very little data are available on the disease progression. We aim to determine the disease natural course and to define the most suitable functional outcome measures, in the perspective of a future clinical trial.

Methods:: In a cohort of 15 European patients with genetically confirmed SMARD1, we collected clinical data including medical history, neurological, pneumological, cardiological, psychomotor and orthopaedic data. Clinical features and functional motor scales were evaluated every six months.

Results:: We enrolled 15 patients (9 girls) aged between 5 months and 21 years. In 10 cases mothers reported prenatal events, 7 of which resulting in preterm birth. The disease onset was within 5 months for all patients, manifesting with weak crying, feeding difficulties, hypotonia, club foot and acute respiratory distress. All patients need continuous ventilatory support: 13 via tracheostomy while 2 with NIV. G-tube has been performed in 14 out of 15 patients. Head control is reached by 53% of the patients, independent sitting only by 20%. Autonomic dysfunction and scoliosis are observed in all patients.

Conclusions:: SMARD1 is a very rare and severe disease, however it presents heterogeneous clinical manifestations. Our case studies broaden the knowledge relating to the natural course of the disease, providing useful data of the evaluation of possible future therapeutic strategies.
MERCURY MASQUERADING AS MOTOR NEURON DISEASE

Deependra Singh¹, Vivek Lal²
¹POST GRADUATE INSTITUTE, CHANDIGARH, Neurology, CHANDIGARH, India, ²PGIMER, Chandigarh, Neurology, Chandigarh, India

Background and Aims:: The causes of sporadic amyotrophic lateral sclerosis (SALS) remain largely unknown. Heavy metals have long been implicated in MND, and it has been shown that mercury selectively enters human locus ceruleus (LC) and motor neurons. Several case reports of mercury poisoning have demonstrated convincing ALS-like clinical symptoms, leading to postulate a causal relationship

Methods::

He presented with h/o developing abnormal movements of muscle over an upper limb and along with tingling, numbness of both UL and LL with no other neurological complaints. He has fasciculation, over tongue and biceps, with normal power. Reflexes - Biceps, triceps, and knee (3+), rest 2(+). Plantar B/L flexor. He was also having significant proteinuria. His kidney biopsy revealed secondary membranous glomerulonephritis. His EMG revealed – fasciculation noted in Biceps, Brachioradialis, vastus, and gastronemiusà neurogenic EMG S/O ant horn cell disorder, NCS – normal study. Mercury levels were high 24 hr à 57.30 (< 20), His other work-up was negative. On repeated questioning to look for the cause of MND, he came with h/o applying some “BHASM” over for his dermatological condition developed 03 months back prior to these symptoms

Results:: MND is a progressive disorder with median survival three to five years. So correct diagnosis is of utmost importance before committing on motor neuron disease. This case also tells about the importance of proper history taking in neurology to come to proper diagnosis.

Conclusions:: Pt is still on chelating agents and “BHASM” is sent for evaluation of mercury level. His repeat mercury level came down to 30
A SIGHT INTO THE ELDERLY ALS PATIENTS IN EMILIA ROMAGNA REGION: EPIDEMIOLOGICAL AND CLINICAL FEATURES OF LATE ONSET ALS IN A PROSPECTIVE POPULATION-BASED STUDY

Background and Aims:: Studies on epidemiology ALS epidemiology are numerous and an increasing incidence rate with aging is well known across different Western Countries. Despite this, few studies explored epidemiological and clinical features of the oldest ALS patients.

Methods:: In this prospective, population-based, epidemiological study we investigate demographic, clinical and genotypic features of patients with late-onset ALS in Emilia Romagna Region, where a register has been collecting cases since 2009.

Results:: In the last decade in our region there were 1398 incident cases of ALS (incidence rate:2.83/100,000) of whom 174 (12.45%) were over 80 years old (“oldest” ALS) at diagnosis. Among the oldest, M:F ratio was 0.77, mean age at diagnosis was 83.98(±3.92)years, and 47.13% had a bulbar onset. With increasing age, there was an increment in diagnostic delay, a worse clinical stage at diagnosis, a lower BMI (23.12 vs 24.57,p<0.01), and a higher progression rate (2.14/month vs 1.30,p<0.01), with several comorbidities, and a shorter median survival (25 vs 38 months, p<0.01). Genetic analyses were carried out less frequently in elderly patients and in these group we could not found C9orf72 expansion, according with the fact that being a carrier of this mutation determines a risk of disease onset at a younger age.

Conclusions:: The oldest ALS patients had peculiar clinical features if compared with other adult patients. These genotypic and phenotypic differences between the two groups may underline the presence of different pathogenetic mechanisms and of a different burden of environmental and genetic risk factors triggering the disease onset at different ages.
PROGNOSIS OF PATHOLOGICALLY CONFIRMED JAPANESE AMYOTROPHIC LATERAL SCLEROSIS, A RETROSPECTIVE HOSPITAL-BASED STUDY

Kiyonobu Komai
Hokuriku Brain and Neuromuscular Disease Center / Iou National Hospital, National Hospital Organization, Department Of Neurology, Kanazawa, Japan

Background and Aims:: We provide medical care for neuromuscular disease patients as a neuromuscular-disease center hospital in Hokuriku area of Japan. It is necessary to understand the prognosis for a better patient’s QOL. We performed retrospective prognostic study to clarify the clinical course and cause of death in pathologically confirmed amyotrophic lateral sclerosis (ALS) patients.

Methods:: We retrospectively reviewed medical records of 120 consecutive autopsied patients between 2008 and 2019. Pathological diagnosis was confirmed when the following two histopathological features were observed. First of them was systematic both upper and lower motor neuronal degeneration, and second was the existence of TDP-43 inclusion body pathology and/or Bunina bodies.

Results:: We identified 54 patients of pathologically diagnosed ALS in this period. Female to male ratio was 16 to 38. Average age of death was 69.6 y.o. (SD=10.6) and median survival time was 45.5 months (SD=50.0). Fifteen patients (28%) chose tracheostomy invasive ventilation (TIV) and 9 patients (17%) decided using non-invasive ventilation (NIV). Female to male ratio of TIV patients was 4 to 11, and that of NIV patients was 1 to 8. TIV prolonged median survival time (105 months), as did NIV (48 months) when compared to non-ventilation supported patients (36 months). Although most common cause of death was respiratory failure due to bronchopneumonia and/or hypoventilation, profiles of complications were depending on the manner of mechanical ventilation.

Conclusions:: From this study, TIV and NIV could improve prognosis of pathologically proved ALS. Respiratory failures due to airway infection were the main cause of death in ALS.
Background and Aims:: Amyotrophic Lateral Sclerosis (ALS) is a fatal neurodegenerative disorder characterized by upper and lower-motorneurons involvement. However, growing evidence suggests a non-neuronal involvement with a particular attention to autonomic disfunction and consequent cardiovascular complication and sudden-cardiac death. In this contest, many authors focused on arrhythmic complications in ALS patients and in other motorneuron diseases such as Kennedy's Disease (KD). While, Brugada Syndrome (BS) is the most frequent arrhythmia associated with KD, only one case of type2 BS has been described in ALS.

Methods:: To the best of our knowledge, this is the first case report of a patient with lower-limb-onset ALS with type1 BS and previous regular cardiovascular assessment.

Results:: A 58-years-old Caucasian woman was admitted to our neurological clinic for progressive respiratory distress. She was diagnosed with ALS 18 months before. She had no history of cardiovascular disorder and an electrocardiogram (ECG), performed pre-Edaravone therapy, showed a sinusual rhythm in absence of any abnormalities. During hospitalization, pulmonary function tests were performed and a bilevel positive airway pressure ventilation were set-up. At the admission an ECG has been performed and it was suggestive of type3 BS. Therefore a cardiovascular assessment with Flecaïnine induction tests revealed a pattern typical for type1 BS. After that the placement of an implantable cardioverter-defibrillator was suggest.

Conclusions:: ALS is a progressive neuromuscular-disorder with significant mortality. Alongside respiratory failure also cardiovascular complications, especially arrhythmias that may need periodic electrocardiographic surveillance, impact on survival. Therefore, we want to increase evidence that cardiovascular assessment need to be included in ALS management.
INCIDENCE AND PREVALENCE OF AMYOTROPHIC LATERAL SCLEROSIS IN SOUTHWESTERN AND EASTERN FINLAND

Jussi Sipilä1,2, Mirka Hanhisuanto1, Eino Solje3,4, Manu Jokela1,5
1University of Turku, Clinical Neurosciences, Turku, Finland, 2Siun Sote North Karelia Central Hospital, Neurology, Joensuu, Finland, 3University of Eastern Finland, Institute Of Clinical Medicine - Neurology, Kuopio, Finland, 4Kuopio University Hospital, Neuro Center, Neurology, Kuopio, Finland, 5Turku University Hospital, Neurocenter, Turku, Finland

Background and Aims:: Amyotrophic lateral sclerosis (ALS) has been suggested to be relatively common in Finland. We aimed to update the incidence and prevalence data.

Methods:: Patients with ALS diagnostic codes were identified from mandatory administrative registries in the provinces of Southwestern Finland (population c. 430,000) and North Karelia (population c. 170,000). The diagnoses were verified, and data extracted by reviewing the patient records. Incidence period was 2010-2018, and the prevalence date was December 31, 2018.

Results:: We identified 213 patients (54% women) with ALS in Southwest Finland and 102 (54% women) in North Karelia (table 1). Women were older than men at the time of diagnosis in Southwest Finland (p=0.008) with no sex difference in North Karelia (p=0.72). Altogether 55 patients (26%) had been genetically tested in Southwest Finland and 34 (33%) in North Karelia (table 2).

AMYOTROPHIC LATERAL SCLEROSIS: A HOME HEALTHCARE MODEL

Luca Guido, Valeria Borsani, Stefania Piscopo, Orsola Sironi, Angelo Mainini
Fondazione Maddalena Grassi, Assistenza Domiciliare Integrata E Cure Palliative Domiciliari, Milano, Italy

Background and Aims:: Aims of this study is to develop a focused home healthcare model for ALS patients being inspired by the home-care indications in Turner-Stokes model (SIN-SICP Congress 2018).

Methods:: The study lasted approximately two years (a year enrollment started in March 2020 and a subsequent year of follow up). An assigned Case Manager Nurse (CM) supports a network strategy and patient/caregiver training, evaluates clinical patient's conditions every month, collects clinical, social and healthcare data updating ALS-FSR scale every three months.

Results:: Evaluated data include patients with three ALS-FSR evaluations at least and dead ones and exclude patients lost in follow-up phase. Our study includes 24 patients (46% women) and an average age of 66. Most frequent onset is bulbar phenotype (79%). Eating and breath conditions

Graphic shows individual ALS-FSR results. Patients with first evaluation ALS < 11
don’t show significant clinical evolutions and nursing care needs; patients with first evaluation ALS > 11 disclose a more variable clinical trend and 63% of them lost more than 3 points in each next evaluation. Home healthcare is divided in Multiprofessionals Home Care (MHC) (75%) and Palliative Home Care (PHC) (25%). During follow up phase, six patients in MHC needed to be assisted in a PHC.

Conclusions:: Patients with first ALS evaluation > 11 disclose a more variable clinical trend: they require a more punctual and frequent oversight both by assigned CM and their Hospital Center.
MODELING AND BIOINFORMATICS IDENTIFY RESPONDERS TO G-CSF IN PATIENTS WITH AMYOTROPHIC LATERAL SCLEROSIS

Background and Aims:: Developing an integrative approach to early treatment response classification using survival modeling and bioinformatics with various biomarkers for early assessment of filgrastim treatment effects in amyotrophic lateral sclerosis patients. Filgrastim, a hematopoietic growth factor with excellent safety, routinely applied in oncology and stem cell mobilization, had shown preliminary efficacy in ALS.

Methods:: We conducted individualized long-term filgrastim treatment in 36 ALS patients. The PRO-ACT database, with outcome data from 23 international clinical ALS trials, served as historical control and mathematical reference for survival modeling. Imaging data as well as cytokine and cellular data from stem cell analysis were processed as biomarkers in a non-linear principal component analysis (NLPCA) to identify individual response.

Results:: Cox proportional hazard and matched-pair analyses revealed a significant survival benefit for filgrastim-treated patients. We generated a model for survival estimation based on patients in the PRO-ACT database and then applied the model to filgrastim-treated patients. Model-identified filgrastim responders displayed less functional decline and impressively longer survival than non-responders. Multimodal biomarkers were then analyzed by PCA in the context of model-defined treatment response, allowing identification of subsequent treatment response as early as within 3 months of therapy. Strong treatment response with a median survival of 3.8 years after start of therapy was associated with age, hematopoietic stem cell mobilization, cytokine plasma profiles, and DTI-MRI changes.

Conclusions:: Long-term filgrastim is safe, well-tolerated, and has significant positive effects on disease progression and survival. Model-based biomarker response classification can identify strong individual treatment responders at early stage of therapy and may pave the way to individualized treatment.
BRAIN 18F-FDG-PET SIGNATURE OF ALS WITH SOD1 AND TARDBP MUTATIONS

Antonio Canosa\(^1\), Umberto Manera\(^1\), Rosario Vasta\(^1\), Francesca Di Pede\(^1\), Maurizio Grassano\(^1\), Maura Brunetti\(^1\), Cristina Moglia\(^1\), Andrea Calvo\(^1\), Marco Pagani\(^2\), Adriano Chio\(^1\)\(^1\) University of Turin, Als Centre, "rita Levi Montalcini" Department Of Neuroscience, Turin, Italy; \(^2\)Consiglio Nazionale delle Ricerche (CNR), Institute Of Cognitive Sciences And Technologies, Roma, Italy

Background and Aims:: We evaluated the brain \(^{18}\)F-FDG-PET features of ALS patients with SOD1 (SOD1-ALS) and TARDBP (TARDBP-ALS) mutations, since this field is quite unexplored.

Methods:: Eighteen SOD1-ALS, 14 TARDBP-ALS (carrying the p.A382T mutation), 46 wild-type sporadic patients (sALS), and 40 healthy controls (HC) were enrolled. SOD1-ALS and TARDBP-ALS were compared to sALS and HC, employing the full factorial design and the two-sample t-test of SPM12 (height threshold P<0.001; P<0.05 FWE-corrected at cluster level). Age and sex were included as covariates in all the analyses, spinal/bulbar onset and King’s stage only in comparisons among patients.

Results:: TARDBP-ALS showed a relative hypometabolism in right precentral and postcentral gyrus, superior and middle temporal gyrus and insula, as compared to sALS. TARDBP-ALS showed a relative hypometabolism in bilateral frontal, parietal, temporal and occipital regions as compared to HC. When compared to SOD1-ALS, sALS patients showed a relative hypometabolism in right precentral and medial frontal gyrus, right paracentral lobule, and bilateral postcentral gyrus. As compared to HC, SOD1-ALS showed a relative hypermetabolism in right precentral gyrus and paracentral lobule. sALS patients showed a relative hypometabolism in frontal, temporal and occipital cortices as compared to HC.

Conclusions:: As compared to sALS, TARDBP-ALS patients showed a relative hypometabolism in motor and extramotor regions. The relative hypometabolism in the motor cortex in sALS as compared to SOD1-ALS might be related to the higher prevalence of pyramidal signs in sALS, while the relative hypermetabolism of SOD1-ALS as compared to HC in motor regions might be due to microglial activation.
EXPANDING THE NEUROPSYCHOLOGICAL PHENOTYPE OF ALS: PRELIMINARY FINDINGS

Giuseppe Fiamingo¹, Luca Diamanti², Marianna Collesi³, Elena Ballante⁴, Stefano Cappa⁵
¹University of Pavia, Department Of Brain And Behavioral Sciences, Pavia, Italy, ²Neurological Institute Foundation C. Mondino IRCCS, Neuro- oncology Unit, Pavia, Italy, ³IRCSS Mondino Foundation, Brain And Behavioral Sciences, Pavia, Italy, ⁴University of Pavia, Mathematics, Pavia, Italy, ⁵University Institute for Advanced Studies, Human And Life Sciences, Pavia, Italy

Background and Aims:: ALS is a neurodegenerative disease primarily affecting the motoneurons. Emerging evidences support the overlap between ALS and frontotemporal dementia (FTD), with cognitive impairment reported in up to 50% of sporadic ALS patients. A recent revision of the ALS diagnostic criteria highlights the importance of assessing the cognitive and behavioral domains, but data collection is still poorly standardized.

Methods:: We enrolled 38 Italian patients with sporadic ALS. Within 3 months from diagnosis, all patients underwent a comprehensive neuropsychological battery of standardized tests for cognitive and behavioral deficits (ECAS), language (SAND), emotion recognition (Ekman test), attention/executive function (Stroop Test) and social cognition (SET) evaluation.

Results:: Only 9 (24%) patients showed cognitive impairment on ECAS global score. When considering ECAS ALS-specific items, 10 patients (26%) were impaired. SAND partial scores were normal, with the exception of “word repetition” (7 patients, 27%). SET and Stroop test global and partial scores were all within normal limits. 2 patients (5.26%) had defective Ekman 60-faces scores.

Conclusions:: Our results indicate a lower prevalence of cognitive and behavioral impairment in comparison with other studies. Our cohort presents a preservation of emotion recognition, social cognition and attention/executive functions. Language is globally preserved with the exception of non-word phonological errors in some subjects. We aim at expanding the cohort for further cross-sectional and longitudinal evaluation.
SAFETY AND EFFICACY OF FIRST-IN-HUMAN INTRATHECAL TRANSPLANTATION OF HUMAN ASTROCYTES (ASTRORX®) IN ALS PATIENTS: PHASE I/IIA CLINICAL TRIAL RESULTS

Michal Izrael1, Marc Gotkine2, Guy Slutsky1, Yossef Lerner2, Judith Chebath1, Graciela Kuperstein1, Elena Estrin1, Yoseph Caraco3, Tamir Ben-Hur2, Arik Hasson1, Tehila Sonnefeld1, Yafit Stark1, Ariel Revel1, Michel Revel1
1Kaidmatem Ltd., Neurology, Nes-Ziona, Israel, 2Faculty of Medicine, Hebrew university Hadassah Medical center, Neurology, Jerusalem, Israel, 3Hadassah Ein Kerm Hospital, Hadassah Clinical Research Center, Jerusalem, Israel

Background and Aims:: AstroRx® is a cell-based therapy, composed of healthy human astrocytes derived from embryonic-stem-cells. AstroRx® can protect neurons by several mechanisms-of -ction that were demonstrated in in-vitro and in vivo preclinical studies. The hypothesis is that transplantation of AstroRx® can compensate for the malfunctioning of endogenous astrocytes by restoring hampered physiological capabilities, i.e. reducing toxic compounds, reducing oxidative stress and secreting multiple neurotrophic factors.

Methods:: We conducted a Phase I/IIa, Open-Label, dose-escalating Clinical Study to Evaluate the Safety, Tolerability and Therapeutic Effects of Transplantation of AstroRx® in Amyotrophic -lateral- Sclerosis (ALS) patients. Enrolled patients were monitored for 3-months of "run-in period" to record their ALS progression. At the end of the run-in period, 5 patients were injected intrathecally with a single dose of 100*106 AstroRx® and 5 patients with a dose of 250*106 cells. After treatment, the patients were monitored for additional 6-months for safety data and assessment of disease-progression, as compared to the run-in period and for additional 6-months for long safety.

Results:: AstroRx® treatment was well tolerated in both doses and no treatment-related serious-adverse-events nor dose-limiting toxicities related to AstroRx® were reported. A potentially clinically meaningful decline in disease-progression, assessed by the ALS Functional-Rating-Scale-Revised (ALSFRS-R), was observed during the first 3-months of the 6-month follow-up period in both cohorts.

Conclusions:: Single-dose transplantation of AstroRx® is safe and demonstrated a promising efficacy during the first 3-months. These results support a further, randomized-controlled, clinical trial with repeated doses of AstroRx® in ALS patients, in order to prolong the time-span of the clinical effect observed by single-dose.
DYSREGULATION OF LINC-RNAS DURING SKELETAL MUSCLE DEVELOPMENT IN A PATIENT- DERIVED IN VITRO MODEL OF AMYOTROPIC LATERAL SCLEROSIS

Silvia Bonanno¹, Eleonora Giagnorio¹, Claudia Malacarne¹, Patrizia Bossolasco², Erika Salvi³, Donatella Bardelli², Antonia Ratti², Giuseppe Lauria⁴, Renato Mantegazza¹, Stefania Marcuzzo¹

Background and Aims:: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease characterized by progressive degeneration of cortical, bulbar and spinal motor neurons, leading to muscle wasting and paralysis. Although MNs are the crucial targets of the pathogenic process in ALS, there is evidence of an early involvement of skeletal muscles, supporting the concept that it might represent a crucial site of disease pathogenesis. Different causative genes associated to ALS are involved in RNA metabolism. Long-non coding RNA (lncRNAs) are emerging as molecular contributors to ALS pathophysiology because of their role in regulating gene expression. Here we analysed the expression levels of IncRNAs known to be involved in development and maintenance of skeletal muscle in control and ALS patient-derived induced pluripotent stem cells (iPSCs) differentiated towards a myogenic destiny.

Methods:: We differentiated control and ALS patients’ derived iPSCs to myofibres using a small molecule-based protocol. We followed the myogenic process by immunostainings and real-time PCR to assess the expression of skeletal muscle development markers at different time points of the skeletal muscle development.

Results:: We reported a different IncRNAs’ expression pattern in ALS-derived cultures compared to controls, particularly at the mesodermal progenitor, early myocyte and myotube stages of the skeletal muscle differentiation process. Further, we predicted the respective IncRNAs’ mRNA targets identifying specific molecular pathways involved in the development and homeostasis of skeletal muscles, potentially dysregulated over ALS course.

Conclusions:: These data suggest that IncRNAs might be important players in muscle dysregulation in ALS and are candidate for the study of mechanisms contributing to ALS pathogenesis.
DIAGNOSTIC AND PROGNOSTIC ROLE OF PLASMA PHOSPHORYLATED NEUROFILAMENT HEAVY CHAIN (PNF-H) IN AMYOTROPHIC LATERAL SCLEROSIS

Maria Teresa Dell’Abate¹, Chiara Zecca¹, Giuseppe Pasculli², Roberta Barone¹, Rosa Capozzo¹, Maria Rosaria Barulli¹, Serena Arima³, Alessio Pollice⁴, Rosanna Tortelli³, Giancarlo Logroscino¹

Background and Aims:: The phosphorylated neurofilament heavy chain (pNf-H) is a promising putative biomarker in Amyotrophic Lateral Sclerosis (ALS). We examined pNf-H concentrations in plasma of ALS patients to investigate its potential as a diagnostic and prognostic biomarker.

Methods:: Incident ALS cases enrolled in a population-based registry were retrospectively selected and matched by sex and age with a cohort of healthy volunteers. Plasma pNf-H levels were measured by an ELISA kit (Neurofilament pNf-H-high sensitive ELISA, Euroimmun) and correlated with clinical parameters. Discrimination ability of pNf-H was tested using Receiving Operating Characteristic (ROC) curves. Kaplan-Meier (KM) univariate analysis was carried-out to determine the survival probability based on plasma pNf-H; univariate and multivariable Cox proportional hazard models were performed to estimate the effect of plasma pNf-H on survival, adjusted for clinically relevant covariates.

Results:: Plasma pNf-H was significantly higher in patients compared to controls. An optimal cut-off of 39.74 pg/ml discriminated cases from controls with 75% sensitivity and specificity. Bulbar-onset cases had higher levels of plasma pNf-H compared to spinal onset (p=0.0033). Furthermore, plasma pNf-H positively correlated with disease progression rate (r=0.19, p=0.031). Survival probability was no different among cases stratified according to pNf-H median value (101pg/mL) (log-rank test χ²= 0.5; p=0.49). In Cox PH regression models plasma pNf-H was not independently associated with a reduced survival in cases (aHR 1, 95% CI 1-1, p = 0.028).

Conclusions:: Our findings confirmed the potential utility of plasma pNfH as a diagnostic biomarker in ALS. However, further evaluations in longitudinal data are needed to corroborate its prognostic value.
Background and Aims:: Neurodegenerative disorders are associated with high burden for patients, their families and the society, with overload of the professionals. We addressed the professional and personal insights and expectations of the latter, including during the COVID-19 pandemic.

Methods:: A survey was developed and made available in google forms (https://docs.google.com/forms/d/1-Gv5gtrl8qb1r7C7ChpJnxs-a4ynIS6sGMu-70wm3Ss/edit#responses), between 26/10-15/11/2020, to professionals working in the neurodegenerative field. Three sections were considered, addressing: characterization of the respondents; patient-professional relation; pathophysiology, genotype-phenotype, pharmacological perspectives. Means and frequencies were calculated. Differences between those working >15 vs =<15 years were assessed using Fisher exact test. P<0.05 was significant.

Results:: Eighty-two professionals, from 5 continents, most Europeans, answered. Most were fullfilled with work, 47 worked >15 years, 67% for >=4 days/week. Clinicians described positive impact on patients/families. Almost all had strategies to cope with the diseases' devastating nature, not affected by the COVID-19 in 44.3% or sometimes in 35.7%. Causative genetic interplay, protein aggregations and common neurodegenerative pathways, with ageing impact, justified a partial or continuous spectrum, with high levels of congruence between respondents =<15 vs >15 years/ work. Most believed in disease improvement, available within 5 years, but a cure only in the far future.

Conclusions:: Professionals working in the neurodegenerative field are satisfied and motivated. Coping strategies may, nevertheless, be influenced by the COVID-19. Causative genetic interplay, protein aggregations, common neurodegenerative pathways and ageing play relevant roles, and justify partial/continuous spectrum, with high levels of congruence between professionals. A cure is not expected in the near future, but hope exists.
CLINICAL AND GENETIC SPECTRUM OF AMYOTROPHIC LATERAL SCLEROSIS IN A TUNISIAN SERIES

Imen Kacem¹,², Ikram Sghaier², Silvia Peverelli³, Antonia Ratti³,⁴, Nicola Ticozzi³,⁵, Amina Gargouri-Berrechid¹,², Vincenzo Silani³,⁵, Riadh Gouider¹,²
¹University Tunis El Manar, Faculty Of Medicine Of Tunis, Tunis, Tunisia, ²Razi University Hospital, Neurology And Lt18sp03, Mannouba, Tunisia, ³IRCCS Istituto Auxologico Italiano, Department Of Neurology - Stroke Unit And Laboratory Of Neuroscience, Milano, Italy, ⁴Università degli Studi di Milano, Department Of Medical Biotechnology And Translational Medicine, Milano, Italy, ⁵Università degli Studi di Milano, Department Of Pathophysiology And Transplantation, Milano, Italy

Background and Aims:: Few studies looking at Amyotrophic Lateral Sclerosis (ALS) among African populations were published. Our aim was to describe clinical characteristics of Tunisian ALS patients and to explore the main candidate genes and their potential associations with ALS phenotype.

Methods:: We included ALS patients followed up in the department of Neurology of Razi University Hospital over a 17-year period. For genotyping, analysis of SOD1, FUS, and TARDBP were sequenced by Sanger, while C9orf72 expansion was performed using PR-PCR. Genetic study was conducted at IRCCS Istituto Auxologico Italiano in Milan and the sequencing platform of faculty of Medicine of Tunis.

Results:: We included 201 patients. In this cohort we had 24 familial ALS and 12 Juvenile ALS form (JALS). Median age of ALS onset was 54.93 years and sex-ratio was 2.0. Among classic forms 76.3% had spinal onset whereas bulbar was seen in 20.1% of patients. Consanguinity was present in 66.7% of JALS. The median survival among JALS was 15 years. TARDBP mutation p.G294A was responsible for 12.93% of cases. SOD1 mutations were present in 10.45% of patients. C9ORF72 repeat expansion was found in 4.47% and no pathogenic variant of FUS were observed. For JALS, we identified 2 Alsin Gene mutations and one SOD1 gene mutation.

Conclusions:: We found a higher frequency of Juvenile forms, an overall slower ALS progression and a high frequencies of mutations in TARDBP, SOD1 and C9ORF72 genes. These findings in a large North African cohort help to shed lights on phenotype and genotype peculiarities in this population.
ALS AND COGNITION IMPAIRMENT

Majlinda Shyti¹, Altin Kuqo², N Stringa³, Jera Kruja¹
¹Faculty of Medicine, UMT, Neurology, Tirana, Albania, ²UHC Mother Teresa, Neurology, Tirana, Albania, ³Amsterdam UMC, Epidemiology And Data Science Dept, Amsterdam, Netherlands

Background and Aims:: Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disorder involving primarily motor neurons in the cerebral cortex, brainstem and spinal cord. Despite the increased awareness of ALS as a multi-system disorder, the cognitive status of most ALS patients attending clinics remains unknown.

Methods:: The study aimed to evaluate cognitive profile and behavioral impairment in ALS patients who came for the first time in Neurology dept., UHC Mother Teresa, Tirana. Methods: In total, 28 patients with the diagnosis of ALS according to the revised El Escorial criteria and 46 age-, education- and gender matched controls participated in the study. Each case was screened for cognitive dysfunction (MOCA; ECAS) and behavioral impairment (ADL; IADL, Quality of life and FBI).

Results:: The mean age of the participants at time of assessment was 59.4 ± 10.1 years and 67.9% were men. ALS patients had a significantly higher frequency of impairment in MOCA, language, verbal fluency, executive function, memory and total ECAS (p value<0.05). Executive function is the most affected domain, followed by memory and language.MOCA and total ECAS was more affected in patients with bulbar onset disease compared to spinal onset( p value respectively 0.065 and 0.099). Respiratory dysfunction was associated with significantly lower scores on MOCA and executive function (0.091 and 0.104 respectively). Most of patients had minimal behavioral impairment.

Conclusions:: These findings suggest that ALS does not selectively affect only the pyramidal motor system, but rather is a multisystem neurodegenerative disease.
Background and Aims:: Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disorder of motor neurons. Spread of pathology to other brain areas leads to development of non-motor symptoms (NMSs). These usually remain undiagnosed because of overwhelming motor problem and are responsible for significant distress to the patient. Our objective was to explore the burden of various NMSs of patients with ALS, compare between limb-onset and bulbar-onset patients, and to correlate with severity and duration of disease.

Methods:: Fifty patients with ALS diagnosed according to revised El Escorial Criteria and 50 healthy controls were included in this study. They were assessed with NMS Questionnaire, Beck's Depression Inventory, Center for Neurologic Study-Lability Scale, Drooling Frequency and Severity Scale, Epworth Sleepiness scale, Bengali Mental State Examination, and Frontal Assessment Battery and relevant statistical analyses were carried out.

Results:: The patients with ALS had significantly increased prevalence of almost all NMSs compared to controls. There was also significant increase in depression, suicidal ideation, pseudobulbar affect, and daytime sleepiness in patients with ALS. The bulbar onset subgroup had significantly increased daytime drooling, dysphagia, nausea and vomiting, whereas the limb onset subgroup reported increased frequency of leg swelling. Executive dysfunction was detected in 24% of patients with ALS and 9.8% had mild cognitive impairment. Weight loss, frequency of falling, insomnia, unpleasant nocturnal leg sensations, difficulty having sex, depression, and cognitive impairment increased significantly with an increase in severity of the disease.

Conclusions:: NMSs were significantly more prevalent in patients with ALS. Some NMSs worsened with advancement of the disease.
TWO CASES OF UNILATERAL WASTING AND WEAKNESS OF DISTAL UPPER LIMB: SIMILAR ONSET AND DIFFERENT DIAGNOSIS IN YOUNG PATIENTS

Alessia Giugno1, Stefania Barone1, Rita Nisticò2, Umberto Sabatini3, Carlo Stanà4, Franco Pucci1, Antonio Gambardella1, Paola Valentino1

1Magna Graecia University of Catanzaro, Institute Of Neurology, Department Of Medical And Surgical Sciences, Catanzaro, Italy, 2National Research Council, Neuroimaging Research Unit, Institute Of Molecular Bioimaging And Physiology, Catanzaro, Italy, 3Institute of Radiology, Neuroradiology Unit, Magna Graecia University, Catanzaro, Italy, 4Magna Graecia University of Catanzaro, Neuroradiology Unit, Magna Graecia University, Institute Of Radiology, Catanzaro, Italy

Background and Aims:: We presented two patients with unilateral weakness and wasting of distal upper limb at onset.

Methods:: A 20-years-old woman (patient 1) and a 16-years-old man (patient 2) developed weakness and wasting of left distal upper limb, subsequently spreading to forearms. Clinical, laboratory, neurophysiological and MRI assessment were performed.

Results:: Both patients exhibited weakness and hypotrophy of forearms and hands muscles on neurological examination, unremarkable laboratory and cerebrospinal fluid work-up, including anti-gangliosides antibodies, and brain MRI. Patient 1: upper and lower limb motor evoked potentials (MEPs) were absent bilaterally. Somatosensory evoked potentials (SSEPs) and nerve conduction study (NCS) were normal. Electromiography showed chronic denervation signs in upper limbs muscles. Cervical spine MRI was normal. Patient 2: SSEPs detected prolonged latencies in lower limbs; upper and lower limb MEPs were absent bilaterally. Electromiography showed chronic denervation signs in upper limbs muscles, with spared brachioradialis muscles. NCS revealed left ulnar axonal neuropathy. Cervical spine MRI, performed on neutral and flexion positioning, detected straight cervical spine, posterior loss of attachment and anterior displacement of extradural space with anterior cord flattening, C4-C7 epidural contrast enhancement on T1-sequence. He was unsuccessfully treated with intravenously immunoglobulins. At one-year follow-up, patient 1 developed diffuse upper and lower motor neuron signs, consistent with motor neuron disease (MND), whereas patient 2 was stable, consistent with Hirayama disease (HD).

Conclusions:: In early stages, HD and MND may be difficult to differentiate, leading to misdiagnosis and mistreatment. Our findings highlight rarity of HD and key role of clinical, neurophysiological and MRI investigations in differential diagnosis.
POTENTIAL OF IMMUNOGLOBULINE TREATMENT IN MOTOR NEURON DISEASES ASSOCIATED TO BLOOD- BRAIN BARRIER DAMAGE

Lucrezia Becattini, Francesca Bianchi, Alessandra Govoni, Erika Schirinzi, Andrea Bacci, Gabriele Siciliano
University of Pisa, Department Of Clinical And Experimental Medicine, Neurological Clinic, Pisa, Italy

Background and Aims:: Motor neuron diseases (MND) are inherently complex and may result in several different diagnoses with challenging treatment. Here, we report two cases of MND showing clinical improvement after immunoglobuline infusion.

Methods:: The first case is a 39-year-old man with a history of proximal upper limbs hyposthenia and fluctuating slurred speech that had appeared one year prior after a flu syndrome. In time, symptoms grew to proximal upper limbs amyotrophia and tongue atrophy with fluctuating dysphagia. The electromyogram showed a chronic neurogenic pattern on the affected muscles with localized acute denervation. The second case is a 59 years old man that showed an acute onset of diffuse muscle weakness and fasciculations, with associated respiratory insufficiency and a recent history of severe weight loss. He presented neurogenic patterns with acute denervation and fasciculation potentials in all the muscles examined at the electromyogram.

Results:: In the first case, due to the persistence of high levels of CRP, the patient underwent a CSF exam that showed blood-brain barrier damage with systemic oligoclonal bands. An intravenous immunoglobulin therapy showed a prompt improvement both in hyposthenia and in bulbar symptoms. Also in the second case, the CSF exam showed blood barrier damage, and intravenous immunoglobulin therapy showed a remarkable improvement both in muscular strength and in respiratory function.

Conclusions:: These cases confirm that immunoglobulins have therapeutic value in treating MND in presence of blood-brain barrier damage, suggesting their careful consideration to treat selected cases.
SYMPTOMATIC C9ORF72 MUTATION IN NON-FLUENT APHASIA WITHOUT NEUROIMAGING SIGNS OF CEREBRAL ATROPHY: A CASE STUDY

Lorenzo Fontanelli¹, Francesca Bianchi¹, Alessandro Galgani¹, Daniela Frosini¹, Irene Ghicopulos², Antonella Fogli³, Gabriele Siciliano¹
¹Azienda Ospedaliero Universitaria Pisana, Neuromuscular Unit, Pisa (PI), Italy, ²University of Pisa, Department Of Clinical And Experimental Medicine, Neurological Clinic, Pisa, Italy, ³Azienda Ospedaliero Universitaria Pisana, Molecular Genetics Unit, Pisa, Italy

Background and Aims:: Expansion mutations in the C9orf72 gene may cause familial amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). Diffuse subcortical brain atrophy, while absent in asymptomatic patients, is frequent in symptomatic C9orf72 subjects, suggesting a direct association with active disease. Therefore, neuroimaging studies may be used as follow-up biomarker in patients carrying the mutation. Here, we describe a case of initial non-fluent aphasia in a C9orf72 patient

Methods:: A 61 years old female patient came to our attention for a rapid onset of dysarthria with agrammatic speech and depressed mood that appeared 18 months prior, following an important grieving. Due to the patient’s familiarity for neurodegenerative disorders in her maternal lineage (sister and grandmother affected by ALS, mother affected by Alzheimer’s disease

Results:: Electromyograms, cerebral FDG PET and a high camp cerebral MRI, all resulted normal. Neurological examination was normal, except for agrammatic speech and saccadization of pursuit at ocular movements’ examination. The NGS analysis revealed a C9orf 72 expansion (137 repetitions of G4C2). Following further evaluations after a year of clinical stability, the patient showed progressive pyramidal and frontal release signs.

Conclusions:: Our patient did not show alterations in brain imaging in spite of having a symptomatic C9orf72 mutation and a long history of language disturbances. This report remarks the complexity of the neurodegenerative process and its molecular-clinical relationships along the C9orf72 related ALS/FTD spectrum.
COMPREHENSIVE APPROACH: NEUROGENESIS, EXTRACELLULAR MATRIX, AUTOPHAGY AND IMMUNE DYSFUNCTION AS TREATMENT TARGETS IN NEURODEGENERATION AS IN ALS - REORGANIZING PHYSIOLOGICAL REPAIR

Ulrich Bogdahn¹, Sebastian Peters¹, Sabrina Küspert¹,², Siw Johannesen³, Tim-Henrik Bruun¹
¹Velvio GmbH, Neurology, Regensburg, Germany, ²University of Regensburg, Neurology, Regensburg, Germany, ³BG Trauma Center, Neurology, Murnau am Staffelsee, Germany

Background and Aims:: Constant physiological remodeling and repair are increasingly dysfunctional in several essential brain systems during neurodegenerative disorders. Once chronic neuroinflammatory mechanisms are activated, a machinery of major cytokines - among them an upregulated TGF-β system - are pushing this process forward. By hitting the TGF-β system as such crucial single target, our aim was to reach many critical downstream mechanisms of neurodegeneration at one time for a long-term treatment approach.

Methods:: A new LNA (Locked Nucelotide Acid) - 16mer gapmer antisense molecule targeting exclusively the human Transforming Growth Factor β Receptor Type II (TGBR2) was designed and validated in vitro. A regulatory 13-week GLP program with repeat intrathecal applications in physiological saline (controls and 3 dose ranges) was performed in cynomolgus monkeys.

Results:: With excellent tolerance and a no observed adverse effect level (NOAEL), drug effects could be attributed to specific downregulation of the target molecule and local / systemic dose dependent tissue levels. Functional activities at the level of mRNA - modulation in stem cell regulation, autophagy, extracellular matrix and immune activation also led to a dose dependent increase in neurogenesis in hippocampus, subventricular zone, and spinal cord of these healthy monkeys. As mode of action, canonical - more so non-canonical - signaling of TGF-β pathways could be identified.

Conclusions:: Single-drug pharmacological intervention has the potential to safely and efficiently address some of the most relevant pathophysiological mechanisms in neurodegenerative disorders at once and now needs clinical development. Brain and spinal cord regeneration in neurodegenerative disorders may have a realistic future perspective.
A SYSTEMATIC REVIEW ON RISKS OF NEURODEGENERATIVE DISEASES IN PROFESSIONAL SPORTS.

Guido Bellomo¹, Paola Piscopo², Antonio Ancidoni¹, Massimo Corbo³, Nicola Vanacore¹, Eleonora Lacorte¹
¹National Institute of Health, National Center For Disease Prevention And Health Promotion, Rome, Italy, ²National Institute of Health, Rome, Italy, Department Of Neurosciences, Rome, Italy, ³Casa di Cura Privata del Policlinico, Department Of Neurorehabilitation Sciences, Milano, Italy

Background and Aims:: Previously published literature reported an association between sports and neurodegenerative diseases (ND), in particular, motor neuron disease (MND), amyotrophic lateral sclerosis (ALS), dementia, mild cognitive impairment (MCI), Chronic Traumatic Encephalopathy (CTE), and Parkinson’s disease (PD). The aim of this systematic review (SR) was to gather available evidence on professional sport as a potential risk factor for NDs.

Methods:: This SR was performed following the methodology stated in the Cochrane handbook and the PRISMA statement. Available literature was searched on PubMed, Discovery, and the Cochrane databases. All case-control and cohort studies reported professional sport as a risk factor for the considered NDs were included.

Results:: Searches yielded 7390 records, and 19 articles were included. Results showed an overall 3.53 (95%CI 2.72-4.57, p<0.001) HR of death due to NDs in professional players and, in particular, a HR of 3.87 for dementia (95%CI 2.86-5.24, p<0.001), 4.33 for MND (95%CI 2.05-9.15, p<0.001) and 2.15 for PD (95%CI 1.17-3.96, p=0.01). Another cohort study found a 3-times higher mortality rate due to NDs in football players (SMR 2.83, 95%CI 1.36-5.2), and an almost 4-times higher mortality rate for ALS (SMR 4.31, 95%CI 1.73-8.87) and for AD (SMR 3.86, 95%CI 1.55-7.95). One study reported a 5-times higher prevalence of MCI in retired football players, who reported ≥3 concussions, and another study reported an association between CTE and boxing (OR 9.50, 95%CI 1.73-52.12, p=0.01).

Conclusions:: Preliminary data showed significant association between NDs and the exposure to some sports at a professional level, such as boxing, soccer and football.
ATYPICAL ONSET OF AMYOTROPHIC LATERAL SCLEROSIS: EIGHT CASES REPORT

Basma Marzouk, Nazha Birouk, Bouchra Kably, Leila Ergguig, Reda Ouazzani
1Hôpital des Spécialités, Department Of Clinical Neurophysiology, RABAT, Morocco, 2Hôpital des Spécialités, Department Of Clinical Neurophysiology, rabat, Morocco

Background and Aims:: Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease that affects both lower motor neurons (LMN) and upper motor neurons (UMN). There is a marked phenotypic heterogeneity between cases. The aim of our study is to present the atypical onset of this disease.

Methods:: This is a retrospective and descriptive study of eight clinical cases of defined ALS with atypical onset, diagnosed in our department.

Results:: Four men and four women aged 30 to 66 years. Unusual onset were: 1) A woman with inaugural neuromyotonia, revealed by painful tonic contractures, cramps, fasciculations, electroneuromyography (ENMG) showed neuromuscular hyperexcitability, etiological assessment remained negative. 2) and 3) Two men with inaugural acute respiratory failure. 4) A young woman presented subacute pseudo-myositis, the initial ENMG showed a myogenic appearance, follow up ENMG disclosed diffuse denervation patterns. 5) A man with isolated pseudobulbar palsy syndrome lasted for more than 4 years before the onset of signs of LMN impairment. 6) A woman with a Flail Leg, associated with sicca syndrome whose treatment was not effective, rapidly progressing to diaphragmatic involvement that required noninvasive ventilation. 7) A woman initially diagnosed with probable Chronic inflammatory demyelinating polyneuropathy with moderate sensory deficit in the lower limbs, without any improvement under IVIg treatment. She died 2 years later. 8) A man with chronic right brachial monoparesis, which remained isolated with focal involvement of LMN in C6-T1 levels for 6 years.

Conclusions:: An unusual onset of ALS necessarily leads to differential diagnoses, clinical and ENMG monitoring remains the key to diagnosis.
PHASE 3 TRIAL OF ULTRA-HIGH DOSE METHYLCOBALAMIN IN EARLY-STAGE AMYOTROPHIC LATERAL SCLEROSIS

Yushin Izumi1, Ryosuke Oki1, Satoshi Kuwabara2, Ryuji Kaji1,3
1Tokushima University, Neurology, Tokushima, Japan, 2Chiba University, Department Of Neurology, Chiba, Japan, 3National Hospital organization Utano Hospital, Director, Kyoto, Japan

Background and Aims:: In the post-hoc analyses of our previous study conducted to verify efficacy and safety of ultra-high dose methylcobalamin against patients diagnosed by the revised El Escorial criteria (rEEC), methylcobalamin may prolong survival and retard symptomatic progression without major side effects if started early (≤12 months' duration). The objective of next trial: The Japanese Early Stage Trial of High Dose Methylcobalamin for Amyotrophic Lateral Sclerosis (JETALS) is to reconfirm the efficacy and safety of ultra-high dose methylcobalamin for ALS patients in their early stages.

Methods:: JETALS is a prospective, multicenter, placebo-controlled, double-blind, randomized phase III study conducted at 25 tertiary neurology centers in Japan. Patients diagnosed with ALS corresponding to the categories of definite, probable, or probable-laboratory supported in the updated Awaji criteria (UAC) within 12 months from onset were registered at observation period, then patients whose the Revised ALS Functional Rating scale (ALSFRS-R) total score has decreased by 1–2 points during 12 weeks proceeded to the treatment period and were randomized at a 1:1 ratio to receive intramuscular injection with methylcobalamin 50 mg or placebo twice a week for 16 weeks. We adopted UAC for the first time in the world to our knowledge, which revealed a higher sensitivity compared to rEEC. The target number of subjects is 128. The primary endpoint is changes in the ALSFRS-R total score at 16 weeks.

Results:: This study was started in October 2017 and 130 patients have been enrolled by the end of October 2019.

Conclusions:: The results of JETALS will be presented at the congress.
BRAIN ENERGY METABOLISM IN ALS: A PHOSPHORUS-31 MAGNETIC RESONANCE SPECTROSCOPY STUDY

Matilde Sassani¹, James Alix¹, Christopher Modermott¹, Kathleen Baster², Nigel Hoggard³, James Wild³, Heather Mortiboys¹, Pamela Shaw¹, Iain Wilkinson³, Thomas Jenkins¹

¹Sheffield Institute for Translational Neuroscience, University of Sheffield, Neuroscience, Sheffield, United Kingdom, ²University of Sheffield, Statistical Services Unit, Sheffield, United Kingdom, ³University of Sheffield, Academic Unit Of Radiology, Sheffield, United Kingdom

Background and Aims:: In vitro and animal studies indicate that bioenergetic dysfunction in brain is an important pathophysiological mechanism in amyotrophic lateral sclerosis (ALS). We aimed to characterise for the first time brain energy metabolism in ALS patients using phosphorus-31 magnetic resonance spectroscopy (³¹P-MRS).

Methods:: Brain spectroscopy was acquired from motor regions in twenty patients and ten age and gender-matched healthy controls. Spectroscopic parameters were estimated with AMARES algorithm and expressed as a proportion of total phosphorus signal. Revised ALS Functional Rating Scale (ALSFRS-R), slow vital capacity (SVC), and upper motor neuron score (UMNS) were assessed.

Results:: Phosphocreatine was reduced in the pons in patients compared to controls (p=0.002) and retained significance after adjusting for voxel partial brain fraction and age. Lower phosphocreatine was associated with greater disability on ALSFRS-R and lower SVC. No differences were found in motor cortex or deep white matter.

Conclusions:: Decreased phosphocreatine is a hallmark of bioenergetic dysfunction in mitochondrial cytopathies. Correlations with ALSFRS-R and SVC suggest clinical relevance. This study is the first to illustrate the presence of cranial bioenergetic dysfunction in vivo in ALS patients, and illustrates the potential of ³¹P-MRS as a biomarker of mitochondrial dysfunction. Acknowledgements: We thank the study participants and Prof Iain Wilkinson for establishing the technique. This work was supported by: the NIHR Sheffield Biomedical Research Centre for Translational Neuroscience, British Medical Association Vera Down, and Neurocare/Ryder Briggs Trust. This work was published in (1). References: (1) Sassani, M., et. Al (2020). "Magnetic resonance spectroscopy reveals mitochondrial dysfunction in amyotrophic lateral sclerosis." Brain 143(12): 3603-3618.
TWO CONTRASTING CLINICAL MANIFESTATIONS OF AMYOTROPHIC LATERAL SCLEROSIS (ALS) RELATED TO FUS MUTATIONS

Francesca Bianchi¹, Lorenzo Fontanelli¹, Alessandro Galgani¹, Lucrezia Becattini¹, Antonella Fogli², Gabriele Siciliano¹
¹University of Pisa, Department Of Clinical And Experimental Medicine, Neurological Clinic, Pisa, Italy, ²Azienda Ospedaliero Universitaria Pisana, Molecular Genetics Unit, Pisa, Italy

Background and Aims:: Alterations of the Fused in Sarcoma FUS gene have been put in relation with an array of neurodegenerative disorders, including juvenile ALS with an aggressive progression. Here, we describe two patients carrying FUS mutations and showing contrasting ALS phenotypes and different histories of disease progression

Methods:: The first patient is a 43-year-old male with a clear family track record for ALS (mother, maternal uncle and maternal grandfather) who initially developed a neurogenic monomelic amyotrophy that remained restricted to the right lower limb for more than one year. He later showed a quick and diffuse involvement of all limbs, bulbar and respiratory muscles. The second patient is 50-year-old male with no history of neurological diseases except for a sister who died of a cerebral malignancy at the age of 40. The patient developed in 2007 a typical form of ALS that a few years later required the positioning of tracheostomy and percutaneous gastrectomy. The patient is still alive

Results:: A NGS analysis reported a heterozygous mutation of Arg>521Cys in the first patient’s FUS gene. The second patient was found to carry a heterozygous variant in c.667_672delCGGCGG, p. GLY223_Gly224 in exon 6 of FUS gene.

Conclusions:: Although in the first patient the FUS alteration results in phenotypes in line with other cases previously described in literature, the disease’ hallmarks in the second patient are not commonly reported in FUS-related ALS. These two cases confirm the wide clinical spectrum that may be related to FUS mutation, prompting to further studies to shed light on its complex pathogenetic mechanisms.
Background and Aims:: ALS (amyotrophic lateral sclerosis) is a multifactorial disorder. Some pathogenic genetic variants are responsible of many cases.

Methods:: To expose a case report about a ALS patient with two probably pathogenic new variants in TBK1 and ANG genes.

Results:: A 63-years-old woman experienced clumsiness in her right leg in the last year. In the last month, she also complained of clumsiness in her right hand. She had not any relevant personal or family medical history except to a sibling with spasticity. In the neurological examination, we detected right hemiparesis, hyperreflexia with clonus, right Babinski sign, and spastic gait. In electromyography, we found denervation activity. Neuroimaging studies were normal. With these findings, the ALS diagnosis was made. We also requested analysis of genes associated with ALS. The result was the presence of two probably pathogenic variants in the TBK1 c.1318C>Tp.(Arg440*) and ANG c.394G>Tp.(Glu132*) genes. We sequenced these in his brother, who was also carrier of both.

Conclusions:: The (TBK1):c.1318C>Tp.(Arg440*) variant has not been reported before, and it is not present in population databases. This variant is expected to lead in an absent or altered protein product. A similar variant (R357X) was reported in a ALS patient. The (ANG):c.394G>Tp.(Glu132*) variant has not been reported before, and it is not present in population databases, either. It causes a premature stop signal at codon 132 of the ANG gene. The alteration is expected to lead in an absent or altered protein product.
MONOMELIC AMYOTROPHY OF UPPER LIMB. 4 CASE REPORTS

Jawad Oumerzouk
Military Hospital of Marrakech. Avicenne. CHU Mohamed VI, Neurology, Marrakech, Morocco

Background and Aims:: Monomelic amyotrophy represent a clinical-electrical and radiological syndrome similar to Hirayama disease, but involving multiple etiologies

Methods:: Nous rapportons les observations cliniques de 4 patients présentant une amyotrophie et une faiblesse progressive d'un membre supérieur, proximale dans 3 cas et distale dans un seul cas, unilatérale dans 3 cas et bilatérale dans un seul cas.

Results:: L'électromyogramme a montré des lésions neurogènes cervicales localisées, et l'imagerie par résonance magnétique (IRM) a montré un hypersignal dans les cornes antérieures du cordon cervical correspondant aux myotomes affectés. L'évaluation étiologique a montré une éosinophilie chez un patient. Deux patients pratiquaient un sport intensif (musculation, art martial), un patient avait des antécédents de traumatisme cervical et un patient avait une infection dans les jours précédant la présentation clinique. Les patients ont reçu un traitement symptomatique avec rééducation fonctionnelle et l'évolution a été marquée par une stabilisation des symptômes.

Conclusions:: Monomelic atrophies correspond to ischemic lesions of the anterior horns, sometimes visible on MRI in the form of hypersignal. The location and extent of ischemic spinal cord involvement vary from different cases. Confusion with Hirayama disease is possible when ischemia is confined to the anterior territories of the C7-D1 levels. Chronic spinal cord ischemia may result not from direct compression of the anterior spinal artery, but also from increased intramedullary pressure, leading to local microcirculation disorder. However, other aetiologies are increasingly implicated in the pathogenesis of the disease, such as infection by viruses which have tropism for the anterior horn and certain immunoallergic disorders.
ALSFRS SCORES IMPROVED AFTER MULTIPLE INFUSIONS OF AUTOLOGOUS ADIPOSE TISSUE-DERIVED STEM CELLS IN ALS PATIENTS

Kazuo Shigematsu¹, Takahisa Takeda², Naoyuki Komori³, Kenichi Tahara⁴, Hisakazu Yamagishi⁵
¹Minami Kyoto Hospital, National Hospital Organization, Neurology, Joyo, Japan, ²Takeda General Hospital, Internal Medicine, Kyoto, Japan, ³Nagitsuji Hospital, Internal Medicine, Kyoto, Japan, ⁴Takara Bio Inc., Bio-industry Support, Kusatsu, Japan, ⁵Kyoto Prefectural University of Medicine, Surgery, Kyoto, Japan

Background and Aims:: The aim of the study was to confirm the safety and to investigate the efficacy of intravenous administration of autologous adipose-derived stem cells (ADSCs) for amyotrophic lateral sclerosis (ALS).

Methods:: Six ALS patients were treated with 4.3-8.7x10⁷ ADSCs administered intravenously three times at 1-2 month intervals. Patients who had already been diagnosed with ALS at other hospitals and who were willing to participate in the study and who could come to the study hospital for intravenous infusion treatment were included in the study. The patient was examined by multiple physicians, including neurologists, and followed up with interviews of the patient and caregivers for up to 3 months after administration.

Results:: One patient died of ALS progression. The patient's ALS Functional Rating Scale (ALSFRS) was 35 before dosing and 14 after dosing. The ALSFRSs of the other 5 patients were 35 to 45, 35 to 27, 46 to 46, 38 to 23, and 16 to 11 before and at 3 months after 3 doses, respectively. No adverse events were observed.

Conclusions:: ADSCs can be collected with minimal invasion, cultured in a serum-free medium, and administered intravenously repeatedly in a safe manner. No side effects were observed. Since this study was open-label and there was no control group, judgments of efficacy must be made with caution. However, the fact that ALSFRS was maintained or improved in 2 of the 6 patients suggests that this treatment may be effective. The results of this study provide a rationale for future trials to verify the efficacy of this treatment.
EFFICACY AND SAFETY OF ULTRA-HIGH DOSE METHYLCOBALAMIN IN EARLY STAGE AMYOTROPHIC LATERAL SCLEROSIS: RESULTS OF A RANDOMIZED, DOUBLE-BLEND, PHASE 3 TRIAL (JETALS)

Yuishin Izumi¹, Ryosuke Oki¹, Satoshi Kuwabara², Ryuji Kaji¹,³
¹Tokushima University Graduate School of Biomedical Sciences, Department of Neurology, Tokushima, Japan, ²Chiba University, Department of Neurology, Chiba, Japan, ³National Hospital Organization Utano Hospital, Director, Kyoto, Japan

Background and Aims:: Clinical and non-clinical studies have shown that intramuscular ultra-high dose methylcobalamin is potentially effective against amyotrophic lateral sclerosis (ALS). Post hoc analyses in a previous phase 2/3 clinical trial showed that methylcobalamin prolonged survival time and arrested functional decline compared to placebo in patients registered within 12 months of ALS onset. The objective of the next trial: The Japanese Early Stage Trial of High Dose Methylcobalamin for Amyotrophic Lateral Sclerosis (JETALS), was to reconfirm the efficacy and safety of ultra-high dose methylcobalamin for ALS patients in their early stages. (NCT03548311)

Methods:: JETALS was a prospective, multicenter, placebo-controlled, double-blind, randomized phase 3 study conducted at 25 tertiary neurology centers in Japan. Eligible patients, diagnosed within 12 months of onset according to the updated Awaji criteria, were randomized at a 1:1 ratio to receive intramuscular injections of 50 mg of methylcobalamin or placebo twice weekly for 16 weeks. The target number of subjects was 128. The primary endpoint was changes in the ALSFRS-R total score from baseline to week 16 weeks.

Results:: A total of 130 patients were randomly assigned to methylcobalamin or placebo group, and 126 patients completed the trial. The changes in the ALSFRS-R total score from baseline to 16 weeks were significantly lower in methylcobalamin group. The incidence of adverse events was similar between the 2 groups.

Conclusions:: Ultra-high dose methylcobalamin was found to be efficacious in slowing functional decline compared with placebo and to have a high safety profile in patients with early-stage ALS.
A PHASE I DOSE ESCALATION STUDY OF BOSUTINIB FOR AMYOTROPHIC LATERAL SCLEROSIS: INDUCED PLURIPOTENT STEM CELL-BASED DRUG REPURPOSING FOR AMYOTROPHIC LATERAL SCLEROSIS MEDICINE (IDREAM) STUDY

Haruhisa Inoue¹, Keiko Imamura¹, Yuishin Izumi², Makiko Nagai³, Kazutoshi Nishiyama³, Yasuhiro Watanabe⁴, Ritsuko Hanajima⁴, Naohiro Egawa⁵, Takashi Ayaki⁵, Ryosuke Oki², Koji Fujita², Akiko Morinaga⁶, Tomoko Hirohashi⁶, Yosuke Fujii⁶, Ryuji Uozumi⁷, Satoshi Morita⁷, Ryosuke Takahashi⁵ ¹Kyoto University, Center For Ips Cell Research And Application, Kyoto, Japan, ²Tokushima University Graduate School of Biomedical Sciences, Department Of Neurology, Tokushima, Japan, ³Kitasato University School of Medicine, Department Of Neurology, Kanagawa, Japan, ⁴Tottori University, Division Of Neurology, Department Of Brain And Neurosciences, Faculty Of Medicine, Tottori, Japan, ⁵Kyoto University, Department Of Neurology, Graduate School Of Medicine, Kyoto, Japan, ⁶Pfizer R&D, Pfizer R&d Japan G.k, Tokyo, Japan, ⁷Kyoto University, Department Of Biomedical Statistics And Bioinformatics, Kyoto, Japan

Background and Aims:: Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease caused by the loss of motor neurons, and the development of an effective medicine is urgently required. Induced pluripotent stem cell-based drug repurposing identified a Src/c-Abl inhibitor, bosutinib which is approved for the treatment of chronic myelogenous leukemia (CML), as a candidate for molecular targeted therapy of ALS.

Methods:: A Phase 1, open-label, multi-center, 3+3 dose escalation study was conducted to evaluate the safety and tolerability of bosutinib in ALS patients. The preliminary efficacy of bosutinib was also evaluated using ALS clinical score ALSFRS-R, and predictive biomarkers were explored. Patients received escalating doses of bosutinib starting from 100 mg QD (quaque die) up to 400 mg QD based on dose limiting toxicity (DLT) occurrence.

Results:: A total of 20 participants were enrolled, 13 of whom received bosutinib treatment and 12 were included in the safety and efficacy analyses. No DLTs were observed up to 300 mg QD whereas three DLTs were observed at 400 mg QD cohort. Safety profile was consistent to what is known for CML treatment, and neither new safety signal nor ALS-specific adverse events were observed. Although the study was conducted in a small number of cases, bosutinib administration was found to halt progression in some of the participants, and 5 of 9 patients showed stable disease. Furthermore, a biomarker enriched highly effective patients.

Conclusions:: Bosutinib administration up to 300 mg QD was safe and well tolerated with promising efficacy for motor symptoms in ALS. (NCT04744532)
MICRONNA-129: AN EMERGING THERAPEUTIC TARGET FOR AMYOTROPHIC LATERAL SCLEROSIS

Ioanna Kaisari, Marianna Marra
University of Athens, Department Of Medicine, Athens, Greece

Background and Aims:: MicroRNAs are increasingly involved in the pathophysiology of Amyotrophic Lateral Disease (ALS). Therapeutic approaches have not been able to modify its course and outcome, so ALS is a source of interest for modern research.

Methods:: We systematically searched and critically appraised studies in PubMed which explored the role of miRNA-129 in the pathophysiology of ALS along with studies relevant to the use of antisense oligonucleotide (ASO), anti-mRNAs and adeno-associated virus.

Results:: The deregulation of miR-129 in ALS is manifested by the upregulation of miR-129-5p, which has a major influence on neurons, and by the overexpression of pre-miR-129-1 with a major effect on the axons. This upregulation has been shown to cause downregulation of the RNA-binding HuD protein, which is encoded by the ELAVL4 gene. Administration of the miR-129-5p ASO inhibitor to a rodent with SOD1 ALS, resulted in a significant increase in survival and an improvement in the neuromuscular phenotype. In axons, overexpression of pre-miR-129-1 inhibits their growth and differentiation by silencing the HuD gene in vitro, while inhibition of pre-miR-129-1 using anti-mRNAs extended survival, maintained body weight and prevented loss of strength. Delivery of ASO or anti-mRNAs in patients with SOD1 ALS can be achieved with a single intrathecal injection of an adeno-associated virus.

Conclusions:: MiR-129 emerges as a therapeutic target that can be modified either by inhibition through the ASO of miR-129-5p or by inhibition of the action of pre-miR-129-1 with anti-mRNAs and adeno-associated virus can contribute in order for these inhibitors to be delivered in patients with SOD1 ALS.
INCIDENCE PATTERN UPDATE OF AMYOTROPHIC LATERAL SCLEROSIS IN THE PROVINCE OF FERRARA

Annibale Antonioni¹, Antonio Turco¹, Michele Laudisi¹, Elisabetta Sette², Maura Pugliatti³, Ilaria Casetta¹, Enrico Granieri¹

¹Section of Clinical Neurology, S. Anna University Hospital, Department Of Neuroscience And Rehabilitation, Ferrara, Italy, ²Department of Neurology, Sant'Anna Hospital, Ferrara, Sant'anna Hospital, Ferrara, Ferrara (FE), Italy, ³University of Ferrara, Dept. Of Neuroscience And Rehabilitation, Interdepartmental Research Center For The Study Of Multiple Sclerosis And Inflammatory And Degenerative Diseases Of The Nervous System, Ferrara, Italy

Background and Aims:: Amyotrophic Lateral Sclerosis (ALS) is a rare progressive neurodegenerative disease affecting motor neurons with an average annual incidence of 1-3 cases/100,000 people worldwide. Its etiopathogenesis is unknown and several possible genetic and environmental factors have been proposed. This study updates the epidemiological data on ALS in the province of Ferrara, northern Italy, between 2017 and 2020, integrating the results with previous studies.

Methods:: The average population was 345,538 inhabitants (51.9% females). 38 patients were included (20 men and 18 women), according to the revised El Escorial diagnostic criteria. We reviewed all the possible sources of case collection.

Results::

Mean crude incidence rate was 2.75/100,000 inhabitants/year (95% CI 1.95-3.76), 3.01 males and 2.51 females; standardized incidence rate to the Italian population of 2.37/100,000 inhabitants/year, 2.08/100,000 inhabitants/year to the European population. Mean age of diagnosis 70 years (SD ± 7.96). Peak incidence: between 60 and 69 years, with a rate of 9.36/100,000 inhabitants (CI 95% 5.55-14.79) in general population (11 in males and 7.83 in females). Rate in urban centers: 2.86/100,000 population/year, in rural centers 2.53/100,000 population/year. Male to female ratio: 1.11. 57.89% had spinal onset, 21.05% bulbar onset and 15.79% mixed onset.

Conclusions:: There is a persistent increase in new diagnoses compared with studies of the early 2000s in accordance with literature, suggesting the importance of environmental factors in genetically
predisposed people. Improvement in diagnostic criteria, increase in average life span (with a greater risk of neurodegenerative diseases), greater prevalence in males and greater frequency of spinal onset mode are evident.
EVALUATION OF SPINAL AND CORTICAL MAGNETIC STIMULATION TOGETHER WITH MSCAN MUNE IN THE EARLY STAGES OF THE DISEASE IN THE DIAGNOSIS OF ALS.

Cansu Aydin Kaya, Abir Alaamel, Hilmi Uysal
Akdeniz University Faculty of Medicine, Neurology Department, Antalya, Turkey

Background and Aims:: Electrophysiological methods are still the leading investigations in the diagnosis of ALS. Although needle EMG is the main finding in demonstrating lower motor neuron involvement, the search continues for a method that supports the diagnosis as high as EMG in the electrophysiological evaluation of upper motor neuron involvement. But it would be valuable to try to develop the standards of the classical transcranial cortical stimulation methods.

Methods:: Spinal and Cortical MEP responses and resting EDC, ADM, APB, AH, FCR, TA, and Soleus H reflex responses were recorded in the early period of 14 ALS patients according to the Revise El Escorial criteria. In addition, MScanMUNEs of the patients were calculated from APB and TA.

Results:: We investigated 14 patients with a mean age of 59.5±9.2 years, 3 of whom were female. Cortical stimulation failed to respond in 38% of APB, 38% of TA, and 54% of both TA and APB. The MScan MUNE of APB was 44±22. MScan MUNE of TA was 96±51. While soleus H reflex was obtained in 92% of the cases, H reflex response could be obtained in 27% of FCR, 17% of APB, AH, TA, and 8% of EDC and ADM. MScan MUNE values in 4 cases with normal TCCS and H reflex findings were lower than normal for APB.

Conclusions:: While MEP responses can be obtained from APB and TA with spinal stimulation, we believe that the inability to obtain MEP responses with cortical stimulation may be a biomarker in demonstrating upper motor neuron involvement with early-stage ALS cases.
THE EPSILON (EARLY PARKINSON WITH L-DOPA/DDCI AND OPICAPONE) STUDY IN EARLY PARKINSON’S DISEASE: DESIGN AND RATIONALE OF A PHASE III, DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED STUDY

Joaquim Ferreira¹, Werner Poewe², Olivier Rascol³, Fabrizio Stocchi⁴, Angelo Antonini⁵, Joana Moreira⁶, José Rocha⁶, Patrício Soares-Da-Silva⁶
¹Faculty of Medicine, University of Lisbon, Laboratory Of Clinical Pharmacology And Therapeutics, Lisbon, Portugal, ²Medical University of Innsbruck, Department Of Neurology, Innsbruck, Austria, ³University of Toulouse, Department Of Neurosciences & Clinical Pharmacology, Toulouse, France, ⁴IRCCS San Raffaele Pisana, Department Of Neurology, Rome, Italy, ⁵University of Padova, Department Of Neurosciences, Padova, Italy, ⁶BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) proved to be effective in the treatment of end-of-dose motor fluctuations in Parkinson’s disease (PD) patients. When OPC is co-administered with levodopa (L-dopa) and dopa decarboxylase inhibitor (DDCis), peripheral catechol-O-methyltransferase (COMT) is inhibited which increases L-dopa bioavailability. This study aims to explore the potential of OPC to enhance the clinical benefit of L-dopa/DDCi in patients with early-stage PD on stable treatment.

Methods:: Patients (aged 30–80 years) with idiopathic PD, treated with 3-4 daily oral doses of up to 500 mg L-dopa, with signs of treatable motor disability but no motor complications will be randomized (1:1) to receive OPC 50mg once-daily or placebo during a 6-month double-blind evaluation period. The L-dopa/DDCi regimen should remain stable throughout the double-blind period. At the end of this period, patients may enter a 1-year, open-label period of OPC 50mg treatment (Figure 1); 162 patients in each group are necessary to detect a minimum clinically-relevant magnitude of effect between arms.

Results:: Change from baseline in the Movement Disorder Society-Unified Parkinson's Disease Rating Scale (MDS-UPDRS) Part III is the primary endpoint. Secondary endpoints include tolerability, functional motor and non-motor assessments (MDS-UPDRS, Non-Motor Symptoms Scale, Parkinson's Disease Questionnaire-39, Parkinson's Disease Sleep Scale-2), and global impression of change scales (Clinical-Global-Impression-of-Change, Patient-Global-Impression-of-Change). First-patient-in is expected for early 2021 and last-patient-out from double-blind period in late 2022. Timelines might be impacted by the COVID-19 pandemic situation.

Conclusions:: This study will evaluate the effect of OPC on motor symptoms when given as add-on to stable L-dopa/DDCi therapy in patients with early-stage PD.
ADOPTION (EARLY LEVODOPA WITH OPICAPONE IN PARKINSON’S PATIENTS WITH MOTOR FLUCTUATIONS) STUDY IN PARKINSON’S DISEASE: DESIGN AND RATIONALE OF A RANDOMIZED PROSPECTIVE, OPEN-LABEL EXPLORATORY TRIAL

Joaquim Ferreira¹, Werner Poewe², Olivier Rascol³, Fabrizio Stocchi⁴, Angelo Antonini⁵, Raquel Costa⁶, Diogo Magalhães⁶, José Rocha⁷, Patrício Soares-Da-Silva⁷
¹Faculty of Medicine, University of Lisbon, Laboratory Of Clinical Pharmacology And Therapeutics, Lisbon, Portugal, ²Medical University of Innsbruck, Department Of Neurology, Innsbruck, Austria, ³University of Toulouse, Department Of Neurosciences & Clinical Pharmacology, Toulouse, France, ⁴IRCCS San Raffaele Pisana, Department Of Neurology, Rome, Italy, ⁵University of Padova, Department Of Neurosciences, Padova, Italy, ⁶BIAL-Portela & Ca S.A., Research And Development Department, Coronado, Portugal, ⁷BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) proved to be effective in the treatment of end-of-dose motor fluctuations in Parkinson’s disease (PD) patients. About 80–100% of PD patients show some degree of wearing-off within 10 years of levodopa (L-dopa) therapy. Approaches to optimize the L-dopa regimen include increasing the dose or ‘fractionating’ the total daily dose. This study aims to explore the potential of adjunctive OPC versus an additional dose of L-dopa/dopa decarboxylase inhibitor (DDCi) to optimize the L-dopa/DDCi regimen as first-line approach to treat wearing-off.

Methods:: Approximately 100 patients (aged ≥30 years) with idiopathic PD, treated with 3–4 daily oral L-dopa doses up to 600 mg, and signs of wearing-off (<2 years) will be equally randomized to receive OPC 50 mg once daily or an additional dose of 100 mg/25 mg L-dopa/DDCi during a 4-week open-label evaluation period (Figure 1).

Results:: Primary endpoint is the change from baseline in OFF-time. Secondary endpoints include tolerability, functional motor and non-motor assessments (Movement Disorder Society (MDS)-Unified Parkinson’s Disease Rating Scale, MDS-Non-Motor Symptoms, Parkinson's Disease Questionnaire-8), and global impression of change scales (Clinical Global Impression of Change, Patient Global Impression of Change). As this is a descriptive/exploratory study, no formal sample size calculation was performed. Study sites are in Germany, Italy, Portugal, Spain, and the UK. First-patient-in is expected for 2021 and
last-patient-out for late 2022. Timelines might be impacted by the COVID-19 situation.

**Conclusions:** This study will evaluate the potential of adjunctive OPC versus an additional dose of L-dopa/DDCi as first-line approach to treat wearing-off in PD patients.
THE OCEAN (OPICAPONE EFFECT ON MOTOR FLUCTUATIONS AND ASSOCIATED PAIN) STUDY IN PARKINSON’S DISEASE: DESIGN AND RATIONALE OF A RANDOMIZED DOUBLE-BLIND PLACEBO-CONTROLLED TRIAL

¹Psychology & Neuroscience at King’s College and Parkinson Foundation International Centre of Excellence at King’s College Hospital, Institute Of Psychiatry, London, United Kingdom, ²Lund University Hospital, Department Of Neurology, Lund, Sweden, ³Faculty of Medicine, University of Lisbon, Laboratory Of Clinical Pharmacology And Therapeutics, Lisbon, Portugal, ⁴University of Padova, Department Of Neurosciences, Padova, Italy, ⁵University of Toulouse, Department Of Neurosciences & Clinical Pharmacology, Toulouse, France, ⁶Functional Movement Disorders Unit, Hospital Ruber Internacional Madrid, Neurology Department, Madrid, Spain, ⁷University of Rostock, Department Of Neurology, Rostock, Germany, ⁸Guy’s Campus, King’s College London, Institute Of Psychiatry, Psychology And Neuroscience, London, United Kingdom, ⁹BIAL-Portela & Ca S.A., Research And Development Department, Coronado, Portugal, ¹⁰BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) proved to be effective in the treatment of end-of-dose motor fluctuations in Parkinson’s disease (PD) patients. End-of-dose motor fluctuations and associated pain are commonly observed in patients with PD receiving levodopa (L-dopa)/DOPA decarboxylase inhibitors (DDCI). Motor fluctuations have a detrimental impact on patients’ quality of life and are in part mediated via dopaminergic pathways. This study aims to evaluate if treatment with OPC can improve pain related to end-of-dose fluctuations, consequently improving patients’ well-being.

Methods:: Patients (≥30 years old) with idiopathic PD, who were treated with 3–8 daily oral doses of L-dopa/DDCI and experienced pain associated with ‘wearing-off’ (end-of-dose deterioration), will be randomized (1:1) to OPC 50 mg once daily or placebo during a 24-week evaluation period (Figure 1). To detect a minimum clinically-relevant magnitude of effect between arms, 70 patients per group are necessary.
**Results:** The primary endpoint is change from baseline in domain 3 (fluctuation-related pain) of the King’s-Parkinson’s-Disease-Pain-Scale (KPPS). Secondary endpoints include tolerability, functional motor and non-motor assessments (KPSS, Movement Disorder Society-Non-Motor Symptoms [NMS], Parkinson's Disease Questionnaire-8 [PDQ-8], Hauser's home diary), and global impression of change scales (Clinical Global Impression of Change [CGI-C], Patient Global Impression of Change [PGI-C]). Study sites are in Germany, Italy, Portugal, Spain, and the UK. First-patient-in is expected for 2021 and last-patient-out for late 2022. Timelines might be impacted by the COVID-19 pandemic situation.

**Conclusions:** This study will evaluate the impact of 50 mg OPC once daily as adjunctive therapy to L-dopa/DDCI on pain associated with motor fluctuations.
INFLUENCE OF ONSET OF MOTOR FLUCTUATIONS ON THE EFFECTIVENESS OF OPICAPONE IN PARKINSON’S DISEASE PATIENTS WITH MOTOR FLUCTUATIONS: FINDINGS FROM THE REAL-WORLD OPTIPARK STUDY

Wolfgang Jost¹, Heinz Reichmann², Andrew Lees³, Daniela Marinho⁴, Diogo Magalhães⁴, José Rocha⁴, Patrício Soares-Da-Silva⁴
¹Parkinson-Klinik Ortenau, Neurology Department, Wolfach, Germany, ²University of Dresden, Department Of Neurology, Dresden, Germany, ³National Hospital for Neurology and Neurosurgery, Department Of Clinical And Movement Neurosciences, London, United Kingdom, ⁴BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) proved to be effective in treating end-of-dose motor fluctuations (MF) in patients with Parkinson’s disease (PD). The OPTIPARK study evaluated OPC 50 mg in a heterogeneous population of patients treated in real-world conditions. This post-hoc analysis evaluated the influence of the onset of motor fluctuations (OMF) on the response to OPC treatment in PD patients with MF.

Methods:: OPTIPARK was a prospective, open-label, single-arm trial conducted in Germany and the UK. PD patients with MF received OPC 50 mg in addition to current antiparkinsonian treatment. The primary efficacy 3-month endpoint was Clinician’s-Global-Impression-of-Change (CGI-C). Secondary efficacy endpoints included Patient’s-Global-Impression-of-Change (PGI-C), 8-item PD-Questionnaire (PDQ-8), Unified PD Rating Scale (UPDRS), and Non-Motor Symptoms Scale (NMSS). Safety assessments included evaluation of treatment-emergent adverse events (TEAEs). The influence of OMF was evaluated for each outcome in patients who completed the study.

Results:: Overall, 393 (82.4%) patients completed the 3-month endpoint (completers-set, Table 1). Of these patients, those with an earlier OMF (>1 year) reported slightly greater improvements in perception on CGI-C and PGI-C compared with those with recent OMF (≤1 year) (Table 2). However, recent fluctuators experienced greater improvements on UPDRS-II, quality-of-life (PDQ-8), and non-motor symptoms (NMSS); no difference was observed for UPDRS-III (Table 3). Furthermore, the incidence of TEAEs considered at least possibly related to OPC was also lower for recent fluctuators (Table 3).

Conclusions:: Overall, these findings indicate that patients with recent OMF may benefit at least as much as patients with earlier OMF from using OPC 50 mg as adjunctive therapy to levodopa.
INFLUENCE OF LEVODOPA DAILY DOSE ON THE EFFECTIVENESS OF OPICAPONE IN PARKINSON’S DISEASE PATIENTS WITH MOTOR FLUCTUATIONS: FINDINGS FROM THE REAL-WORLD OPTIPARK STUDY

Camille Carroll¹, Andrew Lees², Heinz Reichmann³, Diogo Martins⁴, Diogo Magalhães⁴, José Rocha⁴, Patrício Soares-Da-Silva⁴
¹University of Plymouth, Faculty Of Medicine And Dentistry, Plymouth, United Kingdom, ²National Hospital for Neurology and Neurosurgery, Department Of Clinical And Movement Neurosciences, London, United Kingdom, ³University of Dresden, Department Of Neurology, Dresden, Germany, ⁴BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) proved to be effective in treating end-of-dose motor fluctuations (MF) in Parkinson’s disease (PD) patients. The OPTIPARK study evaluated OPC 50mg in a heterogeneous population of patients treated in real-world conditions. We evaluated the influence of levodopa daily dose at baseline on the response to OPC in PD patients with MF.

Methods:: OPTIPARK was a prospective, open-label, single-arm trial conducted in Germany and the UK. PD patients with MF received OPC 50mg in addition to current antiparkinsonian treatment. The primary efficacy 3-month endpoint was Clinician’s-Global-Impression-of-Change (CGI-C). Secondary efficacy endpoints included Patient’s-Global-Impression-of-Change (PGI-C), quality of life (8-item PD Questionnaire [PDQ-8]), Unified-PD-Rating-Scale (UPDRS), and Non-Motor-Symptoms-Scale (NMSS). Safety assessments included evaluation of treatment-emergent adverse events (TEAEs). This post-hoc analysis evaluated the influence of levodopa daily dose at baseline in patients who completed the study for each outcome.

Results:: 393 (82.4%) patients completed the 3-month endpoint (completers-set, Table 1). A greater proportion of patients taking ‘low-levodopa’ daily dose experienced ‘very-much/much improvement’ on CGI-C and PGI-C scales when compared with patients taking ‘high-levodopa’ daily dose (Table 2). Similarly, patients taking ‘low-levodopa’ daily dose reported greater improvements on both UPDRS-II and III, quality-of-life (PDQ-8), and non-motor-symptoms (NMSS) (Table 3). Lower incidence of TEAEs considered at least possibly related to OPC were also reported for patients taking ‘low-levodopa’ daily dose (Table 3).

EFFECTIVENESS OF OPICAPONE IN PARKINSON’S DISEASE PATIENTS WITH MOTOR FLUCTUATIONS ACCORDING TO BASELINE USE OF SAFINAMIDE: FINDINGS FROM THE REAL-WORLD OPTIPARK STUDY

Nicola Pavese¹, Andrew Lees², Heinz Reichmann³, Diogo Martins⁴, Diogo Magalhães⁴, José Rocha⁴, Patrício Soares-Da-Silva⁴
¹Newcastle University, Institute Of Neuroscience, Newcastle upon Tyne, United Kingdom, ²National Hospital for Neurology and Neurosurgery, Department Of Clinical And Movement Neurosciences, London, United Kingdom, ³University of Dresden, Department Of Neurology, Dresden, Germany, ⁴BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) proved to be effective in treating end-of-dose motor fluctuations (MF) in Parkinson’s disease (PD) patients. The OPTIPARK study evaluated OPC 50 mg in a heterogeneous population of patients treated in real-world conditions. We evaluated the effectiveness of OPC in PD patients with MF according to baseline use of safinamide (SAF).

Methods:: OPTIPARK was a prospective, open-label, single-arm trial conducted in Germany and the UK. PD patients with MF received OPC 50 mg in addition to current antiparkinsonian treatment. Primary efficacy endpoint at 3 months was Clinician’s-Global-Impression-of-Change (CGI-C). Secondary efficacy endpoints included Patient’s-Global-Impression-of-Change (PGI-C), quality of life (8-item PD-Questionnaire [PDQ-8]), Unified PD Rating Scale (UPDRS) and Non-Motor Symptoms Scale (NMSS). Safety assessments included evaluation of treatment-emergent adverse events (TEAEs). This post-hoc analysis evaluated the influence of baseline use of SAF in patients who completed the study for each outcome.

Results:: Overall, 393 (82.4%) patients completed the 3-month endpoint (completers-set, Table 1). Of these, patients not using SAF at baseline experienced greater improvements on CGI-C and PGI-C, when compared to patients using SAF at baseline (Table 2). Except for PDQ-8, patients using SAF at baseline experienced greater improvements on UPDRS-II and III, and non-motor symptoms (NMSS), when compared to patients not using SAF at baseline (Table 3). Similar incidence of TEAEs considered at least possibly related to OPC were reported for both subgroups (Table 3).

| Table 1. Baseline characteristics (Completers-Set) |
|---------------------------------|-------------------------------|-------------------------------|
| Category                        | Used SAF at Baseline          | Not Used SAF at Baseline      |
|                                 | N=53                          | N=340                         |
| Age, mean (SD)                  | 66.6 (9.2)                    | 67.2 (9.1)                    |
| Male, n (%)                     | 40 (75.5)                     | 217 (63.8)                    |
| PD duration, mean (SD) years    | 8.3 (4.3)                     | 8.4 (4.7)                     |
| Onset of MF, mean (SD) years    | 2.6 (3.2)                     | 2.4 (3.0)                     |
| L-dopa amount, mean (SD) mg     | 572 (223)                     | 556 (251)                     |
| L-dopa, levodopa, MF, motor fluctuations; PD, Parkinson’s Disease; SAF, safinamide; SD, standard deviation; |
Conclusions:: Overall, these findings indicate that patients may benefit from using OPC 50 mg with or without safinamide as adjunctive therapy to levodopa.
Background and Aims:: Opicapone (OPC), a once-daily catechol-O-methyltransferase inhibitor, proved to be effective in treating end-of-dose motor fluctuations in Parkinson’s disease (PD) patients in two large multinational trials. The OPTIPARK study evaluated OPC 50 mg in a heterogeneous population of PD patients treated in real-world conditions.

Methods:: OPTIPARK was a prospective, open-label, single-arm, multicenter trial conducted in Germany and the UK. PD patients with motor fluctuations received OPC 50 mg in addition to current antiparkinsonian treatment. Primary efficacy endpoint was Clinician’s Global Impression of Change (CGI-C) after 3 months. Secondary efficacy endpoints included Patient’s Global Impression of Change (PGI-C) and Unified Parkinson’s Disease Rating Scale (UPDRS). Safety assessments included evaluation of treatment-emergent adverse events (TEAEs). Here UK-only data are reported.

Results:: A total of 132 patients took ≥1 OPC dose (Safety Set; Table 1) and 102 completed the 3-month treatment. Of 128 patients with post-baseline efficacy data (Full Analysis Set), 72.7% and 78.4% experienced any (very much/much/minimal) improvement on CGI-C and PGI-C after 3 months, respectively (Table 2). There were relevant improvements on UPDRS II and III scores (Table 3). TEAEs considered at least possibly related to OPC were reported for 65.2% of patients, the most frequently reported being dyskinesia (27.3%) and dry mouth (12.1%); 87.8% of TEAEs were of mild or moderate intensity. Serious TEAEs considered at least possibly related to OPC were reported for two (1.5%) patients.

OPICAPONE IN CLINICAL PRACTICE IN PARKINSON’S DISEASE GERMAN PATIENTS WITH MOTOR FLUCTUATIONS: FINDINGS FROM THE OPTIPARK STUDY

Heinz Reichmann1, Andrew Lees2, Diogo Magalhães3, José Rocha3, Patrício Soares-Da-Silva3
1University of Dresden, Department Of Neurology, Dresden, Germany, 2National Hospital for Neurology and Neurosurgery, Department Of Clinical And Movement Neurosciences, London, United Kingdom, 3BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC), a once-daily catechol-O-methyltransferase inhibitor, proved to be effective in treating end-of-dose motor fluctuations in Parkinson’s disease (PD) patients in two large multinational trials. The OPTIPARK study evaluated OPC 50 mg when used in a heterogeneous population of PD patients with motor fluctuations treated in real-world conditions.

Methods:: OPTIPARK was a prospective, open-label, single-arm, multicenter trial conducted in Germany and the UK. Patients with motor fluctuations received OPC 50 mg in addition to current antiparkinsonian treatment. Primary efficacy endpoint was Clinician’s Global Impression of Change (CGI-C) after 3 months. Secondary efficacy endpoints included Patient’s Global Impression of Change (PGI-C) and Unified Parkinson’s Disease Rating Scale (UPDRS). Safety assessments included evaluation of treatment-emergent adverse events (TEAEs). Here Germany-only data are reported.

Results:: In total, 363 patients took ≥1 OPC dose (Safety Set; Table 1) and 291 completed the 3-month treatment. Of 349 patients with post-baseline efficacy data (Full Analysis Set), 70.8% and 76.3% experienced any (very much/much/minimal) improvement on CGI-C and PGI-C after 3 months, respectively (Table 2). There were relevant improvements on UPDRS II and III scores (Table 3). TEAEs considered at least possibly related to OPC were reported for 37.7% of patients, the most frequently reported being dyskinesia (5.8%) and dry mouth (4.4%); 91.7% of TEAEs were of mild or moderate intensity. Serious TEAEs considered at least possibly related to OPC were reported for five (1.4%) patients.

Conclusions: OPC 50 mg was effective and generally well tolerated in German PD patients with motor fluctuations treated in clinical practice.
THE OASIS (OPICAPONE IN SLEEP DISORDER) STUDY IN PARKINSON’S DISEASE: DESIGN AND RATIONALE OF AN OPEN-LABEL, SINGLE-ARM, PILOT TRIAL

Raquel Costa1, Claudia Trenkwalder2, Joaquim Ferreira3, Diogo Magalhães4, José Rocha4, Patrício Soares-Da-Silva4
1BIAL-Portela & Ca S.A., Research And Development Department, Coronado, Portugal, 2Paracelsus-Elena Klinik, Neurology Department, Kassel, Germany, 3Faculty of Medicine, University of Lisbon, Laboratory Of Clinical Pharmacology And Therapeutics, Lisbon, Portugal, 4BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) proved to be effective in the treatment of end-of-dose motor fluctuations in Parkinson’s disease (PD) patients. Non-motor symptoms have a substantial impact on health-related quality of life and are reported in approximately 90% of idiopathic PD patients. End-of-dose motor fluctuations and associated sleep disorders are commonly observed in PD patients who receive treatment with levodopa (L-dopa)/DOPA decarboxylase inhibitors (DDCI). This study aims to evaluate the effects of OPC treatment on sleep disorders in PD patients with ‘wearing-off’.

Methods:: Approximately 30 patients (aged ≥30 years) with idiopathic PD, treated with 3–8 daily doses of L-dopa/DDCI, with ‘wearing-off’ and sleep disorders will receive OPC 50mg once daily during a 6-week evaluation period. L-dopa/DDCI daily dose, but not number of intakes, may be adjusted according to the patients’ response in the first 2 weeks, and is kept unchanged afterwards (Figure 1). As a pilot study, no formal sample size calculation was performed.

Results:: The primary endpoint is change from baseline in total score of Parkinson’s Disease Sleep Scale-2. Secondary endpoints include tolerability, functional motor and non-motor assessments (Movement Disorder Society-Non-Motor Symptoms Scale, Parkinson’s Disease Questionnaire-8, Parkinson’s Fatigue Scale, ON/OFF home diary), and Clinical and Patient Global Impression of Change scales. Study sites are in Germany and Portugal. First-patient-in is expected for early 2021 and last-
patient-out for late 2021. Timelines might be impacted by the COVID-19 situation.

**Conclusions:** This pilot study will provide preliminary data on the potential effect of OPC 50mg once daily as adjunctive therapy to L-dopa/DDCI on PD-associated sleep disorders.
INFLUENCE OF DEMOGRAPHIC CHARACTERISTICS ON THE EFFECTIVENESS OF OPICAPONE IN PARKINSON’S DISEASE PATIENTS WITH MOTOR FLUCTUATIONS: FINDINGS FROM THE REAL-WORLD OPTIPARK STUDY

Biju Mohamed¹, Andrew Lees², Heinz Reichmann³, Diogo Martins⁴, Diogo Magalhães⁴, José Rocha⁴, Patrício Soares-Da-Silva⁴
¹Cardiff and Vale University Health Board, Parkinson’s Specialist Service, Cardiff, United Kingdom, ²National Hospital for Neurology and Neurosurgery, Department Of Clinical And Movement Neurosciences, London, United Kingdom, ³University of Dresden, Department Of Neurology, Dresden, Germany, ⁴BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) proved to be effective in treating end-of-dose motor fluctuations (MF) in Parkinson’s disease (PD) patients. The OPTIPARK study evaluated OPC 50mg in a heterogeneous population of PD patients treated in real-world conditions. We evaluated the influence of baseline demographic characteristics on the response to OPC in PD patients with MF.

Methods:: OPTIPARK was a prospective, open-label, single-arm trial conducted in Germany and the UK. PD patients with MF received OPC 50mg in addition to current antiparkinsonian treatment. Primary efficacy endpoint at 3 months was Clinician’s-Global-Impression-of-Change (CGI-C). Secondary efficacy endpoints included Patient’s-Global-Impression-of-Change (PGI-C), 8-item PD Questionnaire (PDQ-8), Unified PD Rating (UPDRS) and Non-Motor Symptoms (NMSS) scales. Safety assessments included evaluation of treatment-emergent adverse-events (TEAEs). This post-hoc analysis evaluated the influence of demographic characteristics (i.e., age and gender) in patients who completed the study for each outcome.

Results:: Overall, 393 (82.4%) patients completed the 3-month endpoint (completers-set, Table 1). A greater proportion of younger (<67.2 years-old) and female patients experienced ‘very much/much improvement’ on CGI-C and PGI-C when compared, respectively, to older and male patients (Table 2). Except for UPDRS-II, younger and male patients reported greater improvements on UPDRS-III, PDQ-8 and NMSS, when compared to older and female patients (Table 3). Lower incidence of TEAEs considered at least possibly related to OPC were reported for younger and male patients, when compared to older and female patients (Table 3).

Conclusions: These findings indicate that younger PD patients with MF may have an added benefit from using OPC 50mg as adjunctive therapy to levodopa.
EFFECTIVENESS OF OPICAPONE IN PARKINSON’S DISEASE PATIENTS WITH MOTOR FLUCTUATIONS ACCORDING TO BASELINE USE OF DOPAMINE AGONISTS: FINDINGS FROM THE REAL-WORLD OPTIPARK STUDY

Wolfgang Jost¹, Heinz Reichmann², Andrew Lees³, Daniela Marinho⁴, Diogo Magalhães⁴, José Rocha⁴, Patrício Soares-Da-Silva⁴
¹Parkinson-Klinik Ortenau, Neurology Department, Wolfach, Germany, ²University of Dresden, Department Of Neurology, Dresden, Germany, ³National Hospital for Neurology and Neurosurgery, Department Of Clinical And Movement Neurosciences, London, United Kingdom, ⁴BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) proved to be effective in treating end-of-dose motor fluctuations (MF) in Parkinson’s disease (PD) patients. The OPTIPARK study evaluated OPC 50 mg in a heterogeneous population of PD patients treated in real-world conditions. We evaluated the effectiveness of OPC in PD patients with MF according to baseline use of dopamine agonists (DA).

Methods:: OPTIPARK was a prospective, open-label, single-arm trial conducted in Germany and the UK. PD patients with MF received OPC 50 mg in addition to current antiparkinsonian treatment. Primary efficacy 3-month endpoint was Clinician’s-Global-Impression-of-Change (CGI-C). Secondary efficacy endpoints included Patient’s-Global-Impression-of-Change (PGI-C), 8-item PD-Questionnaire (PDQ-8), Unified PD Rating Scale (UPDRS) and Non-Motor Symptoms Scale (NMSS). Safety assessments included evaluation of treatment-emergent adverse events (TEAEs). This post-hoc analysis evaluated the influence of DA use at baseline in patients who completed the study for each outcome.

Results:: Overall, 393 (82.4%) patients completed the 3-month endpoint (completers-set, Table 1). Of these, patients using DA at baseline experienced greater improvements on CGI-C and PGI-C, when compared to patients not using DA at baseline (Table 2). Except for UPDRS-II, patients using DA at baseline experienced greater improvements on UPDRS-III, quality of life (PDQ-8) and non-motor symptoms (NMSS), when compared to patients not using DA at baseline (Table 3). Lower incidence of TEAEs considered at least possibly related to OPC were also reported for patients using DA at baseline (Table 3).
Conclusions:: Overall, these findings indicate that patients may benefit from using OPC 50 mg with or without DA as adjunctive therapy to levodopa.
EFFECTIVENESS OF OPICAPONE IN PARKINSON’S DISEASE PATIENTS WITH MOTOR FLUCTUATIONS ACCORDING TO BASELINE USE OF MONOAMINE-OXIDASE-B INHIBITORS AND DOPAMINE AGONISTS: THE REAL-WORLD OPTIPARK STUDY

Heinz Reichmann1, Tobias Warnecke2, Andrew Lees3, Diogo Martins4, Diogo Magalhães4, José Rocha4, Patrício Soares-Da-Silva4
1University of Dresden, Department Of Neurology, Dresden, Germany, 2University of Muenster, Department Of Neurology, Münster, Germany, 3National Hospital for Neurology and Neurosurgery, Department Of Clinical And Movement Neurosciences, London, United Kingdom, 4BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) proved to be effective in treating end-of-dose motor fluctuations (MF) in Parkinson’s disease (PD) patients. The OPTIPARK study evaluated OPC 50 mg in a heterogeneous population of PD patients treated in real-world conditions. We evaluated the effectiveness of OPC in PD patients with MF according to baseline use of monoamine-oxidase-B inhibitors (MAO-Bi) and dopamine agonists (DA).

Methods:: OPTIPARK was a prospective, open-label, single-arm trial conducted in Germany and the UK. PD patients with MF received OPC 50 mg in addition to current antiparkinsonian treatment. Primary efficacy 3-month endpoint was Clinician’s-Global-Impression-of-Change (CGI-C). Secondary efficacy endpoints included Patient’s-Global-Impression-of-Change (PGI-C), quality of life (8-item PD-Questionnaire [PDQ-8]), Unified PD Rating Scale (UPDRS) and Non-Motor Symptoms Scale (NMSS). Safety assessments included evaluation of treatment-emergent adverse events (TEAEs). This post-hoc analysis evaluated the influence of baseline use of both MAO-Bi and DA in patients who completed the study for each outcome.

Results:: Overall, 393 (82.4%) patients completed the 3-month endpoint (completers-set, Table 1). Of these, patients using MAO-Bi/DA at baseline experienced greater improvements on CGI-C and PGI-C, when compared to patients not using MAO-Bi/DA at baseline (Table 2). Except for NMSS, patients not using MAO-Bi/DA at baseline experienced greater improvements on UPDRS-II and III and quality-of-life (PDQ-8) (Table 3). Lower incidence of TEAEs considered at least possibly related to OPC were also reported for patients using MAO-Bi/DA at baseline (Table 3).

ASSESSMENT OF NON-MOTOR AND AUTONOMIC SYMPTOMS IN WILSON’S DISEASE PATIENTS

Sandra Perillo, Gianluigi Palmieri, Carmen Dello Iacovo, Filomena Di Canio, Margherita Matarazzo, Fabiola Di Dato, Raffaele Iorio, Giuseppe De Michele, Giovanna De Michele, Anna De Rosa

1University of Naples Federico II, Department Of Neurosciences, Odontostomatological And Reproductive Sciences, Naples, Italy, 2University of Naples Federico II, Department Of Translational Medical Science, Naples, Italy, 3University of Naples Federico II, Department Of Translational Medical Science, Section Of Pediatrics, Naples, Italy

Background and Aims:: Wilson’s Disease (WD) is a genetic disorder caused by excessive copper deposition in liver, brain and other organs. The core neurological symptoms mainly consist of movement disorders, though non-motor symptoms (NMS) can occur in early stages of the disease. We aimed to assess whether NMS are more common in WD patients in comparison with healthy subjects and if they correlate with gravity and disease duration.

Methods:: Twenty-five patients with genetically-proven WD (11 F, 14 M) and 26 healthy controls (Ctrl; 13 F, 14 M) comparable for age and education were enrolled. Patients underwent neurological examination, whereas NMS were assessed using the following clinical scales: Minimental State Examination (MMSE), SCOPA-AUT Questionnaire, Apathy Evaluation Scale (AES), Non-Motor Symptoms Scale (NMSS), Questionnaire for Impulsive-Compulsive Disorders in Parkinson’s disease (QUIP-RS), Beck Depression Inventory (BDI), Epworth Sleepiness Scale (ESS), Restless Legs Syndrome Rating Scale (RLSRS).

Results:: We did not find any statistically significant difference between the two groups in the scores of BDI (p=0.955), SCOPA-AUT Questionnaire (p=0.500), QUIP-RS (p=0.789) and RLSRS (p=0.609). Although ESS (p=0.123) and NMSS (p=0.150) scores were comparable, patients more frequently complained excessive daytime sleepiness and cardiovascular NMS (80% vs 19%, p<0.01; 96% vs 73%, p=0.023). Furthermore, global cognitive abilities assessed by MMSE were more impaired among patients, in particular in those with neurological disorders (p<0.001). Finally, disease duration positively correlated with AES scores (p= 0.032).

Conclusions:: Our study suggests that WD patients might more frequently show cognitive impairment and NMS, though these findings should be further investigated to improve disease management and diagnosis.
SUCCESSFUL TREATMENT OF PAROXYSMAL PAINFUL TONIC SPASMS WITH CARBAMAZEPINE IN A PATIENT WITH HYPERTROPHIC OLIVARY DEGENERATION

Alessia Fiore, Pietro Anceschi, Stefania Lazzari, Irene Florindo, Lucia Zinno, Antonio Pavarani, Elisabetta Chierici, Giovanni Pavesi

1Neurosciences Unit, Department Of Medicine And Surgery, University Of Parma, Parma, Italy, 2Neuroradiology Unit, Department Of Diagnostic, Parma University Hospital, Parma, Italy

Background and Aims:: Hypertrophic olivary degeneration (HOD) is a rare phenomenon that can occur after different insults to the so-called Guillain-Mollaret triangle. Clinically, HOD presents as palatal tremor, dentatorubral tremor and/or ocular myoclonus.

Methods:: We report the case of a 75-years-old female patient with a sudden-onset of stereotypical recurrent painful tonic spasms of the left limbs, with dystonic posture, lasting 10-20 seconds, without impairment of consciousness. We performed EEG, neurophysiological tests and Diffusion MRI tensor tractography.

Results:: Inter-ictal neurological examination displayed nistagmus and left Babinski sign. EEG did not show any epileptiform activity during the episodes. Brain MRI revealed a cavernoma in the left cerebellar cortex surrounded by edema and hypertrophy of the right olive with increased T2-signal intensity, suggestive of HOD. Motor evoked potentials showed prolonged central conduction time with low-amplitude responses on the left upper limb. Diffusion tensor tractography showed thinning of the right corticospinal tract compared to the controlateral side. Treatment with carbamazepine, 200 mg two times daily, led to the prompt resolution of the spasms.
Conclusions:: Dystonia in HOD has already been reported in literature with uncertain pathogenesis. Painful tonic spasms as a result of pyramidal tracts dysfunction have been described in demyelinating and vascular diseases. In this case, therapeutic response to carbamazepine, painfulness and shortness of the attacks, clinical and instrumental evidence of pyramidal involvement suggest a diagnosis of painful tonic spasms, more than dystonia. Corticospinal tract lesion could be hypothesized in the medulla oblongata, above pyramidal decussation, near HOD.
RELATIONSHIP BETWEEN CLINICAL SYMPTOMS AND AGEING, PARKINSON DISEASE

Bayasgalan Dagvadorj¹, Altantsetseg Purvee², Boloroo Sukhbaatar³
¹Bayangol District’s Health Center, Ulaanbaatar, Mongolia, Neurology, ulaanbaatar, Mongolia, ²The third central hospital, Neurology, ulaanbaatar, Mongolia, ³Zint clinic, Neurology, ulaanbaatar, Mongolia

Background and Aims:: Background: Ageing remains the biggest risk factor for developing idiopathic Parkinson’s disease (PD).

Methods:: This retrospective survey’s data were obtained from the PD database of the neurology clinics at tertiary care hospitals from January 1, 2017 to March 31, 2020.

Results:: 84 patients with PD (Female 80.6%), mean age 65.7±7.4. The age groups of the patients were 21.8% in middle age, 78.2% old age, while young is not. The duration of the disease after the diagnosis was compared with the Hoehn and Yahr stage, these duration in second stage 1.7±0.9 years; in third stage 5.7±2.8 years; in fourth stage 8.8±1.8 years; in fifth stage 11.4±3.9 years, respectively (p<0.01). Young-onset patients showed significantly longer duration to reach Stage IV, and V but shorter duration to develop wearing off and dyskinesia. In our study PD firstly diagnosed age was 59.4±8.8, in other studies has found similar result that the prodromal stage of PD coincides with midlife. If diagnosed age was young, Hoehn and Yahr stage was increased (p=0.01), (Table 1). Table.1 Hoehn and Yahr stage

Conclusions:: Conclusion: Hoehn and Yahr transition time is a useful measure of disease progression in PD and may be used in clinical studies evaluating therapeutic interventions and prognostic factors in PD.
IMPACT OF COVID-19 ON ESSENTIAL TREMOR AND DYSTONIC TREMOR: EXPERIENCE OF AN ITALIAN CENTRE

Sandy Cartella, Carmen Terranova, Ignazio Arena, Angelo Quartarone, Paolo Girlanda
University of Messina, Department Of Clinical And Experimental Medicine, Messina, Italy

Background and Aims:: Covid-19 had a negative impact on movement disorders, but there are no studies on tremor. The only present studies regard the management of DBS and botulinum toxin. Our aim is to assess the impact of Covid-19 on Essential and Dystonic Tremor, with regard on non-motor symptoms and everyday life.

Methods:: Self-administered survey, based on Hamilton Depression and Anxiety Rating Scale, SARA, Hospital Anxiety and Depression Scale. Motor evaluation (TETRAS) before and after lockdown.

Results:: We analysed 26 patients. Depression worsened in 57,7% of them, anxiety in 26,9% and sleep quality in 34,6%. All these features are related between them and with the patient’s level of education, higher in those who felt more depressed, anxious and had a worsened sleep quality. 19,2% of patients felt their difficulty in concentration increased during lockdown. This is related to the increase in anxiety. None of the features is related to TETRAS score or to years of age or of disease. 38,4% of patients know what telemedicine is, 15,3% used it for a teleconsultation. 42,3% said quality of life worsened. 15,3% managed to practice physiotherapy during lockdown. Only one patient followed a physiotherapy video lesson. For most patients the major problems were the impossibility to go to the hospital and lack of social relationships. Most people emailed our centre to postpone appointments or to seek medical advice, only 1% for Covid-19 related issues and telemedicine consultations.

Conclusions:: Covid-19 had a negative direct impact on non-motor symptoms of ET and DT and an indirect one, with quality of life repercussions.
STUDY DESIGN TO ASSESS THE EFFECT OF OPICAPONE ON LEVODOPA PHARMACOKINETICS IN DIFFERENT LEVODOPA-OPTIMIZED TREATMENT REGIMENS IN PARKINSON’S DISEASE PATIENTS

Joaquim Ferreira1, Werner Poewe2, Olivier Rascol3, Fabrizio Stocchi4, Angelo Antonini5, Joana Moreira6, José Rocha6, Patrício Soares-Da-Silva6
1Faculty of Medicine, University of Lisbon, Laboratory Of Clinical Pharmacology And Therapeutics, Lisbon, Portugal, 2Medical University of Innsbruck, Department Of Neurology, Innsbruck, Austria, 3University of Toulouse, Department Of Neurosciences & Clinical Pharmacology, Toulouse, France, 4IRCCS San Raffaele Pisana, Department Of Neurology, Rome, Italy, 5University of Padova, Department Of Neurosciences, Padova, Italy, 6BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) is a catechol-O-methyltransferase inhibitor with proven efficacy in the treatment of end-of-dose motor fluctuations in Parkinson’s disease (PD) patients. Levodopa (LD) is considered the gold standard treatment of PD, yet comes with side effects including motor fluctuations and dyskinesia. Therefore, many physicians follow an LD-optimization strategy. This study was designed to assess the effect of OPC 50 mg once daily on LD pharmacokinetics (PK) in different LD/carbidopa (CD) treatment-optimized regimens in PD patients with end-of-dose motor fluctuations.

Methods:: 24 medically stable adult PD patients with a total daily LD/CD dose of 500/125 mg (preferably administered 5 times per day [Q5]) will be enrolled. From enrolment up to 14±2 days, an LD/CD-reference treatment of 100/25 mg LD/CD Q5 (500/125 mg total daily dose) will be administered. At baseline, patients will be equally randomized to: Q4 LD/CD-regimen of 400/100 mg total daily dose plus OPC 50mg Q5 LD/CD-regimen of 400/100 mg total daily dose plus OPC 50mg Patients will maintain the LD/CD+OPC regimens for up to 14±2 days. PK assessments for LD/CD-reference will be performed at V3 and V4 for both LD/CD+OPC regimens (Figure 1).

Results:: The primary endpoint will be PK based. Secondary endpoints include tolerability, functional motor assessments (subject diary charts for ON/OFF periods), and Patient Global Impression of Change scale (PGI-C). First-patient-in and last-patient-out are expected in 2021. Timelines might be impacted by the COVID-19 situation.
Conclusions:: This study will evaluate the effect of OPC on LD PK in different LD/CD treatment-optimized regimens in PD patients with end-of-dose motor fluctuations.
EFFECTIVENESS OF OPICAPONE IN PARKINSON’S DISEASE PATIENTS WITH MOTOR FLUCTUATIONS ACCORDING TO BASELINE USE OF ENTACAPONE: FINDINGS FROM THE REAL-WORLD OPTIPARK STUDY

Wolfgang Jost¹, Heinz Reichmann², Andrew Lees³, Daniela Marinho⁴, Diogo Magalhães⁴, José Rocha⁴, Patrício Soares-Da-Silva⁴
¹Parkinson-Klinik Ortenau, Neurology Department, Wolfach, Germany, ²University of Dresden, Department Of Neurology, Dresden, Germany, ³National Hospital for Neurology and Neurosurgery, Department Of Clinical And Movement Neurosciences, London, United Kingdom, ⁴BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims: Opicapone (OPC) proved to be effective in treating end-of-dose motor fluctuations (MF) in Parkinson’s disease (PD) patients. The OPTIPARK study evaluated OPC 50 mg in a heterogeneous population of PD patients treated in real-world conditions. We evaluated the effectiveness of OPC in PD patients with MF according to baseline use of entacapone (ENT).

Methods: OPTIPARK was a prospective, open-label, single-arm trial conducted in Germany and the UK. PD patients with MF received OPC 50 mg in addition to current antiparkinsonian treatment. Primary efficacy endpoint at 3 months was Clinician’s-Global-Impression-of-Change (CGI-C). Secondary efficacy endpoints included Patient’s-Global-Impression-of-Change (PGI-C), quality of life (8-item PD Questionnaire [PDQ-8]), Unified PD Rating Scale (UPDRS) and Non-Motor Symptoms Scale (NMSS). Safety assessments included evaluation of treatment-emergent adverse events (TEAEs). This post-hoc analysis evaluated the influence of baseline use of ENT in patients who completed the study for each outcome.

Results: Overall, 393 (82.4%) patients completed the 3-month endpoint (completers-set, Table 1). Of these, patients not using ENT at baseline experienced greater improvements on CGI-C and PGI-C, UPDRS-II and III, quality of life (PDQ-8) and non-motor symptoms (NMSS), when compared to patients using ENT (and switched) at baseline (Table 2, Table 3). Similar incidence of TEAEs considered at least possibly related to OPC were reported for both subgroups (Table 3).

Conclusions: Overall, these findings suggest that patients might benefit from receiving OPC as first catechol-O-methyl transferase inhibitor as adjunctive therapy to levodopa.
INFLUENCE OF DISEASE DURATION ON THE EFFECTIVENESS OF OPICAPONE IN PARKINSON’S DISEASE PATIENTS WITH MOTOR FLUCTUATIONS: FINDINGS FROM THE REAL-WORLD OPTIPARK STUDY

Tobias Warnecke¹, Heinz Reichmann², Andrew Lees³, Daniela Marinho⁴, Diogo Magalhães⁴, José Rocha⁴, Patrício Soares-Da-Silva⁴
¹University of Muenster, Department Of Neurology, Münster, Germany, ²University of Dresden, Department Of Neurology, Dresden, Germany, ³National Hospital for Neurology and Neurosurgery, Department Of Clinical And Movement Neurosciences, London, United Kingdom, ⁴BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) proved to be effective for end-of-dose motor fluctuations (MF) in Parkinson’s disease (PD) patients. The OPTIPARK study evaluated OPC 50mg in a heterogeneous population of patients treated in real-world conditions. We evaluated the influence of disease duration at baseline on the response to OPC in PD patients with MF.

Methods:: OPTIPARK was a prospective, open-label, single-arm trial conducted in Germany and the UK. PD patients with MF received OPC 50mg in addition to current antiparkinsonian treatment. Primary efficacy 3-month endpoint was Clinician’s-Global-Impression-of-Change (CGI-C). Secondary efficacy endpoints included Patient’s-Global-Impression-of-Change (PGI-C), 8-item PD-Questionnaire (PDQ-8), Unified-PD-Rating-Scale (UPDRS) and Non-Motor-Symptoms-Scale (NMSS). Safety assessments included evaluation of treatment-emergent adverse events (TEAEs). This post-hoc analysis evaluated the influence of disease duration at baseline in patients who completed the study for each outcome.

Results:: 393 (82.4%) patients completed the 3-month endpoint (completers-set, Table 1). Compared with patients with longer disease duration, a greater proportion of patients with shorter disease duration experienced ‘very much/much improvement’ on CGI-C and PGI-C (Table 2). Except for UPDRS, patients with shorter disease duration experienced greater improvements on quality of life (PDQ-8) and non-motor symptoms (NMSS), when compared to patients with longer disease duration (Table 3). Except for patients with PD duration ≥10.5 years, lower incidence of TEAEs considered at least possibly related to OPC were reported for patients with shorter disease duration (Table 3).

Conclusions:: These findings indicate that patients with shorter PD duration (representative of recent fluctuators) may have an added benefit from using OPC as adjunctive therapy to levodopa.
OPICAPONE ANALYSIS OF HEALTH ECONOMIC COSTS IN CLINICAL PRACTICE IN PARKINSON’S DISEASE UK PATIENTS WITH MOTOR FLUCTUATIONS: FINDINGS FROM THE OPTIPARK STUDY

Andrew Lees1, Heinz Reichmann2, Diogo Magalhães3, José Rocha3, Patrício Soares-Da-Silva3
1National Hospital for Neurology and Neurosurgery, Department Of Clinical And Movement Neurosciences, London, United Kingdom, 2University of Dresden, Department Of Neurology, Dresden, Germany, 3BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) proved effective in treating end-of-dose motor fluctuations in Parkinson’s disease (PD) patients in two large trials. The OPTIPARK study evaluated OPC 50mg in a heterogeneous patient population treated in real-world conditions. Data from OPTIPARK were used to assess the influence of OPC treatment on the costs for the care of PD patients.

Methods:: OPTIPARK was a prospective, open-label, single-arm, multicentre trial conducted in Germany (3-month) and the UK (6-month). Patients with motor fluctuations received OPC 50mg in addition to current antiparkinsonian treatment. Primary efficacy endpoint was Clinician’s Global Impression of Change after 3 months. Secondary endpoints included a health economic costs evaluation assessed by Client-Service-Receipt-Inventory (CSRI) questionnaire version adapted to assess the influence of the 6-month OPC treatment on the care costs of UK patients.

Results:: At baseline (N=128), total service costs during the previous 6 months were 284952.79 UK-£, mainly driven by primary/community care doctor (36.3%) and hospital doctor (18.8%) costs. At 6 months (N=95), total service costs were 121280.83 UK-£, mainly driven by hospital doctor (23.4%) and primary/community care doctor (23.2%) costs (Table 1). Average total costs at baseline were 13060 UK-£, including 2226 UK-£ for formal service and 11955 UK-£ for unpaid care costs. Average total costs decreased at 6 month by 3719 UK-£, including a reduction of 987 UK-£ for formal service and 2920 UK-£ for unpaid care costs (Table 2).

Conclusions:: In PD patients with motor fluctuations treated in clinical practice in the UK, OPC 50mg had an apparent cost-saving impact.
LONG-TERM EFFICACY OF OPICAPONE IN THE REDUCTION OF ON-TIME WITH TROUBLESCOME DYSKINESIA IN PARKINSON’S DISEASE PATIENTS WITH MOTOR FLUCTUATIONS AND REPORTING TROUBLESCOME DYSKINESIA

Fabrizio Stocchi¹, Joaquim Ferreira², Olga Klepitskaya³, Diogo Magalhães⁴, José Rocha⁴, Patrício Soares-Da-Silva⁴

¹IRCCS San Raffaele Pisana, Department Of Neurology, Rome, Italy, ²Faculty of Medicine, University of Lisbon, Laboratory Of Clinical Pharmacology And Therapeutics, Lisbon, Portugal, ³Neurocrine Biosciences Inc., Neurology Department, San Diego, United States of America, ⁴BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) proved to be effective in treating end-of-dose motor fluctuations (MF) in Parkinson’s disease (PD) patients in two large multinational trials. We evaluated the evolution of ON-time with troublesome dyskinesia (‘Bad ON-time’) following OPC long-term exposure in PD patients with MF and reporting troublesome dyskinesia.

Methods:: Efficacy data from BIPARK-I and II were pooled for OPC 50mg. This post-hoc analysis evaluated the long-term effect of OPC on ‘Bad ON-time’ in patients randomized to OPC 50mg and already reporting troublesome dyskinesia at baseline, based on patient diaries.

Results:: Full Analysis Set included 216 patients. Of these, 44 (20.4%) patients reported ~2 h of ‘Bad ON-time’ and ~9 h of ON-time without or with non-troublesome dyskinesia (‘Good ON-time’) at baseline. Following initiation with OPC 50mg and up to the end of the double-blind period, an increase of ~1.4 h in ‘Good ON-time’ and decrease of ~5 mins in ‘Bad ON-time’ were observed, with an overall mean levodopa reduction of ~40 mg/day. By the end of the 1-year open-label extension (OLE) period, mean daily ‘Good ON-time’ had increased by approximately 2 h and mean daily ‘Bad ON-time’ had decreased by approximately 1 h. During the OLE, mean daily levodopa dose decreased by an additional 60 mg, ending in a total decrease of 100 mg.

Conclusions:: In PD patients with MF and reporting troublesome dyskinesia, OPC did not increase time with troublesome dyskinesia; in fact, OPC long-term exposure, associated with levodopa dose reduction, led to a relevant reduction of ‘Bad ON-time’ and increase of ‘Good ON-time’.
HIGH RESOLUTION ULTRASOUND SHOWS AXONAL DEGENERATION OF THE VAGUS NERVE IN IDIOPATHIC PARKINSON’S DISEASE

Ferdinando Sartucci1, Tommaso Bocci2, Michela Santin3, Bongioanni Paolo4, Giovanni Orlandi5
1Pisa University Medical School, Department Of Clinical And Experimental Medicine, Cisanello Neurophysiopathology Unit, Pisa, Italy., Pisa, Italy, 2“Aldo Ravelli” Center for Neurotechnology and Experimental Brain Therapeutics, Department Of Health Sciences, International Medical School, University Of Milan, Milan, Milano, Italy, 3Pisa University Medical School, Department Of Clinical And Experimental Medicine, Cisanello Neurophysiopathology Unit, Pisa University Medical School, Pisa, Italy, Pisa, Italy, 4Pisa University Medical School, Department Of Clinical And Experimental Medicine, Neurorehabilitation Unit, Pisa, Italy, 5Pisa University Medical School, Stroke Unit, Pisa, Italy

Background and Aims:: Previous histopathological studies revealed degeneration of the dorsal motor nucleus of the Vagus Nerve (VN) early in Idiopathic Parkinson’s Disease (IPD). Degeneration of VN axons should be detectable by High –Resolution Ultrasound (HRUS) as a thinning of the nerve trunk. In order to establish if the VN exhibits sonographic signs of atrophy in IPD, we investigated patients with IPD compared with age-matched controls.

Methods:: We measured the caliber (cross-sectional area, CSA) and perimeter of the VN in 20 pt. with IPD (8 females and 12 males; mean age 73.0 + 8.6 yrs) and in age-matched controls using HRUS. Evaluation were performed by blinded raters using an Esaote MyLabGamma device in conventional B-Mode with an 8-19 MHz probe.

Results:: In both sides, the VN-CSA was significant smaller in IPD pt. than in controls (right 2,37 + 0.91, left 1.87 + 1.35 mm² versus 6.0 + 1.33, 5.6 + 1.26 mm²;p <0.001), as well as the perimeter (right 5.06 + 0.85, left 4.78 + 1.74 mm versus 8.87 + 0.86, 8.58 + 0.97 mm; p <0.001). There was no significant correlations between VN-CSA and age, the Hohen & Yahr scale, L-dopa therapy and disease duration.

Conclusions:: Our data provide evidence of atrophy of the VNs in IPD patients by HRUS. Moreover, HRUS of the VN represent a non-invasive easy imaging modality of screening in IPD patients independent of disease stage and duration, and an interesting possible additional index of disease.
EFFECT OF TIANEPTINE ON DEPRESSION IN PARKINSON’S DISEASE, AN OBSERVATIONAL PILOT STUDY

Esteban Peña¹, Juan Carlos Martinez-Castrillo², Marina Mata³, Lydia Lopez-Manzanares⁴
¹Hospital Moraleja, Neurology, Madrid, Spain, ²Hospital Ramon y Cajal, Neurology, Madrid, Spain, ³Hospital Infanta Sofia, Neurology, Madrid, Spain, ⁴Hospital La Princesa, Neurology, Madrid, Spain

Background and Aims:: Depression is frequent in Parkinson’s disease (PD). Glutamate is a neurotransmitter involved in non-dopaminergic dysfunction in PD and could be associated with depression. In this sense, tianeptine, an antidepressant with an atypical mechanism of action modulating glutamate, could be useful to treat depression in PD. The aim of this study was to assess the antidepressant effect and safety of tianeptine in PD.

Methods:: We retrospectively analyzed the 17-item Hamilton depression rating scale (HAMD-17) in PD patients treated with tianeptine at the end of follow-up compared to baseline. Comparisons were conducted using the Wilcoxon test (p<0.05). Criteria for total response, partial response and non-response were defined as ≥50%, 25%–49% and <25% of improvement. For depression severity the criteria were: remission (HAMD-17 ≤7), mild (HAMD-17=8-16), moderate (HAMD-17=17-23) and severe (HAMD-17 ≥24). Adverse events were also assessed. Data were shown as median[range]

Results:: n=11, female=8/11, age(years)=77[62-95], Hoehn&Yahr=3[1-4], levodopa equivalent dose(mg/day)=400[200-950], follow-up(months)=4[1-6]. Baseline data: HAMD-17=19[8-24], depression severity: mild=2/11 moderate=8/11 severe=1/11. Data at the end of follow-up: HAMD-17=17[6-22], HAMD-17 improvement=4[0-7], p=0.0073, average improvement of 21% (no patient showed total response but 5/11 showed partial response), depression severity: remission 2/11 mild 3/11 moderate 6/11 (6/11 improved depression severity). 1/11 patients showed mild adverse events (discomfort and dizziness)

Conclusions:: We reported a moderate and significant improvement of depression in PD patients treated with tianeptine with two patients showing remission. It supports the role of glutamate in depression development in PD. Tianeptine was well tolerated. Further studies are needed to confirm our findings and to establish factors of better response.
Efficacy of Opicapone at Different Levodopa Regimens Up to a Threshold of 600 mg/day Levodopa in Parkinson’s Disease Patients with Motor Fluctuations

Peter Lewitt1, Fabrizio Stocchi2, Joaquim Ferreira3, Olga Klepitskaya4, Diogo Magalhães5, José Rocha5, Patrício Soares-Da-Silva5

1Henry Ford Hospital, Wayne State University School of Medicine, Department Of Neurology, West Bloomfield, United States of America, 2IRCCS San Raffaele Pisana, Department Of Neurology, Rome, Italy, 3Faculty of Medicine, University of Lisbon, Laboratory Of Clinical Pharmacology And Therapeutics, Lisbon, Portugal, 4Neurocrine Biosciences Inc., Neurology Department, San Diego, United States of America, 5BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) proved to be effective for end-of-dose motor fluctuations in Parkinson’s disease (PD) patients. We evaluated the efficacy of OPC in PD patients with motor fluctuations being treated with different levodopa regimens up to a threshold of 600 mg/day levodopa.

Methods:: Efficacy data from BIPARK-I and II were combined for the placebo (PLC) and OPC-50mg groups. Primary efficacy endpoint was change from baseline in OFF-time. Subgroup analyses were performed to evaluate the efficacy of OPC-50mg in different levodopa regimens up to a threshold of 600 mg/day levodopa (300–400, 400–500 and 500–600 mg/day).

Results:: Full Analysis Set included 239 patients (PLC, n=118; OPC-50mg, n=121). Mean OFF-time reduction was at least two-fold greater than PLC when OPC-50mg was added to any levodopa regimen: mean (95% confidence interval) changes from baseline in absolute OFF-time for OPC-50mg versus PLC were -102.2 (-138.1, -66.3) versus -53.4 (-89.6, -17.3) min for patients treated with levodopa 300–400 mg/day, -110.0 (-146.7, -73.3) versus -37.2 (-77.7, 3.3) min for patients treated with levodopa 400–500 mg/day, and -117.6 (-152.6, -82.6) versus -23.1 (-67.8, 21.6) min for patients treated with levodopa 500–600 mg/day. It was notable that, with increasing levodopa dose regimens, there was a trend towards decreasing magnitude of effect in the PLC group, compared with a trend towards a slight increase in magnitude of effect in the OPC-50mg group (Figure 1).
Conclusions:: OPC-50mg showed at least a two-fold greater OFF-time reduction than placebo, with a slight increase in magnitude of effect with increasing levodopa regimens.
EFFICACY OF OPICAPONE ACCORDING TO DIFFERENT LEVODOPA DAILY INTAKES IN PARKINSON’S DISEASE PATIENTS WITH MOTOR FLUCTUATIONS

Georg Ebersbach¹, Werner Poewe², Joaquim Ferreira³, Diogo Magalhães⁴, José Rocha⁴, Patrício Soares-Da-Silva⁴
¹Beelitz Hospital, Movement Disorders Clinic, Beelitz, Germany, ²Medical University of Innsbruck, Department Of Neurology, Innsbruck, Austria, ³Faculty of Medicine, University of Lisbon, Laboratory Of Clinical Pharmacology And Therapeutics, Lisbon, Portugal, ⁴BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC), a once-daily catechol-O-methyltransferase inhibitor, proved to be effective in treating end-of-dose motor fluctuations in Parkinson’s disease (PD) patients in two large multinational trials. We evaluated the efficacy of OPC in PD patients with motor fluctuations according to different levodopa daily intakes.

Methods:: Efficacy data from BIPARK-I and II were combined for the placebo (PLC) and OPC 50 mg groups. The studies had similar designs, eligibility criteria and methodologies. Primary efficacy endpoint was change from baseline in absolute OFF-time. Safety was assessed by evaluating the incidence of treatment-emergent adverse events (TEAEs). Subgroup analyses were performed to evaluate consistency and potential trends between subgroups based on different levodopa daily intakes at baseline (Table 1). Efficacy pairwise subgroup analyses were performed using Analysis of Covariance. Safety assessments were analysed descriptively.

Results:: Overall, 522 patients were randomised to PLC (n=257) and OPC 50 mg (n=265) (Table 1). OPC 50 mg was significantly more effective than PLC for all subgroup analyses (p<0.05), except for the subgroup of patients treated with ≥6 levodopa daily intakes (p=0.0623; Table 2). Moreover, OPC 50 mg demonstrated enhanced magnitude of effect in patients who had less frequent levodopa intakes (Table 2). There was also a trend towards a lower incidence of dopaminergic-related TEAEs in the same subgroups of patients (Table 3).

IMPACT OF 3-MONTH EARLIER VERSUS LATER INITIATION OF OPICAPONE VERSUS ENTACAPONE IN LEVODOPA-TREATED PATIENTS WITH PARKINSON'S DISEASE AND MOTOR FLUCTUATIONS

Camille Carroll¹, Andrew Lees², Joaquim Ferreira³, Miguel Fonseca⁴, Diogo Magalhães⁵, José Rocha⁵, Patrício Soares-Da-Silva⁵  
¹University of Plymouth, Faculty Of Medicine And Dentistry, Plymouth, United Kingdom, ²National Hospital for Neurology and Neurosurgery, Department Of Clinical And Movement Neurosciences, London, United Kingdom, ³Faculty of Medicine, University of Lisbon, Laboratory Of Clinical Pharmacology And Therapeutics, Lisbon, Portugal, ⁴BIAL-Portela & Ca S.A., Bioinformatics & Pharmacometrics Office, Coronado, Portugal, ⁵BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) proved to be effective for end-of-dose motor fluctuations in Parkinson’s disease (PD) patients.  
Methods:: OPC 50 mg and entacapone (ENT) data from the BIPARK-I study were analyzed. The primary efficacy endpoint was change from baseline in absolute OFF-time. Secondary endpoints included ON-time without dyskinesia, Unified-PD-Rating-Scale (UPDRS)-II and III. Patients receiving levodopa/dopa-decarboxylase inhibitor (DDCi) were randomized to OPC 50 mg or ENT for a 3-month, double-blind phase, after which all patients received open-label levodopa/DDCi plus OPC for up to 1 year. This post-hoc analysis evaluated the impact of 3-month earlier versus later initiation of OPC by comparing outcomes of patients who received OPC in the double-blind phase (‘early start’) with those who received ENT in the double-blind phase and then switched to OPC (‘later start’), at the end of the double-blind phase and at a 3-month cut-off after the initiation of the open-label phase.  
Results:: Overall, 198 patients switched from OPC 50 mg (n=98) or ENT (n=100) to 1-year OPC open-label extension (Table 1). At the 3-month double-blind endpoint, OPC versus ENT showed a greater reduction in OFF-time, UPDRS-II and III, and an increase in ON-time without dyskinesia (Table 2; Figure 1). At the 3-month open-label cut-off, OPC ‘early start’ versus ‘later start’ showed a greater reduction in OFF-time, UPDRS-III, and an increase in ON-time without dyskinesia (Table 2; Figure 1). OPC 50 mg was well tolerated by both groups.

Conclusions:
These data suggest that early rather than later initiation of OPC to levodopa/DDCi provides an extended benefit over ENT.
INSUFFICIENT TREATMENTS OF PATIENTS WITH PARKINSON’S DISEASE RECEIVING HOME MEDICAL CARES AND IN NURSING HOMES

Takeshi Oki
Trinity Neurology Clinic, Neurology, Sakura City, Chiba, Japan

Background and Aims:: Patients with Parkinson’s disease (PD) may be destined to receive home medical cares (HMCs) or enter nursing homes (NHs) because PD is a progressive disease. I am worried about stopped consultation with neurologists and treated insufficiently after receiving HMCs or entering NHs on patients with PD. So, I planned to investigate consultation with neurologists and treatments about patients with PD receiving HMCs and entering NHs.

Methods:: I send questionnaires with faxes to all visiting doctor offices, all visiting nurse stations, and all nursing homes in Sakura city. I asked with these questionnaires whether they had patients with PD or not, and whether the patients continuously consulted neurologist or not. I also asked with these questionnaires the patient’s ages, sexes, ages at onsets, disease durations, Hoehn & Yahr (HY) stages and medications.

Results:: Twenty-one (35%) of sixty facilities answered to my questionnaires with total forty-five patients with PD. Twenty-nine of these patients with PD continuously consulted neurologists and sixteen did not. Male sexes in the patients consulting neurologists or not were 12 (41.4%) and 6 (37.5%), average ages were 77.9±7.4 and 80.7±6.5, average ages at onsets were 69.3±10.8 and 69.3±7.7 years old, disease durations were 8.6±6.9 and 10.3±5.5 years, HY stages were 3.7±1.2 and 4.3±1.1, and levodopa equivalent daily doses were 416±295 and 309±263 mg/day, respectively.

Conclusions:: Within the patients with PD receiving HMCs and in NHs, the patients not continuously consulting neurologists were older, received less medication and had more motor severities than the patients continuously consulting neurologists.
Background and Aims: Cannabis use is frequent in Parkinson disease (PD), despite limited data regarding effects. This study aims to determine efficacy and tolerability of relatively high cannabidiol (CBD) and low D-9-tetrahydrocannabinol (THC) in 60 persons with PD. Interim data on tolerability is presented.

Methods: In this randomized, double-blind, controlled, parallel study participants that took a CBD cannabis extract (from National Institute of Drug Abuse) oral sesame oil solution with 100mg/mL CBD and 3.33mg/mL THC. Study drug started at 1.25mg/kg/day and increased to 2.5mg/kg/day CBD for 10-14 days. Unblinded study staff assigned participants to two groups, A or B, according to treatment randomization, which were matched in age, sex and stage of disease.

Results: Between 09/2018 and 04/2020, 41 (66% men) took study drug: mean age 69.2 (SD 7.4). Mean daily dose was 2.3 (0.4) mg/kg/day, i.e., 189.6 (55.3) mg CBD and 6.3 (1.8) mg THC, and participants were on study drug for 16.5 (5.6) days. Group A (n=22) reported AEs 206 times (2 SAEs), and 19 (86%) reported an AE: dizziness (59%); fatigue, feeling of relaxation, headache, decreased concentration, (36%); feeling abnormal, feeling drunk, nausea, somnolence (27%); confusion, (23%). Group B (n=19) reported AEs 93 times (no SAEs), and 17 (89%) reported an AE: headache (37%); somnolence (26%); feeling of relaxation (21%). Most AEs were mild; one participant withdrew due to intolerance.

Conclusions: Interim data suggests relatively high CBD/low THC (likely Group A) is well tolerated in PD, with a broad range of mild AEs.

EFFICACY OF OPICAPONE ACCORDING TO LEVODOPA’S DURATION OF USE IN PARKINSON’S DISEASE PATIENTS WITH MOTOR FLUCTUATIONS

Angelo Antonini¹, Georg Ebersbach², Olivier Rascol³, Diogo Magalhães⁴, José Rocha⁴, Patrício Soares-Da-Silva⁴
¹University of Padova, Department Of Neurosciences, Padova, Italy, ²Beelitz Hospital, Movement Disorders Clinic, Beelitz, Germany, ³University of Toulouse, Department Of Neurosciences & Clinical Pharmacology, Toulouse, France, ⁴BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC), a once-daily catechol-O-methyltransferase inhibitor, proved to be effective in treating end-of-dose motor fluctuations in Parkinson’s disease (PD) patients in two large multinational trials. We evaluated the efficacy of OPC in PD patients with motor fluctuation according to levodopa’s duration of use.

Methods:: Efficacy data from BIPARK-I and II were combined for the placebo (PLC) and OPC 50 mg groups. The studies had similar designs, eligibility criteria and methodologies. Primary efficacy endpoint was change from baseline in absolute OFF-time. Safety was assessed by evaluating the incidence of treatment-emergent adverse events (TEAEs). Subgroup analyses were performed to evaluate consistency and potential trends between subgroups based on levodopa’s duration of use at baseline (Table 1). Efficacy subgroup analyses were performed using Analysis of Covariance. Safety assessments were analysed descriptively.

Results:: Overall, 522 patients were randomised to PLC (n=257) and OPC 50 mg (n=265) (Table 1). OPC 50 mg was significantly more effective than PLC for all subgroup analyses (p<0.05), except for the subgroup of patients treated with levodopa for ≥7 years and ≥8 years (Table 2). Moreover, OPC 50 mg demonstrated enhanced efficacy in patients with shorter levodopa treatment duration in each subgroup threshold (Table 2). There was also a trend towards a lower incidence of dopaminergic-related TEAEs in the same subgroups of patients (Table 3).
Conclusions: These findings indicate that there may be an added benefit from using OPC 50 mg earlier in a course of treatment with levodopa and promptly in the motor fluctuations spectrum of PD.
OPICAPONE IN CLINICAL PRACTICE IN PARKINSON’S DISEASE PATIENTS WITH MOTOR FLUCTUATIONS AND COMPLICATIONS OF THERAPY AT BASELINE: FINDINGS FROM THE OPTIPARK STUDY

Heinz Reichmann1, Andrew Lees2, Miguel Fonseca3, Diogo Magalhães4, José Rocha4, Patrício Soares-Da-Silva4

1University of Dresden, Department Of Neurology, Dresden, Germany, 2National Hospital for Neurology and Neurosurgery, Department Of Clinical And Movement Neurosciences, London, United Kingdom, 3BIAL-Portela & Ca S.A., Bioinformatics & Pharmacometrics Office, Coronado, Portugal, 4BIAL-Portela & Ca S.A., Global Parkinson’s Disease Department, Coronado, Portugal

Background and Aims:: Opicapone (OPC) proved to be effective for end-of-dose motor fluctuations (MF) in Parkinson’s disease (PD) patients. The OPTIPARK study evaluated OPC 50mg in a heterogeneous population of patients treated in real-world conditions. We evaluated OPC’s effects in patients with MF and complications of therapy (CoT) at baseline.

Methods:: OPTIPARK was a prospective, open-label, single-arm trial conducted in Germany and the UK. Patients with MF received OPC 50mg in addition to current antiparkinsonian treatment. Primary efficacy 3-month endpoint was Clinician’s-Global-Impression-of-Change. Secondary assessments included Unified-Parkinson’s-Disease-Rating-Scale (UPDRS) and treatment-emergent adverse events (TEAEs). This post-hoc analysis evaluated OPC’s impact in patients who completed the study and reported CoT at baseline, assessed by UPDRS IV.A-32 (waking-day-dyskinesias [WdD]).

Results:: 393 (82.4%) patients completed the 3-month endpoint (completers-set); 150 reported WdD at baseline (Table 1). Most baseline WdD were not -or mildly- disabling and not -or slightly- painful. Approximately 26% of WdD completers reported dyskinesia as TEAE. At endpoint, most of the patients (131 [88%]) demonstrated either maintained (54%) or improved (34%) WdD. Most remaining WdD were still not -or mildly- disabling and also not -or slightly- painful (Table 2, Figure 1). Notably, none worsened to either severe -or complete- disabling and severe -or marked- painful. Approximately 54% of dyskinesias reported as TEAE resolved following a mean daily levodopa decrease of ~67 mg (Table 2).

DRIVING MOTOR CORTEX OSCILLATIONS MODULATES BRADYKINESIA IN PARKINSON’S DISEASE

Andrea Guerra, Donato Colella, Margherita Giangrosso, Antonio Cannavacciuolo, Giulia Paparella, Giovanni Fabbri, Antonio Suppa, Alfredo Berardelli, Matteo Bologna
Sapienza University of Rome, Department Of Human Neurosciences, Rome, Italy

**Background and Aims::** In Parkinson’s disease (PD), beta (β) and gamma (γ) oscillations are altered in the basal ganglia, and this abnormality contributes to bradykinesia pathophysiology. However, it is unclear whether β and γ rhythms at the primary motor cortex (M1) level influence bradykinesia. We aimed at clarifying this issue by using transcranial alternating current stimulation (tACS), a neurophysiological technique that enhances cortical rhythms by entraining endogenous oscillations.

**Methods::** We tested whether β- and γ-tACS on M1 modulate bradykinesia in PD patients by analyzing the kinematic features of repetitive finger tapping. We also verified whether possible tACS-induced bradykinesia changes depended on modifications in specific M1 circuits, as assessed by short-interval intracortical inhibition (SICI) and short-latency afferent inhibition (SAI). Patients were studied OFF and ON therapy.

**Results::** Movement velocity significantly worsened during β-tACS and movement amplitude improved during γ-tACS, while the sequence effect did not change. In addition, SAI decreased (reduced inhibition) during β-tACS and SICI decreased during both γ- and β-tACS. The effects of tACS were comparable between OFF and ON sessions. In patients OFF therapy, the degree of SICI modulation during β- and γ-tACS correlated with movement velocity and amplitude changes, respectively. Moreover, there was a positive correlation between the effect of γ-tACS on movement amplitude and motor symptoms severity.

**Conclusions::** Our results demonstrate that β and γ oscillations at the M1 level are relevant in the pathophysiology of bradykinesia in PD. Changes in inhibitory GABA-A-ergic interneuronal activity may reflect compensatory M1 mechanisms to counteract bradykinesia.
LONG-TERM EFFECT OF SAFINAMIDE ON PRIMARY MOTOR CORTEX EXCITABILITY AND PLASTICITY IN PARKINSON’S DISEASE: A TMS STUDY

Valentina D’Onofrio¹, Andrea Guerra¹,², Francesco Ascì¹,², Giovanni Fabbrini¹,², Alfredo Berardelli¹,², Antonio Suppa¹,²
¹Sapienza University of Rome, Department Of Human Neurosciences, Rome, Italy, ²IRCCS Neuromed, Irccs Neuromed, Pozzilli, Italy

Background and Aims:: In a recent Transcranial Magnetic Stimulation (TMS) study, we demonstrated abnormally enhanced Short-Interval Intracortical Facilitation (SICF) in patients with Parkinson’s Disease (PD). These abnormalities reflect increased glutamatergic transmission in primary motor cortex (M1). A short-term treatment with safinamide at 100 mg/day can restore SICF in PD by reducing glutamatergic transmission via blockade of voltage-gated sodium channels. We here examined the long-term effect of chronic treatment with safinamide 100 mg/day on SICF and other measures of M1 excitability and plasticity in PD.

Methods:: 25 PD patients underwent 3 separate sessions: before starting safinamide (T0), after 2 weeks (T1) and after 12 months (T2) of safinamide 100 mg/day. Patients were tested when OFF and ON therapy. Motor evaluation included MDS-UPDRS-II and UDysRS-III. We tested Input/output curve, Short-Interval Intracortical Inhibition (SICI), Intracortical Facilitation (ICF) and SICF. In a subgroup of 15 patients, we also examined responses to intermittent theta burst stimulation (iTBS).

Results:: UPDRS-III and UDysRS-III scores were comparable at T0-T1-T2, indicating overall clinical stability over one-year follow-up. In PD patients, safinamide 100 mg/day restored SICF at both T1 and T2. Moreover, safinamide improved responses to iTBS at T1 and T2. Drug-induced changes in SICF correlated with responses to iTBS at T2.

Conclusions:: Our results overall support the pathophysiological role of abnormally enhanced glutamatergic transmission in M1 in PD patients. Safinamide at 100 mg/day induces short- and long-term improvement of excitability and plasticity measures in M1. These results support the antigu glutamatergic effect of the drug when given at 100 mg/day.
THE ANTIPARKINSONIAN DRUG SAFINAMIDE IS NOT HARMFUL FOR THE HUMAN RETINA. A NEUROPHYSIOLOGICAL STUDY

Fabio Bandini¹, Giovanni Di Bon², Lucilla Vestito³
¹ASL 3 Genovese, Neurology, Genova, Italy, ²ASL 2 Savonese, Neurology, Savona, Italy, ³IRCCS Policlinico Ospedale San Martino, Di. N.o.g.mi, Genova, Italy

Background and Aims:: Safinamide is a selective MAO-B inhibitor, indicated for the treatment of Parkinson's disease (PD). The European patient information leaflet warns about the "Potential for retinal degeneration in patients with presence/prior history of retinal disease: Safinamide should not be administered to patients with ophthalmological history that would put them at increased risk for potential retinal effects". The available literature, however, misses any data concerning this potential retinal toxicity. This prompted us to implement a neurophysiological study concerning a possible drug-related retinal damage.

Methods:: Twenty PD patients were investigated. All patients had corrected visual acuity above 7/10. Safinamide was titrated to 100 mg/day over 15 days. All the subjects underwent a neurophysiological study of the visual function, namely full field ERG, multifocal ERG (mfERG), pattern ERG (PERG) and pattern VEP. The neurophysiological and clinical (UPDRS) evaluations were carried out at the same time of the day, at the baseline, after one, six and twelve months.

Results:: PD patients showed a significant delay of the latency values of PERG and VEP, while ERG and mfERG results were within the normal limits. Over one year, however, ERG, mfERG, PERG and PEV did not show any significant changes. No visual disturbances were reported. The mean UPDR scores improved significantly (p <0.01).

Conclusions:: The current results provide evidence that Safinamide is not harmful for the human retina, both for diffuse (full field ERG) and focal (mfERG, PERG) functional damage, even over a long period of time (one year). The optic nerve (VEP) was not involved as well.
COMBINED GCASE/ALPHA-SYNUCLEIN PATTERN MAY IDENTIFY SPECIFIC PRODOMAL PD PATTERNS IN GBA CARRIERS: A CLUSTER ANALYSIS STUDY

Micol Avenali¹, Silvia Cerri², Chiara Cerami², Chiara Crespi⁴, Matthew Gegg⁵, Stephen Mullin⁵, Marco Toffoli⁵, Derraly Hughes⁶, Enza Valente⁷, Cristina Tassorelli¹, Anthony Schapira⁵, Fabio Blandini⁸

Background and Aims:: Glucocerebrosidase (GBA) gene mutations are the most frequent genetic risk factor for Parkinson Disease (PD). Relationship between GBA status and increased risk for GBA-PD is still unclear. We investigated whether glucocerebrosidase activity (GCase) and α-synuclein levels in blood cells in asymptomatic subjects carrying GBA mutations (GBA carriers) are associated with a more severe prodromal PD profile.

Methods:: 31 GBA carriers, 28 GBA-PD and 38 healthy controls (HC) were enrolled in this study. A two-step cluster analysis was performed to split the subjects into different clusters based on their biochemical profile analysing GCase and α-synuclein separately and in combination. Motor and non-motor features (UPDRS-III, BDI, SCOPA-AUT, MoCA, RBDsq, PDSS, UPSIT) for prodromal PD were merged in a 7-item cumulative clinical index (CI). One-way ANOVA assessed the effect of cluster analysis groupings on the CI.

Results:: Cluster analysis based on combined GCase activity/α-synuclein levels provided the best performance splitting the sample into a benign (high GCase/mid-low α-synuclein) and malignant (low GCase/high α-synuclein) profile, discriminating HC from both GBA carriers and GBA-PD. Therefore we found a significant effect of combined GCase/α-synuclein clusters (F(1.95)=15.495, p<0.001) on clinical profile, revealing a significant difference between the malignant and the benign profiles, with the first showing significantly higher values in the CI with dysautonomia, mood and sleep disorders as the most relevant features.

Conclusions:: Our study provides novel information about the relationship between biochemical and phenotypic prodromal PD signatures of GBA carriers.
LONGITUDINAL CLINICAL, COGNITIVE AND NEUROANATOMICAL CHANGES OVER FIVE YEARS IN GBA-POSITIVE PARKINSON’S DISEASE PATIENTS

Michela Leocadi1,2, Elisa Canu2, Giulia Donzuso3, Tanja Stojkovic4, Silvia Basaia2, Nikola Kresojevic4, Iva Stankovic4, Noemi Piramide1,2, Aleksandra Tomić4, Vladana Markovic4, Igor Petrovic4, Elka Stefanova4, Vladimir Kostic4, Federica Agosta1,2,5, Massimo Filippi1,2,6

1Vita-Salute San Raffaele University, N/a, Milan, Italy, 2IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Division Of Neuroscience, Milan, Italy, 3University of Catania, Department “g.f. Ingrassia”, Section Of Neurosciences, Catania, Italy, 4University of Belgrade, Clinic Of Neurology, Faculty Of Medicine, Belgrade, Serbia, 5IRCCS San Raffaele Scientific Institute, Neurology Unit, Milan, Italy, 6IRCCS San Raffaele Scientific Institute, Neurology Unit, Neurorehabilitation Unit And Neurophysiology Service, Milan, Italy

Background and Aims:: To study the longitudinal disease course of Parkinson’s disease (PD) patients with glucocerebrosidase (GBA) mutation (GBA-positive) compared to PD noncarriers (GBA-negative) along a five-year follow-up.

Methods:: Ten GBA-positive and 20 GBA-negative PD patients underwent clinical, neuropsychological and MRI assessments (cortical thickness and subcortical, hippocampal and amygdala volumes) at study entry and once a year for five years. At baseline and at the last visit, each group of patients was compared with 22 age-matched healthy controls. Clinical, cognitive and MRI features were compared between groups at baseline and over time.

Results:: At baseline, GBA-positive and GBA-negative PD patients had similar clinical and cognitive profiles. Compared to GBA-negative and controls, GBA-positive patients showed cortical thinning of left temporal, parietal and occipital gyri. Over time, compared to GBA-negative, GBA-positive PD patients progressed significantly in motor and cognitive symptoms, and showed a greater pattern of bilateral cortical thinning involving also frontal cortices. After five years, compared to controls, GBA-negative PD patients showed a pattern of cortical thinning similar to that showed by GBA-positive cases at baseline. The two groups of patients showed similar patterns of subcortical, hippocampal and amygdala volume loss over time.

Conclusions:: Compared to GBA-negative PD, GBA-positive patients experienced a more rapid motor and cognitive decline together with a greater, earlier and faster cortical thinning. Cortical thickness measures may be a useful tool for monitoring and predicting PD progression in accordance with the genetic background. Funding: Ministry of Education and Science of the Republic of Serbia (Grant #175090).
HD LIKE PRESENTATION OF HIV IN ADULT: RARE CASE REPORT

Dnyaneshwar Jadhav, Sangeeta Ravat, Neeraj Jain, Rushikesh Joshi
Seth GSNC and KEM hospital Mumbai, Neurology, Mumbai, India

**Background and Aims:** Movement disorders including parkinsonism, tremor, myoclonus, and dystonia have been reported in patients with HIV (human immunodeficiency virus) encephalopathy. Chorea and ballismus have been reported in AIDS (acquired immune deficiency syndrome) complicated by CNS toxoplasmosis infection. Huntington disease (HD) is common cause of chorea in adult with chronic history. Generalised chorea as a presenting symptom of HIV rare. We are reporting this HD like presentation of HIV in adult as it is probably the rare case report after thorough review of literature.

**Methods:** A 54-year-old male presented with 1.5-year history of generalized hyperkinetic movement involving face, limb and trunk with 1 year history of behavioural symptoms in the form increased irritability and impulsivity. Family history was negative. Neurological examination showed generalized chorea involving upper face, peri-oral region, tongue, limb and trunk with frontal dysfunction. Rest of examination was unremarkable.

**Results:** On evaluation, all blood investigation including blood glucose, renal function test, serum electrolytes, thyroid function test and ceruloplasmin were normal. Peripheral smear’s for acanthocyte were negative. MRI brain showed bilateral moderate caudate atrophy. Genetic study for HD negative. He tested positive for HIV.

**Conclusions:** This case highlights that HIV can present with typical HD phenotype clinically as well radiologically in adult. It should be considered in differential diagnosis of patients without genetic etiology.
HEMI-CHOREA-BALLISM; AN UNCOMMON PRESENTING PHENOMENOLOGY IN WILSON’S DISEASE

Vithoosan Sahathevan, Bimsara Senanayake
National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

Background and Aims:: Hemi chorea – ballism is usually seen in the elderly, secondary to stroke and uncontrolled diabetes. It is an uncommon phenomenology in the young, especially without a structural brain pathology. We describe a case of a young girl presenting with hemi chorea with normal brain imaging secondary to neuro Wilsons disease (WD).

Methods:: Case Report A 16 year old girl presented with left hemi chorea involving both upper and lower limbs over a period of one week. She had no movement abnormality elsewhere. She was cognitively normal with no emotional lability. History of sore throat two weeks prior was noted along with symmetrical small joint arthritis. Except for the hemi chorea neurological examination was normal.

Results:: 2D echocardiogram revealed grade two mitral regurgitation. Her hematology including an auto immune screen, thyroid function, inflammatory markers were normal. However elevated ASOT 800IU/ml was detected. Copper screen showed an elevated 24 hour urinary copper (2.89 umol/24 hours (0.23-1.09), with a normal serum caeruloplasmin level. Subsequently bilateral KF rings were detected on slit lamp. Genetic confirmation with ATP 7 B mutation for WD is awaited. Copper chelation therapy with penicillamine was initiated resulting in near complete resolution of the movement abnormality.

Conclusions:: Hemi chorea in childhood is an exceptionally rare movement phenomenology especially without a structural brain lesion. Sydenham chorea is more generalised and bilateral. High ASOT level seen in this patient could occur in recurrent sore throat. Although WD can present with most types of movement disorders hemi chorea as a presenting feature is rarely described.
SEX-SPECIFIC WHOLE-BRAIN NETWORK TOPOLOGIC ORGANIZATION IN DRUG NAÏVE PARKINSON’S DISEASE PATIENTS

Sara Satolli¹, Federica Agosta², Rosa De Micco¹, Silvia Basaia², Mattia Siciliano¹, Camilla Cividini², Gioacchino Tedeschi¹, Massimo Filippi², Alessandro Tessitore¹
¹Università degli studi della Campania "Luigi Vanvitelli", Department Of Advanced Medical And Surgical Sciences, Napoli, Italy, ²IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Division Of Neuroscience, Milan, Italy

Background and Aims:: Compelling evidence suggests that a gender-specific pattern and functioning within the nigrostriatal dopaminergic pathway may underlie different outcomes in patients with Parkinson’s disease (PD). We aim to investigate the potential effect of sex on the whole-brain network topologic organization in a cohort of drug-naïve PD patients using resting-state functional MRI and correlations with baseline and longitudinal clinical features.

Methods:: 3T MRI images of 147 drug-naïve PD patients (85/62 male/female), and 38 controls (20/18 male/female) were acquired. Graph analysis and connectomics were used to assess global and local topological network properties and regional functional connectivity (FC) in female PD patients compared to males. Multivariate linear and logistic regressions investigated whether functional imaging data at baseline were predictors of clinical outcome over a 4-year period.

Results:: At 4-year follow-up, female PD patients were more likely to present treatment-related motor complications, especially dyskinesia. At baseline, female PD patients showed a preserved global functional brain architecture compared to controls. Male PD patients showed altered functional topological properties within the basal ganglia network compared to female PD patients. No FC differences were detected between male and female controls. Functional connectivity changes within the basal ganglia at baseline were correlated with risk of motor complications at follow-up.

Conclusions:: Our findings revealed the presence of a disease-related, sex-specific functional basal ganglia architecture in a cohort of early PD patients. These findings may be related to the presence of different gender-specific nigrostriatal dopaminergic pathways and might be potentially used to predict disease progression over time.
ALPHA-SYNUCLEIN PATHOLOGY AND ENTERIC GLIA IN ADVANCED PARKINSON’S DISEASE: A STUDY FROM GASTROINTESTINAL BIOPSIES

Michele Sandre1,2,3, Aron Emmi1,2,4, Giulia Tombesi3, Federica Garri1, Francesco Paolo Russo5, Fabio Farinati5, Raffaele De Caro4, Luigi Bubacco3, Angelo Antonini1
1University of Padova, Parkinson And Movement Disorders Unit, Department Of Neuroscience, Padova, Italy, 2University of Padova, Padua Neuroscience Center (pnc), Padova, Italy, 3University of Padova, Department Of Biology, Padova, Italy, 4University of Padova, Institute Of Human Anatomy, Department Of Neuroscience, Padova, Italy, 5University of Padova, Gastroenterology Unit, Department Of Surgery, Oncology And Gastroenterology, Padova, Italy

Background and Aims:: In Parkinson’s Disease (PD), recent evidence points towards the involvement of gut-brain axis as one of the primary physio-pathological mechanisms underlying α-Syn aggregation and propagation to CNS. Furthermore, gastrointestinal dysfunctions represent one of the main non-motor symptoms in PD, often preceding the development of proper motor symptoms. Our aim was to investigate the enteric nervous system (ENS) in PD by characterizing α-Syn alterations and glial responses in stomach-duodenum biopsies of PD patients.

Methods:: 16 patients with advanced PD which underwent Duodopa Percutaneous Endoscopic Gastrostomy and Jejunal Tube (PEG-J) placement were included in the study. A mean of 4 (2mm3) wall biopsies were sampled from each patient. Immunohistochemistry was performed with anti-aggregated-α-Syn (5G4) and GFAP antibodies. The presence of phospho-α-Syn in conjunction with βIII-tubulin was investigated by immunofluorescence. Morphometrical-semi-quantitative analysis was performed to characterize 5G4+ and GFAP+ density and size. Duodenal control biopsies were included from 8 age-and-sex-matched patients undergoing routine diagnostic endoscopy.

Results:: Elevated immunoreactivity for both phosphorylated and aggregated α-Syn was identified in all biopsies of PD patients compared to controls. Immunohistochemistry was performed with anti-aggregated-α-Syn (5G4) and GFAP antibodies. The presence of phospho-α-Syn in conjunction with βIII-tubulin was investigated by immunofluorescence. Morphometrical-semi-quantitative analysis was performed to characterize 5G4+ and GFAP+ density and size. Duodenal control biopsies were included from 8 age-and-sex-matched patients undergoing routine diagnostic endoscopy.

Conclusions:: The ENS could be one of the earliest implicated structures in the patho-physiology of PD. The analysis of enteric glia could represent a precocious biological marker of the disease, as its responses to pathological α-Syn could unveil a link between gastrointestinal neural and immune systems in PD inflammation.
LONG-TERM CLINICAL, NEUROPHYSIOLOGICAL AND NEUROIMAGING FOLLOW-UP OF A PATIENT WITH HEMIPARKINSON-HEMIATROPHY SYNDROME

Angelo Pascarella¹, Lucia Manzo¹, Anna Estraneo²,³
¹Magna Graecia University of Catanzaro, Institute Of Neurology, Catanzaro, Italy, ²SM della Pietà General Hospital, Neurology Unit, nola, Italy, ³Don Gnocchi Foundation, IRCCS, Neurorehabilitation Unit, Florence, Italy

Background and Aims:: Hemiparkinsonism-hemiatrophy syndrome (HPHA) is a rare form of secondary parkinsonism characterized by unilateral body atrophy associated to early onset ipsilateral parkinsonism, with slow progression, inconstant contralateral involvement and variable response to levodopa. For the first time, we describe a long-term clinical and instrumental follow-up of a patient with HPHA.

Methods:: Case report: a 16-year-old male developed a gradually worsening mild slowness and stiffness of left limbs. At age 19, he showed slight rigidity, bradykinesia and distal dystonic posturing on his left side (UPDRS-III motor scores: 30) and mild ipsilateral somatic atrophy. Longitudinal assessment: at baseline, neurological examination after L-Dopa administration, brain MRI, [123I]-FP-CIT DAT-SCAN, genetic analysis for PINK1 and PRKN gene, transcranial magnetic stimulation (TMS) before and after DOPA; during the 18-year follow-up: repeated clinical assessments and instrumental evaluations (i.e. neuroimaging after 15 years, yearly TMS during the first four years).

Results:: At baseline: 1. unremarkable brain MRI; 2. negative genetic analysis; 3. bilateral asymmetric (right-left) decrease of striatal transporter binding on DAT-SCAN; 4. significant clinical improvement (UPDRS-III: 11) after 200-mg oral levodopa; 5. reduced TMS short intracortical inhibition in the right hemisphere, unmodified after levodopa. Diagnosis of HPHA syndrome was confirmed and rotigotine, 4 mg/die, was started with clinical improvement. Neurological exam showed a slight worsening of limb dystonia in the 18 years of follow-up (UPDRS-III: 32). No changes were found on TMS, brain MRI and DAT-SCAN.

Conclusions:: The present long-term multimodal clinical and instrumental assessment confirmed the slow clinical progression of HPHA, whereas structural/metabolic brain damages and neurophysiological findings remained unchanged.
TEST-RETEST RELIABILITY OF STATIC POSTURAL BALANCE VARIABLES IN NATURAL AND FEET-TOGETHER STANCE CONDITIONS

Do-Young Kwon, Jiwon Kim
Korea University Ansan Hospital, Neurology, Ansan-city, Korea, Republic of

Background and Aims:: The aim of this study was to investigate the test-retest reliability of postural balance variables during the natural and feet-together stance conditions. It is important to confirm the reliability of postural balance variables because the results of balance tests would be different with different balance test protocols, i.e., stance conditions such as natural and feet-together stances.

Methods:: Sixteen young healthy adults were instructed to sustain their center of body mass as stably as possible on the force plate. As balance standing conditions, natural (a comfortable self-selected stance width) and feet-together stances (placing the feet 0’ apart) were selected. The mean distance, mean velocity, mean frequency, and 95% confidence ellipse area were derived from the center of pressure (COP) time series in the overall, anteroposterior (AP), and mediolateral (ML) directions. To evaluate the test-retest reliability of the postural balance variables, Cronbach’s alpha coefficient was calculated in each stance condition.

Results:: Mean velocity was the most reliable variable particularly in three times balance test with in both the natural and feet together stances (α = 0.805 – 0.921). The reliability of all variables of three times balance test was greater than that of twice balance test , mainly in the natural stance. In contrast, the mean ML distance of the feet-together stance had poor reliability despite three balance tests (α = 0.243).

Conclusions:: These results suggest that the balance test protocol should consider the appropriate stance conditions as well as the number of balance trials to select the reliable postural balance variables.
Background and Aims:: Complex Regional Pain Syndrome (CRPS) is a chronic inflammatory disease severely disabling also characterized by neurological complications. Dystonia and dystonic tremor may occur in the chronic phase of CRPS, however movement disorders associated with CPRS are often underrecognized. Here we report a case series of 3 patients with dystonias associated with CRPS.

Methods:: Cases. The first one was a young man of 18 years of age who developed CRPS after a traumatic injury to the right forearm. Dystonic posture with adducted arm, flexed forearm and pronated hand occurred after 13 months from CRPS onset. The second patient was a 66 year-old female patient who progressively developed a dystonic tremor and dystonia of the left arm after 12 months time of pain, swelling and cutaneous allodynia in the same limb. The third patient was a 46 year-old male who developed dystonia of left limbs after a 12-month period with recurrent pain and swelling of the left hand and foot. All patients underwent intravenous treatment with neridronate.

Results:: All patients had clinical improvement and reduction of CSS scores after treatment with neridronate. The first two patients had complete regression of pain and dystonia with complete restoration of limb range of motion. The third patient showed a partial improvement of dystonic postures.

Conclusions:: Our data indicate that dystonias due to CRPS if treated early could have a complete remission. Physicians should be aware that CRPS may be associated with treatable dystonia in the chronic phase of the disease.
PARKINSON’S DISEASE RISK FACTORS AND AGE

Enkhjargal Bavaasan, Dariimaa Surenjav
the third central hospital, Head Of Department Of Neurology, ulaanbaatar, Mongolia

Background and Aims:: Objective: Aim to study some risk factors in patients with Parkinson disease (PD).
Methods:: It was a retrospective analysis conducted in the Department of Neurology, Third Central Hospital of Mongolia from January 2016 to December 2019. We assessed 71 patients history with PD. They were diagnosed according to criteria of The United Kingdom Parkinson’s Disease Society Brain Bank clinical diagnostic criteria (UKPDSBB).
Results:: Total 71 patients (female 82.3%) enrolled in this study. The respondents 29.7% are at the age of 40-59 years, 70.3% are above the age of 60 and the average age is 65.6±7.3. Age at onset of sign of the PD was divided into three group: 3.5% at below 39 years, 45% at 40-59 years, 51.5% at more than 60 years. Average age is 58.6±9. We compared the age at onset of sign and some risk factor that in the middle age they had trauma of brain in 26.8%, combined factor in 53.5%, and in the old age diagnosed with patient they had metabolic in 5.1%, psychiatric disorder in 8.2% environmental factors in 6.7%, vascular disorders in 47.4% and concomitant disorders in 32.6%. About 6% of patients have a family history of PD.
Conclusions:: Risk factors for PD are more likely to be age-related vascular disorders and middle-aged brain injury. The age of the respondent and the age at which the onset of the disease (age at which the onset of the first symptoms appeared) accounted ages over 60, and the clinical symptoms became more advanced with age.
STRUCTURAL GRAY AND WHITE MATTER LONGITUDINAL ALTERATIONS IN PARKINSON’S DISEASE WITH REM SLEEP BEHAVIOR DISORDER

Pietro Giuseppe Scamarcia¹,²,³, Federica Agosta¹,²,³, Edoardo Gioele Spinelli¹,²,³, Tanja Stojkovic⁴, Silvia Basaia⁵, Iva Stankovic⁴, Vladana Markovic⁴, Igor Petrovic⁴, Elka Stefanova⁴, Vladimir Kostic⁴, Massimo Filippi¹,²,⁵

¹IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Division Of Neuroscience, Milan, Italy, ²Vita-Salute San Raffaele University, N/a, Milan, Italy, ³IRCCS San Raffaele Scientific Institute, Neurology Unit, Milan, Italy, ⁴University of Belgrade, Clinic Of Neurology, Faculty Of Medicine, Belgrade, Serbia, ⁵IRCCS San Raffaele Scientific Institute, Neurology Unit, Neurorehabilitation Unit And Neurophysiology Service, Milan, Italy

Background and Aims:: In Parkinson’s disease (PD), the presence of REM sleep behavior disorder (RBD) is associated with cortical and subcortical abnormalities. We aimed to longitudinally investigate structural differences in patients with PD, according to the presence of RBD.

Methods:: 153 PD patients underwent clinical assessment, neuropsychological evaluation and Magnetic Resonance Imaging (MRI) scan once a year up to 48 months. Patients were classified as RBD+ (n=45) or RBD- (n=108) according to RBD-questionnaire scores (cut-off = 5). Cortical thickness and deep nuclei volumetry were assessed at each timepoint. Moreover, white matter hyperintensities (WMH) were identified on T2-weighted images and WMH total volume was computed for each scan. Clinical and cognitive variables, gray matter (GM) and WMH volumes at baseline were compared, and their longitudinal progression was investigated with age-adjusted linear mixed-effects models.

Results:: At baseline, RBD+ PD patients were older, showed worse global motor and cognitive performance, higher WMH volume and higher degree of atrophy in frontal, temporal and occipital areas, as well as bilaterally in basal ganglia. Longitudinally, the RBD+ group showed worse longitudinal progression in motor and cognitive performance, WMH volume and atrophy in thalami and accumbens nuclei bilaterally, left nucleus pallidum and right putamen compared to RBD- group.

Conclusions:: Our study showed extensive brain alterations in both GM and WM in PD patients with RBD, with more evident clinical, cognitive and structural MRI alteration worsening over time, suggesting more rapid neurodegeneration in PD with RBD. Funding: Ministry of Education and Science Republic of Serbia (Grant #175090).
NEW PRION PROTEIN MUTATION (T183S) WITH ATYPICAL PARKINSONISM AND GSS-LIKE NEUROPATHOLOGY.

Gerard Jansen¹, Benjamin Lam², Josee Lynch³, J. Knox⁴, Michael Coulthart³
¹University of Ottawa, Pathology And Laboratory Medicine, Ottawa, Canada, ²Sunnybrook Health Science Centre, Neurology, Toronto, Canada, ³Public Health Agency of Canada, Cjd Surveillance System, Ottawa, Canada, ⁴National Microbiology Centre, Prion Diseases Section, Winnipeg, Canada

Background and Aims:: The Canadian CJD surveillance, active since 1998, has reported 1133 prion disease cases. The mortality rate of CJD in Canada averaged 1.96/1,000,000 over the past 5 years. 7% of the cases were genetic in origin.

Methods:: Case report

Results:: We report the case of an at death 78-year-old gentleman with three-year history of slowly progressive mild cognitive impairment, Parkinsonism (mainly bradykinesia), and vertical gaze palsy; poorly responsive to Dopa. He rapidly declined two months before his death with profound dementia, myoclonus, and akinetic mutism. An MRI showed subtle cortical restricted diffusion, EEG showed periodic triphasic waves, QuIC testing was negative, hTau positive, and 14-3-3 was borderline. Genetic testing revealed a T183S mutation of PRNP. Genetic testing of family members has not yet been performed.

Neuropathology revealed multicentric prion protein plaques (12F10) in the deeper neocortical layers, hippocampus, and the molecular layer of the cerebellum. Spongiosis was minimal and focal, and unassociated with plaques. The morphology is consistent with GSS or GSS-like prion disease. No PD or PSP neuropathological changes were present.

Conclusions:: The clinical presentation in this patient with T183S mutation is different from the CJD profile present in patients with T183A mutation. A similar dimorphic situation occurs with mutations on codon 232. T183S has similarities to the D202N mutation which also shows atypical Parkinsonism with GSS neuropathology (Plate et al, Mov Disord 2013; 28: 241-244). In the clinically challenging group of atypical Parkinsonism, it is good to consider a prion disease in the differential diagnosis, alongside more likely candidates such as PSP.
BRADYKINESIA IN PATIENTS WITH VALPROATE-INDUCED TREMOR

Alessandro De Biase¹, Giulia Paparella², Luca Angelini¹, Antonio Cannavacciuolo¹, Donato Colella¹, Carlo Di Bonaventura¹, Anna Teresa Giallonardo¹, Alfredo Berardelli¹,², Matteo Bologna¹,²
¹Sapienza University of Rome, Department Of Neuroscience And Mental Health, Rome, Italy, ²IRCCS Neuromed, Irccs Neuromed, Pozzilli, Italy

Background and Aims:: Valproate is one of the most effective treatments for epilepsy. Among its side effects, tremor and parkinsonism have been reported. Earlier neurophysiological observations showed bradykinesia (movement slowness) during upper limb movement in patients with valproate-induced tremor. However, the pathophysiological mechanisms of this movement abnormality are unclear.

Objective: To investigate the possible occurrence of bradykinesia in patients with valproate-induced tremor during finger movements and possible distinguishing features with bradykinesia in Parkinson’s disease.

Methods:: 22 patients with valproate-induced tremor, 22 patients with Parkinson’s disease, and 22 healthy controls were enrolled. All participants underwent a standardized neurological examination, video recordings, and kinematic assessment of the finger tapping. Rest, postural and kinetic tremor of the upper limbs was also objectively recorded in patients using a motion analysis system. One-way analysis of variance was used for between-group comparisons. Correlations analysis was used to test possible correlations between clinical data and kinematic features in patients.

Results:: Clinical evaluation and kinematic analysis showed that patients with valproate-induced tremor were slightly bradykinetic, i.e. slower, than healthy controls (both p<0.05). Unlike Parkinson’s disease patients, however, patients with valproate-induced tremor did not present a decrement in amplitude (sequence effect) during finger tapping. Finally, there was no correlation between bradykinesia and tremor severity in patients.

Conclusions:: Bradykinesia (movement slowness) without decrement is a common motor feature in patients with valproate-induced tremor which may suggest distinctive pathophysiological mechanisms.
DEEP BRAIN STIMULATION IN MOVEMENT DISORDERS: 15 YEAR EXPERIENCE OF KING FAISAL SPECIALIST HOSPITAL & RESEARCH CENTER

Hamad Aldraye
KFSHRC, Neurosciences, Riyadh, Saudi Arabia

Background and Aims:: Deep brain stimulation is a revolutionary intervention that treats specific movement disorders through targeting particular areas in the brain. DBS offers hope for patients that do not reach sufficient benefit from medical management. King Faisal Specialist Hospital and Research Center has been providing DBS treatments since 2003 and has since provided the full spectrum of care surrounding the surgical and medical elements of implanting a DBS Device and monitoring the results through follow ups, programming and medical management support. The existence of this vast experience will serve as a reliable and detailed reference to navigate the decision, choice, management and follow ups for the use of DBS in movement disorders patients.

Methods:: a retrospective chart review of all the patients who underwent DBS in KFSH&RC with an aim to during the period of 2003 to 2020

Results:: The results currently under review will characterize indications, contraindications, complications, and disease response to DBS.

Conclusions:: Deep Brain Stimulation is a revolutionary intervention and has the potential to provide benefit for many patients, the review of a resourcesful and experienced tertiary healthcare center with a significant number of DBS procedures and follow ups would provide an indepth look on the spectrum of benefit provided by Deep Brain Stimulation for our patients.
IDENTIFICATION OF PARKINSON’S DISEASE BIOMARKERS THROUGH RNA SEQUENCING OF PERIPHERAL BLOOD LEUKOCYTES

Valentina Tommasini¹, Mauro Catalan¹, Maurizio Romano², Giulia Mazzon¹, Tatiana Cattaruzza¹, Lucia Antonutti¹, Paola Polverino¹, Claudio Bertolotti¹, Emanuele Buratti³, Paolo Manganotti¹
¹University of Trieste, Neurology Unit, Department Of Medical, Surgical And Health Sciences, Cattinara University Hospital, Asugi, Trieste, Italy, ²University of Trieste, Department Of Life Sciences, Trieste, Italy, ³International Centre for Genetic Engineering and Biotechnology (ICGEB), Molecular Pathology Group, Trieste, Italy

Background and Aims:: Identifying reliable biomarkers for early diagnosis and staging of Parkinson’s disease (PD) is a priority and a challenge in the field. Transcriptomics is becoming an important tool to investigate the potential of cells to adapt gene expression in different physiological and pathological states. However, only few studies have focused so far on transcriptomic profiling as PD biomarker, and research of such biomarkers in peripheral blood is particularly lacking. The aim of this study is to investigate gene expression changes occurring in peripheral blood leukocytes (PBL) as potential biomarkers of PD.

Methods:: Blood leukocyte samples were collected from four different groups of patients: early PD (EPD), advanced PD with dementia (PDD), Alzheimer’s disease (AD) and healthy volunteers as controls (CTR). RNAseq - MACE (Massive Analysis of cDNA ends) has been performed on available samples to obtain an unbiased landscape of transcript expression changes between patients and controls.

Results:: Our high throughput analysis has enabled us to identify a number of genes that are most upregulated/downregulated in the patients’ PBL and which are specific for any disease condition (EPD, PDD, or AD) (Figure 1-3). Importantly, we detected several gene expression changes that could represent potential biomarkers for PDD (1055), EPD (328) and AD (400).
Conclusions:: Validation studies of the top-ranking candidate genes are currently ongoing by recruiting new independent cohorts of patients. The results of the present study seem to be promising in the short/mid-term challenge to improve PD diagnosis, assess disease severity, and prognosticate course of disease.
COGNITIVE OUTCOME FOLLOWING BILATERAL SUBTHALAMIC NUCLEUS DEEP BRAIN STIMULATION IN PARKINSON’S DISEASE: A COMPARATIVE OBSERVATIONAL STUDY IN THE INDIAN POPULATION

Kshiteeja Jain¹, Remya Ramesh¹, Syam Krishnan¹, Krishnakumar Kesavapisharady², Divya Kp¹, Gangadhara Sarma¹, Sankara Sarma³, Asha Kishore¹
¹SREE CHITRA TIRUNAL INSTITUTE FOR MEDICAL SCIENCES AND TECHNOLOGY, Neurology, THIRUVANANTHAPURAM, India, ²SREE CHITRA TIRUNAL INSTITUTE FOR MEDICAL SCIENCES AND TECHNOLOGY, Neurosurgery, THIRUVANANTHAPURAM, India, ³SREE CHITRA TIRUNAL INSTITUTE FOR MEDICAL SCIENCES AND TECHNOLOGY, Achutha Menon Centre, THIRUVANANTHAPURAM, India

Background and Aims:: The improvement in motor outcomes after bilateral subthalamic nucleus deep brain stimulation (STN DBS) has been well established in patients with Parkinson’s disease (PD). However, the cognitive changes related to STN DBS are debatable, with studies showing divergent results.

Methods:: We conducted a prospective comparative observational study to assess the effects of bilateral STN DBS on cognition at minimum two years of neurostimulation when compared to a group of patients with PD on medical management alone. 34 patients in each group were compared for various neuropsychological scores. The two groups were matched for age, severity of disease, LEDD at baseline and duration of PD.

Results:: At a mean follow up of around 33 months, we found a significant decline in verbal fluency scores in the DBS group, and a trend for decline was noted in digit span test, both measures of frontal executive function. Though other cognitive scores declined over time in each group, there was no difference between the surgical and medically managed groups, indicating that these were attributable to the natural progression of PD.

Conclusions:: Our study demonstrated impairment in the selective cognitive task of verbal fluency and a trend towards impairment in attention, with no other major significant neuropsychological outcomes attributable to STN DBS. We postulate that these effects on fluency and attention are attributable to STN stimulation and modulation of the fronto-striatal circuits. DBS of STN can be considered safe from the cognitive viewpoint in patients with idiopathic Parkinson’s disease.
BIBLIOGRAPHIC REVIEW OF THE ALTERATION IN THE ELEMENTS OF MOVEMENT HUMAN IN PERSONS WITH MULTIPLE SCLEROSIS

German Augusto Baquero Sastre
Manuela Beltran University, Physical Therapy, Bogota, Colombia

Background and Aims:: The Multiple Sclerosis is a disease with affection of diverses elements of human movement for the process of affection of myelin and in this context exist impacts in the tone, coordination, balance, posture and sensibility that in the evolution of diseases have negative implications in the chronic and progressive course of disease for the functionality and the interaction of the persons with the environment

Methods:: This investigation is a bibliographic review around alteration in the elements of human movement in multiple sclerosis, the data base was Sciences Direct, Ebsco, Pubmed, and Elsevier, the key words in the search was multiple sclerosis and human movement alterations, multiple sclerosis and functionality and the criterias of selection was original article with full text with publication in the last 10 years

Results:: In the investigation has 12 Articles, of this 7 was experimental study, 3 was no experimental studies, 1 was correlational study, an 1 article was analytic study. The principal elements with negative implications was the tone, sensibility, functional capacities, posture, coordination, balance, gait and endurance

Conclusions:: The principal implications in the human movement for the multiple sclerosis for alterations in the myelin are in the tone that generate negative impacts for the functional capacities, posture, balance and gait and in this points are more big the alterations for the problems in the coordination producing a interaction in the problems of tone and the coordination for the human movement in persons with multiple sclerosis in the progressions of diseases
THE PROGNOSTIC VALUE OF G325R GBA MUTATION ON THE LONG-TERM DEEP BRAIN STIMULATION OUTCOME IN PARKINSON’S DISEASE

Claudia Ledda1,2, Carlo Alberto Artusi1,2, Maurizio Zibetti1,2, Marco Bozzali1,2,3, Elisa Montanaro2, Alberto Romagnolo1,2, Gabriele Imbalzano1,2, Mario Giorgio Rizzone1,2, Leonardo Lopiano1,2
1University of Torino, Department Of Neuroscience “rita Levi Montalcini”, Turin, Italy, 2A.O.U. Città della Salute e della Scienza di Torino, Neurology 2 Unit, Turin, Italy, 3Brighton and Sussex Medical School, 7) department Of Neuroscience, Falmer, United Kingdom

Background and Aims:: GBA mutations are the most common genetic risk factor for Parkinson’s disease (PD), which are typically observed in younger and cognitively more impaired individuals. However, only a few GBA variants described in PD (n=130) have been associated with patients’ clinical phenotype. We describe here the case of a rare GBA mutation who was followed-up for over 20 years.

Methods:: A 32-year-old lady was diagnosed with early-onset PD in 1998 for the presence of rigidity, bradykinesia, constipation, and episodic urinary incontinence. Five years later she developed severe motor fluctuations for which, in 2007, she underwent bilateral subthalamic Deep-Brain-Stimulation (DBS) surgery. She was genetically screened using an extensive panel.

Results:: DBS resulted in remarkable improvement of both motor and nonmotor PD symptoms. Two years after lead implantation, in 2009, our patient developed psychiatric symptoms for which she received a diagnosis of bipolar disorder. Nonetheless, psychiatric symptoms remained well compensated over time. Fourteen years after DBS, motor symptoms and complications were still well controlled, apart from mild dyskinesia, and there was no evidence of cognitive decline on neuropsychological testing. Genetics revealed the presence of heterozygous GBA mutation c.1090G>A–p.(Gly364Arg) (G325R), which was previously reported in severe forms of Gaucher disease and in a single case of PD.

Conclusions:: In contrast to most common GBA variants, G325R, albeit infrequent, associates with a benign disease course and long-lasting response to DBS. Although the underlying neurobiological mechanisms remain to be clarified, the prognostic value of different GBA variants should be analyzed to inform prognosis and response to DBS.
MOVEMENT DISORDERS RELATED TO PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA: 
TWO NOVEL CASES AND A LITERATURE REVIEW

Piergiorgio Grillo1, Francesca Di Giuliano2, Roberto Massa1, Nicola Mercuri1, Tommaso Schirinzi1
1University of Roma Tor Vergata, Neurology Unit, Department Of Systems Medicine, Roma, 
Italy, 2University of Roma Tor Vergata, Neuroradiology Unit, Department Of Biomedicine And Prevention, 
Roma, Italy

Background and Aims:: Primary CNS Lymphoma (PCNSL) is a rare and aggressive extranodal non- 
Hodgkin lymphoma (NHL), occurring either in immuno-deficient or immuno-competent subjects. It is often 
located in subcortical areas, often accounting for motoric disorders. Here, we reviewed PCNSL-related 
 movement disorders (MDs), outlining the main features, in order to improve the clinical management of 
the condition.

Methods:: We conducted a retrospective analysis on a cohort of patients with PCNSL presenting with 
MDs, including all existing cases identified by a systematic literature review (source: Medline; period: 
1946-2020) and two unreported cases. Data on phenomenology, neuroimaging, pathology, and clinical 
course were collected.

Results:: We included 13 patients from eleven previous reports and two novel unreported cases from our 
center, for a total of 15 subjects. We observed that the most frequent PCNSL-related MD was a 
parkinsonian syndrome, appearing at about 60 years of age, unresponsive to levodopa, associated with 
other neurological signs. Chorea, dystonia, and dyskinesia were rarer, and presented some degree of 
responsiveness to symptomatic treatments. PCNSL was localized in basal ganglia in most cases. MDs 
often ameliorated after tumor mass reduction.

Conclusions:: This study defined the main features of PCNSL-related MDs, providing useful clues 
especially to early diagnose the disease. In fact, since the therapeutic scenario of PCNSL is changing, a 
timely diagnosis is crucial to ensure adequate treatments to patients.
ANALYSIS OF DYSGRAPHIA IN ADVANCED PARKINSON’S DISEASE PATIENTS FOLLOWING BILATERAL STN-DBS – A PROSPECTIVE STUDY

Swapnil Kolpakwar¹, Rajesh Alugolu¹, Mudumba Vijayasardhi¹, Rukmini Kandadai², Rupam Borgohain²
¹Nizam’s institute of medical sciences, Department Of Neurosurgery, Hyderabad, India, ²Nizam’s Institute of Medical Sciences, Department Of Neurology, Hyderabad, India

Background and Aims:: Parkinson’s disease is characterized by varying intensities of bradykinesia, rigidity and tremor leading to disturbances in writing skills of the patient. We undertook this study to evaluate dysgraphia features in advanced Parkinson’s disease cases and changes in these features after bilateral Subthalamic Nucleus Deep Brain Stimulation.

Methods:: All idiopathic PD cases who underwent DBS at our centre were included in this study. Patients were assessed preoperatively for dysgraphia by analysis of handwriting in OFF phase by a single investigator on bedside testing. For quantification of micrographia, vertical length of first letter and width of the word written was calculated. An analysis of legibility of handwriting was also done for all patients using Fahn-Tolosa-Marin Tremor Rating Scale (FTMTRS). Patients were analysed for dysgraphia at 6 months post-surgery in Drug OFF phase and outcomes were correlated with baseline parameters.

Results:: There were a total of 51 patients who were included in our study. Significant reduction was noted in postoperative UPDRS III scores (P = 0.0001). Age more than 65 years was associated with less improvement in FTMTRS Scores. Prevalence of micrographia reduced in postoperative period, but the difference was not statistically significant. Mean FTMTRS score in preoperative OFF phase and postoperative OFF phase was 2.38 + 0.74 and 1.61 + 1.03 respectively. Difference in pre and post-surgery FTMTRS scores was found to be statistically significant (P =0.0001).

Conclusions:: Subthalamic Nucleus Deep Brain Stimulation results in substantial improvement in handwriting skills of patient particularly in cases with age less than 65 years.
COMMON FACTORS REDUCING SLEEP QUALITY OF PATIENTS WITH PARKINSON’S DISEASE IN KYRGYZSTAN.

Ayzhamal Il’Yazova¹, Cholpon Shambetova²
¹Movement Disorders and Parkinson’s Disease Alliance of CIS countries, Movement Disorder Clinic, Bishkek, Kyrgyzstan, ²Movement Disorders and Parkinson’s Disease Alliance of CIS countries, Clinical Hospital Of The Administrative Department Of Presidential And Government Affairs Of The Kyrgyz Republic, Bishkek Medical Clinic, Bishkek, Kyrgyzstan

Background and Aims:: Patients with PD often suffer from sleep disorders, which may be caused by nocturnal symptoms, early morning symptoms, painful leg cramps, vivid dreams, nightmares, etc. Aim is to identify common factors that reduce sleep quality in patients with Parkinson’s disease (PD) in Kyrgyzstan.

Methods:: 29 PD patients participated in the survey, conducted at movement disorder clinic in Bishkek, 18 males and 11 females. The mean age was 66.59+/−8.753(48-85) years. Pittsburgh Sleep Quality Index (PSQI) questionnaire was used in the paper-based study.

Results:: Most of participated patients indicated sleep disturbances (93%), while only 2 of the 29 respondents had optimal sleep indices (4 points). Some responses showed a discrepancy between the subjective sleep assessment and their total PSQI score. Thus, 86% patients with a score over 5 points assessed the quality of their sleep as “fairly good”. Figure 1 shows the overall results of each patient who participated in the study.

Table 1 indicates a detailed analysis of PSQI component #5 responses, where the most common sleep issues are waking up in the middle of the night or early morning (69%), waking up for using the bathroom (66%), failing to fall asleep within 30 minutes (45%).
Only 21% of the patients indicated having breathing problems, and 31%—sleep problems associated with pain during the past month period. **Conclusions:** Sleep disturbances affect the majority of participated PD patients. Sleep problems are caused mainly by early morning symptoms, nocturnal symptom, and trouble with falling asleep, directly affecting the amount and quality of sleep. Further study of the matter is crucial due to its influence on patients’ quality of life.
RESCUE OF STRIATAL LONG-TERM DEPRESSION BY CHRONIC MGLU5 RECEPTOR NEGATIVE ALLOSTERIC MODULATION IN DISTINCT DYSTONIA MODELS

Paola Imbriani¹,², Giuseppina Martella¹,², Paola Bonsi¹, Giuseppe Sciamanna¹, Huu Phuc Nguyen³, Libo Yu-Taeger³,⁴, Manfred Schneider⁵, Sonia Poli⁵, Robert Lutjens⁵, Antonio Pisani⁶,⁷
¹IRCCS Fondazione Santa Lucia, Laboratory Of Neurophysiology And Plasticity, Rome, Italy, ²Tor Vergata University Of Rome, Department Of Systems Medicine, Rome, Italy, ³Ruhr University Bochum, Department Of Human Genetics, Medical Faculty, Bochum, Germany, ⁴University Of Tuebingen, Institute Of Medical Genetics And Applied Genomics, Tuebingen, Germany, ⁵Addex Therapeutics, Addex Therapeutics, Geneva, Switzerland, ⁶University Of Pavia, Department Of Brain And Behavioral Sciences, Pavia, Italy, ⁷IRCCS Fondazione Mondino, Neurology And Neurorehabilitation, Pavia, Italy

Background and Aims:: An impairment of long-term synaptic plasticity is a peculiar endophenotype of distinct forms of dystonia. We previously demonstrated a complete loss of corticostriatal long-term synaptic depression (LTD) in rodent models of two distinct isolated dystonias, resulting from mutations in the TOR1A (DYT1), and GNAL (DYT25) genes. Broad-spectrum antimuscarinic drugs are used to counteract abnormal striatal acetylcholine-mediated transmission, which plays a crucial role in dystonia pathophysiology. The aberrant excitability of striatal cholinergic cells can also be modulated by group I metabotropic glutamate receptor subtypes. Here, we tested the efficacy of the negative allosteric modulator of mGlu5 receptor (dipraglurant) on striatal LTD.

Methods:: Tor1a¹/∆GAG mice and GNAL¹⁻⁰⁻⁻ rats were randomly divided into four groups and injected intraperitoneally with either dipraglurant (50 mg/kg) or vehicle (ringer lactate) for 7 days. Then, the animals were sacrificed for electrophysiological recordings of striatal spiny projection neurons (SPNs), performed through conventional sharp technique.

Results:: Whereas acute treatment failed to rescue LTD, chronic dipraglurant rescued this form of synaptic plasticity both in DYT1 mice and GNAL rats. The pharmacokinetic profile of dipraglurant revealed a relatively short half-life, uncovering a peculiar time-course of recovery based on the timing from last dipraglurant injection. Indeed, SPNs recorded within 2 hours from last administration showed full expression of LTD, whilst the extent of recovery progressively diminished when SPNs were recorded 4-6 hours after treatment.

Conclusions:: Our findings suggest that distinct dystonia genes may share common signaling pathway dysfunction and that dipraglurant might be a potential novel therapeutic agent for this disabling disorder.
DEFINITION OF PARKINSON’S DISEASE AND ESTIMATION OF ITS INCIDENCE BASED ON NATIONWIDE PRESCRIPTION- AND DIAGNOSTIC DATA

Julia Tuominen¹, Jannicke Igland¹, Julia Romanowska¹, Trond Riise¹, Kjetil Bjørnevik²
¹University of Bergen, Department Of Global Public Health And Primary Care, Bergen, Norway, ²Harvard University, T.h. Chan School Of Public Health, Boston, United States of America

Background and Aims:: Health registers that cover entire Nordic nations present a valuable source of data for epidemiologic research. However, identification of incident cases based on register data is especially challenging for Parkinson disease (PD) due to the lack of a clinical gold standard and the existence of diseases with similar symptomatology. Some registered PD diagnoses may therefore be erroneous. Similarly, records of filled antiparkinsonian medicines may reflect other treatment indications or testing the presence of PD pathology. Our aim was to validate and facilitate the use of Norwegian Prescription Database (NorPD) and Norwegian Patient Registry (NPR) in epidemiologic research on PD by evaluating the congruence of information in these registers and by suggesting algorithms for identifying probable PD patients. The incidence of PD in Norway is also estimated.

Methods:: Cohen's Kappa and receiver operating characteristic (ROC) analysis with Youden index were employed.

Results:: The number of PD diagnoses and levodopa prescriptions were highly mutually predictive. Specificity of 0.90 and sensitivity of 0.92 were obtained when identifying individuals with >= 4 primary PD diagnoses based on having filled >= 4 levodopa prescriptions. The annual incidence rate corresponded to those generally reported in countries with similar demographic structure.

Conclusions:: The high correlation between diagnoses and prescriptions most likely reflects the process of testing treatment efficacy to verify the diagnosis. It also suggests the sufficiency of selecting PD patients based on information from either register alone in future studies. A clinically well-defined patient cohort is needed for further validation.
THE NEUROPROTECTIVE EFFECTS OF GINKGOLIDE K ON MPTP MICE

Qiang Miao¹, Xiao-Hui Li¹, Jing Wang¹², Qing Wang¹, Zhi Chai¹, Yan-Qing Li¹, Li-Juan Song¹², Jie-Zhong Yu¹,², Tao Meng³, Jian-Jun Huang⁴, Bao-Guo Xiao⁵, Cun-Gen Ma¹²,³
¹Shanxi University of Chinese Medicine, Research Center Of Neurobiology / The Key Research Laboratory Of Benfiting Qi For Acting Blood Circulation Method To Treat Multiple Sclerosis Of State Administration Of Traditional Chinese Medicine, Jinzhong, China, ²Shanxi Medical University, Physiology/neurology, Taiyuan, China, ³Shanxi Datong University, Institute Of Brain Science / Shanxi Key Laboratory Of Inflammatory Neurodegenerative Diseases, Datong, China, ⁴General Hospital of National Medicine and Datong Coalmine, Neurosurgery, Datong, China, ⁵Fudan University, Institutes Of Brain Science And State Key Laboratory Of Medical Neurobiology, Shanghai, China

Background and Aims:: Ginkgolide K (GK), a natural product isolated from Ginkgo biloba, exhibited an ability to promote the clearance of α-synuclein in A53T mutation cells, implying it may be a potential agent for Parkinson’s disease. However, it has not been reported whether GK can protect MPTP-induced dopaminergic neuron damage. Our aim was to observe the therapeutic potential and possible mechanisms of GK for protecting dopaminergic neurons through MPTP-induced PD model.

Methods:: PD model was induced by intraperitoneal injection of MPTP into male C57BL/6 mice, followed by GK treatment (20 mg/kg/day) for 7 consecutive days at the end of modeling. The motor coordination in mice was measured with the DigiGait system. The brain histopathological changes were determined by immunofluorescence staining. Peripheral immune changes of T cells and α-synuclein antibody were observed by flow cytometry and ELISA respectively.

Results:: GK ameliorated the gait dysfunction and dopaminergic neuron loss when mice were upon acute MPTP exposure. Simultaneously, GK switched microglia to M2 phenotype and decreased the microglia-mediated inflammation. GK treatment also inhibited peripheral CD4⁺IFN-γ⁺ and CD4⁺IL-17⁺ T cells and α-synuclein specific autoantibodies in MPTP mice.

Conclusions:: GK exerts a protective effect on dopaminergic neurons, which is related to the regulation of microglia polarization, the inhibition of inflammatory response modified by microglia, and the suppression of peripheral immune responses. (NNSF of China 81473577, 81971194; The Key Laboratory of Medicinal Resources and Natural Pharmaceutical Chemistry of Ministry of Education, Shaanxi Normal University 2019004. Ma and Xiao are corresponding authors)
PROSPECTIVE ANALYSIS OF MOTOR MANIFESTATIONS FOLLOWING STN-DBS AND THEIR CORRELATION WITH ELECTRODE POSITION

Rajesh Alugolu¹, Mudumba Vijayasaradhi¹, Swapnil Kolpakwar¹, Rukmini Kandadai², Rupam Borgohain²
¹Nizam’s institute of medical sciences, Department Of Neurosurgery, Hyderabad, India, ²Nizam’s Institute of Medical Sciences, Department Of Neurology, Hyderabad, India

Background and Aims:: Deep brain stimulation (DBS) has been proven to be a safe, reversible, cost effective procedure for treatment of Parkinson’s disease. Final electrode position remains a significant factor in determining the outcomes of STN-DBS. This study aims to analyze the final lead position in three-dimensional plane and its effect on motor outcomes in cases operated for STN-DBS.

Methods:: Patients of advanced Parkinson’s disease who underwent bilateral STN DBS were prospectively followed for improvement in gross motor outcomes at 6 months. Postoperative outcomes were correlated with final electrode position.

Results:: A total of 64 Patients (128 leads) were analyzed. There were 47 (73.44%) males and 17 (26.56%) females. The mean age of the patients was 57.23 ± 9.70 years (Range 36-83 years). Patients who were less than 65 years of age at time of surgery had more significant reduction in UPDRS III (p = 0.02). Cases with medio-lateral deviation of left x less than 3 mm had significant reduction in UPDRS III (p = 0.05) and speech sub-scores (p = 0.05). Deviation less than 2 mm in left x was significantly associated with more than 50% reduction in gait sub-scores (p = 0.04). Optimal placement of right y electrode was significantly associated with reduction in UPDRS III in postoperative period (P = 0.02).

Conclusions:: Subthalamic nucleus deep brain stimulation results in significantly improved functional outcome particularly in patients with age less than 65 years. Accurate final electrode position in relation to proposed target is associated with maximum clinical benefit.
THE ROLE OF REPAIR GENES IN THE PATHOGENESIS OF PARKINSON'S DISEASE

Maria Nikitina¹, Nadezhda Babushkina², Elena Bragina², Valentina Alifirova¹, Densema Gomboeva², Ekaterina Koroleva¹, Elena Devyatkin²
¹Siberian State Medical University, Neurology And Neurosurgery, Tomsk, Russian Federation, ²Tomsk NRMC, Institute Of Medical Genetics, Tomsk, Russian Federation

Background and Aims:: At least 14 genes are known to have mutations leading to the development of Parkinson’s disease (PD). The presence of modifying effects of a number of associated genes and environmental influences has been proved [Hamza et al.,2010]. The aim of our study was to research the association of repair genes with PD.

Methods:: Two groups were studied (homogeneous by gender, age): I – 109 patients with Parkinson’s disease (PwPD) (mean age: 66.3±9.6; onset age: 58.16±9.55; H&Y stages 1–4), II – demographically-homogeneous population control group without PD (433 people: 51% men; 49% women). Comparing groups of PwPD with a population sample provides a number of advantages, since when comparing with a population control, the probability of obtaining false-positive results is significantly less than when comparing samples of PwPD with healthy ones. The clinical and neuropsychological assessment was performed.

Results:: An associative analysis of 8 SNPs in genes encoding proteins of various repair systems was performed: TP53BP1 (rs560191), NBN (rs1805800, rs709816), MRE11 (rs473297), ATM (rs189037, rs1801516), MLH1 (rs1799977), PMS2 (rs1805321). Gene products NBN, MRE11, ATM, TP53BP1 participate in the repair of double-stranded DNA breaks; genes MLH1, PMS2 are involved in mismatch repair processes. Statistically significant differences between the group of PwPD and the population sample in the frequencies of alleles and genotypes were found for rs1805800 (gene NBN), rs1801516 (ATM), rs1799977 (MLH1), (p<0.001).

Conclusions:: Thus, the association of polymorphism of repair genes with the development of PD was revealed, which indicates their involvement in the development of neurodegenerative disease. It is necessary to study these relationships further in a larger sample of PD patients.
THE PROTECTIVE EFFECT OF GINKGOLIDE B ON MPTP-INDUCED PARKINSON MICE

Jun-Jun Yin¹, Qiang Miao¹, Qing Wang¹, Jing Wang¹,², Xiao-Hui Li¹, Wen-Yuan Ju¹, Zhi Chai¹, Li-Juan Song¹,², Jie-Zhong Yu¹,³, Jian-Jun Huang⁴, Bao-Guo Xiao⁵, Cun-Gen Ma¹,²,³

¹Shanxi University of Chinese Medicine, Research Center Of Neurobiology / The Key Research Laboratory Of Benefiting Qi For Acting Blood Circulation Method To Treat Multiple Sclerosis Of State Administration Of Traditional Chinese Medicine, Jinzhong, China, ²Shanxi Medical University, Physiology/neurology, Taiyuan, China, ³Shanxi Datong University, Institute Of Brain Science / Shanxi Key Laboratory Of Inflammatory Neurodegenerative Diseases, Datong, China, ⁴General Hospital of National Medicine and Datong Coalmine, Neurosurgery, Datong, China, ⁵Fudan University, Institutes Of Brain Science And State Key Laboratory Of Medical Neurobiology, Shanghai, China

Background and Aims:: Parkinson's disease (PD) is caused by progressive loss of dopaminergic (DA) neurons in the substantia nigra pars compacta (SNpc). Ginkgolide B (GB) is an important active ingredient of Ginkgo biloba, and plays an important role in anti-oxidation and nerve protection. Our aim was to observe the therapeutic potential of GB in PD mode and explore its possible mechanism of action.

Methods:: In vitro cell experiment, SH-SY5Y cells were divided into control group, MPP+ group and GB group. In animal model, mice were divided into normal group, PD group and PD+GB group, in which mice received GB by intraperitoneal injection at the beginning of the second week for 7 consecutive days.

Results:: Compared with the control group, GB promoted the expression of TH in SH-SY5Y induced by MPP+. Compared with MPTP-PD mice, GB effectively relieved motor symptoms and increased TH+ expression in SNpc. Similarly, TH protein expression was enhanced in GB brain extracts. Immunohistochemical staining showed that GB inhibited the abnormal activation of microglia and astrocytes. Compared with the model group, GB inhibited the expression of TLR4 on microglia and astrocytes, decreased the expression of TNF-α, inhibited iNOS expression in activated microglia.

Conclusions:: GB inhibits DA neuron damage, improved the clinical symptoms of PD, which is related to the inhibition of microglia and astrocyte-mediated neuroinflammatory responses, and the polarization of M2 microglia. (NNSF of China 81473577, Open Projects of The Key Laboratory of The Ministry of Education 2019004 and Chinese Academy of Sciences 2020-MDB-KF-09, China Postdoctoral Science Foundation 2020M680912, Ma and Xiao are corresponding authors)
SPECTRUM OF MOVEMENT DISORDERS AMONG CHILDREN WITH SUBACUTE SCLEROSING PANENCEPHALITIS (SSPE): A CROSS-SECTIONAL STUDY

Divyani Garg¹, Vanshika Kakkar², Dipti Kapoor², Suvasini Sharma³, Sharmila Mukherjee³, Harish Pemde³
¹Lady Hardinge Medical College, New Delhi-110001, Neurology, New Delhi, India, ²Lady Hardinge Medical College, Pediatrics, New Delhi, India, ³Lady Hardinge Medical College, Pediatrics (neurology Division), New Delhi, India

Background and Aims:: Subacute sclerosing panencephalitis (SSPE) is a rare neurodegenerative disorder due to persistent mutant measles virus infection, affecting children and young adults. Although movement disorders are known to occur in SSPE, their spectrum is poorly described in literature. We aimed to assess spectrum of movement disorders associated with pediatric SSPE.

Methods:: We conducted a single-center cross-sectional study and enrolled consecutive children (1 month-18 years) with SSPE who fulfilled modified Dyken criteria. We collected demographic, clinical and laboratory features and modified Rankin score (mRS) and Jabbour stage at presentation. All children were exhaustively examined for movement disorders.

Results:: We enrolled 30 children (20 males; 66.7%). Median age at presentation and onset was 5.4 (range: 2.5-14) years and 4.65 (1.5-14) years. Median duration of illness was 3 (0.3-36) months. Median mRS at presentation was 4 (2-5) and Jabbour staging 2 (1-3). Presenting complaints included myoclonus (n=28; 93.3%), cognitive issues (26; 86.7%), recurrent falls (12; 40%), seizures (10; 30%) and ataxia (5; 16.7%). Of these, 13 (43.3%) patients demonstrated movement disorders other than myoclonus. These included chorea/athetosis (4; 13.3%), tremor (3; 10%), parkinsonism (3; 10%), dystonia (2; 6.7%) and repetitive behaviors (2; 6.7%). There were no significant differences in terms of age at onset, sex, duration of illness or non-movement disorder clinical features among children with SSPE with and without movement disorders.

Conclusions:: Movement disorders are a common clinical feature among children with SSPE. This possibility must be considered among children presenting with movement disorders, especially in combination with myoclonus and cognitive impairment.
HYDROXYFASUDIL AMELIORATES PARKINSON’ S DISEASE POSSIBLY THROUGH ANTI-INFLAMMATION AND NEUROPROTECTION

Guo-Guo Chu¹, Jing Wang¹,², Guang-Yuan Han¹, Zhu-Yue Miao¹, Qing Wang¹, Li-Juan Song¹,², Zhi Chai³, Hong-Zhen Zhang¹, Jie-Zhong Yu¹,², Jian-Jun Huang⁴, Bao-Guo Xiao⁵, Cun-Gen Ma¹,²,³

Background and Aims:: Fasudil is effective in the treatment of Parkinson’s disease(PD). But its fast metabolism and narrow safety window limit the clinical application. Hydroxyfasudil, active metabolite of Fasudil in vivo, exhibits higher Rho kinase selectivity and longer half-period. Our aim was to observe the therapeutic potential of Hydroxyfasudil in PD, and explore its possible mechanisms.

Methods:: PD model was induced by intraperitoneal injection(ip) of MPTP into male C57BL/6 mice, which were divided into MPTP group, Hydroxyfasudil group. Hydroxyfasudil was injected (40mg/kg/day) for one week from the second week. The injection of saline was set up as control in a similar manner.

Results:: Hydroxyfasudil effectively improved the motor symptoms of PD mice, and resulted in a significant attenuation of dopamine cell loss. Hydroxyfasudil also reduced the cytokines TNF-α, IL-6, IL-1β which were produced by Lipopolysaccharide(LPS)-induced BV2 cells and bone marrow-derived macrophages in vitro. Meanwhile, Hydroxyfasudil inhibited inflammatory response with the transformation of inflammatory M1 to anti-inflammatory M2 microglia, decreased the activation of TLR4. Compared with the MPTP group, the astrocytes and neurons in the Hydroxyfasudil group expressed more BDNF and GDNF (p<0.05).

Conclusions:: Hydroxyfasudil reduces the loss of dopaminergic neurons in the substantia nigra and improves motor symptoms by inhibiting inflammation and promoting the secretion of neurotrophic factors. (NNSF of China 81473577, Open Projects of The Key Laboratory Of The Ministry of Education 2019004 and Chinese Academy of Sciences 2020-MDB-KF-09, China Postdoctoral Science Foundation 2020M680912, Ma and Xiao are corresponding authors)
SEXUAL DIVERGENCIES IN MONOAMINERGIC PROJECTIONS IN PARKINSON’S DISEASE: A 123I-FP-CIT SPECT STUDY

Stefano Masciocchi¹, Andrea Pilotto¹, Enrico Premi¹, Maddalena Toffali¹, Alberto Imarisio¹, Paghera Barbara², Alessandro Padovani¹
¹University of Brescia, Department Of Neurology, Brescia, Italy, ²ASST Spedali Civili di Brescia, Nuclear Medicine, Brescia, Italy

Background and Aims:: Background: preclinical and clinical studies suggest sex as important modulator of Parkinson’s disease presentation and progression. No studies largely evaluate sexual dimorphism in monoaminergic pathways in healthy subjects and Parkinson’s disease. Purpose: To investigate sex differences in nigrostriatal and extrastriatal 123I-FP-CIT SPECT monoaminergic projections in healthy subjects and Parkinson’s disease (PD)

Methods:: Established PD patients and 123I-FP-CIT SPECT imaging entered the study. Differences in 123I-FP-CIT binding between male and female healthy subjects and PD patients were separately evaluated by using whole brain SPM analyses adjusting for the effect of age, UPDRS-III and disease duration.

Results:: One-hundred forty-nine PD patients and 77 controls entered the study and underwent 123I-FP-CIT SPECT imaging. SPM analysis revealed higher binding in female in basal ganglia (p=0.001) and thalamus (p=0.001) in controls and PD patients. Conversely, male subjects (patients as well as controls) showed higher binding in frontal lobes and brainstem (p=0.001) compared to females.

Conclusions:: Conclusion: Healthy subjects and PD patients have similar sexual dimorphisms in monoaminergic pathways, suggesting that the impact of sex on incidence and progression of PD is driven by constitutional dimorphism rather than disease-specific alterations in dopaminergic and serotonergic systems.
PAIN AND BIOMECHANICAL CHANGES IN PATIENTS WITH PARKINSON’S DISEASE.

Olga Kurushina, Alexandr Barulin
Volgograd State Medical University, Neurology, Neurosurgery, Medical Genetics, Volgograd, Russian Federation

Background and Aims:: There are a lot of pain syndromes of different localization in patients with Parkinson's disease (PD). This issue dedicated to the investigation of the pathogenesis of pain in PD.

Methods:: The study involved 243 patients with Parkinson's disease at different stages. To study the phenomenon of pain and comorbid disorders biomechanical tests, visual-analogue scale, the scale of "Quality of Life" were made.

Results:: Pain syndromes were detected in 221 patients (90.9%) with PD. The pain in the back - in 137 (56.4%) cases, headache - in 93 (38.3%) cases, mix pain - in 57 (23.5%) patients. A direct correlation between the types of pain and disease duration was demonstrated. Intensity of back pain was 7.1 ± 0.6 points, headache - 5.3 ± 1.1 points, widespread musculoskeletal pain - 6.9 ± 0.7 points. In patients with stage 1 - 5.1 ± 0.6 points, second - 6.8 ± 0.8 points, and the third - 7.5 ± 0.3 points. Chronic pain - 59 (24.3%) persons. The growth of chronic pain increases with the duration PD the disease. Biomechanical changes: spinal scoliosis - 76.1%. Asymmetry (frontal and sagittal planes) - in 236 (97.1%) patients, a violation of posture in conjunction with a change in the symmetry of shoulder girdle, shoulder blades - 203 (83.5%) of participants.

Conclusions:: The pain has a significant negative impact on the course of Parkinson's disease and quality of life of these patients. It is shown that pathogenesis of pain is due to biomechanical changes, that indicates the need for correcting the biomechanical disorders.
ADULT ONSET SPORADIC CHOREA: A SINGLE-CENTRE RETROSPECTIVE STUDY

Roberta Bovenzi¹, Matteo Conti¹, Rocco Cerroni¹, Mariangela Pierantozzi¹, Alessandro Stefani¹, Antonio Pisani², Nicola Mercuri¹, Tommaso Schirinzi¹
¹Policlinico Tor Vergata, University of Rome “Tor Vergata”, Neurology, Rome, Italy, ²Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy, N/a, N/A, Italy

Background and Aims:: Adult Onset Sporadic Chorea is a rare movement disorder due to several causes, including genetic, pharmacologic, metabolic and structural ones. Here we provided a retrospective analysis of adult patients with sporadic chorea admitted to a single Italian centre, in order to highlights those features that may assist in appropriate clinical management.

Methods:: 11071 medical charts of patients admitted to the Neurology Unit of Tor Vergata University Hospital (Rome, Italy) during a nine years long period (2012-2020) were reviewed, identifying 28 patients with Adult Onset Sporadic Chorea (genetic forms excluded). Data regarding phenomenology, diagnostic workup, aetiology, treatments, and long-term outcome from this cohort were collected and analysed.

Results:: Adult Onset Sporadic Chorea occurred more frequently in females and presented with an acute-subacute onset. Cerebrovascular diseases accounted for 68% of aetiology; further causes were structural brain lesions, autoimmunity and others movement disorders syndromes. Clinical course was mild, with spontaneous resolution or minimal disturbances in 82% of cases. Appropriate clinical examination alone allowed diagnosing the 14% of Adult Onset Sporadic Chorea, neuroimaging the 76% of them, and basic laboratory tests the 10%.

Conclusions:: This study described the main clinical features of adult patients with sporadic chorea, showing that the vascular aetiology was the most common and that females were most frequently affected. Although in the majority of cases Adult Onset Sporadic Chorea may run with mild clinical course and good response to symptomatic therapy, a fast diagnostic workup is essential to identify those threatening conditions requiring immediate treatments.
ACUTE ONSET HEMIBALLISMUS/HEMICHOREA DUE TO VARIOUS ETIOLOGIES: A CASE SERIES

Tugba Eyigurbuz, Zerrin Yıldırım, Nurhan Kaya Tutar, Nilufer Kale
Bagcılar Training and Research Hospital, Neurology, Istanbul, Turkey

Background and Aims:: Chorea is irregular, non-rhythmic, involuntary movements that can spread from one part of the body to another for a short time. Ballismus, on the other hand, is characterized with high amplitude choreic movements in the proximal extremities. The mechanism of acute hemichorea/hemiballismus has not been clearly explained. It is generally caused by lesions in the contralateral subthalamic nucleus (STN) and its afferent and efferent connections. Although vascular causes are the most common etiology, toxic-metabolic, inflammatory, infectious, demyelinating, and drug-induced causes have also been reported. Our aim is to present 6 patients with hemiballismus and/or hemichorea.

Methods:: The clinical and laboratory findings of six patients who came to outpatient clinics of Bagcılar Training and Research Hospital were retrospectively evaluated.

Results:: A 59-year-old male patient with thalamic hemorrhage due to cerebral amyloid angiopathy, a 67-year-old male patient with nonketotic hyperglicemia, a 59-year-old male patient with hypertensive thalamic hemorrhage, a 72-year-old male patient with infarction of left parietal lobe, a 26-year old female patient with demyelinating disease, a 75-year-old male patient with a history of flu medication usage were presented with hemichorea and/or hemiballismus. Three patients was started haloperidol treatment and one patient levetiracetam. Two patients were not given additional medication for chorea. Three of six patient showed full recovery.

Conclusions:: Hemichorea and/or hemiballismus may occur acutely and may result from etiologies that may require early intervention. More studies are needed to understand the pathophysiology, and particularly on managing treatment-resistant conditions.
INTRINSIC FUNCTIONAL CONNECTIVITY CORRELATES OF RBD IN COGNITIVELY UNIMPAIRED DRUG-NAIVE PARKINSON’S DISEASE PATIENTS

Simone Aramini1, Rosa De Micco1, Mattia Siciliano1,2, Federica Di Nardo1, Sara Satolli1, Giusy Caiazzo1, Fabrizio Esposito1,3, Gioacchino Tedeschi1, Alessandro Tessitore1

1University of Campania “Luigi Vanvitelli”, Department Of Advanced Medical And Surgical Sciences, Naples, Italy, 2University of Campania “Luigi Vanvitelli”, Neuropsychology Laboratory, Department Of Psychology, Caserta, Italy, 3University of Salerno, Scuola Medica Salernitana, Department Of Medicine, Surgery And Dentistry, Baronissi, Italy

Background and Aims:: REM Behavioural Disorder (RBD) is characterized by lack of skeletal muscle atonia during REM sleep and affects around 50% of patients with Parkinson’s disease (PD). PD patients with RBD present an increased risk of worse motor progression and dementia. We investigated intrinsic brain intra and inter-network connectivity correlates of RBD in a cohort of cognitively unimpaired drug-naive PD patients and correlated neuroimaging findings to clinical and cognitive measures.

Methods:: 3T MRI images of 56 drug-naive PD patients (25 PD-RBD and 31 PD-no-RBD) were acquired. RBD presence and severity were assessed by means of a clinical interview and the RBD Screening questionnaire (RBDSQ). Single-subject and group-level independent component analysis was used to investigate intra and inter-network functional connectivity differences within the default mode (DMN), frontoparietal (FPN), salience (SN) and executive control (ECN) networks between patients sub-groups. Linear regression analysis was used to investigate correlations between imaging and clinical data.

Results:: Compared to PD-no-RBD patients, PD-RBD showed an increased SN and ECN connectivity, a decreased FPN connectivity and both an increased and a decreased DMN connectivity. This imaging pattern was correlated with both RBD severity and cognitive outcomes in PD patients.

Conclusions:: Abnormal intrinsic brain connectivity within and between the major neurocognitive networks may represent a potential neural correlate of RBD symptoms and severity in early PD patients. This aberrant connectivity is correlated with cognitive outcomes even in the absence of cognitive impairment and may potentially be proposed to develop a sensitive and early biomarker of dementia in PD.
SLEEP DISTURBANCES IN IDIOPATHIC PARKINSON’S DISEASE: RELATIONSHIP WITH AGE AT ONSET AND DISEASE DURATION.

Michela Sforza¹, Edoardo Bianchini¹, Francesco Pontieri¹, Silvia Galli¹, Domiziana Rinaldi¹, Marika Alborghetti²
¹Sapienza University of Rome, Neuroscience, Mental Health And Sensory Organs (nesmos), Rome, Italy, ²Sapienza, University of Rome. Sant’Andrea Hospital, Nesmos, Rome, Italy

Background and Aims:: Sleep disorders (SDs) are a common and disabling non-motor symptom (NMS) of Parkinson’s disease (PD), mostly in the form of REM-sleep behavior disorder. The PRIAMO study demonstrated that SDs are more frequently reported in patients with longer disease duration. In this retrospective study, we investigated the relationships between the occurrence of SDs, age at onset and disease duration.

Methods:: Medical records from 308 PD patients referring to our Movement Disorder Service between 2015 and 2020 were screened for the presence of SDs. This was defined as a score ≥2 in item 2 of the PD-Non Motor Symptoms Scale (NMSS). Patients were divided according to age at onset of motor symptoms (<65 years, n=157; 65-74 years, n=110; >74 years, n=41) and disease duration (≤10 years, n=187; >10 years, n=121).

Results:: Patients with age at onset <65 years displayed higher prevalence of SDs compared to the other two groups (75% vs. 62% vs. 46%; p<0.001). This difference was still significant considering the subgroups of patients with a disease duration ≤10 years (72% vs.54% vs. 43%; p=0.007) while there was no difference across all three groups in patients with a disease duration >10 years (79% vs. 77% vs. 67%; p=0.78).

Conclusions:: SDs are more prevalent in early-onset compared with later-onset PD patients. This difference disappears with disease progression while overall prevalence increases with disease duration.
ADHERENCE TO DRUG TREATMENT IN PATIENTS WITH PARKINSON'S DISEASE: EVALUATION OF A BRAZILIAN COHORT

Vanderson Carvalho Neri¹, Ayne Sepulveda², Marina Barreto², Thaina Lopes², Luiz Figueiredo²
¹Hospital Federal da Lagoa, Neurology, Rio de Janeiro, Brazil, ²Faculdade de Medicina de Campos, Neurology, Campos dos Goytacazes, Brazil

Background and Aims: Aims: To verify adherence to treatment and to identify intervening factors related to treatment abandonment or non-compliance with therapeutic guidelines among patients with Parkinson Disease (PD).

Methods: Descriptive, quantitative, observational epidemiological study Interview and application of questionnaires in PD attended between January 2019-July 2019; review of medical records. Hoehn&Yahr and Schwab-England Scale and knowledge and degree of adherence to drug therapy: Morisky and Green (1986) and Evaluation instrument for medication intake were evaluated. Considered adherent according to Morisky score between 6-8 [Figure 1].
Results:: Eighty-nine patients were interviewed, mean age was 68.8 years, 50.6% women. Regarding schooling, 47.2% had up to 4 years of training, 36% up to 12 years, 13.5% with more than 12 years. All the interviewees were using antiparkinsonian drugs. All of them used Levodopa / benzeraside, the most common formulation being 400/100mg / day (53.9%); 28% Pramipexole, 32.5% Amantadine, 8% Rasagiline (1mg/day) and 4% Selegiline (10mg/day). 48.3% of the patients used two to three drugs [Figure 2]. According to the Morisky Score were considered adherents to treatment 40 (44.9%) [Table 1].

According to the Evaluation instrument for medication intake, 19 (21.3%) have positive attitudes to maintain their treatment. There was a significant relationship between drug adherence and patient age (p = 0.02) and treatment time (p = 0.01).

Figure 1: Morisky Medication Adherence Scale (1986) and Evaluation instrument for medication intake (validated for Brazil).
Conclusions:

Most PD patients in this study did not fully adhere to the drug treatment. Patients with the lowest adhesion rate were those with greater age and longer disease duration. Social and family aspects and motor impairment of the disease did not influence the treatment.

FRONTAL CORTEX DEFICITS IN PARKINSON’S DISEASE PATIENTS VULNERABLE TO PAREIDOLIAS.

Gajanan Revankar1, Noriaki Hattori1, Yuta Kajiyama1, Tetsuya Shimokawa2, Tomohito Nakano1, Masahito Mihara3, Etsuro Mori1, Hideki Mochizuki1
1Osaka University, Neurology, Osaka, Japan, 2NICT, Osaka, Cinet, Osaka, Japan, 3Kawasaki Medical School, Neurology, Okayama, Japan

Background and Aims:: Parkinson’s disease (PD) patients susceptible to visual hallucinations experience prodromal events in the form of ‘pareidolias’. Pareidolias are visual phenomena wherein ambiguous forms appear meaningful due to incorrect perception. Here, we studied the brain and behavioral signatures of pareidolias that affect the fronto-parietal circuitry influencing visual processing.

Methods:: 21 PD patients and 10 age-matched healthy controls participated. Neuropsychological tests included evaluations for cognition, attention and executive functions. Pareidolias were evoked using a computerized noise pareidolia test with simultaneous EEG and eye-tracking measurement. PD patients were divided into those with pareidolias (N=10) and those without (N=11). Responses were evaluated ‘during’ and ‘preceding’ the presentation of stimuli. Eye movement behavior were measured using fixation metrics. EEG amplitudes were analyzed in the presaccadic phase. Finally, pre-stimulus EEG spectral connectivity were evaluated using graph networks.

Results:: PD patients with pareidolia were older and under-performed on neuropsychological tests. Eye-tracking data in this group showed longer fixation and visit durations, with EEG showing higher presaccadic potentials on frontal electrodes independent of saccade sizes. Pre-stimulus spectral EEG in the low-alpha (8-10Hz) range showed a tendency towards higher frontal activity, and graph networks demonstrated increased small-world properties with lower frontal degree centrality in the pareidolia group.

Conclusions:: Pareidolias in PD are due to abnormal top-down modulation of visual processing defined by (i) frontal cortex alterations affecting visual attention and guidance to ambiguous stimuli and (ii) network alterations in the pre-stimulus phase due to a dissonance between patients’ internally generated mental-processing with external stimuli.
COMPLETE REMISSION OF SYMPTOMS IN A CASE OF LANCE-ADAMS SYNDROME: A 17-YEAR FOLLOW-UP

Jose Ricardo Lopez Castellanos¹, Jose Lopez-Contreras²
¹University of Arkansas for Medical Sciences, Neurology, Little Rock, United States of America, ²Instituto Salvadoreño del Seguro Social, Clínica De Movimientos Anormales, Servicio De Neurología, San Salvador, El Salvador

Background and Aims:: Objective: To describe a case of Lance-Adams syndrome in a Movement Disorder Clinic in El Salvador. Background: Chronic post-hypoxic myoclonus, also known as Lance-Adams syndrome, is a rare complication of successful cardiopulmonary resuscitation.

Methods:: We report a case of Lance-Adams Syndrome followed for 17 years with periodic clinical evaluations, video recordings, Barthel Index scale and response to treatment.

Results:: A 50-year-old woman presented with acute intoxication by inhalation of carbamate, followed by bronchospasm, generalized seizures and cardiorespiratory arrest. Brain MRI and EEG were normal. Upon regaining consciousness, she presented spontaneous, action and reflex myoclonus and negative myoclonus, with significant impairment on her activities of daily living and mild cognitive impairment. She presented progressive clinical improvement in response to treatment with valproic acid, phenobarbital and clonazepam. After 4 years of treatment, cognitive impairment and movement disorder resolved, followed by a slow taper of all medications without reoccurrence of symptoms.

MCI: Mild Cognitive Impairment

Conclusions:: We report a case of Lance-Adams syndrome with complete remission of her symptoms after 4 years of treatment and has remained asymptomatic for 13 years after tapering off of medications to control myoclonic activity.
DOES NON-MOTOR PHENOTYPE OF ‘FREEZERS’ DIFFER FROM ‘NON-FREEZERS’ IN PARKINSON’S DISEASE? – A CROSS-SECTIONAL COMPARATIVE STUDY

Ashish Susvirkar
DIVINE LIFE HOSPITAL, KUTCH, Neurology, MUMBAI, India

Background and Aims:: Parkinson disease (PD) is a multi-system disorder having motor and often disabling non-motor manifestations. Pathophysiology of freezing of gait (FOG) seems to be extending beyond motor circuits, into sensory, cognitive and affective neuronal circuits; and, involvement of both dopaminergic and non-dopaminergic mechanisms underlying nonmotor symptoms seem to be involved in FOG also. Aim: To compare the difference in non-motor symptoms between PD patients with freezing of gait (freezers) & those without freezing of gait (non-freezers) matched for age, disease duration, levodopa equivalent doses (LEDD).

Methods:: a) PD-FOG group/ Freezers: Consecutive patients with clinically diagnosed PD (n= 50) using the standard diagnostic criteria (United Kingdom Parkinson’s disease Brain Bank Diagnostic Criteria- Hughes et al 1992) having FOG (diagnosed as per FOG Questionnaire)

b) PD- Non-freezers: PD Patients without FOG who are matched for age, disease duration and LEDD dosage with the PD-FOG group (n= 50). The assessment was done using UPDRS, Hoehn – Yahr scale and Non-motor symptoms assessment using Non-motor symptoms scale (NMSS).

Results::
The freezers group showed statistically significant higher score in domain 2, 3 and 9 which represent sleep/fatigue, mood/cognition, and miscellaneous entities (pain, taste, smell, weight change, excess sweating) respectively, and the total score. Freezers also had statistically significant higher depression scores (BDI).

**Conclusions:** There exists a different nonmotor phenotype in PD patients with FOG with higher nonmotor involvement.

Background and Aims:: Wuzi Yanzong Pill(WYP) has a potential therapeutic effect on Parkinson's Disease(PD) Mice, but the mechanism is not clear. To explore the therapeutic effect of WYP on PD mice and its regulation mechanism on UPR signaling pathway.

Methods:: PD mice were randomly divided into Normal, PD and WYP groups. WYP group were orally administrated with WYP for two weeks and the PD group were treated with same dosage of saline at the same time. Gait test were used to evaluate the behavioral performance. The positive expression of TH was detected by Immunohistochemical staining. The levels of GRP78, p-IRE1α, XBP1, p-PERK, p-eIF2α and ATF4 in brain were detected by Western Blot.

Results:: The results showed that WYP treatment increased the left forelimb angle and findlimb stride length(P<0.05), decreased the total paw area and hindlimb stance width(P<0.05), accompanied by the improvement of TH positive cells(P<0.01). Further observation found that WYP treatment reduced the expressions of GRP78, XBP1, p-PERK, p-eIF2α(P<0.01), ATF4 and p-IRE1α(P<0.05).

Conclusions:: Oral treatment with WYP can alleviate the behavioral and pathological changes in PD mice. Its mechanism may be related to the regulation of IRE1 and PERK signaling pathways.(Grants: NNSF of China 81102552 and 81703978, Central Government Guided Local Funding Projects for Science and Technology Development YDZX2020140001483, Returned Chinese Scholars Technology Activities Preferred Project, Shanxi Province of China 202000026, Natural Science Foundation of Shanxi Province 201901D111334, Key Research and Development Projects of Shanxi Province 201803D31209, Shanxi University Science and Technology Innovation Project 2019L0724.*corresponding authors: Prof. C.G. Background and Aims:: Wuzi Yanzong Pill(WYP) has a potential therapeutic effect on Parkinson’s Disease(PD) mice, but the effect to ERS-mediated apoptosis pathway in PD were not studied. To determine the therapeutic effect of WYP on PD mice and explore its mechanism.

Methods:: C57BL/6 mice were randomly divided into normal control, PD control, and WYP groups. The WYP group was orally administrated with WYP for 14 days while the normal and PD groups were treated with saline. The ethology were detected by open field and pole tests. The positive expression of TH was detected by Immunohistochemical method. Western Blot were used to detect the contents of Caspase-9, CHOP, ASK1, p-JNK, Caspase-3 and Caspase-12.

Results:: Compared with the model group, WYP reduced the pole climbing and total resting time(P<0.05), enhanced the total distant(P<0.01) and mean speed(P<0.05). TH+ neuron in substantia nigra increased after WYP treatment(P<0.05), while the levels of CHOP(P<0.01), Caspase-9 and Caspase-12 decreased(P<0.05). There was no statistically significant change in protein content of ASK1, p-JNK and Caspase-3 in all the three groups.

Conclusions:: WYP can improve the balance and coordination ability and alleviate the pathological changes in PD mice. Its mechanism may be related to inhibit the CHOP and Caspase-12 apoptosis pathways.(Grants: NNSF of China 81102552 and 81703978,Central Government Guided Local Funding Projects for Science and Technology Development YDZX20201400001483, Returned Chinese Scholars Technology Activities Preferred Project, Shanxi Province of China 20200026,Natural Science Foundation of Shanxi Province 201901D111334,Key Research and Development (R&D) Projects of Shanxi Province 201803D31209,Shanxi University Science and Technology Innovation Project 2019L0724.*corresponding authors: Prof. C.G. Background and Aims:: Network pharmacology is a biological network analysis method that combines systems biology, pharmacology and computer technology To explore the prevention and treatment of Wuzi Yanzong Pill(WYP) on Parkinson's Disease(PD) mice based on the PI3K/Akt signaling pathways.

Methods:: Network pharmacology was used to screen the potential signaling pathways of WYP in treating PD. PD model was established by MPTP. At the same time, oral administration of WYP was carried out twice a day for 14 consecutive days. Mice motor function was evaluated by Pole test. Expression of dopamine in brain tissue were detected by ELISA. The expression levels of tyrosine hydroxylase(TH) was determined by immunofluorescence analysis. Expression of PI3K, p-PI3K, Akt and p-Akt were determined by Western Blot.

Results:: The results of network pharmacology identified 125 candidate targets, and pathways analysis showed that the treatment mechanism for PD mainly involved HIF-1, PI3K/Akt signaling pathways, dopaminergic synaptic and insulin resistance pathways and so on. Behavioral test showed that the motor performance of mice was improved after WYP treatment. WYP enhanced the number of TH neurons and expression of dopamine (P<0.05). The expressions of p-PI3K and p-Akt were increased after WYP administration (P<0.05) in PD model.

Conclusions:: Maybe WYP protect dopamine neurons from loss in the MPTP mice model of PD through activation of PI3K/Akt signaling pathways.(Grants: NNSF of China 81102552 and 81703978, Central Government Guided Local Funding Projects for Science and Technology Development YDZX20201400001483, Natural Science Foundation of Shanxi Province 201901D111334, Shanxi University Science and Technology Innovation Project 2019L0724.*corresponding authors: Prof. C.G. 1Lady Hardinge Medical College, New Delhi-110001, Neurology, New Delhi, India, 2Christian Medical College, Neurology, Vellore, India, 3Post Graduate Institute of Medical Education and Research, Pediatrics, Chandigarh, India, 4Deenanath Mangeshkar Hospital and Research Center, Pediatric Neurology, Pune, India, 5Bharati Vidyapeeth Medical College, Pediatrics, Pune, India, 6KEM Hospital, Pediatrics, Pune, India, 7Jagannath Hospital, Pediatrics, Bhubaneswar, India, 8NIMHANS, Neurology, Bangalore, India, 9JN Medical College, Pediatrics, Belgaum, India, 10Maulana Azad Medical College, Pediatrics, Delhi, India, 11PD Hinduja Hospital, Pediatrics, Mumbai, India, 12Lady Hardinge Medical College, Pediatrics (neurology Division), New Delhi, India

Background and Aims:: Inherited hypermanganesemia (IH-Mn) is a rare inherited manganese (Mn) transport defect, characterized by two phenotypes due to mutations in SLC30A10 and SLC39A14 genes. We aimed to describe clinical, laboratory and genetic profile of children with IH-Mn.

Methods:: We conducted a multicentric retrospective study across 11 centers in India. We collected data pertaining to clinical, laboratory profile and treatment outcomes among children between 1 month-18 years of age with genetically confirmed/ clinically probable IH.

Results:: We enrolled 27 children from 20 families (19 girls). Fourteen harbored SLC39A14 mutations; nine had SLC39A14 mutations. The SLC39A14 cohort had lower median age at onset [1.3 (IQR 0.7-5.5) years] versus SLC30A10 cohort [2.9 (IQR 1.6-4.5) years]. The most frequent neurological features were dystonia (100%), gait abnormality (80.8%; n=21), falls (69.2%; n=18) and parkinsonism (61.5%; n=16). Median blood Mn levels among SLC39A14 [101.8 (IQR 28.5-200.0) mcg/L] were higher than SLC30A10 cohort [34.0 (23.9-100.0) mcg/L]. Median hemoglobin was higher in SLC30A10 [16.1 (IQR 15.2-17.5) g/dL] versus SLC39A14 cohort [11.7 (IQR 8.8-13.2) g/dL]. The SLC39A14 cohort had more severe disease evidenced by more frequent generalized dystonia, dependent ambulation and blood Mn. All children underwent chelation with disodium-calcium edetate. Children with SLC39A14 mutations had poorer response, scored on a Likert scale. Nine children were lost to follow-up.

Conclusions:: We describe the largest pediatric cohort of IH till date. Children with SLC39A14 mutations were younger, had more severe disease and poorer treatment response versus SLC30A10 mutations. There is emerging need to better define management strategies for these children.
PREFRONTAL ACTIVITY IMBALANCE AND ABERRANT RECONFIGURATION ACROSS FUNCTIONAL NETWORKS IN PATIENTS WITH PARKINSON’S DISEASE AND SOMATIC SYMPTOM DISORDER

Stefano Delli Pizzi, Raffaella Franciotti, Piero Chiacchiaretta, Antonio Ferretti, Astrid Thomas, Laura Bonanni, Stefano Sensi, Marco Onofrj
Università “G. d’Annunzio” di Chieti-Pescara, Department Of Neuroscience, Imaging And Clinical Science, Chieti, Italy

Background and Aims:: The altered activity and neurotransmission of the medial prefrontal cortex (mPFC), a key node of the default-mode network, has been associated with the presence of somatic symptom disorder (SSD), a highly prevalent neuropsychiatric disorders in Parkinson's disease (PD). We investigated whether, in SSD patients, the altered activity of the mPFC promotes a functional reconfiguration across brain networks and whether these changes are specific hallmarks of the presence of SSD in PD.

Methods:: A multimodal magnetic resonance imaging (MRI) protocol assessed the neurochemistry and functioning of the mPFC in a cohort of sixty-six individuals. The study cohort included seventeen PD patients with SSD, eighteen PD patients, twelve SSD patients unaffected by any neurological or other psychiatric condition, and nineteen healthy control (HC) subjects.

Results:: Compared to HC or PD individuals, PD+SSD and SSD patients exhibited altered prefrontal activity. They also showed increased functional connectivity between the mPFC and critical nodes of the fronto-parietal control network. While SSD patients’ enhanced connectivity was limited to the lateral prefrontal cortex, the distinct functional reorganization of PD+SSD patients also included posterior brain regions. Compared to HC subjects, PD+SSD patients, but not SSD patients, exhibited an anterior-to-posterior shift of resting-state brain activity that involved the same areas that showed increased connectivity.

Conclusions:: Our findings identify a pathophysiologic role of the dysfunctional activity of the mPFC. The data indicate an aberrant reconfiguration across DMN and Cont, a potential functional SSD signature in patients with PD.
GAIT AND TURNING ALTERATIONS IN IDIOPATHIC REM SLEEP BEHAVIORAL DISORDER AND EARLY PARKINSON’S DISEASE: A CROSS-SECTIONAL STUDY WITH MOBILE HEALTH TECHNOLOGY.

Marcello Catania¹, Andrea Pilotto¹, Andrea Galbiati², Clint Hansen³, Rob Romijnders³, Andrea Corbani¹, Sara Nocivelli¹, Stefano Masciocchi⁴, Alberto Imarisio¹, Maria Rizzetti⁵, Luigi Ferini-Strambi², Walter Maetzler⁶, Alessandro Padovani⁷

Isidoro, Trescore, Italy, ⁶University of Brescia, Italy, Neurology Unit, Department Of Clinical And Experimental Sciences, Brescia, Germany, ⁷University of Brescia, Dept. Clinical And Experimental Sciences, Brescia, Italy

Background and Aims:: Subtle motor impairment and slowness of movements are early features of Parkinson’s disease and might be present already in the prodromal phase. Subjects with idiopathic REM sleep behavior disorder (RBD) are at high risk of developing PD.

Methods:: The aim of the study was investigate the differences in performances of gait and turning under supervised conditions in healthy controls, idiopathic REM sleep behavior disorder (RBD) and patients with Parkinson’s disease. Each participant underwent a supervised mobile health technology-instrumented assessment including the timed up and go test and one minute walking tasks with turns in normal and dual task conditions (cognitive task, motor task).

Results:: Results Sixty-eight PD patients (26 drug naïve and 42 under treatment, mean UPDRS-III 15±9), 18 RBD (mean UPDRS-III 1±1) and 33 age-matched controls entered the study. Compared to controls, PD patients (both naïve and under treatment) needed more time to perform the TUG. During straight walking, the showed higher stride time, higher double limb support variability and a higher asymmetry index. Moreover, they turned slower than controls. Compared to controls, RBD subjects showed a higher swing time and turned slower.

Conclusions:: Discussion This study suggests that RBD patients have a gait pattern that is distinguishable from controls and show features comparable to early PD patients. These results partly support results from a recent study investigating RBD gait in free-living conditions (Del Din et al, JPD, 2020), and build a bridge between the control and PD state. Future studies using mobile health technology are needed to evaluate the predictive capacity of the method, to define RBD subjects that are in prodromal PD phases.
ASSOCIATION BETWEEN SLEEP DISORDERS AND COGNITIVE DYSFUNCTIONS IN ADVANCED PARKINSON’S DISEASE

Elisa Montanaro\textsuperscript{1,2}, Alberto Romagnolo\textsuperscript{1,3}, Carlo Alberto Artusi\textsuperscript{1,3}, Margherita Fabbri\textsuperscript{4}, Gabriele Imbalzano\textsuperscript{1,3}, Mario Giorgio Rizzone\textsuperscript{1,3}, Leonardo Lopiano\textsuperscript{1,3}, Maurizio Zibetti\textsuperscript{1,3}

\textsuperscript{1}A.O.U. Città della Salute e della Scienza di Torino, Neurology 2 Unit, Turin, Italy, \textsuperscript{2}University of Torino, Department Of Neuroscience “rita Levi Montalcini”, Turin, Italy, \textsuperscript{3}University of Torino, Department Of Neuroscience “rita Levi Montalcini”, Turin, Italy, \textsuperscript{4}University of Toulouse, Department Of Neurosciences, Clinical Investigation Center Cic 1436, Parkinson Toulouse Expert Center, Ns-park/fcrin Network And Neurotoul Coen Center, Toulouse, France

\textbf{Background and Aims::} Parkinson’s disease (PD) is increasingly recognized as a multidimensional disorder, characterized by several non-motor symptoms, including cognitive and sleep disturbances. Our aim is to explore associations between subjectively reported sleep alterations and cognitive functions in advanced PD.

\textbf{Methods::} 181 advanced PD patients completed two self-administered sleep measures: the PD Sleep Scale (PDSS-2) and the Epworth Sleepiness Scale (ESS). Neuropsychological assessment encompassed five cognitive domains: reasoning [Raven Coloured Progressive Matrices Test (RCPMT)]; memory [Corsi’s Block Tapping Test (CBT), Paired Associate Learning (PAL)]; attention [Digit Cancellation Test (DCT), Trail Making Test A (TMT-A)]; frontal executive functions [Trail Making Test B (TMT-B), Frontal Assessment Battery (FAB)]; language [phonemic and semantic verbal fluency (PVF, SVF)].

\textbf{Results::} Patients showed mild to moderate sleep problems (PDSS-2: 23.4±1.2) and mild daytime sleepiness (ESS: 8.6±5.1). A significant correlation was observed between higher PDSS-2 scores, indicative of greater sleep disturbances and measures of reasoning (RCPMT: $\beta=-0.214$; $p=0.002$), attention (DCT: $\beta=-0.194$; $p=0.007$), executive functions (FAB: $\beta=-0.139$; $p=0.049$; TMT-B: $\beta=0.156$; $p=0.031$) and category verbal fluency (CVF: $\beta=-0.167$; $p=0.027$). No significant correlations were found between PDSS-2 scores and memory test scores, nor between ESS score and any of the neuropsychological tests.

\textbf{Conclusions::} Our study shows that in advanced PD, sleep disturbances selectively correlate with subcortical neuropsychological functions and not with short-term memory and consolidation. Further studies are needed to determine whether sleep disorders are risk factors for cognitive decline and dementia in PD, and to understand the underlying mechanisms.
RECENT ADVANCES IN THE SEARCH OF SPECIFIC BIOMARKERS FOR SYNUCLEINOPATHIES

Vincenzo Donadio, Rocco Liguori
IRCCS Institute of Neurological Sciences of Bologna, Uoc Clinica Neurologica, Bologna, Italy

Background and Aims:: Synucleinopathies are neurodegenerative disorders characterized by the abnormal deposition of misfolded α-synuclein (α-syn) mainly in neurons. They include common disorders such as Parkinson disease or Dementia with Lewy bodies. The premortem diagnosis of synucleinopathies lacks a specific biomarker and their diagnosis is mainly based on clinical criteria, leading to frequent misdiagnosis. The search of easily applicable diagnostic test with high sensitivity and specificity is not currently available for synucleinopathies in the clinical practice although urgently needed. This review gives an overview on the sensitivity and specificity of new diagnostic tools to identify in vivo pathological α-syn.

Methods:: We analysed papers reporting new diagnostic tools aimed at disclosing in vivo misfolded α-syn. We focused our analysis on diagnostic accuracy and practicability in the clinical routine work. Furthermore, our analysis addresses methodological problems and the lack of standardized procedures of these techniques. Finally, we give an outlook on the future of these techniques as a potential diagnostic tool

Results:: In the recent years two promising tools have been settle up to identify in vivo misfolded α-synuclein: immunofluorescence (IF) and RT-QuIC. They both show a high diagnostic accuracy in differentiating patients with synucleinopathies from different neurodegenerative and other neurological disorders and present an excellent practicability in the clinical work. However IF displayed an optimal level of reproducibility which needs to be established for RT-QuIC

Conclusions:: Emerging techniques as immunofluorescence (IF) and RT-QuIC show promising diagnostic accuracy and practicability for the in vivo diagnosis of synucleinopathies although some aspects need to be improved to increase their clinical application
Background and Aims:: BACKGROUND/AIMS: Statins are speculated to be neuroprotective and are associated with the reduced risk of Parkinson’s disease (PD) but only a few studies have investigated the influence of statins on PD progression. To evaluate whether long-term statin use may affect motor progression in a large cohort of de novo patients with PD.

Methods:: METHODS: We conducted a 4-year retrospective observational cohort study assessing patients with PD who were consecutively recruited from a single tertiary center between January 2015 and January 2017. Information on motor function was obtained using the MDS-Unified Parkinson Disease Rating Scale (UPDRS)-III and all subjects were extensively characterized, including about lifestyle habits, cardiovascular risk factors and cholesterol blood levels.

Results:: RESULTS: Of the 181 participants included in the study, 104 patients were evaluated for eligibility (42 patients were exposed to statin therapies and 62 were not treated with statins). Patients presented similar scores in UPDRS III at baseline but statin users had a lower motor impairment at 4 years compared to non-users PD patients. Additionally, statin treatment resulted in less progression of rigidity score of UPDRS over 4 years. No other significant differences were observed between PD patients with and without statins.

Conclusions:: CONCLUSIONS: Early PD patients with long-term statin usage showed lower motor deterioration after 4 years of disease duration compared with patients not taking statins at diagnosis, suggesting a possible influence of statins on disease progression in PD. Further investigation is warranted in order to understand the potential beneficial effects of statin treatment on clinical symptoms in PD.
INTRODUCTION TO THE TOPIC:

Intrinsically Functional Connectivity Changes in Drug-Naïve Parkinson’s Disease Patients with Mild Cognitive Impairment

Emilia Norma Mosca¹, Rosa De Micco¹, Mattia Siciliano¹,², Sara Satolli¹, Federica Di Nardo¹, Giusy Caiazzo¹, Fabrizio Esposito¹,³, Gioacchino Tedeschi¹, Alessandro Tessitore¹

¹University of Campania “Luigi Vanvitelli, Department Of Advanced Medical And Surgical Sciences, Naples, Italy, ²University of Campania “Luigi Vanvitelli”, Neuropsychology Laboratory, Department Of Psychology, Caserta, Italy, ³University of Salerno, Scuola Medica Salernitana, Department Of Medicine, Surgery And Dentistry, Baronissi, Italy

Background and Aims:: Mild cognitive impairment (MCI) is a common nonmotor symptom in Parkinson’s disease (PD) and it is considered a risk factor for developing dementia. Using resting-state functional MRI, we investigated intrinsic brain networks connectivity correlates of MCI in a cohort of drug-naïve patients with PD.

Methods:: 3T MRI images of 40 drug-naïve non-depressed PD patients (PD-MCI and PD-noMCI), and 20 matched healthy controls (HCs) were analyzed. MDS Task Force Level II diagnostic criteria were applied to determine the presence of MCI. Single-subject and group-level independent component analysis was used to investigate intra and inter-network functional connectivity differences within the major neurocognitive networks between patients subgroups and HCs. Linear regression analysis was used to investigate correlations between imaging and clinical data.

Results:: Compared to PD-noMCI patients, PD-MCI patients showed decreased connectivity within the right frontoparietal, the default-mode and the ventral attention networks. Inter-network connectivity between default-mode/dorsal attention and default-mode/ventral attention networks were significantly positive in PD-MCI patients compared to PD-noMCI. Functional connectivity changes within and between neurocognitive networks were found to be correlated with neuropsychological outcomes.

Conclusions:: Our findings demonstrate the presence of specific intrinsic functional connectivity changes involving the most important neurocognitive networks in early PD patients with MCI. This connectivity pattern is not biased from dopaminergic medication and it is also correlated with symptoms severity. We hypothesize that this functional architecture may reflect the presence of diffuse neuropathological changes, which may represent a potential early biomarker for developing clinically significant cognitive impairment over time.
Background and Aims:: Vascular Parkinsonism (VP) is a type of Parkinson's disease (PD), the course, treatment, and origin of these two diseases are radically different.

Methods:: To compare the first signs of the disease, clinical-anamnestic, neurological examination and retrospective analysis of 47 patients with PD and 40 patients with VP hospitalized at the TMA were carried out, and a special questionnaire was compiled.

Results::

<table>
<thead>
<tr>
<th>Gender and age</th>
<th>PD (n=47)</th>
<th>VP (n=40)</th>

</tbody>
</table>

When the origin of VP was studied in patients, 27.5% of patients developed VP after stroke, 40% developed on the background of diabetes mellitus, 72.5% of patients developed VP on the background of chronic cerebral ischemia, 22.5% of patients had a history of myocardial infarction in diabetic patients. These results confirm that diabetes mellitus, chronic cerebral ischemia, strokes, and myocardial infarction are among the factors contributing to the development of VP. In 40% of cases, the first symptoms of the disease began with slowing of movement, only in 9% of cases the first sign of the disease began with tremors. In PD, the first sign of the disease was tremors, in 86% of patients was unilateral onset, in 72% of patients tremors only in the hands, and in 42% only in foot. In VP, the disease was observed symmetrically in 68% of cases and began mainly in the foot.

Conclusions:: Although both VP and PD are associated with movement disorders, the diagnosis and treatment of this disease require a different approach due to the fact that they are radically different.
NEUROPROTECTIVE EFFECT OF HYPEROSIDE ON MPTP/MPP+-INDUCED PD MODEL

Background and Aims:: Hyperoxide (HYP), the natural active component of Wuzi Yanzong Pill, showed a therapeutic potential on Parkinson's disease (PD) mice. To explore the therapeutic effects and its possible mechanisms of HYP on PD mice.

Methods:: SH-SY5Y cells were incubated with MPP⁺ for 24 h with or without HYP treatment, followed by a detection of cell viability and mitochondrial membrane potential. The male C57BL/6 mice were randomly divided into three groups: normal, MPTP and HYP group. PD model was induced by intraperitoneal administration of MPTP for 7 days and simultaneously received intraperitoneal injection of HYP for 7 or 14 days, followed by a detection of gait test and pathology alternations by immunofluorescence and western blot. In mice brain homogenate and cell supernatant, inflammation factors and oxidative stress were measured by ELISA, respectively.

Results:: HYP treatment declined the apoptosis of SY5Y cells under MPP⁺ injury. Compared with the PD mice, HYP treatment significantly improve the motor dysfunction of PD mic after 7 or 14 day and increased the number of TH⁺ neuron. Meanwhile, HYP treatment significantly increased the expression of p-AKT in SY5Y cells and GFAP⁺ or Iba1⁺ cells. HYP treatment also significantly decreased in the expression of inflammatory factors (IL-6, IL-1β and TNF-α) and the level of MDA and GSH both in vitro and in vivo.

Conclusions:: These results revealed the neuroprotective of HYP for PD through anti-inflammation and antioxidation via enhancing the phosphorylation of AKT.(Grants: NNSF of China 81102552 and 81703978,Central Government Guided Local Funding Projects for Science and Technology Development No. YDZX20201400001483.*corresponding authors: Prof. C.G. Ma or Prof. H.J. Fan)
FINGERPRINT OF GAIT APPLIED TO PARKINSON’S DISEASE

Emahuel Troisi Lopez¹, Pierpaolo Sorrentino², Marianna Liparoti¹, Roberta Minino¹, Antonella Romano¹, Enrico Amico³, Giuseppe Sorrentino¹
¹University of Naples “Parthenope”, Department Of Motor Sciences And Wellness, Naples, Italy, ²Aix-Marseille University, Institut De Neurosciences Des Systemès, Marseille, France, ³Center for Neuroprosthetics, EPFL, Institute Of Bioengineering, Geneva, Switzerland

Background and Aims:: Many Neurological diseases provoke motor impairment. In order to obtain early diagnosis and effective assessment of therapeutic outcomes, it is desirable to quantify gait features and alterations. In this study, we showed that human gait is characterized by replicable patterns of consensual accelerations/decelerations of body segments, that are highly regulated. Hence, we analysed motion analysis data through a graph theoretical approach and applied this framework in Parkinson’s disease (PD), showing the utility of our newly proposed technique in clinical settings.

Methods:: We recruited twenty-three PD patients, off medication, and twenty-tree healthy subjects (HS). Both groups underwent gait analysis through a stereophotogrammetric system acquiring the instantaneous position of 21 anatomical markers and computed their velocity, acceleration, and jerk. We correlated the time series among the markers, obtaining an adjacency matrix of the consensual movements of the body segments, that we named “kinectome”. Beyond a fingerprint analysis we performed a topological analysis considering the markers as nodes, and the correlation coefficients between markers as edges.

Results:: The PD group kinectomes showed higher standard deviation values compared to HS, showing that the gait patterns are steadier in the healthy. Consequently, while kinectomes allow the identification of each individual, PD showed lower identifiability as the motor impairment increases. Topological analysis revealed a reduction of the centrality of the markers corresponding to the upper limbs proportional to the reduction of stability of gait.
HS group

PD group
Conclusions: Network analyses of human movement through kinectome is a novel technique for movement analysis and is able capture and characterize motor impairment in PD.
**FOLLOW-UP EVALUATION OF MOTOR AND NON-MOTOR SYMPTOMS IN ESSENTIAL TREMOR**

Luca Angelini¹, Alessandro De Biase¹, Giulia Paparella², Antonella Di Vita¹, Matteo Panfili¹, Annalisa Maraone¹, Alfredo Berardelli¹, Matteo Bologna¹,²
¹ “Sapienza” University of Rome, Department Of Human Neuroscience, Rome, Italy, ²IRCCS Neuromed, Irccs Neuromed, Pozzilli, Italy

**Background and Aims::** Essential Tremor (ET) is a common and heterogeneous movement disorder characterized by action tremor of upper limbs and other body parts, as well as non-motor symptoms (e.g., cognitive and psychiatric abnormalities). However, only few studies have attempted to estimate symptoms progression in ET.

**Methods::** We enrolled 18 patients with ET. Each patient underwent the same evaluation at baseline and during a follow-up assessment (mean follow-up interval: 33.5 months; range: 21 – 45 months). We assessed tremor by mean of clinical rating scales and kinematic recordings; patients also underwent neuropsychological tests for cognitive assessment and structured interviews to investigate psychiatric disorders.

**Results::** At follow-up evaluation we observed higher Tremor Rating Scale scores than baseline (31.1±13.3 vs. 20.9±10; $P<0.05$) reflecting the involvement of more than one body segment e.g., upper limb plus head, voice, tongue, and lower limbs (baseline: 38.9% vs. follow-up: 77.8%; $P<0.05$). Kinematic analyses, however, did not reveal amplitude and frequency changes of head or upper limb tremor over time (all $P_s<0.05$). Also rest tremor was less frequent at baseline compared to follow-up (33.3% vs. 77.8%; $P<0.05$). Cognitive assessment showed cognitive worsening in 6 out of 18 cases (33.3%). Finally, psychiatric assessment showed a trend toward reduction in anxiety and depression over time.

**Conclusions::** ET is a progressive disorder with tremor spread in multiple body segments over time and emergence of soft signs, e.g., rest tremor and cognitive abnormalities. Further observations are needed to identify possible predictors in the rate of progression of motor and non-motor domains.
FREEZING OF GAIT IN SUBTHALAMIC DEEP BRAIN STIMULATION FOR PARKINSON DISEASE: A PILOT STUDY ON SAFETY AND TOLERABILITY OF VARIABLE VERSUS LOW FREQUENCIES STIMULATION

Roberta Balestrino1,2, Margherita Fabbri3, Francesca De Matteis4, Salvatore Bonvenga5, Elisa Montanaro2, Carlo Alberto Artusi2, Alberto Romagnolo5, Marco Bozzali2,8, Maurizio Zibetti2, Leonardo Lopiano2, Mario Rizzone2

1IRCCS Ospedale San Raffaele and Vita-Salute San Raffaele University, Department Of Neurosurgery And Gamma Knife Radiosurgery, milano, Italy, 2Università di Torino, Department Of Neuroscience ‘Rita Levi Montalcini’, Torino, Italy, 3University of Toulouse, Department Of Neurosciences, Clinical Investigation Center Cic 1436, Parkinson Toulouse Expert Center, Ns-park/fcrin Network And Neurotoul Coen Center, Toulouse, France, 4Ospedale degli Infermi di Rivoli, Neurologia, rivoli, Italy, 5IRCCS Istituto Neurologico Carlo Besta, Parkinson And Movement Disorders Unit, Milano, Italy, 6Brighton and Sussex Medical School, 7) department Of Neuroscience, Falmer, United Kingdom

Background and Aims:: Background and aims: Low frequency (LS) subthalamic deep brain stimulation (STN-DBS) may have a benefit on Parkinson’s disease (PD) axial sings, especially on freezing of gait (FOG). However, this benefit seems to not be maintained over time. Phenomena of neuronal adaptation could be related to the development of this tolerance. The aim of this study is to verify the safety and tolerability of variable frequency (VF) versus LFS among PD patients with severe FOG.

Methods:: a randomized-double blind pilot study on PD patients with STN-DBS with severe FOG underwent one month of LFS during 24h/day and one month of VFS (LF during 16 h/daytime and high frequency stimulation [HFS] during 8h night-time) in a randomized fashion. Motor and cognitive outcome were assessed at each timepoint.

Results:: we recruited 10 patients with a median age and disease duration of 66 [IQR: 62-71] and 17.5 [IRQ: 13.5 – 21.2] years. Two patients were excluded, three patients dropped out after one week of VFS. Among the five remaining patients, comparing both LFS and VFS with HFS, we found a not statistically significant improvement of FOG. No statistically cognitive changes were found, and no adverse event occurred with both stimulation parameters.

Conclusions:: VFS seems to be as effective as safe as LFS among patients with severe FOG, offering a benefit on axial signs. The small sample of recruited patients of our pilot study did not allow to reach statistically significant results. Our findings need to be confirmed in a larger cohort of patients.
Background and Aims:: The aim of this study was to analyze the clinical features of benign essential blepharospasm (BEB) in Latvian patients. To our knowledge, this is the first study describing clinical features of BEB patients in Latvia.

Methods:: 56 patients were included in this retrospective analysis. The data were collected from medical records and phone interviews.

Results:: The mean age of the disease onset was 57.5 +/- 11.7 (range, 23-80 years), 77% (n=43) were women. Antagonistic maneuvers were positive in 57% (n=32) of all cases. The most common aggravating factor was bright light (75%, n=42) and watching at screens (38%, n= 21). [Image1]. Only 13% (n=7) denied any aggravating factors. In this study, 50% (n=23) of patients reported stressful event before symptom development, the most common - a death of a relative (40% of those cases, n=9). Non-motor symptoms (psychiatric, sleep disturbances and ocular non-motor symptoms) were positive in 75% (n=42). Almost one third of patients (30%, n=17) had co-existing depression, 20% (n=11) – general anxiety disorder. 46% (n=26) of patients experienced sleep disturbances.

The time from symptom onset till first injection with botulinum toxin type A (BoNT) was 5.5 +/- 7.7 (range, 0-49 years), half of patients received BoNT injection treatment within first three years.

Conclusions:: Whether a coincidence or triggering factor but 50% of patients linked a stressful event with beginning of BEB. In Latvia half of the patients still receive treatment more than 3 years after the onset of symptoms. Non-motor symptoms in BEB is a major component of condition, which are often overlooked.
GLUCOCEREBROSIDASE ACTIVITY AND TRANSPORT TO LYSOSOMES IN PRIMARY MACROPHAGES FROM PATIENTS WITH MUTATIONS IN THE GBA GENE

Alena Kopytova1, Mikhail Nikolaev1, Darya Bogdanova1, Artem Izymchenko1, Konstantin Senkevich1, Galina Baydakova2, Irina Miliukhina2, Ekaterina Zakharova2, Sofya Pchelina1
1Petersburg Nuclear Physics Institute named by B.P.Konstantinov of NRC «Kurchatov Institute», Molecular And Radiation Biophysics Division, Gatchina, Russian Federation, 2Research Center for Medical Genetics, Hereditary Metabolic Diseases Laboratory, Moscow, Russian Federation, 3Institute of Human Brain of RAS, Department Of Neurology, Saint-Petersburg, Russian Federation

Background and Aims:: Mutations in GBA alters glucocerebrosidase (GCase) transport to lysosomes and leads to Gaucher disease (GD) development and also the most important genetic risk factor for Parkinson's disease (PD). However, the majority of GD patients and carriers do not develop PD, suggesting the possibility of other disease modifying factors. To study the glucocerebrosidase (GCase) activity and translocation to lysosomes in primary macrophages derived from PD patients with GBA mutations (GBA-PD) and asymptomatic carriers of GBA mutations (asympGBA).

Methods:: Mononuclear fraction was isolated from whole blood of GBA-PD (N=9), asympGBA (N=12) and healthy controls (N=22). With subsequent differentiated into macrophages using RPMI supplemented with 10% FBS, 1% streptomycin-penicillin and 10 ng/ml M-CSF for 4 days. GCase enzymatic activity was measured by LC-MS/MS in dry macrophage cell spots on filter paper. The translocation of GCase (Alexa Fluor 488) to lysosomes (LAMP2(Cy3)) was demonstrated in primary macrophages using a Leica TCS-SP5 confocal microscope.

Results:: In our study, we showed differences in GCase activity in primary macrophages derived from GBA-PD, asympGBA patients and controls (Table 1).

Table 1. GCase activity in PBMC-derived macrophages.

<table>

* compared to controls

A decreased translocation of GCase to lysosomes by decreased colocalization of GCase with the lysosomal marker LAMP2 was observed in primary macrophages derived from GBA-PD 0.64 (0.48-0.86) and asympGBA 0.63 (0.54-0.688) patients compared to controls 0.76 (0.62-0.86) (p<0.0001, p=0.0001).

Conclusions:: GCase transport to lysosomes is impaired in primary macrophages derived from patients with GBA mutations. Asymptomatic carriers of GBA mutations characterized by decreased GCase activity in primary macrophages. The study was supported by RSF № 19-15-00315.
A POTENTIAL RESCUE STRATEGY IN A CASE OF STN-DBS OFF-TARGETING: THE ANODIC STIMULATION.

Serena Coniglio¹, Giulia Di Rauso¹, Anna Vaudano¹, Francesco Cavallieri², Annette Puzzolante³, Alberto Feletti⁴, Francesca Antonelli⁵, Stefano Meletti¹, Franco Valzania⁶, Vittorio Rispoli⁶
¹University of Modena and Reggio Emilia, Neurology Unit, Department Of Biomedical, Metabolic And Neural Science, Modena, Italy, ²University of Modena and Reggio Emilia, Clinical And Experimental Medicine PhD Program, Modena, Italy, ³Azienda Ospedaliero-Universitaria di Modena, Neurosurgery, Neuroscience Head Neck Department, Modena, Italy, ⁴University of Verona - AQUI Verona, Institute Of Neurosurgery, Department Of Neurosciences, Biomedicine And Movement Sciences, Verona, Italy, ⁵Azienda Ospedaliero-Universitaria di Modena, Neurology, Neuroscience Head Neck Department, Modena, Italy, ⁶Azienda USL-IRCCS di Reggio Emilia, Neurology Unit, Neuromotor & Rehabilitation Department, Reggio Emilia, Italy

Background and Aims: An off-targeting implantation remarkably interferes with deep brain stimulation outcome, because of the engagement of nearby cerebral structures and therefore side effects. This study aims at evaluating the potential therapeutic opportunities offered by advanced programming for off-targeting DBS.

Methods: A 56 y.o. male was implanted with bilateral STN-DBS with directional leads and an implantable pulse generator able of Multiple Independent Current Control. Low amplitude threshold for left facio-brachial tonic spams was revealed at monopolar review, interfering with the clinical outcome. Reducing the amplitude in monopolar (even directional) stimulation, programming in bipolar or as guarded cathode did not improve the therapeutic window. This prompt us to explore novel programming options, namely low/high frequency, low pulse width and anodic stimulation, after carrying out a post-operative neuroimaging processing.

Results: As suggested by monopolar review, left lead run laterally to the planned target within the medial part of the corticospinal tract at the postprocessing neuroimaging. We found that anodic stimulation decreased the corticospinal tract engagement compared to the cathodic one with further improvement of bradykinesia and rigidity by lowering the pulse width. Moreover, bilateral high frequency resulted in tremor reduction.

Conclusions: This case highlights the potential advantages of anodic stimulation in lateral off-targeting in STN-DBS, lowering the corticospinal tract engagement.
KINEMATIC ASSESSMENT OF BRADYKINESIA DUE TO FOCAL BASAL GANGLIA LESION: A SERIES OF TWO ISCHEMIC STROKE CASES

Antonio Cannavacciuolo\textsuperscript{1}, Giulia Paparella\textsuperscript{2}, Donato Colella\textsuperscript{1}, Luca Angelini\textsuperscript{1}, Andrea Guerra\textsuperscript{2}, Alfredo Berardelli\textsuperscript{1,2}, Matteo Bologna\textsuperscript{1,2}
\textsuperscript{1}Sapienza University of Rome, Department Of Human Neurosciences, Rome, Italy, \textsuperscript{2}IRCCS Neuromed, Irccs Neuromed, Pozzilli, Italy

Background and Aims:: Focal lesions of the basal ganglia due to stroke can induce various movement disorders, including parkinsonism. To date, there are no objective measurement of bradykinesia features in patients with parkinsonism due to structural lesions of the basal ganglia and it is unknown whether they differ from those observed in parkinsonism of other origins. We here reported two cases of focal ischemic stroke of the basal ganglia and unilateral parkinsonism. Besides the clinical description, we also aimed to characterize the kinematic features bradykinesia in these two patients.

Methods:: Repetitive finger tapping was kinematically recorded using a motion analysis system in one patient with a lesions of the left substantia nigra (case 1) and in one patient with a lesion of the right stratum (case 2). Movement velocity, amplitude, rhythm, and decrement (sequence effect) were measured. Patients' kinematics were compared with those of 65 healthy controls.

Results:: In Case 1, the prominent bradykinesia features were severe movement slowness with sequence effect. In Case 2, we observed severely reduced movement amplitude and to a lesser extent slowness and altered rhythm, but no sequence effect.

Conclusions:: Bradykinesia has heterogeneous features in parkinsonism due to focal brain lesions, depending on the lesion topography, and it may resemble bradykinesia features previously observed in idiopathic Parkinson’s disease and atypical parkinsonism. The results may give insight for a better understanding of bradykinesia pathophysiology and support the hypothesis of bradykinesia as a network disorder, in which the disfunction of specific nodes results in the different features.
A FRAMEWORK ANALYSIS ON DYSTONIC PATIENTS’ EXPERIENCES OF FIRST-WAVE OF COVID-19 PANDEMIC

Giulia Di Rauso¹, Serena Coniglio¹, Vittorio Rispoli², Matías Eduardo Díaz Crescitelli³, Francesco Cavallieri²⁴, Francesca Antonelli², Stefano Meletti¹², Luca Ghirotto³, Franco Valzania⁵
¹University of Modena and Reggio Emilia, Neurology Unit, Department Of Biomedical, Metabolic And Neural Science, Modena, Italy, ²Azienda Ospedaliero-Universitaria di Modena, Neurology, Neuroscience Head And Neck Department, Modena, Italy, ³AUSL - IRCCS di Reggio Emilia, Qualitative Research Unit, Reggio Emilia, Italy, ⁴University of Modena and Reggio Emilia, Clinical And Experimental Medicine Phd Program, Modena, Italy, ⁵Azienda USL-IRCCS di Reggio Emilia, Neurology Unit, Neuromotor & Rehabilitation Department, Reggio Emilia, Italy

Background and Aims:: The first wave of the SARS-CoV2 pandemic imposed healthcare reorganization in order to tackle the infection spread. Prioritizing COVID-19 related management risked leaving rare chronic diseases without proper care response. This study aims at analysing the dystonic patients’ (DPs) experiences during the pandemic.

Methods:: A nation-wide survey consisting of 37 items (demographic, dystonic syndrome and qualitative information) was disseminated online before the second wave spread and DP were anonymously recruited. The data collected were analyzed by descriptive statistics and qualitative framework analysis.

Results:: 62 DPs answered the survey, half of them from the Italian “red-zones”. Pandemic elicited negative emotions in 50% of participants. DPs experienced a rebound of motor and non-motor symptoms with severe repercussion on job and daily functionings. In-person outpatient clinics (including i.e. botulinum neurotoxin injection, physiotherapy session) were shutdown with high rate, where less frequently telephone/mail contacts with the healthcare providers. Despite efforts, DPs felt were not satisfactorily supported.

Conclusions:: During the first wave pandemic, dystonia-related issues were frequently not well-managed with negative consequences on symptoms and DPs’ daily functioning. We hope these findings might raise awareness about DPs’ unmet needs. Comprehending DPs’ perspectives may inform healthcare provision in the next step of this pandemic. Despite efforts, telemedicine might not be leveraged alone for movement disorders management during this pandemic. We acknowledge the support of the Italian Association of the research against Dystonia (Associazione Italiana per la Ricerca sulla Distonia).
GUT MICROBIOTA DYSBIOSIS IN PARKINSON'S DISEASE PATIENTS: EARLY FEATURE AND BIOMARKER OF DISEASE PROGRESSION?

Rocco Cerroni¹, Daniele Pietrucci², Matteo Conti¹, Mariangela Pierantozzi¹, Valeria Unida², Silvia Biocca², Nicola Mercuri², Alessandro Desideri², Alessandro Stefani¹
¹University of Rome "Tor Vergata", UOSD Parkinson, Department Of System Medicine, Rome, Italy, ²University of Rome Tor Vergata, Department Of Biology, Rome, Italy, ³University of Roma Tor Vergata, Department Of Systems Medicine, Rome, Italy

Background and Aims:: Gut microbiota dysbiosis is considered an hallmark in Parkinson's disease (PD). However, it is still unclear whether microbiota alterations, in PD, represent a pathogenetic starting point or also a consequence of disease. Our aim was to investigate microbiota alterations in PD patients at the time of diagnosis and in later stages of the disease, in order to identify dysbiosis not only as an early non-motor feature but also as a biomarker of disease progression.

Methods:: 108 faecal samples were collected from 30 PD patients at the time of diagnosis (de novo PD), 38 PD patients in advanced stages (defined by H&Y stage≥3 and/or LEED>850mg) and 40 healthy controls (HC), represented almost exclusively by cohabitants. Microbiota compositions was studied through 16rRNA amplicon sequencing and classified to taxonomic rank through bioinformatic analysis. A multivariate statistical analysis was performed to identify differential abundant taxa between the three groups (de-novo PD, advanced PD, HC) considering the effect of potential confounding factors, like lifestyle and eating habits.

Results:: The three groups showed differences both in alfa-diversity and in beta-diversity comparisons. We found a progressive reduction in Lachnospiraceae, Bacteroidaceae, Prevotellaceae and Clostridiaceae families moving from HC to de novo PD and finally to advanced PD and a reverse trend in Enterobacteriaceae and Lactobacillaceae families.

Conclusions:: Our study confirms the presence of microbiota alterations from the earliest stages of PD. Furthermore, a greater and more severe alteration in microbiota composition seems to characterize PD advanced stages, highlighting how this non-motor feature progresses with the severity of disease.
WHITE MATTER MICROSTRUCTURAL CHANGES PRECEDING THE DEVELOPMENT OF IMPULSE CONTROL DISORDERS IN PATIENTS WITH PARKINSON’S DISEASE

Simone Aloisio¹, Rosa De Micco², Giusy Caiazzo², Mattia Siciliano³, Federica Di Nardo², Fabrizio Esposito⁴, Gioacchino Tedeschi⁵, Alessandro Tessitore⁴
¹AOU Luigi Vanvitelli, Neurology, Napoli, Italy, ²University of Campania “Luigi Vanvitelli, Department Of Advanced Medical And Surgical Sciences, Naples, Italy, ³University of Campania L. Vanvitelli, Department Of Advanced Medical And Surgical Sciences, Naples, Italy, ⁴University of Campania Luigi Vanvitelli, Department Of Advanced Medical And Surgical Sciences, Napoli, Italy, ⁵University of Campania “Luigi Vanvitelli”, Dept. Of Neurology, Naples, Italy

Background and Aims:: Impulse control disorders (ICD) can be triggered by dopamine replacement therapies in patients with Parkinson’s Disease (PD). Previous studies have identified several risk factors associated with ICD. In this study we investigated the presence of white matter (WM) microstructural changes at baseline in a cohort of drug-naïve PD patients who successively developed ICD over a 36-month follow-up period (ICD+) compared with patients who did not (ICD-).

Methods:: Baseline 3T MRI images of 48 drug-naive PD patients and 20 matched healthy controls (HCs) were analyzed. The ICD presence and severity at follow-up were assessed by means of the Questionnaire for Impulsive-Compulsive Disorders in Parkinson’s Disease Rating Scale. Diffusion tensor imaging with tract-based spatial statistic analysis was used to evaluate the WM integrity at baseline in 24 ICD+ patients, compared to 24 ICD- and 20 HCs.

Results:: Between-groups analysis revealed a statistically significant increase of radial diffusivity of the main fasciculi of WM in ICD+ compared to ICD- patients. In details, these differences were detectable bilaterally in thalamic radiations, cortico-spinal tracts, inferior longitudinal, superior longitudinal and uncinate fasciculi and in the splenium of corpus callosum.

Conclusions:: We demonstrated, in PD patients who will eventually develop ICD, the presence of WM changes at baseline, in several areas strongly involved in cognitive and behavioural functions, with a central role played in the reward system and motor inhibition. The evidence of early axonal damage may represent a potential biomarker and an additional risk factor for the emergence of ICD in PD patients.
IMPACTS OF CLASSICAL MUSIC AND DANCING ON COGNITIVE FUNCTIONS IN PARKINSON’S DISEASE.

Shokhijakhon Shokhimardonov, Kuzieva Shakhnoza
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: In the modern world, Parkinson's disease is the second most common neurodegenerative disease. And variety of non-pharmacological methods and technologies occupy an important place rehabilitation. To study changes in the cognitive plan among patients with Parkinson's disease after conducting dance classes and listening to classical music based on rehabilitation therapy under the TMA program, evaluate the dynamics of changes in such cognitive functions, memory, speech, attention, etc. according to MMSE and MoCa rating scales

Methods:: Patients were divided into two groups. The first group (n = 27) underwent therapy with rehabilitation therapy with TMA and the control group (n = 26) who received standardized treatment without this program. The lesson was held once a week for 1 hour for 12 weeks at the base of rehabilitation of neurological patients at the TMA clinic. Patients had an early stage of PD without cognitive impairment (Addenbrook score: DG = 92.3 ± 2.7, CG = 90.8 ± 3.9). Both groups took cognitive function tests on the first day of admission, as well as on days 21 and 48.

Results:: Comparison of the results showed that the cognitive functions of patients such as verbal training (= 28%), delay (= 28%), recall delay (= 20%), memory capacity for verbal material (= 12%) improved in relation to the control group. (p <0.05)

Conclusions:: Rehabilitation with the help of dance lessons and classical music have a clear benefit from psychological symptoms, preservation and optimization of cognitive function. Long-term studies are necessary to confirm the persistence of these effects.
COMPARATIVE EVALUATION OF THE EFFECTIVENESS OF GROUP COGNITIVE REHABILITATION AND RELAXATION THERAPY IN PATIENTS WITH PARKINSON’S DISEASE

Shokhijakhon Shokhimardonov, Kuzieva Shakhnoza
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: Compare the effectiveness of group cognitive rehabilitation and relaxation therapy in patients with Parkinson's disease (PD).

Methods:: We examined 20 patients with PD and conducted a prospective, single-blind, randomized clinical trial. Participants passed tests to evaluate cognitive function to assess the presence of mild cognitive impairment or dementia in PD. All patients were divided into two groups by the group of cognitive rehabilitation and relaxation therapy group in random order. CRG participants (n = 12) trained cognitive functions in the perspective of household life. This group focused on strategies for restoring, compensating, and optimizing cognitive brain function. Patients of the second group (n = 8) also performed home training. They underwent music therapy and art therapy. All trainings were 2 times a week for 10 weeks.

Results:: The results showed a significant improvement in CRG demonstrated in verbal learning (by = 28%), retention (by = 28%), delayed recall (by = 20%), memory capacity for verbal material (by=12%). There were significant improvements in the WG that were demonstrated in verbal learning (by = 36%) deferred recall (by = 40%), the amount of memory for verbal material (by = 12%) and the total amount of recall in non-verbal memory (by = 36%).

Conclusions:: Based on the results obtained, it can be concluded that CR does not have a specific effect on short-term memory performance in patients with PD. These requests require further research in the long term because other types of interventions may also be effective in relation to the cognitive functions of patients with PD.
INFLUENCING FACTORS ON COGNITIVE FUNCTION IN PARKINSON'S DISEASE

Bekzod Muminov, Rustambek Matmurodov, Eldor Abdukodirov, Khanifa Khalimova
Tashkent medical academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: The cognitive impairment in Parkinson's disease is influenced by many factors, including sleep disturbance. To clarify clinical features of sleep disorders in patients with Parkinson’s disease (PD) and their effect on cognitive function.

Methods:: The study involved 106 patients with PD (55 men and 51 women) mean age 56.04±10.9 years. The control group consisted of 20 patients without Parkinsonism matching by age and sex. The diagnosis of PD was established by criteria A.Hughes. To determine cognitive disorders we used neuropsychological tests.

Results:: 83 patients (78.3%) had sleep disorders. In the structure of sleep disorders: 49 (59.0%) patients had insomnia and 18 (21.6%) patients - parasomnia and 16 (19.4%) - hypersomnia. In a control group, numbers were 4.5 times less. The analysis showed that the structure of sleep disorders correlates with the form of PD. So, insomnia is more rapidly met in akinetic-rigid form (57.5%), whereas hypersomnia is presented in mixed form. Patients with insomnia present 38% of predementia cognitive impairment and 36% of dementia (66.7% of mild degree dementia and 33.3% moderate dementia severity). Whereas, in patients with hypersomnia 35% of predementia cognitive impairment, 60% of dementia (54.6% and 45.4%) were observed. Among patients with permanent drowsiness 32.4% of predementia cognitive impairment and 59.6% of dementia (44.8% and 55.2%) were diagnosed. Dementia (66.7%) was observed more in patients with sudden sleep (42.8% and 57.2%).

Conclusions:: Cognitive impairment in Parkinson's disease does not depend only on the form, stage and duration of the disease, but also depends on sleep disturbance.
CORTICO-SUBCORTICAL FINDINGS IN IDIOPATHIC REM SLEEP BEHAVIOR DISORDER (IRBD) AND PARKINSON'S DISEASE: A VBM STUDY.

Giulia Donzuso¹, Raffaele Squillaci¹, Loretta Giuliano¹, Calogero Cicero¹, Antonina Luca¹, Giovanni Mostile¹, Stefano Palmucci², Mario Zappia¹, Alessandra Nicoletti¹

¹University of Catania, Department “g.f. Ingrassia”, Section Of Neurosciences, Catania, Italy, ²University Hospital “Policlinico-San Marco, Radiodiagnostic And Radiotherapy Unit, Catania, Italy

Background and Aims:: Idiopathic rapid eye movement sleep behavior disorder (iRBD) is a parasomnia characterized by the loss of physiological atonia with abnormal behavior during REM sleep. RBD could be the prodromal manifestation of neurodegenerative diseases, such as Parkinson's disease (PD). Neuroimaging studies showed the presence of structural and functional abnormalities involving cortical and subcortical regions in RBD.

Methods:: Patients with iRBD, diagnosed based on thorough clinical interviews and VPSG, were recruited. Patients with PD according to the UK Brain Bank criteria were evaluated with the RBD Single-Question Screen and categorized into PD with RBD (PD-RBD+). A group of healthy controls (HC) were also recruited. Each subject underwent a brain MRI.

Results:: Sixteen patients with iRBD, 13 PD-RBD+, and 30 HC were enrolled. VBM-ANOVA analysis revealed a pattern of grey matter atrophy (GM) from HC to PD-RBD+, involving left middle temporal gyrus. Clusters of GM increase in PD-RBD+ and iRBD were found in bilateral caudate body, midbrain, middle occipital, middle frontal and post central gyri (p<0.05 FWE).

Conclusions:: We found the reduction of GM density in temporal areas with a decreasing pattern of atrophy from PD-RBD+ to HC, and the presence of increased GM volume in basal ganglia structures, together with the involvement of midbrain and cortical structures, with an inverse pattern. According to previous findings showing abnormalities in cortical and subcortical structures involved in REM sleep mechanisms, these data could suggest the presence of a neurobiological link connecting RBD to a-synucleinopathies.
BACKGROUND AND AIMS:: In temperate climates, many factors that may influence function in Parkinson's disease (PD) vary according to season [Ronald B Postuma, 2005]. Goal of our research was the determination of connection between symptoms in patients with Parkinson's disease (PwPD) and seasons.

METHODS:: This study included 204 PwPD, but only 128 got to the end of the research. Some patients left because of severe cognitive impairment, refusals to continue, death. This study was held for 3 years (2018-2020) with patients' examination four times per year: one survey every season. Neurological examination was based on MDS-UPDRS, AIMS, Schedule for the Assessment of Drug-Induced Movement Disorders(SADiMoD), Apathy scale, HADS, Epworth Sleepiness Scale(ESS), SCOPA-AUT, MoCA-test, QUIP-RS, C-SSRS, PDQ-39.

RESULTS:: Increased NMS were observed in off-season: autonomic symptoms($p=0.021$), falls($p=0.026$), hallucinations($p=0.037$), perception problems($p=0.041$), a tendency to sleepiness and fatigue($p=0.031$). One should note there was no change in depression indicators during the seasons to explain these differences. Though some patients indicate that their motor ability is better in summer, no correlation found between MDS-UPDRS subscores and season ($p > 0.05$).

CONCLUSIONS:: Thus NMS in PwPD change throughout the year with symptoms becoming worse in autumn and spring and relieving in summer ($p<0.05$). What concerns motor symptoms they doesn't aggravate in seasons. This should be taken into account when changing treatment regimens and interpreting the clinical trials results. This study should be continued to get more information.
RISK FACTORS FOR FREEZING OF GAIT AND RELATED NON-MOTOR SYMPTOMS IN PARKINSON’S DISEASE

Kuzieva Shakhnoza
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: To identify possible risk factors and the anamnestic association of gait freezing (FOG) in patients with Parkinson’s disease (PD).

Methods:: 84 patients with PD were evaluated on the basis of a sample on the following scales: MDS-UPDRS scale, modified Hoehn and Yahr (HY) Stage, MMSE and Clinical Dementia Rating scale. MDS-UPDRS was used to evaluate and determine PIGD, as well as for the Balance-Gait (PIGD minus FOG) score, non-motor symptoms (nM-EDL) and motor complications (MC). To clarify the clinical signs and their relationship with FOG, one-way tests were followed up with subsequent nominal logistic regression (Log Regr).

Results:: 36% of patients had FOG, these cases were associated with stage HY (≥3, p <0.0001), 70% of patients had PIGD. Patients with FOG + more often had MC and a higher equivalent dose of levodopa (LED) (p <0.0001) compared with PIGD / FOG patients, PIGD / FOG + patients had a longer duration of PD duration during the disease, a higher score of Bal-Gait, a higher indicator of LED, a higher frequency of psychosis, they are more likely to have dyskinesia, a higher rate of impact on motor vibrations and a general deviation from the norm and problems with urination, while differences in cognitive status were not significant.

Conclusions:: It can be said that for in PD the obvious factors for the development of FOG are PIGD, MC / LED and Cog impairment. Their nature may be additive in its effect. Patients with FOG more pronounced motor dysfunctions, in particular Balance-Gait disorder are more characteristic.
COULD THE ANESTHETIST IMPROVE THE MOVEMENT DISORDERS SPECIALIST JOB?

Serena Coniglio¹, Giulia Di Rauso¹, Giulio Gazzani², Vittorio Rispoli³, Stefano Meletti¹, Francesca Antonelli⁴
¹University of Modena and Reggio Emilia, Neurology Unit, Department Of Biomedical, Metabolic And Neural Science, Modena, Italy, ²University of Modena and Reggio Emilia, Faculty Of Medicine And Surgery, Department Of Biomedical, Metabolic And Neural Science, Modena, Italy, ³Azienda Ospedaliero-Universitaria di Modena, Neurology, Neuroscience Head And Neck Department, Modena, Italy, ⁴Azienda Ospedaliero-Universitaria di Modena, Neurology, Neuroscience Head Neck Department, Modena, Italy

Background and Aims:: Deep brain stimulation (DBS) is a neurosurgical procedure consisting in implant of electrodes in specific brain areas to improve clinical outcome of some neurodegenerative disorders i.e. Parkinson disease (PD). No clear data are available about what is the best anesthetic protocol in those patients. This study aims at demonstrating the impact of the anesthetic protocol choice on outcomes of DBS in patients affected by PD.

Methods:: We performed a prospective analysis on patients affected by PD who underwent DBS between March 2013 and October 2015. They were divided in two groups on the bases of the anesthetic protocol used during the procedure: group A for Propofol-Dexmedetomidine and group B for Propofol-Ramifentanil. We analyzed a series of factors such as vital signs during surgery, surgical time, micro-recording data, surgical complications, UPDRS III before and at the end of the procedure, days of Hospital discharge, and the delta levodopa equivalent daily doses.

Results:: We included 19 patients, with a mean age of 57 ± 5 years; 10 of them were included in Group A. We found that in group A the days of Hospital discharge (p-value 0.0355) were significantly less, as well as the surgical time (p-value 0.0300) compared to those found in the Group B.

Conclusions:: The study shows that patients undergone Propofol-Dexmedetomidine protocol had lower surgical time and less days of hospitalization, and that means a more rapid recovery from surgery compared with patients undergone Propofol-Ramifentanil protocol.
TECHNOLOGY USE IN PARKINSON'S DISEASE AND PARKINSONISM: A MULTICENTER SURVEY IN REAL-LIFE HEALTHY EAST LOMBARDY PARKINSON (HELP-)NETWORK

Clinical And Experimental Sciences, University Of Brescia, Brescia, Italy

Background and Aims:: Background: technology use is increasing in the ageing population but no large studies evaluated the access to internet and digital technology in parkinsonian patients. Objective: to evaluate the real-life use of internet and technological devices in parkinsonian patients

Methods:: a real-life survey in a network of movement disorder outpatient clinics in Lombardy Region, Italy was conducted. Consecutive Parkinson’s disease (PD) or atypical parkinsonism patients were asked to complete a standardized questionnaire evaluating the use of technology, internet and devices; the severity of the disease and milestones of disability were evaluated in the cohort.

Results:: Four hundred-fifty-four patients in 11 centres were included (mean age 70.5 + 9.7 years, mean dis duration 7.1 + 5.2 years), namely 411 PD (16.3% with dementia and 44% with motor fluctuations) and 43 atypical parkinsonism. 43% PD and 23.7% of atypical parkinsonism had access to email with a mean use of 6.4 hours per week. 75% of patients had smartphone 12% tablet and 14% computer with no difference between patients with and without motor fluctuations. OFF-line patients were older and exhibited worse motor and non-motor symptoms compared to patients with internet access.

Conclusions:: the survey highlighted an heterogeneous use of digital technology and internet in the population. The wide global internet access, prominent via smartphone highlight its potential for monitoring symptoms in clinical routine or in clinical trials. OFF-line patients have an increased risk of disability thus requiring specific interventions from clinicians and health care systems.
Background and Aims:: Especially in recent years, there has been increased interest in the clinical use of brain markers such as S100B proteins. To study the activity of the protein S100B in the blood serum of patients with striatal hyperkinesis (SH), depending on the duration of disease.

Methods:: The material of this study was 42 patients receiving inpatient and outpatient treatment in the 1-Republican Clinical Hospital Ministry of Health of the Republic of Uzbekistan. Patients ranged in age from 36 to 66 years (mean age 52.4±7.6 years). Duration of the disease is 1 to 8 years.

Results:: The study on the content of S100B serum of patients with secondary SH level was increased, while in the basic group was 116.2±5.8 ng/l and the control group, 72.6±2.6 ng/l (p<0.05). We conditionally allocated patients into 3 groups depending on the duration of the disease: one group of patients, the duration ranged from 6 months to 1 year, 2 patients from group 1 to 3 years and 3-band more than 3 years. These results show that the level S100B serum depends on the duration of the disease, whereas the duration of more than 3, the level of the protein was observed at a higher level than the duration of 6 months to 1 year, 112.4±5.6-153.7±6.8-178.7±6.5 ng/l, respectively. In primary striatal hyperkinesis, the protein S100B level was closer to the control group, 86.5±1.1 ng/l

Conclusions:: Serum S100B activity in patients with secondary hyperkinesis indicates the influence of serum factors that are already in the early stages.
CANNABINOIDS’ NEUROPROTECTIVE EFFECT AS AN ALTERNATIVE TREATMENT FOR PARKINSON’S DISEASE: A SYSTEMATIC REVIEW

Ana Carolina Ortiz¹, Aline Gavioli², Sandra Regina Ortiz²
¹Faculdade de Medicina do ABC, Centro Universitário Saúde ABC, Medicine, Santo André, Brazil, ²São Judas Tadeu University, Postgraduate Program In Aging Sciences, São Paulo, Brazil

Background and Aims:: Parkinson's disease (PD) is a neurodegenerative disease caused by the deterioration of substantia nigra pars compacta’s dopaminergic pathways, resulting in a decrease in stimulation of the motor cortex and symptoms linked to the reduction of automatic movements. It is known that several substances have protective effects against PD, among them cannabinoids (CB), obtained from Cannabis sativa, with emphasis on Cannabidiol (CBD) and Δ⁹-tetrahydrocanbinol (Δ⁹-THC). The aim of this study was to assess previous data describing the protective role of cannabinoids in PD and their mechanisms of action, focused on improving symptoms and quality of life of individuals with the disease.

Methods:: Searches in PubMed and PMC were performed and articles published within the last 5 years that described protective effects of cannabinoids in individuals with PD, addressing their mechanism of action, were included.

Results:: Until now, 179 articles that establish a link between cannabinoids and PD were found. Their initial analysis revealed significant neuroprotective effect, but the mechanisms of action of CB in the central nervous system, which contribute to the regression of PD, still vary and there is no consensus on which theory is the most acceptable.

Conclusions:: The literature that reports the effects of PD cannabinoids is not conclusive, but studies show that there is a connection between the activation of cannabinoid pathways, Parkinson's disease and BDNF production that can be explored to obtain favorable clinical outcomes. Future studies are necessary to determine which of these substances’ mechanism of action actually guarantees their protective effect against neurodegeneration.
HYPOGLYCEMIC ENCEPHALOPATHY MANIFESTING WITH HEMIBALLISMUS AND CONTRALATERAL CORTICAL FRONTO-PARIETAL LESIONS

Francesco Pasini¹, Aristotelis Karantzoulis¹, Gaia Fanella¹, Francesco Brovelli¹, Davide Iacobucci¹, Vittoria Aprea¹, Benedetta Storti², Francesco Santangelo¹, Francesco Canonico², Paolo Remida², Carlo Ferrarese¹, Laura Brighina¹

¹University of Milano-Bicocca, Medicine & Surgery, Monza, Italy, ²ASST San Gerardo Hospital, Neuroradiologia, Monza, Italy

Background and Aims: Severe hypoglycemia is associated with a broad range of neurological deficits and alterations on cerebral magnetic resonance imaging (MRI). Typically, hypoglycemic encephalopathy causes symmetrical lesions to the cerebral cortex, with temporal lobes and basal ganglia appearing most susceptible. Cortical involvement usually correlates with a poor functional outcome.

Methods: A 71-year-old man was admitted to hospital for acute hypoglycemic coma in poorly controlled type 2 diabetes mellitus. He promptly regained consciousness after intravenous glucose administration but during hospitalization he developed prominent intermittent ballistic movements of his right limbs intermixed with rare distal choreic movements. The involuntary movements did not respond to anticonvulsants and subsided within 12 days since admission in parallel with the improvement of glycemic control. Four months later, his neurological examination was normal.

Results: At hospital admission, CT brain scan was normal. Serial EEGs registered during the atypical movements failed to note any epileptic activity. Brain MRI showed left fronto-parietal cortical-subcortical T2-hyperintense lesions, with cingulate gyrus involved. DWI and T2-FLAIR sequences were hyperintense, ADC was reduced. Follow-up MRI imaging showed progressive regression of the abnormalities. After 80 days, cerebral MRI was normal.
Conclusions: This is the first report of cingulate gyrus damage in hypoglycemic encephalopathy. Unilateral cortical involvement could be explained by a generalized asymmetry of the cerebral vascularization. This is also the first evidence of pure cortical dysfunction in hypoglycemia-induced hemiballismus. This case also suggests that certain patients with cortical involvement in hypoglycemic encephalopathy may present a good clinical outcome, likely, if normal glycemic levels are promptly restored.
Background and Aims:: Markers for early detection of striatal hyperkinesis (SH) has not yet been fully explored not only in Uzbekistan, but in others the efforts of the world.

To study the basic clinical and non-clinical factors affecting the quality of life of patients with SH.

Methods:: The study involved 62 patients with SH (32 men and 30 women) and the control group consisted of 20 patients without SH. All patients underwent clinical neurological examination, including a detailed assessment of movement disorders. To evaluate the quality of life was used the EuroQoL-5D.

Results:: Compared with patients with SH motor and non-motor disorders significantly affect quality of life. It was found that 35 patients (56,4%) with SH have addressed to the doctor after 4-6 years from the onset of the disease, 19,3% (12) patients with SH were not even examined by specialized doctors, 24.3% (15) patients with SH had never applied to see a doctor. Among patients with SH who did not go to the doctor motor changes occurred in 92.3% of cases, pain/discomfort 85.1%, and anxiety/depression in 87.7% of cases, these rates among patients go the doctors amounted to 84.3 %, 78.4% and 76.2% respectively, and have created some problems (p<0,05). One of the factors affecting the quality of life is the late diagnosis of undifferentiated and SH.

Conclusions:: The deterioration of the quality of life of patients with SH depends on clinical factors in the form of motor and non-motor disorders, late treatment of patients to the doctor, undifferentiated and late diagnosis, untimely differential treatment.
**Background and Aims::** One of the most common circadian rhythm disorders in Parkinson's disease is a sleep cycle disorder.

**Methods::** A special questionnaire was developed to assess sleep disorders in Parkinson's disease (PD) and Vascular parkinsonism (VP). The study included 47 patients with PD and 40 patients with VP. Patients were divided into two groups and one group was recommended only basic treatment, while the second group was recommended 3mg of melatonin 40 minutes before bedtime. Patients' results were analyzed using scale of assessment of sleep disorders in modified PD and MMSE scale during four-week period.

**Results::** Prior to treatment, insomnia was observed in both groups, in the PD and VP patient groups. The addition of melatonin therapy to the main treatment provided significant efficacy, with an efficacy of 16% observed in the first week and was almost 10%, whereas in the second week it was higher efficacy of 26%, and in week 4 there was an increase in efficacy to 39%. Among VP patients melatonin therapy showed high efficacy in monitoring, with an efficacy of 10% after the first week of treatment, 19% after the second week, 32% after the third week, and 45% after the fourth week. Before treatment MMSE score was 21.3 ± 3.2 for PD patients and 24.3 ± 3.2 for PD patients receiving basic treatment, and 26.4 ± 2.1 for patients receiving basic treatment + melatonin therapy. And patients with VP the mean MMSE score before treatment was 20.4 ± 4.4, and 23.1 ± 3.2 in patients receiving basic treatment, patients receiving basic treatment + melatonin therapy had a mean MMSE score of 27.4 ± 2.1.

**Conclusions::** The results show that adding melatonin therapy to basic treatment for circadian rhythm disorder in PD and VP improves treatment efficacy and prevents deepening of cognitive impairment.
FROIN SYNDROME- A RARE MIMIC OF SPINOCEREBELLAR ATAXIA

Abeer Goel¹, Neeraj Balaini², Sahil Mehta¹, Vivek Lal³, Karthik Mahesh¹, Chirag Ahuja⁴
¹PGIMER, Neurology, Chandigarh, India, ²PGIMER, Chandigarh, Neurology, Chandigarh, India, ³Postgraduate Institute of Medical Education and Research (PGIMER), Neurology, Chandigarh, India, ⁴Postgraduate Institute of Medical Education and Research (PGIMER), Neuroradiology, Chandigarh, India

Background and Aims:: Spinocerebellar ataxias are degenerative heritable disorders affecting cerebellum accompanied by changes in brainstem and other parts of central nervous system. This case highlights the same and emphasizes on the importance of recognizing clinical and radiological clues for identification of secondary causes of cerebellar degeneration for timely intervention and management of patient.

Methods:: We present a 52-year-old female with 10-year history of progressive frontal predominant behaviour disturbances in form of apathy and impaired judgement accompanied with progressive pan cerebellar involvement and spastic quadriparesis with urinary incontinence. Her MRI brain showed diffuse cortical and cerebellar atrophy with communicating hydrocephalus with irregular wavy borders of dilated sylvian fissure and low signal with blooming seen along cortical and cerebellar sulci. Further CSF showed xanthochromia with raised csf protein. Provisional diagnosis of spinal cord tumour with secondary superficial hemosiderosis was kept and MRI spine was done which showed T2 heterogenous hyperintense lesion in spinal cord opposite lumbar (L1-L2) vertebrae which was removed.

Results:: The spinal cord lesion removed was diagnosed as Grade 1 myxopapillary ependymoma on histopathology with secondary froin syndrome and superficial hemosideros. On followup, patient's behaviour changes and spasticity has improved though her cerebellar signs persist.

Conclusions:: It is important to always have high degreee of suspicion for treatable causes of chronic progressive cerebellar dysfunction especially when accompanied by other signs of neuraxis involvement and subtle imaging findings.
SACCADIC BRADYKINESIA IN PARKINSON’S DISEASE: PRELIMINARY OBSERVATIONS

Nehzat Koohi¹, Matthew Bancroft¹, Jay Patel², Patricia Castro², Harry Akram², T Warner³, Diego Kaski¹
¹University College London, Centre For Vestibular And Behavioural Neuroscience, Department Of Clinical And Movement Neurosciences, Institute Of Neurology, London, United Kingdom; ²University College London Hospitals, Adult Diagnostic Audiology, London, United Kingdom; ³University College London, Queen Square Brain Bank For Neurological Disorders, Ucl Queen Square Institute Of Neurology, London, United Kingdom

Background and Aims:: Bradykinesia and hypokinesia of limb movements are features of Parkinson’s Disease (PD), exacerbated when patients perform self-guided, repetitive limb movements— the so-called ‘sequence effect’. In the oculomotor system, both hypometria and slowing of voluntary saccades have been described in PD (1) but never as a change over time, which is the defining feature of this phenomenon.

Methods:: We examined six mildly- or moderately-impaired PD patients (Unified Parkinson’s Disease Rating Scale: UPDRS motor part, 11±2.8 points; duration of illness, 2.2±0.4 years) aged 69±5 yrs (one female) and seven age-matched healthy control individuals (five female, 56±7 years). Voluntary and reflexive horizontal saccadic eye movements were recorded with infrared binocular videonystagmography (VNG) sampled at 250Hz.

Results:: Voluntary horizontal saccades without visual targets led to a progressive decrease in PD saccadic amplitude over time (hypometria). Additionally, PD saccadic velocity progressively reduced over time, even when accounting for smaller saccadic amplitudes main sequence effect. Group (PD vs. Controls) and time (first six vs. final six saccades) interacted for both amplitude and velocity (F(1,11)>6.1; p<0.0031), with a decrease over time in PD (p≤0.001) but not controls (p>0.110). PD saccadic velocity in the final six saccades was lower than normative amplitude-matched velocities (p=0.039) whereas no difference was present in the first six saccades (p=0.547).

Conclusions:: Saccadic bradykinesia was apparent in all consecutive patients, but absent in age-matched controls. “Saccadic bradykinesia” may be a useful and early clinical sign of PD and future studies should confirm these findings and assess its specificity as a clinical biomarker of disease progression.
ASPECTS OF THE VEGETATIVE DISORDERS OCCURRENCE IN THE PARKINSON'S DISEASE AND VASCULAR PARKINSONISM

Shokh-Jakhon Khamdamov¹, Dilshoda Akramova²
¹Tashkent Medical Academy, Neurology, Beruniy B, Uzbekistan, ²Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: Vegetative disorders are among the most common and diagnostically significant disorders in Parkinson’s disease(PD) and Vascular Parkinsonism(VP) after motor disorders.

Methods:: A clinical neurological examination was carried out in 47patient with PD and 40with VP who hospitalized in the Department of Neurology of the TMA. A special survey was carried out, the results of the survey were analyzed.

Results:: According to the results of the survey, the incidence of general hyperhidrosis was predominant in the group of PD patients and consisted 74.4%. In the group of VP patients total hyperhidrosis was observed in 7.5%, constipation was observed in 64% patients with PD, in VP patients this figure was observed in VP patients this figure was 10%, similarly, salivation was high in PD patients, in 46.8% of cases, in VP it was observed in 3 patients, ie in 7.5% of cases, and orthostatic hypotension was observed in high indicators in the group of VP patients. It has been suggested that the observation of idiopathic orthostatic hypotension in the VP group with a high frequency is related to the changes observed in the blood vessels. Similarly, angiotrophalic changes were observed in 42% of patients in the VP group and in 7% of patients in the PD.

Conclusions:: Although Peripheral Vegetative Deficiency Syndrome occurs in both diseases, it manifests in two forms of the disease in terms of origin and appearance. These changes are important in the diagnosis of the disease.
ASPECTS OF METABOLIC DISORDERS IN PARKINSON'S DISEASE, VASCULAR PARKINSONISM AND CHRONIC CEREBRAL ISCHEMIA

Nigora Akramova¹, Dilshoda Akramova²
¹Tashkent Medical Academy, Neurology, Beruniy B, Uzbekistan, ²Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: Although the origin of Parkinson’s disease is not the result of a metabolic disorder, metabolic acceleration plays an important role in the development of this disease and the development of motor symptoms. To identify and analyze the features of metabolic disorders in Parkinson's disease, vascular parkinsonism and chronic cerebral ischemia

Methods:: Anthropometric analysis and bioimpedensitometry were performed in 47 patients with Parkinson's disease (PD), 40 with Vascular parkinsonism (VP) and 30 with Cerebral chronic ischemia (CCI) to found metabolic disorders in PD, VP, CCI.

Results:: It found that, in the group of patients with PD, in 32% BMI was <18.5 below, and in 53% of patients BMI was between 18.5 and 24.9, and in 15% of patients BMI was above 25. In 15% of patients with VP, the BMI was less than <18.5, in 30%, the BMI was in the range of 18.5–24.9, and in 65%, the BMI was higher than 25. In the group of patients with PD, in 31% of patients muscle mass was 46.1 ± 1.76, in 50% of patients muscle mass was 48.1 ± 1.40 and in 19% of patients 64,664.6 ± 1.8. In 18% of patients with VP, muscle mass was 54.0 ± 1.02, in 61% of patients muscle mass was 51.1 ± 1.39, and in 21% of patients, muscle mass was 49.9 ± 1.36. In the CCI group of patients muscle mass averaged 47.0 ± 1.02.

Conclusions:: The results obtained show that a decrease in muscle mass in Parkinson's disease is less common than in vascular parkinsonism and chronic cerebral ischemia.
Background and Aims:: Essential Tremor is one of the common causes of tremor affecting elderly worldwide. It is believed to be genetically inherited. Many cases seem to be familial. About half of the cases are due to a genetic mutation and the pattern of inheritance is most consistent with autosomal dominant transmission. Objective: to study the demographics of patients with ET in a tertiary hospital in Penang, Malaysia whether there are any sporadic cases, or solely genetically linked and mainly affect elderly.

Methods:: This is a retrospective analysis of patients with ET from 1988 -2020.

Results:: A total of 159 patients were identified as having essential tremor. There were 43% (n=68 ) males and 57% (n=91 )females. The racial distribution was Malay 20%, Chinese 64% and Indian 15%. The age of patients ranged from (19 - 89) years with a majority (55.9%, n=89) within the age group of > 61 years. 77.35% of the cohort had tremors on their right hand, while 46 patient had titubation. Among the 159 patients, 11.32% (n = 18), not received any treatment, 53 patients are taking propanolol only, 10 patients received primidone monotherapy, 0 patients received 2 drugs (propanolol and primidone). 3 patients has PD superimposed with ET Total 9 patients on clonazepam but 6 patients on Clonazepam as mono therapy while 3 patients on proponolol and clonazepam.

Conclusions:: Our study found that ET is significantly higher among Chinese race with female predominance. A combination of treatment with beta blockers or Phenobarbitals (Primidone) have led to improvement in symptoms.
CSF LEVEL OF ANTI-AGING PROTEIN A-KLOTHO IS INVERSELY ASSOCIATED WITH A-SYNUCLEIN IN PARKINSON’S DISEASE PATIENTS

Giulia Maria Sancesario¹, Giulia Di Lazzaro², Piergiorgio Grillo², Emilia Giannella¹, Sergio Bernardini³, Carlo Caltagirone⁴, Nicola Mercuri³, Antonio Pisani⁵, Tommaso Schirinzi²
¹IRCCS FONDAZIONE SANTA LUCIA, Biobank, ROMA, Italy, ²University of Roma Tor Vergata, Department Of Systems Medicine, Rome, Italy, ³University of Roma Tor Vergata, Rome, Italy, Department Of Experimental Medicine, Rome, Italy, ⁴IRCCS Fondazione Santa Lucia, Dipartimento Di Neurologia Clinica E Comportamentale, Roma, Italy, ⁵University of Pavia, Department Of Brain And Behavioral Sciences, Pavia, Italy

Background and Aims:: α-Klotho (KL) is an “anti-aging” protein involved in several age-related and neurodegenerative disorders. However, its role in Parkinson’s disease (PD), especially in vivo, is still poorly explored.

Methods:: We assessed the level of KL, α-synuclein and other neurodegenerative biomarkers, amyloid-β42 and amyloid-β40 (Aβ42 and Aβ40), total tau and phospho-tau181, in cerebrospinal fluid (CSF) of 36 PD patients and 9 control subjects, affected by other neurological diseases.

Results:: CSF KL was increased in PD compared to controls (689±193 pg/ml vs 527±225; p<0.05), independently from age and sex; as expected, CSF α-synuclein was decreased in PD patients compared to controls (PD 943±184 pg/ml; control 1186±249; p<0.005). Levels of Aβ42, Aβ40, total tau and phospho-tau181 were similar in both groups. We found that CSF KL levels and α-syn were inversely associated, suggesting a greater KL expression in those patients with more severe brain synucleinopathy, measured by the reduction of CSF α-synuclein. No correlations between KL and other biomarkers or clinical parameters were found.

Conclusions:: In PD, KL level is increased and may have a neuroprotective role to counteract accumulating synucleinopathy.
ROLE OF OLFACTORY AND GUSTATORY DISFUNCTIONS IN THE REGULATION OF BODY WEIGHT IN PATIENTS WITH PARKINSON’S DISEASE

Gianni Orofino¹, Carla Masala², Paolo Solla³, Pinna Ilenia², Tommaso Ercoli⁴, Manuela Pintus⁵, Maria Margherita Sechi⁶, Giovanni Defazio⁷

¹Department of Emergency, University-Hospital of Cagliari, Cagliari, Italy, Department Of Neurology, University Of Cagliari, Cagliari, Italy, Monserrato, Italy, ²University of Cagliari, Section Of Physiology, Department Of Biomedical Sciences, Cagliari, Italy, ³University of Sassari, Department Of Neurology, Sassari, Italy, ⁴Department of Medical Sciences and Public health, Institute of Neurology, University of Cagliari, Cagliari, Italy, ⁵Department Of Medical Sciences And Public Health, Institute Of Neurology, University Of Cagliari, Cagliari, Italy, ⁶Azienda Ospedaliero Universitaria di Cagliari, Institute Of Neurology, Cagliari, Italy, ⁷University of Caglieri, Department Of Medical Sciences And Public Health, Monserrato, Italy

Background and Aims:: Parkinson’s disease (PD) is a neurodegenerative disorder characterized by motor symptoms bradykinesia, rigidity, tremor and postural instability. However, PD is usually associated with non-motor symptoms (NMS) that include olfactory and gustatory dysfunctions, neuropsychiatric symptoms such as apathy, anxiety and cognitive impairment, sleep problems, and autonomic dysregulation. Few data are available regarding the contribution of NMSs and motor symptoms on body weight change in PD patients. The aim of this study was to assess the effect of olfactory and gustatory dysfunction, apathy, fatigue and motor symptoms on weight regulation in PD patients.

Methods:: We analyzed 112 participants, 63 PD patients (mean age ± SD, 69.2 ±10.1), and 49 controls (mean age ± SD, 68 ± 9.6). For each participant we collected age, weight, height, olfactory and gustatory function, cognitive performance, apathy and fatigue.

Results:: Our data showed that 61.9% (n = 39) of PD patients had hyposmia, while 38.1% (n = 24) had anosmia. In PD patients, we observed a significant effect of Unified Parkinson’s Disease Rating Scale (UPDRS), apathy, odor threshold, sweet perception and fatigue on body weight regulation. Instead, there was no significant effect for levodopa equivalent daily dosage (LEDD).

Conclusions:: Our results suggest that in PD non-motor symptoms such as olfactory, gustatory, deficits and mood disorders may influence body weight. This study may provide better knowledge in PD patients on the mechanism underlying food intake and weight regulation.
EFFECT OF VITAMIN B12, FOLATE, AND ENTACAPONE ON HOMOCYSTEINE LEVELS IN LEVODOPA-TREATED PARKINSON’S DISEASE PATIENTS: A RANDOMIZED CONTROLLED STUDY

Chumpol Anamnart, Ram Kitjarak
King Prajadhipok Hospital: Prapokklao Hospital, Medicine, Chanthaburi, Thailand

**Background and Aims:** Previous studies have suggested a significant increase in plasma homocysteine (Hcy) levels in levodopa-treated Parkinson's disease (PD) patients, and vitamin B12 and folate supplementation may decrease Hcy levels. However, the effects of catechol-O-methyltransferase inhibitors on levodopa-induced increase in Hcy levels were conflicting. The aim of this study was to evaluate whether Hcy levels are increased in levodopa-treated PD patients and to evaluate the effects of vitamin B12 and folate or entacapone on Hcy levels in levodopa-treated PD patients.

**Methods:** We analyzed and compared plasma Hcy levels in 20 levodopa-naïve PD patients and 42 levodopa-treated PD patients, followed by randomized assignment of 42 levodopa-treated patients to treatment groups with either vitamin B12 and folate, entacapone, or no medication.

**Results:** Plasma Hcy levels in levodopa-treated PD patients were higher than those in the control group, but the difference was not statistical significant (15.25 ± 6.70 and 13.13 ± 4.68, P = 0.216). Patients treated with vitamin B12 and folate had a significant decrease in plasma Hcy levels (P < 0.001). In the entacapone group, Hcy levels were mildly decreased, but the change did not reach statistical significance.

**Conclusions:** Levodopa-treated PD patients had higher plasma Hcy than levodopa-naïve PD patients. Unlike entacapone, combination supplementation with vitamin B12 and folate was associated with significantly decreased plasma Hcy. We suggest that plasma Hcy levels should be monitored during levodopa treatment, and supplementation with inexpensive vitamin B12 and folate is beneficial for levodopa-treated patients.
ASYMMETRY IN SACCADIC EYE VELOCITY AND LATENCY MAY DISTINGUISH CORTICOBASAL DEGENERATION FROM OTHER ATYPICAL PARKINSONISMS

Clara Grazia Chisari¹,², Giovanni Mostile¹,³, Claudio Terravecchia¹, Antonina Luca¹, Giorgia Sciacca¹, Giulia Donzuso¹, Calogero Cicero¹, Cristina Rascunà¹, Roberta Terranova¹, Alessandra Nicoletti¹, Mario Zappia¹
¹University of Catania, Department "g.f. Ingrassia", Section Of Neurosciences, Catania, Italy, ²University of Catania, Department Of Medical And Surgical Sciences And Advanced Technologies "g.f. Ingrassia", Catania, Italy, ³Oasi Research Institute-IRCSS, Troina, Italy.

Background and Aims:: Corticobasal degeneration (CBD) is a neurodegenerative condition exhibiting a notable overlap in clinical and pathological characteristics with other atypical parkinsonisms. Several eye movement abnormalities have been described in patients with CBD; however, oculomotor signs are variable and often resemble those of other parkinsonian disorders. This study aimed to define the distinguishing patterns of eye motility dysfunctions in CBD patients compared to other atypical parkinsonisms.

Methods:: This study screened patients having diagnosis of atypical parkinsonisms including CBD, according to the diagnostic criteria. All patients underwent a complete neuroophthalmological examination and the video-oculography (Eyelink®1000 Plus), consisting of three eye motility tasks in order to evaluate fixation, smooth pursuit and saccades.

Results:: A total of 11 patients with CBD (4 males [36.4%], age 67.3±7.2 years) and 33 parkinsonian syndromes, including 23 (69.7%) progressive supranuclear palsy (PSP) and 10 (30.3%) multiple system atrophy (MSA), were enrolled. The inter-eye differences (ID) for saccadic velocity and latency were higher in CBD patients compared to PSP and MSA (91.1±63.1 versus 17.1±23.5 and versus 8.4±9.0, p<0.001; 65.9±64.1 versus 16.3±21.6 and versus 18.4±24.6, p<0.001, respectively). Receiver-operating characteristics (ROC) analysis showed that an ID for velocities measurement >20°/s distinguishes CBD from other parkinsonisms with a sensitivity of 90.9% and a specificity of 90.6%, and the area under the ROC curve was calculated as 0.98 (95% CI 0.95-0.99, P < 0.001).

Conclusions:: CBD exhibit distinct oculomotor features. The asymmetrical involvement of saccadic abnormalities may help to distinguish CBD from PSP and MSA.
Changes in Personality Associated with Deep Brain Stimulation in Parkinson Disease

Francesca Mameli, Fabiana Ruggiero, Sara Marceglia, Marco Prenassi, Linda Borellini, Filippo Cogiamanian, Benedetta Capetti, Denise Mellace, Michelangelo Dini, Maurizio Vergari, Elena Pirola, Marco Locatelli, Alberto Priori, Sergio Barbieri, Filippo Cogiamanian, Benedetta Capetti, Denise Mellace, Michelangelo Dini, Maurizio Vergari, Elena Pirola, Marco Locatelli, Alberto Priori, Sergio Barbieri

Background and Aims: Subthalamic deep brain stimulation (STN-DBS) is an effective treatment option in Parkinson's disease (PD), producing robust motor improvements in the motor symptoms and allowing the reduction of antiparkinsonian drugs dosage. There is, however, increasing evidence that STN-DBS may be associated with a higher incidence of adverse changes in behavior when compared to other stimulation sites (1). To date, no study has investigated the effect of the amount of total electrical energy delivered (TEED) on behavioral adverse changes. To characterize this issue, we assessed personality traits correlated with TEED in twenty PD patients before and 12 months after the start of neurostimulation.

Methods: 20 PD patients (12 women, mean [±SD] age 57.6±7.6 years) with advanced L-dopa responsive PD were included in this study. We tested psychological issues before and 12 months after bilateral DBS-STN. To assess personality we used MMPI-2 according to CAPSIT-PD procedure (2).

Results: After 12 months, patients showed a significant increase only in MMPI-2 subscale D for depression (preDBS mean: 55.43, SD:8.95; 12 Months mean:61.73, SD:10.15; p=0.0053, r=-0.41, Wilcoxon signed-rank test). All the other subscales did not differ before and after 12 months DBS. We found a correlation between the changes in MMPI-2 subscale D after 12 months and TEED on the right hemisphere (Spearman's rho=-0.68, p=0.007).

CLINICAL FEATURES OF PRIMARY PARKINSONISM TAKING INTO ACCOUNT THE RESULTS OF MOLECULAR-GENETIC DIAGNOSTICS

Feruzjon Rakhimov, Yulduz Musaeva, Gulnora Rakhimbaeva
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: INTRODUCTION. Parkinson's disease (PD) is a progressive neurodegenerative disease, which is based on a decrease in the number of dopaminergic neurons in the substantia nigra. Genetic defects of the PARK2 gene are responsible for the development of 50% of cases of autosomal recessive juvenile parkinsonism (JP) and 10-20% of PD with early onset. The gene LRRK2 is the second most important gene, mutations in which cause the development of autosomal dominant and sporadic forms of PD. PURPOSE OF THE STUDY. Study of clinical features taking into account the results of molecular genetic diagnostics of patients with primary parkinsonism (PP).

Methods:: METHODS. Family history data, neurological status, results of molecular genetic diagnostics were examined - PCR, sequencing, denaturing high performance liquid chromatography, restriction analysis.

Results:: RESULTS. The group of patients with PP consisted of 62 people: 60 with PD (of which 35 PD with early onset before the age of 45 years) and 2 patients with JP. The prevalence of women among all patients was revealed; their ratio with men was 1.1: 1. The age of the examined persons was from 27 to 77 (52.1 to 19.3); the age of onset of the disease was from 19 to 72 years (44.9 11.2). In the group of PD patients with early onset: age from 27 to 74 (47.29.5), age of onset of the disease from 22 to 45 years (37.3 to 7.1).

Conclusions:: The group of patients with PP consisted of 62 people: 60 with PD and 2 patients with JP
QUALITY OF LIFE OF PATIENTS WITH PARKINSON'S DISEASE AND THEIR CAREGIVERS DURING THE COVID-19 PANDEMIC

Keisuke Suzuki¹, Ayaka Numao¹, Tomoko Komagamine¹, Yasuo Haruyama², Akiko Kawasaki¹, Kei Funakoshi¹, Hiroaki Fujita¹, Shiho Suzuki¹, Madoka Okamura¹, Tomohiko Shiina¹, Koichi Hirata¹
¹Dokkyo Medical University, Department Of Neurology, Mibu, Japan, ²Dokkyo Medical University, Integrated Research Faculty For Advanced Medical Science, Mibu, Japan

Background and Aims:: The coronavirus disease 2019 (COVID-19) pandemic has negatively affected the mental health of the general population. The determinants of quality of life (QOL) in Parkinson’s disease (PD) patients and their caregivers during the COVID-19 pandemic were assessed.

Methods:: We performed a single center, cross-sectional study including 100 patients with PD and their caregivers/spouses. The Hospital Anxiety and Depression Scale was used to assess anxiety and depression. To assess health-related QOL, the physical component summary (PCS) and mental component summary (MCS) scores of the short form (SF)-8 were used.

Results:: Regarding health-related QOL, physical function, role physical, general health, vitality and the PCS score were significantly worse in PD patients than in caregivers. Worsening of PD-related symptoms, increased stress, and decreased physical activity were observed in 29.0%, 37.0% and 44.0% of PD patients, respectively. Sixteen patients (16.0%) experienced problems accessing the hospital, but none reported medication shortages. Approximately half of the participants had strong concerns about COVID-19. In PD patients, increased gait disturbance and rigidity, disease severity, smoking, the levodopa equivalent dose and decreased body weight predicted a worse PCS score, while anxiety, depression, female sex, stress and long disease duration predicted a worse MCS score. In caregivers, age and smoking contributed to a worse PCS score, while depression, stress and worsening patient mood contributed to a worse MCS score.

Conclusions:: We showed the negative impacts of the COVID-19 pandemic on health-related QOL and its determinants in PD patients and their caregivers.
AFFECTIVE DISORDERS AND QUALITY OF LIFE IN PATIENTS WITH CERVICAL DYSTONIA REGULARLY TREATED WITH BOTULINUM TOXIN

Robert Ibatullin, Mansur Kutlubaev, Rim Magjanov
BGMU, Neurology, Ufa, Russian Federation

Background and Aims:: Cervical dystonia (CD) is the most common type of dystonia. Anxiety and depression affects up to 70% of patients with CD and markedly reduce health-related quality of life. The most effective method of treatment of CD is local injections of botulinum toxin. Reduction of motor symptoms should improve not only motor symptoms, but also decrease the severity of depression, anxiety and increase quality of life. Aim: To evaluate quality of life, anxiety and depression in patients with CD regularly treated with botulinum toxin.

Methods:: 10 patients (6 females and 4 males) with mean age 41,4±5,1 years were assessed. The severity of CD was assessed using Toronto Western Spasmodic Torticollis Rating Scale (TWSTRS), quality of life - by SF-36, affective disorders – by Beck depression inventory and Silberger anxiety inventory. Second assessment was performed in 2-4 years after regular treatment with botulinum toxin.

Results:: Severity of CD (TWSTRS) decreased from 39,0±8,0 to 29,9±6,5 (p<0,05). Physical component of SF-36 decreased from 41,1±7,5 to 34,9±10,7 (p<0,05)

Conclusions:: Regular treatment of CD with botulinum toxin improved physical component of the quality of life, which corresponds to the improvement of the overall severity of CD. However, no changes in the severity of the affective disorders were noticed, moreover mental health component of SF-36 worsened in the half of the patients. Psychological changes seem to play an important role in the health-related quality of life in patients with CD. They do not respond to the treatment of motor symptoms of CD and probably have more complex etiology than physical presentation.
A PILOT RANDOMIZED TRIAL OF MOBILE-HEALTH DELIVERED REHABILITATION FOR PARKINSONS DISEASE IN GHANA

Fred Sarfo¹, Vida Obese¹, Sheila Adamu¹, Bruce Ovbiagele²
¹Kwame Nkrumah University of Science & Technology, Medicine, Kumasi, Ghana, ²University of California, San Francisco, Neurology, San Francisco, United States of America

Background and Aims:: In addition to dopaminergic drug therapy, rehabilitation is key component of holistic Parkinsons disease (PD) management strategy. Rehabilitation however is severely constrained in sub-Saharan Africa (SSA) due to access barriers. We sought to assess the comparative efficacy of a domiciliary mobile health telerehabilitation intervention vs in-person rehabilitation among patients with PD in Ghana.

Methods:: A pilot randomized clinical trial was conducted at the Neurology clinic at the Komfo Anokye Teaching Hospital in Kumasi, Ghana. Eligible participants were PD patients with Hoehn and Yahr stage 1-3. Participants were randomized to either the telerehab intervention administered daily for 5 days a week for 3 months using the 9zest App on a Smartphone vs usual care i.e. in-person rehabilitation as determined by physician/physiotherapist. Primary outcomes were change Unified Parkinsons Disease Rating Score (UPDRS) II-III and PDQ-39 Summary index at month 3.

Results:: 26 participants were allocated to the intervention vs 30 to usual care with median ages of 60 years vs 64 years respectively, p=0.03. At month 3, the mean change in UPDRS II-III scores was -1.76 ± 7.37 on the intervention vs -0.83 ± 5.43, p=0.59 while PDQ-39 summary index was 13.1% ± 10.0 on the intervention vs 19.9% ± 12.7 in the usual care, p=0.03. Participants on the telerehab arm reported good to excellent satisfaction with the intervention.

Conclusions:: We demonstrate feasibility and comparable preliminary efficacy of telerehabilitation for PD in a resource-limited setting. Wider scale testing of this promising intervention across low-and-middle income countries is warranted.
INCOMPLIANCE IN LONG-TERM TREATED PATIENTS WITH NEUROLOGICAL WILSON’S DISEASE

Sara Samadzadeh¹, Max Novak¹, Theo Kruschel¹, Philipp Albrecht¹, Christian J Hartmann¹, Sven G Meuth¹, Harald Hefter²
¹University Hospital of Düsseldorf, Department Of Neurology, Düsseldorf, Germany, ²University Hospital of Düsseldorf, Department Of Neurology, Düsseldorf, Germany

Background and Aims:: This study aimed to analyze the compliance in long-term treated patients with neurological Wilson’s disease (WD).

Methods:: Retrospective chart analysis of 112 patients with diagnosed WD who were seen in the outpatient department of the university hospital in Düsseldorf (Germany) on a regular basis over the last 35 years. Clinical neurological scores and repeated laboratory testings were analyzed.

Results:: Duration of follow-up ranged from 1 to 35 years. During the first two years after diagnosis patients were seen between 1 to 4 times per year in the out-patient department. Thereafter frequency of contact declined to 1/year during the next 5 years and to 1/2years during the next 5 years. The severity of neurological symptoms rapidly improved during the first three years and then remained stable. In parallel, excellent liver recovery was observed. Most patients were continuously compliant in adhering to the visit schedule and treatment regimen. However, about 25% of the patients presented with considerable variability of laboratory findings, indicating reduced compliance. The presence of psychiatric symptoms appeared to be a risk factor for incompliance. One patient died after he had stopped medication for one year.

Conclusions:: After rapid initial improvement of neurological symptoms the long-term outcome is stable, but careful monitoring of therapy is recommended because of possible incompliance, especially in patients with psychiatric symptoms.
A (VERY) EARLY ONSET PARKINSONISM

Francesco Paolo Bonifacio¹, Rosa De Micco¹, Simone Aramini¹, Sara Satolli¹, Anna Lauraa Torella², Francesca Del Vecchio Blanco², Vincenzo Nigro², Gioacchino Tedeschi¹, Alessandro Tessitore¹
¹University of Campania “Luigi Vanvitelli”, Department Of Advanced Medical And Surgical Sciences, Naples, Italy, ²University of Campania “Luigi Vanvitelli”, Department Of Precision Medicine, Naples, Italy

Background and Aims:: A 51 years-old woman was admitted to our Neurology department, because of poor control of her Parkinson’s disease’s (PD) symptoms. Her history started when she was 11 years old, with an abrupt onset of gait disturbances and a dystonic posture in the left lower limb. She then progressively developed bilateral arm tremor and axial rigidity. She was diagnosed with PD at the age of 24, and then started dopaminergic medication, still ongoing. Her personal history revealed a 30 years old-psychiatric disorder treated with neuroleptics. Her father presented cognitive impairment.

Methods:: At our clinical examination, she was presenting with unpredictable motor and non-motor levodopa-induced fluctuations, namely dystonic postures during the OFF-state and lower limbs dyskinesia during the ON-state. The presence of a fixed dystonic posture of left lower limb and facial-facial-finger myoclonus were also detected. We performed a brain MRI, showing diffuse cerebral atrophy, and an extensive neuropsychological evaluation showing multiple cognitive deficit (MMSE 21.31).

Results:: Given the early symptoms onset, the presence of motor and non-motor features and the family history, we performed a next generation sequencing genetic testing, which revealed a double heterozygosis within the ATP13A2 gene (PARK9). These mutations have not been described yet and are potentially diagnostic for a Kufor-Rakeb syndrome (KRS).

Conclusions:: This case highlights the importance of considering genetic testing in the presence of family history for neurological disorders as well as early onset and occurrence of both motor and behavioral disturbances. The presence of facial-facial-finger myoclonus is a clue clinical sign suggesting the diagnosis of KRS.
APPLICATION OF TEMPORHYTHMIC CORRECTION NEUROREHABILITATION EXERCISE COMPLEX IN PARKINSON'S DISEASE

Dilshoda Akramova, Gulnora Rakhimbaeva
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims: Temporhythmic correction (TRC) is a new complex of neurorehabilitation exercises used in Parkinson’s disease. In this method, exercises that develop fine motor skills are performed with music.

Methods: The effectiveness of TRC was evaluated in the Department of Neurology of the Clinic of the Tashkent Medical Academy in patients with a diagnosis of Parkinson's disease. Patients were divided into 2 groups: the first group received only basic treatment, the second group received basic treatment + TRC. In patients, TRC was performed for ten days. Step length was measured before and after treatment. A special survey was conducted to assess the level of quality of life.

Results: The mean step length was 57.3 before treatment in the first group and 61.2 after treatment. In the second group, it was 56.3 before treatment and an average of 70.4 after treatment. According to the survey, 67% of patients after TRC had a decrease in tremor frequency, 72% had a decrease in rigidity, 69% had improved sleep quality, 58% had improved self-care, and Decreased difficulty in stepping was observed in 56% of patients. 53% of patients felt that no mood disorders were observed after TRC. Muscle tone normalized after TRC in 32% of patients.

Conclusions: TRC is effective in all types of Parkinson's disease, improves quality of life in patients, increases the effectiveness of drug treatment. TRC effectively treats gait and movement disorders in patients, and improves sleep quality.
BOTULINUM TOXIN A AND CERVICAL DYSTONIA: A LONG-TERM MONOCENTRIC EXPERIENCE

Luca Bosco1, Carla Butera2, Giacomo Sferruzza1, Stefano Amadio2, Roberta Guerriero2, Roberto Santangelo1, Stefano Tronci1, Camilla Mirella Strano1, Francesca Bianchi3,4, Ubaldo Del Carro2, Massimo Filippi5,6

1San Raffaele Hospital, Neurology Unit, Milano, Italy, 2IRCCS Ospedale San Raffaele, Neurophysiology, Milano, Italy, 3University of Pisa, Department Of Clinical And Experimental Medicine, Neurological Clinic, Pisa, Italy, 4Azienda Ospedaliero Universitaria Pisana, Neuromuscular Unit, Pisa (PI), Italy, 5IRCCS San Raffaele Scientific Institute, Neurology Unit, Neurorehabilitation Unit And Neurophysiology Service, Milan, Italy, 6IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Divisione Of Neuroscience, Milano, Italy

Background and Aims:: Treatment with botulinum toxin A (BoNT-A) is the first-line therapy of cervical dystonia (CD). The aim of this study is to evaluate long-term efficacy and tolerability of BoNT-A and treatment efficacy predictors in a CD monocentric cohort, over two decades.

Methods:: We retrospectively analyzed treatment data of 178 consecutive CD patients in our outpatient clinic, treated with BoNT-A according to clinical practice, from July 2002 to March 2021. Dosage, treatment pattern, time between visits and follow-up duration were adopted as explanatory variables. Variations in objective (TWSTRS) and subjective scales (GTS), as well as duration of the benefit and side effects, were used as outcome measures to assess treatment efficacy.

Results:: We analyzed 4039 treatment sessions, with a median follow-up of 5 years [IQR: 1-11]. A end-dose mitigation in severity from baseline was observable in the majority of cases (median ΔTWSTRS: -10[IQR: -19; -1]), no development of resistance was reported. Instead, we observed a tendency in stabilizing the dosage after the first years of treatment. None of the explanatory variables emerged as a clear predictor for efficacy, reflecting the heterogeneity in disease courses. Side effects included mild dysphagia(8%), muscle weakness(1%), and local pain(2%), the latter correlating with infiltrations of the splenius(p=0.01). Frequent reasons for therapy discontinuation included treatment failure(12%) and persistent benefits(8%).

Conclusions:: BoNT-A treatment is an effective therapy for CD, even over many years. Due to the intrinsic heterogeneity of the disease, a deterministic predictor of treatment response is yet to be found in the out-patient setting. Treatments need to be patient-tailored, majorly relying on physician experience.
CHRISTIANSON SYNDROME MANIFESTED AS ATYPICAL PARKINSONISM: A CASE REPORT

Carmen De Rojas Leal, Mariam Afkir Ortega, Alba Aguilar Monge, Silvia Jesus Maestre, Maria Jose Gómez Heredia, Francisco Pérez Errazquin

1Hospital universitario Virgen de la Victoria, Neurology, Málaga, Spain, 2Hospital Universitario Virgen de la Victoria, Neurology, Málaga, Spain, 3University Hospital Virgen de la Victoria, Neurology, Málaga, Spain, 4Hospital Universitario Virgen del Rocio, Neurology, Sevilla, Spain, 5Hospital virgen de la Victoria, Neurología, Malaga, Spain, 6Universitario Virgen de la Victoria, Neurology, Málaga, Spain

Background and Aims:: Christianson syndrome (CS) is an X-linked disorder characterized by cognitive dysfunction, behavioral abnormalities and neurologic findings such as ataxia, abnormal eye movement, feeding difficulties, lack of facial expression, hyperkinesia and seizures. Here, we describe a case of a male with CS with severe parkinsonism.

Methods:: Case report.

Results:: A 41 year-old man with intellectual disability consulted for slowness of movements, progressive cognitive decline, sleep disturbances and hypersalivation with swallowing problems. The medical exam showed severe bradykinesia, hypomimia, generalized dystonia, left asymmetric tremor and supranuclear gaze palsy. In the personal medical history, the mother suffered from genetic Parkinson (LRKK2). Treatment with carbidopa/levodopa did not improve the symptoms. Therefore, a diagnosis of atypical parkinsonism was made. Blood tests (including TSH, CK and ceruloplasmin) and Brain-MRI were unremarkable. DATSCAN showed neuronal loss via the presynaptic nigrostriatal with greater involvement of the right striatum. Extensive genetic study (including LRRK2, PARK-1-3-6-7, SCA 1-2-3-7-8-17, DYT-5, FXTAS, Nieman-Pick and Huntington) was negative. Whole-exome sequencing showed a hemizygous c.767GA (p.S256N) missense pathogenic variant in the SLC9A6 gen on the X-chromosome associated with Christianson syndrome. A genetic study of the mother and two sisters showed the same pathogenic variant in the SLC9A6 gen (female carriers).

Conclusions:: CS may present with severe bradykinesia and supranuclear gaze palsy, mimicking an atypical parkinsonism syndrome. Neurologist should be aware that, although hyperkinesia is a frequent symptom, bradykinesia may be present difficulting the diagnosis of CS. Therefore, we highly recommend performing an extensive genetic testing aimed for genetic counseling.
SEX DIFFERENCES IN CORTICAL HEMODYNAMIC RESPONSE TO LEVODOPA IN PARKINSON’S DISEASE PATIENTS: A FUNCTIONAL NIRS STUDY

Gennarina Arabia¹, Andrea Quattrone¹, Roberta Vasta², Vera Gramigna², Giuseppe Olivadese², Alessandro Mechelli³, Alessia Giugno⁴, Maurizio Morelli⁵, Antonio Gambardella⁵, Aldo Quattrone⁶

¹Magna Graecia University, Institute Of Neurology, Department Of Medical Sciences, Catanzaro, Italy, ²Magna Graecia University, Neuroscience Research Center, Department Of Medical And Surgical Sciences, Catanzaro, Italy, ³University Magna Graecia, Institute Of Neurology, Department Of Medical Sciences, Catanzaro, Italy, ⁴Magna Graecia University of Catanzaro, Institute Of Neurology, Department Of Medical And Surgical Sciences, Catanzaro, Italy, ⁵University Magna Graecia, Department Of Medical And Surgical Sciences, Catanzaro, Italy, ⁶University Magna Graecia, Neuroscience Research Centre, Catanzaro, Italy

Background and Aims:: The aim of this study was to investigate sex differences in hemodynamic response of the cortical motor system after levodopa intake, in patients affected by Parkinson’s disease (PD) with levodopa-induced dyskinesias (LID), by means of functional near-infrared spectroscopy (fNIRS).

Methods:: Patients fulfilling UK Brain Bank criteria for PD, referring to the Movement Disorders Center of the University “Magna Graecia” of Catanzaro, were consecutively recruited. Main inclusion criteria were a) presence of LID; b) duration of levodopa treatment greater than 6 months; c) stable dosages of levodopa treatment for at least 4 weeks. All patients were evaluated by means of motor UPDRS and AIMS scale at baseline (T0), after 1 (T1), and 2 (T2) hours from levodopa intake. NIRS study was performed at the same time-points.

Results:: Nine PD patients with LID were included. Four were females (age: 60.83 ± 4.17 years, mean ± SD) and five were males (age: 61.00 ± 14.00 years; p=0.978). In NIRS study, in men a gradual increase in oxygenated-hemoglobin (HbO) concentrations of motor cortex was observed at T1 and T2, in comparison to T0. By contrast, women showed a reduction in HbO concentrations at T1 in comparison to T0, followed by a return to baseline hemodynamic activation levels after 2 hours from levodopa intake.

Conclusions:: Our preliminary results of this fNIRS study showed a significant difference in the motor cortical haemodynamic responses to levodopa intake in male and female patients with PD and dyskinesias. Further studies on sex-disaggregated data to interpret differential cortical activation in PD are needed.
THE HUMAN M-OPIOID RECEPTOR GENES POLYMORPHISM IS NOT ASSOCIATED WITH LEVODOPA-INDUCED DYSKINESIA DEVELOPMENT IN RUSSIAN PATIENTS WITH PARKINSON’S DISEASE

Gulnara Akhmadeeva¹, Irina Khidiyatova², Irina Gilyazova², Gulnaz Tayupova³, Salavat Umutbaev⁴, Azamat Baitimerov³, Rim Magjanov¹
¹Bashkir State Medical University, Ministry Of Healthcare Of The Russian Federation, Ufa, Russian Federation, ²Institute of Biochemistry and Genetics, Ufa Research Study Center, Ufa, Russian Federation, ³National medical holding Limited Liability Company «Medstandart», Clinical Institute Of Neurology And Rehabilitation, Ufa, Russian Federation, ⁴State budgetary healthcare institution Kuvatov Republican clinical hospital, Ministry Of Healthcare Of The Russian Federation, Ufa, Russian Federation

Background and Aims:: Levodopa-induced dyskinesia (LID) occurs in the vast majority of PD patients after several years of levodopa therapy. But the time of their development and severity differ in different individuals - it depends on pharmacological factors and individual characteristics. Opioid systems can also be involved in the development of LID - opioids are co-transmitters in both the direct and indirect pathways of the basal ganglia.

Methods:: Our clinical study was included 631 sporadic PD patients from the Republic of Bashkortostan. Patients used levodopa for not less than 1 year. The analysis of polymorphism rs1799971 - the human μ-opioid receptor genes (OPRM1) SNP was performed. Dyskinesia was assessed using of MDS-UPDRS scale (parts IV). Were taken into account sex, age of onset PD, duration of levodopa therapy, and a total daily dose of antiparkinsonian medication (levodopa equivalent dosage, LED). The SPSS software was used for statistical analysis. Linear regression and one-way analysis of variance (ANOVA) were used. A P-value<0.05 was considered statistically significant.

Results:: Thus, the presence of all motor levodopa-induced complications was assessed in 212 PD patients. Dyskinesias were identified in 106 (50.00%) patients (67 female, 39 male). There is no association between the rs1799971 genotype and LID development.

Conclusions:: Studies using positron emission tomography in patients with LID have shown a lower binding of opioid ligands in the striatum and thalamus. Other studies have found that this SNP of the OPRM1 gene affects the timing of dyskinesia development in PD patients. Further research is needed. The work was supported by RFBR grant #19-015-00331
THE PREVELANCE OF RESTLESS LEG SYNDROME IN ULAANBAATAR CITY’S ADULTS

Anujin Davaadorj¹, Puntsagdulam Byambajav¹, Oyuntugs Byambasukh², Tsolmon Jadamba², Byambasuren Dargjantsan¹
¹Mongolian National University of Medical Sciences, Department Of Neurology, Ulaanbatar, Mongolia, ²Mongolian National University of Medical Sciences, Department Of Endocrinology, Ulaanbatar, Mongolia, ³Mongolian National University of Medical Sciences, Graduate School, Ulaanbatar, Mongolia

Background and Aims:: Introduction: The most of people with restless leg syndrome (RLS) rarely seek medical attention, usually through a screening. Accordingly, it has a significant impact on the quality of life. Health and socioeconomic impact of sleep related disorders reveals that the prevalence of RLS is high in the population and it has effect on the quality of life. Objective: To determine the prevalence of restless syndrome in Ulaanbaatar.

Methods:: A total of 826 adults aged 18-65 years were included and screened by a questionnaire.

Results:: 6.7% (n=55) of the people had a RLS. There was a statistically significant difference in mean age and sex between the demographics of those who were diagnosed and those who were not (p <0.01). 5.9% of men (n = 12) and 7.2% of women (n = 43) were found to have RLS, which is statistically more likely to frequent in women (p <0.01). In terms of age, RLS is more prevalent in the elderly (35-55 years old).

Conclusions:: Conclusion: The prevalence of RLS in Ulaanbaatar is 6.7% which is higher in women and in both sexes aged 35-55 and older.
THE EFFECTS OF LEVODOPA CHALLENGE TEST ON EYE MOVEMENTS IN PARKINSON’S DISEASE: INSIGHTS FROM A DE NOVO COHORT.

Claudio Terravecchia1, Giovanni Mostile1,2, Clara Grazia Chisari1, Antonina Luca1, Roberta Terranova1, Giulia Donzuso1, Cristina Rascunà1, Calogero Cicero1, Giorgia Sciacca1, Alessandra Nicoletti1, Mario Zappia1
1University of Catania, Department "g.f. Ingrassia", Section Of Neurosciences, Catania, Italy, 2Oasi Research Institute-IRCCS, Department Of Neurology Ic, Troina, Italy

Background and Aims:: Clinical eye movement quantitative assessment represents a promising non-invasive tool to investigate both pathophysiology and clinical aspects of neurodegenerative disorders. In Parkinson’s disease (PD), eye movements abnormalities involving both saccadic and smooth pursuit movements were described and investigations about the effects of antiparkinsonian drugs on eye motility provided conflicting evidences. Notably, only few studies with small sample sizes assessed Levodopa (LD) effects on a drug-naïve population through a standardized Levodopa Challenge Test (LCT). Moreover, few data are available about vertical eye movements after LD administration while nothing is known about fixation parameters. Here we aimed to widely investigate eye motility effects of LCT in a de novo PD population.

Methods:: De novo patients fulfilling MDS diagnostic criteria for clinically-probable PD were enrolled. Eye movement were recorded by Eyelink 1000 Plus. Horizontal and vertical visually-guided saccades, horizontal and vertical smooth pursuit movements (SPM) and fixation parameters were assessed at baseline and after 2 hours from the administration of Levodopa/Carbidopa 250/25 mg.

Results:: Forty de novo PD patients were enrolled [23 Men (57.5%); age (mean±SD) 64.5±6.9 years; disease duration 1.7±1.1 years; baseline UPDRS-ME 25.8±8.3; peak UPDRS-ME 21.3±8.3]. We found an improvement in saccadic velocities and accuracy as well as reduced horizontal latencies after LD administration. Moreover, a reduction of saccadic inclusion rate in fixation tasks and an increased vertical SPM gain were demonstrated.

Conclusions:: Our findings from a de novo population partially confirmed literature evidences, enlighting interesting insights about acute LD effects on SPM, fixation parameters and saccadic latencies.
ROLE OF APOLIPOPROTEIN E IN THE CLINICAL PROFILE OF ATYPICAL PARKINSONIAN SYNDROMES

Amina Nasri1, Ikram Sghaier2, Saloua Mrabet3, Mouna Ben Djebara4, Imen Kacem4, Riadh Gouider5
1Razi University Hospital-Faculty of medicine of Tunis, University Tunis El Manar, Department Of Neurology And Lr18sp03, Mannouba, Tunisia, 2Razi University Hospital, Department Of Neurology And Lr18sp03, La Manouba, Tunisia, 3Razi University Hospital, Faculty of Medicine, University Tunis El Manar, Department Of Neurology And Lr18sp03, La Manouba, Tunisia, 4Razi University Hospital, Faculty of Medicine of Tunis, University Tunis El Manar, Department Of Neurology And Lr18sp03, La Manouba, Tunisia, 5Razi University Hospital, Faculty Of Medicine of Tunis, University Tunis El Manar, Department Of Neurology And Lr18sp03, La Manouba, Tunisia

Background and Aims:: Atypical parkinsonian syndromes (APS) encompass a spectrum of neurodegenerative diseases including dementia with Lewy bodies (DLB), Progressive Supranuclear Palsy (PSP), Multiple System Atrophy (MSA) and corticobasal syndrome (CBS). The effects of the ApoE gene on the clinical features of these diseases are controversial and understudied in several populations. Our aim was to explore the influence of ApoE genotype on clinical features across the different APS subgroups in a Tunisian population.

Methods:: In a retrospective cross-sectional descriptive study in the department of Neurology of Razi Hospital, we included clinically-diagnosed APS patients genotyped for ApoE. The associations between clinical, neuropsychological data and ApoE genotype were analyzed.

Results:: A total of 328 APS patients were included: 184 DLB, 58 PSP, 49 MSA and 37 CBS. Executive dysfunction was more pronounced among patients with ApoE ε4 allele, specifically among DLB and less observed in MSA cases. Memory disorders were also associated to ApoE ε4 allele and more frequent among DLB and PSP carriers. Conversely, ApoE ε4 carrying status was not associated with gender, age of disease onset, nor parkinsonism onset.

Conclusions:: Our findings suggested a role of ApoE ε4 in defining a more altered cognitive phenotype in APS patients, especially in DLB carriers.
OPICAPONE-INDUCED REVERSIBLE MYOPATHY IN A PATIENT WITH ADVANCED PARKINSON’S DISEASE AND FAMILIAL HYPERCKEMIA

Jolanda Buonocore1, Maurizio Morelli2, Andrea Quattrone2, Stefania Barone3, Federico Tosto4, Antonio Gambardella5, Aldo Quattrone6

1Magna Graecia University of Catanzaro, Istitute Of Neurology, Department Of Medical And Surgical Sciences, Catanzaro, Italy, 2Magna Graecia University, Institute Of Neurology, Department Of Medical Sciences, Catanzaro, Italy, 3Institute of Neurology, Department Of Medical And Surgical Sciences - Magna Graecia University, Catanzaro, Italy, 4AOU Mater Domini, Magna Graecia University, Department Of Medical And Surgical Sciences, Institute Of Neurology, Catanzaro, Italy, 5University Magna Graecia, Department Of Medical And Surgical Sciences, Catanzaro, Italy, 6National Research Council, Neuroimaging Research Unit, Institute Of Molecular Bioimaging And Physiology, Catanzaro, Italy

Background and Aims:: Opicapone (OPC) is a third-generation catechol-O-methyltransferase inhibitor, which has proven effective in Parkinson disease (PD) patients. Among common adverse events, several studies have reported OPC induced mild and reversible increase of blood creatine phosphokinase (CK). We present a case report of a 70-year-old man with PD admitted to our department with bilateral drooping eyelids, progressive difficulties in climbing stairs and severe increases of blood CK levels after addition of OPC to levodopa treatment.

Methods:: The patient was not taking drugs for other medical conditions and denied trauma. The serum CK level, after rest, was increased (CK = 9329 U/l, normal range: 0–175 U/l) as well as LDH and myoglobin. The other laboratory hematology and biochemistry tests, chest radiography, abdomen echography, ECG and echocardiography were all normal. EMG with quantitative motor unit potential (MUP) analysis showed signs of mild myopathic damage.

Results:: After discontinuing OPC administration, the patient completely recovered in 5 weeks. One month after full recovery, CK value was 280 U/l. An EMG, 3 months after recovery, showed a normalization of the PUM analysis. Additional interrogation of the medical history revealed that the patient had been occasionally suffering cramps and myalgia after vigorous muscle exercise. Thus, we extended laboratory studies to all available adult family members, and routine serum chemistry revealed an elevated CK level at rest in three relatives.

Conclusions:: CK dosage before and during OPC therapy in PD patients is recommendable. A family history positive for hyperCKemia in PD patients might be a risk factor for marked OPC-related CK increase.
COGNITIVE PROFILES BASED ON MRI VENTRICULAR SIZE MEASUREMENTS IN PATIENTS WITH IDIOPATHIC NORMAL PRESSURE HYDROCEPHALUS AND ALZHEIMER DISEASE. IMPLICATIONS FOR A DIAGNOSTIC APPROACH

Roberta Terranova, Antonina Luca, Giulia Donzuso, Giovanni Mostile, Roberta Manna, Concetta D’Agate, Claudio Terravecchia, Cristina Rascunà, Calogero Cicero, Alessandra Nicoletti, Mario Zappia

Background and Aims:: To evaluate the association between ventricular size measurements and cognitive performances in patients with cognitive complaints validating measurements with confirmed clinical diagnosis.

Methods:: We identified patients with cognitive impairment who underwent both standardized neuropsychological evaluation and MRI study demonstrating cerebral ventricular enlargement. Evans’ Index (EI), Temporal Ratio (TR) and Parieto-Occipital Ratio (POR) were calculated based on neuroimaging. After the diagnostic workup, a diagnosis of idiopathic Normal Pressure Hydrocephalus (iNPH) or Alzheimer Disease (AD) was made. Considering discriminating cut-off values of each index, cognitive performances between patients were compared. Sensitivity and specificity of computed indices in discriminating iNPH from AD were estimated.

Results:: Fifty-two patients were identified. Regardless clinical diagnosis, 27 patients with normal EI had statistically-significant lower score on Rey Auditory Verbal Learning Test (RAVLT), both immediate (p=0.22) and delayed recall (p<0.001) as compared to 25 patients with abnormal EI. Thirteen patients with normal TR had statistically-significant lower score at the RAVLT-delayed recall (p<0.027) as compared to 38 patients with abnormal TR. No statistically-significant differences in cognitive performances were found between identified two groups on POR (8 pathological vs 44 normal). Twenty-six patients were diagnosed as iNPH (20 probable iNPH, 6 possible iNPH). Twenty-six patients received a diagnosed of probable AD. Sensitivity and specificity of MRI measures in differentiating iNPH vs AD were respectively: 84%(95%CI:65.1-95.6) and 87%(95%CI:60.6-93.4) for EI; 100%(95%CI:86.3-100) and 50%(95%CI:29.9-70) for TR; 30.7%(95%CI:14.3-51.8) and 100%(95%CI:86.7-100) for POR.

Conclusions:: EI and TR measures differentiated amnestic patterns among study subjects. EI demonstrated the best accuracy in distinguish iNPH from AD.
**Background and Aims::** Ataxia, defined as loss of balance and coordination, is a clinical symptom of a heterogeneous group of diseases with acquired, inherited, or sporadic etiology. The disorder is caused by dysfunction of the cerebellum, spinal cord, brainstem, vestibular nuclei, thalamic nuclei, cerebral white matter, cortex (frontal), or peripheral sensory nerves. Toxic-metabolic, immune-mediated, paraneoplastic, degenerative, infectious, hereditary, or functional disorders might lead to sporadic ataxia: a neurological condition affecting adults with negative family history.

**Methods::** A 39-year-old woman had been presented with a two-year history of sudden-onset tremor and rapid progressive ataxia. Her family history was unremarkable, and there was no history of consanguinity. On in-depth examination, she had no nystagmus, normal external-eye-movements and speech, mild postural wrist flexion-extension tremor (right> left), ataxic gait with severe difficulties on standing, and tandem walk. Her writing did not suggest any tremor-dystonic features. Brain MRI showed normal cerebral and cerebellar parenchyma, SPECT DAT scan excluded dopamine-deficit, SEP, EMG, as well as blood and cerebrospinal fluid exams (antibodies against the central nervous system, thyroid function, rheumatologic antibodies, gluten sensitivity, vitamin E, vitamin B12, ceruloplasmin, serum and urine copper, alpha-fetoprotein, neurotropic viruses), were normal.

**Results::** The patient followed a rehabilitation program, improving her gait and balance. At follow-up, she reported marriage breakdowns, and we detected variability, distractibility, entrainability, and suggestibility on her tremor and standing imbalance. Functional ataxia-tremor disorder was diagnosed.

**Conclusions::** Adult-onset ataxia should be first investigated for organic etiologies; however, careful anamnesis and detail neurological examination is mandatory not to miss functional disorder.
Background and Aims:: Mutations in the cytoplasmic dynein 1 heavy chain 1 (DYNC1H1) gene are associated with autosomal dominant lower extremity-predominant spinal muscular atrophy, neuromuscular and neurodevelopmental disorders and hereditary spastic paraplegia. We report a case of adult-onset Parkinson’s disease associated to a mutation of DYNC1H1 gene.

Methods:: Case presentation and literature review.

Results:: A 58-years-old caucasian man developed progressive motor slowing in the right limbs. His medical history revealed diabetes mellitus and hypertension. His brother suffered from intellectual disability, epilepsy and interatrial septum aneurysm. The patient presented strabismus, antiverse nares and fleshy lips; occipitofrontal circumference measured 58.5 cm (>97°c). He showed parkinsonism predominantly in the right limbs. Brain MRI scan displayed corpus callosum hypoplasia. DaTscan SPECT imaging showed decreased uptake in the striatum bilaterally. The neuropsychological evaluation revealed a globally poor cognitive performance at the frontal battery and cognitive slowing. Routine laboratory work-up was unremarkable. Poor response to L-dopa challenge test and long-term L-dopa therapy was observed. Molecular analysis for FMR1 gene and array-CGH were normal. Next generation sequencing of customized panel targeting 63 genes associated with neurodevelopmental disorders and macrocephaly was performed, detecting c.13783C>T (p.Gln4595Ter) heterozygous variant in DYNC1H1 gene.

Conclusions:: Unlike a previous described case with DYNC1H1 mutation and parkinsonism, our patient was unresponsive to the dopaminergic therapy and showed corpus callosum hypoplasia. Further studies are required to define the effect of this mutation and its possible causative role in parkinsonism. 1 Szczaluba, (2018), A de novo loss-of-function DYNC1H1 mutation in a patient with parkinsonian features and a favourable response to levodopa. Clin Genet.
CEREBROSPINAL FLUID A/T/(N) PROFILE AND MILD COGNITIVE IMPAIRMENT IN PARKINSON’S DISEASE

Federico Paolini Paoletti, Giovanni Bellomo, Elena Chipi, Simone Simoni, Nicola Tambasco, Lucilla Parnetti
Section of Neurology, Department Of Medicine And Surgery, University Of Perugia, Perugia, Italy

Background and Aims:: In synucleinopathies, the presence of an underlying Alzheimer’s disease (AD) pathology can be involved in cognitive decline. Cerebrospinal fluid (CSF) profile consistent with amyloidosis, as well as CSF AD signature are sometimes reported in Parkinson’s disease (PD) with dementia. Additionally, decreased CSF Aβ42 levels predict earlier appearance of cognitive decline in PD. However, contradictory results are available for CSF AD biomarkers in PD patients with mild cognitive impairment (PD-MCI). Our aim was to assess potential correlation between CSF AD biomarkers and PD-MCI.

Methods:: CSF samples were collected from 50 cognitively unimpaired PD and 48 PD-MCI patients. We measured CSF Aβ42/Aβ40 ratio, p-tau and t-tau levels as biomarkers of amyloidosis (A), tauopathy (T) and neurodegeneration (N), respectively. A/T/(N) profile was considered for each patient.

Results:: No significant differences were found between PD and PD-MCI groups in terms of CSF Aβ42/Aβ40 ratio, p-tau and t-tau levels, that were in the normal range for most patients. Accordingly, the A-/T-/N- profile was the most frequent in both PD and PD-MCI groups, with low frequencies of A+ (10% and 12% respectively), T+ (4% and 6% respectively) and N+ (16% and 12% respectively), without showing differences.

Conclusions:: The CSF A/T/(N) profile of PD-MCI patients did not differ from cognitively unimpaired PD patients, being the A-/T-/N- the most frequent pattern in both groups. Thus, MCI in PD is not necessarily associated with amyloidosis or AD-pathology, but rather it is a heterogeneous entity in which other pathologies might be involved.
SHORT- AND LONG-TERM MOTOR OUTCOME OF STN-DBS IN PARKINSON'S DISEASE: FOCUS ON GENDER DIFFERENCES.

Nico Golfrè Andreasi¹, Roberta Telese¹, Luigi Romito¹, Roberto Cilia¹, Antonio Elia¹, Alessio Novelli¹, Giovanni Tringali², Giuseppe Messina², Vincenzo Levi², Grazia Devigili¹, Sara Rinaldo¹, Angelo Franzini², Roberto Eleopra¹

¹Fondazione IRCCS Istituto Neurologico Carlo Besta, Department Of Clinical Neurosciences, Parkinson And Movement Disorders Unit, Milan, Italy, ²Fondazione IRCCS Istituto Neurologico Carlo Besta, Neurosurgery Department, Functional Neurosurgery Unit, Milano, Italy

Background and Aims:: STN-DBS is an established treatment for Parkinson’s Disease with motor fluctuations and dyskinesias but studies on the long-term outcome are still scarce. In this study, we describe the long-term motor outcome of STN-DBS in a cohort of patients consecutively treated in our centre, with a focus on the possible differences associated with gender.

Methods:: We reviewed all patient charts from our electronic database and retrospectively collected demographical and clinical data at baseline and at three follow-up visits: 1 year, 5 years and 10 years. 107 patients were included. 41 reached 10-years follow-up.

Results:: We found and long-lasting effect of DBS on motor complications, despite a progressive worsening of motor performances in the ON medication condition. Females showed a trend towards worsening in bradykinesia already at 1-year follow-up and possible poorer scores in non-dopaminergic features at 10-years follow-up. Levodopa Equivalent Daily Dose (LEDD) was significantly reduced after surgery however, while in males remained significantly lower than baseline, in females LEDD returned at baseline values at 10-years follow-up. Males showed a sustained effect on dyskinesias but this benefit was less clear in females and the Total electrical energy delivered by STN-DBS was consistently lower in females compared to males. The profile of Adverse Events did not appear to be influenced by gender.

Conclusions:: Our data suggest that there are no major differences on the motor effect of STN-DBS between males and females. However, there may be some slight differences that should be specifically investigated in the future and may influence therapeutic decisions.
PERAMПANEL INHIBITS Α-SYNUCtEIN TRANSMISSIΟΝ IN PΑRKΙНSON’S DISEASE MODELS

Jun Ueda, Norihito Uemura, Ryosuke Takahashi
Kyoto University Graduate School of Medicine, Department Of Neurology, Kyoto, Japan

Background and Aims:: The intercellular transmission of pathogenic proteins plays a key role in the clinicopathological progression of neurodegenerative diseases. Previous studies have demonstrated that this uptake and release process is regulated by neuronal activity. The aim of this study is to examine the effect of perampanel, an antiepileptic drug, on α-synuclein transmission in cultured cells and mouse models of Parkinson’s disease.

Methods:: Mouse primary hippocampal neurons were transduced with α-synuclein preformed fibrils to examine the effect of perampanel on the development of α-synuclein pathology and its mechanisms of action. An α-synuclein preformed fibrils-injected mouse model was used to validate the effect of oral administration of perampanel on the formation of α-synuclein pathology in vivo.

Results:: Perampanel inhibited the development of α-synuclein pathology in mouse hippocampal neurons transduced with α-synuclein preformed fibrils. Interestingly, perampanel blocked the neuronal uptake of α-synuclein preformed fibrils by inhibiting macropinocytosis in a neuronal activity-dependent manner. We confirmed that oral administration of perampanel ameliorated the development of α-synuclein pathology in wild-type mice inoculated with α-synuclein preformed fibrils.

Conclusions:: Targeting neuronal activity with perampanel could represent a new therapeutic strategy for Parkinson’s disease.
SUSTAINED IMPROVEMENTS IN MOTOR AND NON-MOTOR SYMPTOMS IN ADVANCED PARKINSON’S DISEASE PATIENTS TREATED WITH CARBIDOPA LEVODOPA ENTERAL SUSPENSION IN A ‘REAL-WORLD’ STUDY

K Ray Chaudhuri¹, Jason Aldred², David Standaert³, Norbert Kovacs⁴, Francesco Pontieri⁵, Paul Bourgeois⁶, Thomas Davis⁷, Esther Cubo⁸, Marieta Anca-Herschkovitsch⁹, Robert Iansek¹⁰, Mustafa Siddiqui¹¹, Mihaela Simu¹², Lars Bergmann¹³, Pavit Kukreja¹³, Weining Robieson¹³

Background and Aims:: We evaluate effect of levodopa–carbidopa intestinal gel(LCIG, carbidopa-levodopa enteral suspension[CLES] in USA)on motor and nonmotor symptoms in a multi-country observational study in advanced Parkinson’s disease (PD) patients treated with LCIG in routine clinical practice.

Methods:: DUOGLOBE is a prospective multinational observational study (including US sites) of LCIG/CLES naïve patients treated in routine clinical practice with 3-years follow-up planned (NCT02611713). Assessments included “Off” time, Unified Dyskinesia Rating Scale (UDysRS), Non-Motor Symptoms Scale (NMSS), sleep symptoms (PD Sleep Scale-2, PDSS-2), Quality of Life (8-item PD questionnaire, PDQ-8), and Serious Adverse Events (SAEs). Interim outcomes from baseline up to month (M) 24 are presented.

Results:: In this interim analysis, 196 patients were included (62% male, 78% ≥65 years old; 51% ≥10 years’ PD duration). Mean (SD) LCIG treatment duration was 711 (368) days with a median daily LCIG/CLES infusion of 16.0 h/d. Significant improvements (mean change from baseline to M24) were observed in “Off” time (~3.7 h/d; 95% CI -4.3 to -3.1; p<.001), UDysRS total scores (~7.9; 95% CI -12.5 to -3.2; p<.001), NMSS total scores (~22.2; 95% CI -30.7 to -13.7; p<.001), PDSS-2 total score (~5.8; 95% CI -8.2 to -3.3; p<.001), and QoL (~5.8; 95% CI -10.0 to -1.5; p=0.009). Overall, 52% of patients experienced SAEs. 23% (n=45) of patients discontinued the study due to AEs as primary reason.

Conclusions:: This interim analysis shows sustained real-world long-term improvements with LCIG/CLES in routine clinical practice on motor and non-motor symptoms in advanced PD patients. Safety was consistent with the established LCIG/CLES profile.
Background and Aims:: Deep brain stimulation (DBS) is an effective treatment in patients with movement disorders (MD). DBS program was adapted in every country differently and patients’ visits became mostly via telemedicine in this pandemic time.

Methods:: We present organizing problems and management of DBS in Croatia and compare outcomes of DBS implanted for MD in year 2019 and 2020 by using standard scales for PD, essential tremor and dystonia.

Results:: When we compared implanted patients, we had more in 2019 (60/20). It was hard to organize operation due to transition UHC Dubrava (the only DBS center in Croatia) in National COVID 19 hospital and operation had to be carefully planed in other UHC hospitals between shifts of DBS team’s members in COVID-19 hospital and free operations rooms. The motor symptoms’ outcomes in PD, dystonia and essential tremor were without significant difference in both years, but anxiety was bigger in 2020. Transient hallucinations were slightly more often in 2020 (2/60 vrs. 3/20). We had 3 previously operated patients with discharged battery and worsening of symptoms due to their hesitation to report that to our DBS team in time.

Conclusions:: This COVID 19 pandemic presents unique challenge for management of DBS in MD. A lot of centers must deal with quick moving and adjustments of DBS program to other hospitals and invest more effort in maintaining it. Neuropsychiatric symptoms had to be monitored all the time, especially in this pandemic time.
INVESTIGATION OF OROPHARYNGEAL SWALLOWING AND SWALLOWING-BREATHEING COORDINATION IN PATIENTS WITH PARKINSONIAN SYNDROMES. AN ELECTROKINESIOGRAPHIC APPROACH.

Giuseppe Cosentino¹, Sebastiano Arceri², Massimiliano Todisco¹, Cristina Tassorelli³, Enrico Alfonsi²
¹University of Pavia, Italy, Department Of Brain And Behavioral Sciences, PAVIA, Italy, ²IRCCS Mondino Foundation, Neurophysiopatology, pavia, Italy, ³University of Pavia, Brain And Behavioral Sciences, Pavia, Italy

Background and Aims:: Multiple system atrophy (MSA) is a neurodegenerative disorder characterized by dysautonomia in combination with parkinsonian and cerebellar signs. Dysphagia typically occurs in the early stages of the disease also representing a life-threatening condition that is at least in part responsible for the poorer prognosis with respect to Parkinson disease (PD). The pathophysiology of dysphagia in MSA is still poor understood. Aim: To investigate with an electrokinesiographic approach abnormality of swallowing and coordination between swallowing and breathing in different MSA phenotypes in comparison with PD and age-matched normal subjects.

Methods:: We recruited 45 patients with MSA (35 with parkinsonian, MSA-P, and 14 with cerebellar phenotype, MSA-C), 20 patients with PD and 15 healthy subjects. The electrokinesiographic study of swallowing consisted in a combined evaluation of different electrophysiological and mechanical aspects of oropharyngeal swallowing also including recording of nasal airflow during swallowing to evaluate the physiological swallowing respiratory pause.

Results:: Oropharyngeal alterations similar to that of PD were observed in patients with MSA (oropharyngeal bradykinesia, piecemeal deglutition, posterior spillage, incomplete relaxation of the cricopharyngeal muscle). Additional abnormalities compatible with incoordination between the oral and pharyngeal phase of swallowing and between swallowing and breathing were observed in patients with MSA-C.

Conclusions:: The pathophysiology of dysphagia may differ between different MSA phenotypes. In particular, an additional cerebellar dysfunction could contribute to dysphagia in MSA-C.
PROGRESSIVE SUPRANUCLEAR PALSY: CLINICAL, INSTRUMENTAL AND NEUROPSYCHOLOGICAL EVALUATION OF A CASE IN THE PRESYMPTOMATIC PHASE

Emanuele Caggia, Erika Firrincieli, Jole Bongiorno, Valeria Lingenti, Valentina Maci
ASP 7 Ragusa, Neurologia, ragusa, Italy

Background and Aims:: Atypical parkinsonisms are a group of sporadic neurodegenerative diseases. Atypical Parkinsonisms include Multiple System Atrophy (MSA), Progressive Supranuclear Palsy, Cortico-Basal Syndrome and Lewy Body Dementia. The present study aims to describe a very interesting clinical case while no clinical signs are presented, characteristic signs emerge from instrumental examination. PSP is characterized by early postural instability, vertical gaze paralysis, parkinsonism, pseudobulbar symptoms, absent response to Levodopa.

Methods:: We describe the case of a 50-year-old man who presented the onset of a motor epileptic seizure. A CT scan was performed on the patient that showed no pathological data. A brain MRI was also performed, showing atrophy of the midbrain with penguin and mickey mouse sign. Brain PET scan showed diffuse inhomogeneity of radiopharmaceutical fixation. The neuropsychological evaluation has integrated several components.

Results:: The results of the neuropsychological evaluation are in the table
Conclusions: Neuropsychological examination show deficits in episodic memory anterograde for both verbal and non-verbal material, which are associated with defects of consolidation; deficits in working memory and executive functions to which are associated reduced verbal fluency and moderate deflection of mood. Nevertheless, the patient has good communication skills and verbal comprehension, praxic-constructive and fair logical reasoning skills. The patient's neuropsychological profile appears congruent with an impairment of diencephalic, temporomental, and fronto-subcortical structures. Our patient on the
The phonemic verbal fluency test is able to produce 6 words in 1 minute. It has been reported that patients who produce fewer than 7 words in a minute are much more likely to have PSP than PD.
LOW CONCENTRATIONS OF BILIRUBIN PROTECT FROM DOPAMINERGIC NEURON LOSS IN AN EX VIVO MODEL OF PARKINSON DISEASE

Sri Jayanti1,2,3, Rita Moretti4, Claudio Tiribelli1, Silvia Gazzin1
1Italian Liver Foundation, (fondazione Italiana Fegato), Trieste, Italy, 2University of Hasanuddin, Faculty Of Medicine, Makassar, Indonesia, 3University of Trieste, Molecular Biomedicine, Trieste, Italy, 4University of Trieste, Neurology Clinic, Department Of Medical, Surgical, And Health Sciences, Trieste, Italy

Background and Aims:: Disease-modifying therapy for Parkinson’s disease (PD) is still an unmet medical need. Hence, we investigated the protective effects of unconjugated bilirubin (UCB) in an ex vivo PD model and identified the protective UCB concentrations threshold.

Methods:: A slow-progressing ex vivo PD model obtained by exposing organotypic brain cultures (OBCs) of substantia nigra from 5 days old Wistar rat to low doses of rotenone, has been co-challenged for 24 hours with a range concentration (0.5μM to 4μM) of UCB. Immunofluorescence was used to counts the number of DOPAn. RT-qPCR was used to monitor the early alteration of genes involved in the DOPAn demise (oxidative stress: Srnx1: sulfiredoxin 1; inflammation: Tnfα: tumor necrosis α, Il6: interleukin 6, Cox2: cyclo-oxygenase 2; and neurotrophic genes: Bdnf: brain-derived neurotrophic factor).

Results:: The DOPAn number was significantly reduced in Rot-treated OBCs (-35%, p < 0.01), associated with significant induction of all tested genes (all p<0.05). A full reversal of DOPAn number was obtained with 0.5 μM and 1 μM UCB challenging (both p<0.05 vs. Rot). 0.5μM UCB reverted Tnfα expression (p<0.01 vs. Rot). Meanwhile, 1μM UCB restored the expression of Tnfα, Il6, and Bdnf (p<0.05, p<0.01, and p<0.05, respectively). 2μM UCB decreased the expression of Il6 (p<0.01), while 4μM UCB increased the mRNA level of all the selected markers above the expression in Rot challenged slices.

Conclusions:: Low concentrations of UCB have a protective effect on the PD model as anti-inflammatory agents at 0.5μM and 1μM
IMPACT OF MEDIUM-CHAIN SATURATED FATTY ACIDS ON MOTOR FUNCTION IN PATIENTS WITH PARKINSON’S DISEASE

Jana Ponce1, Erin Cameron-Smith2, John Bertoni2, Jenna Wuebker3, Danish Bhatti2, Diego Torres2, Mariah Jackson1, Megan Timmerman1, Corrine Hanson1

1University of Nebraska Medical Center, College Of Allied Health Professionals, Omaha, United States of America, 2University of Nebraska Medical Center, Department Of Neurological Sciences, Omaha, United States of America, 3Nebraska Medicine, Department Of Pharmaceutical And Nutrition Care, Omaha, United States of America

Background and Aims:: Medium-chain saturated fatty acids (Octanoic acid (C8:0) and Decanoic acid (C10:0)) are found in high levels in coconut oil and palm kernel oil, commonly used in processed foods in the United States. They have reportedly positive effects on neuronal function in epilepsy and on cognition in Alzheimer’s Disease. However, negative effects have been described in vascular diseases (such as stroke). Less is known about the impact of these fatty acids in Parkinson’s Disease (PD). This study explored the association between their dietary intake and motor function in PD.

Methods:: We prospectively enrolled patients from Comprehensive PD Clinic at the University of Nebraska Medical Center and completed Harvard food frequency questionnaire (FFQ) for quantification of dietary intake along with baseline assessments. Linear regression was used to evaluate the association between Octanoic and Decanoic acid intake and the Unified Parkinson Disease Rating Scale (UPDRS) motor score, with adjustment for relevant confounders.

Results:: 117 participants with Parkinson’s Disease were included in the final analysis. Mean Octanoic and Decanoic acid intakes were 0.2 and 0.4 g/day, respectively. A significant association between dietary intake and UPDRS motor score was observed for Octanoic acid ($\beta = 0.21$, $p= 0.03$) while Decanoic acid approached significance ($\beta = 0.17$, $p = 0.07$).

Conclusions:: Increased intakes of Medium Chain Saturated fatty acids may adversely affect motor function in subjects with Parkinson’s Disease, requiring further exploration.
THERAPEUTIC POTENTIAL OF INHIBITION OF FORMYL PEPTIDE RECEPTOR SIGNALING IN PARKINSON’S DISEASE

Ivan Limanjaya¹, Ching-Chi Chiu², Tzu-Jen Kao³, Tu-Hsueh Yeh⁴
¹College of Medicine, Taipei Medical University, International Master/phd Program In Medicine, Taipei, Taiwan, ²Chang Gung Memorial Hospital, Neuroscience Research Center, Taoyuan, Taiwan, ³Taipei Medical University, College Of Medical Science And Technology, Taipei, Taiwan, ⁴Taipei Medical University Hospital, Neurology, Taipei, Taiwan

Background and Aims:: Microglia-mediated neuroinflammation is one of the major pathogenesis of Parkinson’s Disease (PD). Evidences suggest that formyl peptide receptors (FPRs), a family of transmembrane chemoattractant receptors, are implicated in the activation of microglia into the pro-inflammatory subtype. The present study investigated the mechanism and neuroprotective effect of dipeptide N-(N-benzoyl-L-tryptophanyl)-D-phenylanlanine methyl ester (HCH6-1), an inhibitor of FPR, in a neuroinflammation model of PD.

Methods:: The neuroinflammatory in vitro model was established by using co-culture system consisting of neuronal SH-SY5Y cells and microglial EOC-20 cells. Cells were then subjected to either Lipopolysaccharides (LPS) stimulation only or combination of HCH6-1 pre-treatment and LPS stimulation.

Results:: LPS stimulation resulted in increased cell apoptosis, oxidative stress, ER stress, and inflammatory reactions. HCH6-1 pre-treatment attenuated LPS-induced apoptotic cell death in a dose-dependent manner as measured by cell viability and TUNEL assay. Subsequent immunofluorescence assay of intracellular reactive oxygen species (ROS) and malondialdehyde (MDA) lipid peroxidation assay revealed that HCH6-1 reduced LPS-induced increase of oxidative stress. Furthermore, western blot analysis demonstrated that HCH6-1 pre-treatment decreased the expression levels of both ER stress related protein markers, GFP78, ATF6, activated caspase-12, and inflammatory protein markers, AIM2, NLRP3, ACS/TMS1, TNF-α, IL-1β, activated caspase-1.

Conclusions:: The results showed that HCH6-1 is effective to reduce apoptotic cell death and attenuate oxidative stress, ER stress, and inflammation in LPS-induced neuroinflammation model of PD. FPR1 blocking might be promising to develop neuroprotective therapy for PD.
EFFICACY AND SAFETY OF FOSLEVODOPA/FOSCARBIDOPA VERSUS ORAL CARBIDOPA/LEVODOPA IN ADVANCED PARKINSON'S DISEASE PATIENTS: DESIGN OF A PHASE 3, RANDOMIZED, DOUBLE-BLIND, DOUBLE-DUMMY, ACTIVE CONTROLLED 12-WEEK TRIAL

Maurizio Facheris¹, Weining Robieson¹, Nahome Fisseha¹, David Standaert²
¹AbbVie, Rdcd, North Chicago, United States of America, ²University of Alabama at Birmingham, Neurology, Birmingham, United States of America

Background and Aims:: We compare efficacy and safety of 12-week continuous subcutaneous infusion (CSCI) of foslevodopa/foscarbidopa, a new soluble formulation of carbidopa (CD) and levodopa (LD) prodrugs formally known as ABBV-951a, versus oral CD/LD for the treatment of motor fluctuations in advanced Parkinson's disease (PD) patients.

Methods:: This phase 3, randomized, double-blind, double-dummy, parallel-group, active-controlled, multicenter study includes patients (≥30 years) whose motor symptoms are no longer adequately controlled by their current therapy and experience a minimum daily average of 2.5h of “Off” time per day (with a minimum of 2.0h each day). The study is comprised of a screening period, and an oral CD/LD stabilization period, followed by randomization into the 12-week double-blind treatment period. Patients will receive either 24-hour/day CSCI of foslevodopa/foscarbidopa plus oral placebo or 24-hour/day CSCI of placebo solution plus oral CD/LD. Assessments include the change from baseline to Week 12 in "On" and “Off” times from PD Diaries, MDS-UPDRS scores, quality of life, sleep symptoms, and PD symptoms measured using a wearable device. Local and systemic safety and tolerability will be assessed using the Infusion Site Evaluation Scale and adverse event monitoring.

Results:: This study will enroll approximately 130 advanced PD patients from an estimated 80 sites in the United States and Australia (clinicaltrials.gov ID: NCT04380142).

Conclusions:: This study will provide important data on the safety and efficacy of foslevodopa/foscarbidopa, a potentially new advanced treatment option, delivered 24-hour/day via CSCI versus oral CD/LD in advanced PD patients.
FOSLEVODOPA/FOSCARBIDOPA SUBCUTANEOUS INFUSION MAINTAINS EQUIVALENT LEVODOPA EXPOSURE TO LEVODOPA-CARBIDOPA INTESTINAL GEL DELIVERED TO THE JEJUNUM

Matthew Rosebraugh, Sven Stodtmann, Wei Liu, Maurizio Facheris
AbbVie, Rdcd - Pharma Development, North Chicago, United States of America

Background and Aims:: Levodopa-Carbidopa Intestinal Gel (LCIG) 16-hour infusion offers superior symptomatic control than oral levodopa/carbidopa in patients with advanced Parkinson's disease (aPD); however, it requires percutaneous endoscopic gastrostomy tube placement. Foslevodopa/foscarbidopa is an investigational drug being developed for treatment of aPD providing 24-hour therapeutic levels of levodopa following subcutaneous (SC) delivery. We characterize levodopa pharmacokinetics (PK) following foslevodopa/foscarbidopa SC infusion and LCIG jejunal infusion in healthy volunteers.

Methods:: This open-label, 2-way crossover study randomized, 20 healthy volunteers. In each period, subjects received either 24-hour foslevodopa/foscarbidopa SC infusion to the abdomen or 16-hour LCIG infusion to the jejunum through a nasojejunal tube followed by two separate nighttime oral levodopa/carbidopa (LD/CD) doses. Serial blood samples were collected to assay for levodopa concentrations. Equivalent levodopa exposure was predefined as the ratio (ABBV-951/LCIG) and 90% confidence interval of exposure parameters between 0.8 and 1.25. Safety and tolerability were assessed throughout.

Results:: Foslevodopa/foscarbidopa SC infusion provided equivalent levodopa levels to LCIG infusion over the 16-hour interval and maintained those levels throughout the nighttime. Exposure difference between the two regimens was less than 8% and well contained within defined equivalence range. Based on PK predictions, overall levodopa exposures over 24 hours also showed equivalence between foslevodopa/foscarbidopa SC infusion and LCIG. Both regimens were generally safe and well tolerated in healthy volunteers. All adverse events considered to be “possibly related” to study drug were mild and did not lead to discontinuation from the study.

Conclusions:: Foslevodopa/foscarbidopa SC infusion delivers equivalent levodopa exposure to LCIG infusion with and without nighttime oral LD/CD dosing.
EVALUATION OF THE CHANGING CLINICAL OUTCOMES AND DISEASE BURDEN IN ADVANCED PARKINSON’S DISEASE PATIENTS WITH DIFFERENT TREATMENT PATTERNS: PROSPECT STUDY

Pavnit Kukreja, Omar Ladhani, Ali Alobaidi, Yash Jalundhwala, Jorge Zamudio, Koray Onuk
AbbVie, Rdma - Medical Affairs, North Chicago, United States of America

Background and Aims:: There is limited prospective real-world data describing the long-term changes in clinical outcomes and disease burden for individual advanced PD patients. The understanding of the treatment patterns and their differential impact over time is also limited. We describe the changing clinical outcomes and disease burden of advancing Parkinson’s disease in patients with motor fluctuations no longer controlled by current PD medications.

Methods:: PROSPECT is a 24-month, prospective, observational study of advanced PD patients (>30 years of age) no longer adequately controlled by their current therapy and have a minimum of 2.5 hours of “Off” time per day. Study assessments will be performed at baseline (ie, study enrollment) and 4 follow-up visits at months 6, 12, 18, and 24. Assessments will include the current treatment regimen, severity of disease (H&Y stage), changes in motor (“Off” and dyskinesia time) and non-motor symptoms (NMS scale and PD Sleep Scale-2), activities of daily living (UPDRS II), quality of life (PD Questionnaire-39 and EQ-5D), cognitive function (Mini-Mental State Evaluation), health care resource utilization, caregiver burden (Modified Caregiver Strain Index), treatment satisfaction and patient global impression of change in severity (PGIC-S). Comparative assessments between patients with different treatment patterns will occur at baseline to month 12 and month 24.

Results:: This study will enroll approximately 550 advanced PD patients from an estimated 90 multinational sites.

Conclusions:: This study will describe real-world long-term prospective insights on the natural progression of disease burden, clinical outcomes, and potential value of timely initiation of advanced therapies among patients with advanced PD.
A RETROSPECTIVE STUDY EVALUATING THE USE OF ANTI-PARKINSONIAN MEDICATIONS IN PATIENTS WITH ADVANCED PARKINSON’S DISEASE TREATED WITH LEVODOPA-CARBIDOPA INTESTINAL GEL AND DEEP BRAIN STIMULATION

Jason Aldred¹, Fahd Amjad², Anita Johnson³, Pavnit Kukreja³, Omar Ladhani³, Irene Malaty⁴, Sotirios Parashos⁵, Junaid Siddiqui⁶, Raghav Govindarajan⁶, Mustafa Siddiqui⁷, Jorge Zamudio⁶, Sandeep Thakkar⁸

¹Inland Northwest Research & Selkirk Neurology, Neurology, Spokane, United States of America, ²Georgetown University, Department Of Neurology, Washington, D.C., United States of America, ³AbbVie, Rdma - Medical Affairs, North Chicago, United States of America, ⁴University of Florida, Department Of Neurology - Movement Disorder, Gainesville, United States of America, ⁵Struthers Parkinson's Center, Neurology, Golden Valley, United States of America, ⁶University of Missouri, Department Of Neurology, Columbia, United States of America, ⁷Wake Forest School of Medicine, Neurology, Winston Salem, United States of America, ⁸Hoag Memorial Hospital Presbyterian, Department Of Neurology, Newport Beach, United States of America

Background and Aims:: Patients using deep brain stimulation (DBS) with adjunctive oral therapy may require additional therapies like levodopa-carbidopa intestinal gel (LCIG), known as CLES in the United States. We examine use of oral/transdermal anti-parkinsonian medications in advanced Parkinson’s disease (APD) patients with history of or current treatment with DBS, receiving LCIG.

Methods:: PD-DUAL, a multicenter, US study included APD patients with history of DBS and ≥2 recorded visits before LCIG initiation and 2 visits (6 months) follow-up after LCIG initiation. Primary endpoint is mean decrease of oral levodopa-equivalent daily dosage (LEDD) during a 16-hour waking day after LCIG initiation from baseline to 6 months. Secondary endpoints include percentage of individuals with reductions from baseline in total oral levodopa daily dose after LCIG initiation, latency from LCIG initiation until introduction/tapering of each PD medication, and percentage of patients treated with DBS and LCIG for whom LCIG is a monotherapy.

Results:: As of 10 July 2020, 34 patient records were evaluable. The mean age is 67 years and 73% are male. Of 34 patients, 31 (91.2%) were taking levodopa-containing medications and 25 (73.5%) were taking non levodopa-containing anti-PD medications. For the primary endpoint, 20 patients had >75% reduction (10 patients with 100% reduction); 5 had >50% to ≤75% reduction; and 3 had 0 to ≤25% reduction. Two patients had no medication at baseline, and one had no reduction.

Conclusions:: Interim results demonstrated a median reduction of oral/transdermal LEDD (92%) 6 months post LCIG initiation in APD patients with a history of or current treatment with DBS.
NON-MOTOR SYMPTOMS AND THEIR IMPACT IN QUALITY OF LIFE IN MORROCAN PATIENTS WITH PARKINSON DISEASE: PROSPECTIVE STUDY:

Yasmina Zakaria, Najib Kissani, Mohamed Chraa
university hospital Mohamed VI, Neurology, marrakesh, Morocco

Background and Aims:: INTRODUCTION: Patients with Parkinson disease (PD) are more impaired by Non-motor symptoms (NMS) than motor symptoms, especially in advanced stages. Unfortunately, in most cases, it is underdiagnosed and undertreated. The aim of this study is to evaluate the frequency of NMS and their impact on the quality of life in patients with PD.

Methods:: This is a prospective observational study conducted in the neurology department of Mohammed VI university hospital, on NMS in Moroccan patients with PD, using the non-motor symptoms questionnaire (NMSQ) and the Parkinson's disease quality of life questionnaire Summary Index score (PDQ-39IS).

Results:: We report 115 patients (Males 61.5%) diagnosed over a period of 18 months. The mean age of onset was 53.71 (ranged from 23 to 76 years). Pain (60.3%), constipation (59%), urinary urgency (52.6%), sleep disturbances (57.7), and depression (47.4%), were the most frequent NMS in our cohort, while hallucinations (29.5%), diplopia (12.8%) and memory impairment (30.8%) were less frequent. Depressed mood, anxiety and sleep problems were more common in females, while urinary disorders, constipation, sexual dysfunction were more common in males. NMS are positively correlated to the H&Y stage and to duration of the disease. Our results showed that the impact affected mainly the emotional well-being (47, 81%). Mobility was affected in second place (44.13%), followed by daily activities (42, 9%).

Conclusions:: Conclusio: NMS can be very disabling and should be treated in the different stages of the disease. They can also be responsible of a decreasing on the patient's quality of life.
DISEASE SEVERITY IN THE DUOGLOBE PATIENT POPULATION BASED ON MANAGE-PD SECTION 2 DOMAINS: INTERIM SUBGROUP ANALYSIS

K Ray Chaudhuri¹, Jason Aldred², Lars Bergmann³, Pavnit Kukreja³, Tianming Gao³, Mihaela Simu⁴, Norbert Kovacs⁵
¹King’s College and King’s College Hospital, Institute Of Psychiatry, London, United Kingdom, ²Selkirk Neurology & Inland Northwest Research, Neurology, Spokane, United States of America, ³AbbVie, Rdma - Medical Affairs, North Chicago, United States of America, ⁴Victor Babes University of Medicine and Pharmacy, Department Of Neurology, Timisoara, Romania, ⁵University of Pecs, Neurology, Pecs, Hungary

Background and Aims:: DUOGLOBE is an ongoing global, observational study assessing long-term effectiveness of levodopa-carbidopa intestinal gel (LCIG) in advanced Parkinson’s disease (APD) patients (NCT02611713). This post-hoc analysis assessed disease burden among subgroups of DUOGLOBE patients based on the frequency/severity of symptoms in the domains of Section 2 of MANAGE-PD, a clinician-reported screening tool to identify APD patients uncontrolled on oral/transdermal medications.

Methods:: MANAGE-PD Section 2 domains were applied at baseline to DUOGLOBE patients. Patients were grouped by 1+, 3+, or 6 affected domains. Domains include “Off” time, troublesome dyskinesias, freezing of gait during “Off” time, falls, ADL impairment, and hallucination/psychosis. Efficacy and safety outcomes (Table 1) were evaluated at baseline and for mean change from baseline to Month 24 (M24).

Results:: Of 176 patients with available Section 2 responses, 94.3%, 42.6%, and 1.7% had a high enough frequency/severity in 1+, 3+ or 6 Section 2 domains, respectively. For patients with 1+ or 3+ affected domains, all efficacy outcomes improved from baseline to M24 except UPDRS II. Patients with more domains affected demonstrated greater numerical improvement. AE incidences were similar across groups.

Conclusions:: A high percentage of patients demonstrated frequent/severe enough symptoms in at least 1 MANAGE-PD Section 2 domain at baseline prior to LCIG, indicating insufficient symptom control. At M24 all groups showed improvements in key outcome measures. The subgroups with 3+ and 6 domains have higher disease severity; however, only 1 affected domain of MANAGE-PD Section 2 is required to consider device-aided therapy. Safety data were consistent with the profiles from phase 3 trials.

Patients were grouped based number of affected domains of MANAGE-PD section 2. APD = advanced Parkinson’s Disease; LCIG = levodopa carbidopa intestinal gel; SD = standard deviation; U DysRS = Unified Dyskinesia Rating Scale; NMSS = Non-motor Symptoms Scale; UPDRS II = Unified Parkinson’s Disease Rating Scale; PDQ-8 = Parkinson’s Disease Questionnaire-8; MCSI = Modified Caregiver Strain Index.
FIRST EXPERIENCE IN THE UNITED STATES WITH TRUE REMOTE PROGRAMMING IN DEEP BRAIN STIMULATION THERAPY FOR MOVEMENT DISORDERS

Corneliu Luca¹, Jennifer Hislop¹, Srivastan Pallvaram², Henry Moore¹, Ihtsham Ul Haq¹
¹University of Miami, Neurology, Miami, United States of America, ²Abbott, Neuromodulation, Austin, United States of America

Background and Aims:: DBS in Parkinson’s disease and Essential tremor requires multiple in-person programming sessions burdening patients and caregivers. The recent FDA approved NeuroSphere™ Virtual Clinic enables clinicians for the first time to remotely connect into patient IPGs to perform system checks and actively adjust stimulation parameters. This is the first report describing clinical workflow and experience with the platform.

Methods:: 15 patients provided signed written consent to Abbott or verbal consent to the Clinician to be enrolled. The enrolled Abbott Infinity™ IPGs were securely mapped to authorized Clinicians. Software on programming devices was upgraded without requiring any hardware or firmware changes. Patients initiated remote sessions and Clinicians securely connected to the IPGs using unique logins and multi-factor authentication. Stimulation changes were synchronized with integrated video and a failsafe mechanism ensured continuity of therapy in case of network failure.

Results:: Of 15 DBS patients, 13 have undergone remote programming. The average time to establish connection has been less than 1 minute. There has been no perceptible difference in running system checks and of the order of 1 second for stimulation changes. Both English and Spanish speaking patients reported no difficulties using the platform. In one patient dysarthria was resolved and in another patient battery replacement was recommended remotely.

Conclusions:: Remote programming with this new platform is both clinically viable and meaningful. We expect to collect more objective metrics including impact on QoL, access, change in perceived quality of care with the adoption of this technology by both patients and neurologists.
MENTAL FLEXIBILITY IN PARKINSON’S DISEASE WITH CENTRAL FATIGUE: DATA FROM THE FRONTAL ASSESSMENT BATTERY

Andrea Maffucci\textsuperscript{1}, Caterina Paletti\textsuperscript{1}, Daniela Mannarelli\textsuperscript{1}, Alessia Petritis\textsuperscript{1}, Chiara Minelli\textsuperscript{2}, Francesco Fattapposta\textsuperscript{1}

\textsuperscript{1}Sapienza University of Rome, Human Neurosciences, Rome, Italy, \textsuperscript{2}University of Padova, Radiology, Padova, Italy

\textbf{Background and Aims::} Central fatigue is defined as a reduced energy level or an increased perception of effort, often associated to a failure in initiating and maintaining tasks that require self-motivation. It is common in Parkinson's disease population and it has been hypothesized to be related to a dysfunction in the striato-thalamo-prefrontal loop. The aim of the present study was to explore the association between fatigue and executive functions as index of integrity of the striato-thalamo-prefrontal loop.

\textbf{Methods::} Twenty-nine non-demented PD patients without fatigue - PDnF, 28 non-demented PD patients with fatigue - PDF and 26 age and sex-matched controls underwent an evaluation with the Frontal Assessment Battery (FAB), MMSE, PSQI, BDI, STAI Y1-2, PDQ-39. Differences between groups in FAB scores (total and subitems) were analyzed by means of Kruskal-Wallis test. Moreover, a correlation between fatigue and FAB was also analyzed.

\textbf{Results::} Overall parkinsonian population displayed worse performance than controls in frontal scores especially inhibitory control (p=0.008) and sensitivity to interference (p=0.014). PDF displayed significantly worse than PDnF in verbal fluency (p=0.05). Fatigue severity inversely correlated with executive performance (p<0.001).

\textbf{Conclusions::} Phonemic fluency tasks are thought to reflect the simultaneous engagement of several executive functions such as attention, working memory, retrieval, information processing. The association of central fatigue with a deficit in mental flexibility, could support the hypothesis that central fatigue is a reliable index of the impairment of higher executive functions needed in order to effectively assess costs and benefits related to adaptive decision-making behavior.
POST ANOXIC MYOCLONIC ENCEPHALOPATHY SYNDROME OR LANCE- ADAMS: CASE REPORT

Sandra Jurado López¹, Sandra Jurado López²
¹Universidad del Boyaca, Hospital Universitario San Rafael Tunja, Boyaca, Tunja, Colombia, ²Universidad del Sinú, Hospital Universitario San Rafael Tunja, Boyaca, Tunja, Colombia

Background and Aims:: Introduction: Lance Adams syndrome (LAS) a post anoxic myoclonic encephalopathy, an infrequently described entity since 1963, currently less than 200 cases have been reported1, characterized by myoclonic limb-acting movements and cerebellar ataxia with generally preserved higher mental functions, which typically appears hours or days after a cerebral hypoxia event (prolonged hypotension, cardiorespiratory arrest) and certain structures of the brain stem, cerebellum and diencephalon are thought to be involved in myoclonus due to hypoxia1-5.

Methods:: Case report

Results:: Case report: 60-year-old male patient with a history of systemic arterial hypertension, chronic renal failure under renal replacement therapy, presented cardiorespiratory arrest due to dialysis emergency, with successful cardiopulmonary resuscitation, post-resuscitation management in the critical care unit; presenting 24 hours later, persistent myoclonic movements of facial action and upper extremities that increased with sensory stimuli. Brain tomography (CT) and brain magnetic resonance (MRI) showed punctate hyperintensities in T2 and FLAIR in the basal ganglia, hippocampus and cerebellar vermis (Figure 1). Management with clonazepam and valproic acid was started with good response. One month later she presented mild cerebellar ataxia, without myoclonic movements, with preserved higher mental functions.

Conclusions:: In SLA, action myoclonias can also be triggered by different stimuli (tactile, sonorous, emotional), predominantly involving the extremities, with preservation of higher mental functions being a fundamentally clinical diagnosis; neuroimaging is usually normal and sometimes functional PET or SPECT studies are necessary, demonstrating increased glucose consumption in affected areas.1. Treatment is symptomatic, the first choice being clonazepam, valproic acid and levetiracetam with favorable clinical response. 1-5.
PREVALENCE OF VITAMIN B1 DEFICIENCY IN SUBJECTS WITH ADVANCED PARKINSON’S DISEASE SYMPTOMS

Jana Ponce¹, Erin Cameron-Smith², John Bertoni², Jenna Wuebker³, Danish Bhatti², Diego Torres², Corrine Hanson¹

¹University of Nebraska Medical Center, College Of Allied Health Professionals, Omaha, United States of America, ²University of Nebraska Medical Center, Department Of Neurological Sciences, Omaha, United States of America, ³Nebraska Medicine, Department Of Pharmaceutical And Nutrition Care, Omaha, United States of America

Background and Aims:: Vitamin deficiencies impact neurological conditions and may present as progression of Parkinson’s Disease (PD). We have previously shown 6.1% of a cohort of subjects with PD were deficient in Vitamin B1 and that dietary intake of vitamin B1 was significantly lower in those with deficiency (p = 0.02). Here, we aim to assess the prevalence of serum vitamin B1 deficiency in subjects with advanced PD symptoms.

Methods:: Prospective enrollment of subjects was conducted within a PD Comprehensive Clinic. The ordinal scores (0-4) for postural stability, gait and arising from chair from the Unified Parkinson’s Disease Rating Scale (UPDRS) motor score evaluation and serum vitamin B1 were collected as part of routine care. A Harvard Food Frequency questionnaire was administered to quantify dietary intake. Percent of subjects with Vitamin B1 deficiency were evaluated within each available ordinal score and a Pearson Chi-Square exact test was used to compare groups. A p-value <0.05 was considered statistically significant.

Results:: In our analysis of 169 subjects with PD, the percent of patients with Vitamin B1 deficiency was significantly higher in the most severe symptom category for gait (0=10.5%, 1=9.1%, 3=13.0%, 4=50%; p=0.08) and arising from chair (0=8.33%, 1=10.2%, 3=50%, 4=N/A; p=0.002). Percent of deficient patients was also higher in patients with worsening postural stability (0=8.6%, 1=5%, 2=35.6%, 3=16.7%; p=0.007).

Conclusions:: A high percentage of PD patients with severe motor symptoms have vitamin B1 deficiency. Further research on the relationship between vitamin deficiencies and motor outcomes in PD patients is warranted.
Background and Aims: Little is known about the neuropsychiatric dimension of Parkinson disease in Moroccan patients. The aim of this work is to investigate the neuropsychiatric profile of Parkinson disease and the impact of symptoms on quality of life in a Moroccan cohort in an academic hospital.

Methods: A structured questionnaire, the Neuropsychiatric Inventory (NPI) and the Parkinson disease questionnaire (PDQ-8) were administered to a cross-section of 32 patients diagnosed with idiopathic Parkinson disease in the movement disorder clinic of the Mohammed VI University Medical Center of Marrakesh, Morocco.

Results: A slight male predominance was observed (sex ratio: 1.1). Age, onset and duration of disease were 58.5±9.3, 51.4±9.4, and 7.2±4.2 years respectively. All patients were on L-dopa; 25% were on antidepressants. The presence of neuropsychiatric symptoms was noted in 90.6% of patients, with clinically significant symptoms in 84.3%. Depression (75%), anxiety (65.6%) and irritability (62.5%) were the most frequent symptoms. The mean total NPI score was 22.4±16.7, with females reporting higher means (t=2.8, p=0.008). For symptomatic patients, sleep problems were the most distressful (7.71±2.99). The mean number of symptoms was 4.2±1.8, with females reporting significantly higher numbers (t=2.56, p=0.016). The mean PDQ-8 score was 13.0±7.2. No difference was observed in terms of gender (t=0.27, p=0.79). A negative correlation was observed between age of onset and quality of life (r=-0.39, p=0.26).

Conclusions: Neuropsychiatric symptoms are frequent in our patients and do impact quality of life but remain under treated. As such, it is imperative to screen and treat them if present.
Background and Aims:: Quality of life (QoL) in Parkinson’s Disease (PD) worsens as bradykinesia, rigidity, rest tremor, gait disturbance, and cognitive changes progress over time. We searched for treatable conditions that masquerade as worsening PD. Vitamin deficiencies are common in PD patients, and many can cause neuropathies that worsen gait and cause falls. Deficiencies in B1 and B12 cause cognitive decline, and deficiencies in D increase the risk of fractures with falls. The goal of this research is to improve QoL in patients with PD by identifying and treating vitamin deficiencies.

Methods:: We collected 178 cases from our Comprehensive PD Clinic using prospective and retrospective methods. Statistical analyses were performed on serum vitamin levels (B1, B6, B12, and D), the United Parkinson’s Disease Rating Scale (UPDRS) Part III Motor Exam and the Harvard Food Preference Questionnaire.

Results:: 40% of patients had at least one vitamin deficiency. Deficiencies of vitamins B1, B6, B12, and D were found in 6%, 26%, 6%, and 30% respectively. Hallucinations disappeared within 3 days of oral replacement of low vitamin B1 in one patient. Many other patients improved or stabilized after vitamin replacement, especially if treated early.

Conclusions:: Vitamin deficiencies are “the Great Imitator” of PD progression and are correctable. A high index of suspicion, early detection, and aggressive correction of vitamin deficiencies can prolong and improve the QoL of PD patients. Future data analyses will look at changes in the UPDRS correlating with serum vitamin levels and how food preferences affect vitamin deficiency risk.
NEURORADIOLOGICAL FINDINGS IN HEMICHOREIC DISORDER AND GLYCEMIC DECOMPENSATION: CASE REPORT.

Sandra Jurado López¹, Jamir Muñoz Torres²
¹Universidad del Sinú, Cartagena, Cartagena, Colombia, ²Universidad del Boyacá, Boyaca, Tunja, Colombia

Background and Aims:: Chorea and ballismus are involuntary movement disorders. Conditions such as cerebrovascular insufficiency, neurodegenerative, neoplastic, immunologic, infectious, and metabolic diseases are secondary causes of the disorder, with nonketotic hyperglycemia being the most common metabolic cause. Several reports describe on brain magnetic resonance imaging (MRI) unilateral hyperintense lesions of the putamen, caudate in T1; the etiology and pathogenesis is unclear, frequent in elderly women, strict glycemic control and neuroleptics leads to good prognosis in most patients. 1-5

Methods:: Caso report

Results:: Clinical Case

66-year-old woman with insulin-dependent type 2 diabetes mellitus and hypertension of 5 years of evolution, with unsatisfactory glycemic control in the last 2 years, consults for 2 days of evolution consisting of choreiform movements of the right body, laboratories show glycemia 348 mmol /L, HbA1c in 11.1%, plasma osmolarity 318 mOsm /L and negative ketonuria; compatible with non-ketotic glycemic decompensation, paraneoplastic syndromes were ruled out. Brain MRI showed occipital subacute lacunar infarcts and right semioval center, left peratral, microangiopathic leukoencephalopathy, left putamen hyperintensity in T1, T2 and FLAIR, diffusion pseudonormalization, with discrete enhancement with gadolinium (figure 1), spectroscopy with normal levels of metabolites without lactate peak.
Management with haloperidol and clonazepam, chorea started to resolve after 10 days of successful glycemic control.

**Conclusions:** The hemichorea observed in association with hyperglycemia, hyperintensity on T1-weighted MRI is universally recognized, the pathophysiologic mechanism remains unknown and these findings indicate that it is not simply due to cerebral infarction, but involves a vasculopathy exclusively restricted to the putamen and/or striatum in diabetic patients. 6-10
ESSENTIAL TREMOR AND COGNITIVE FUNCTIONING: A CLINICAL AND IMAGING STUDY

Fabiana Novellino¹,², Valeria Saccà³, Carmelina Chiriaco¹, Maria Salsone¹, Giuseppe Nicoletti¹, Rita Nisticò¹, Andrea Quattrone⁴, Maurizio Morelli⁴, Gennarina Arabia⁴, Aldo Quattrone⁴,⁵
¹National Research Council, Neuroimaging Research Unit, Catanzaro, Italy, ²Complutense University of Madrid, Department Of Pharmacology And Toxicology, Medicine School, Madrid, Spain, ³Massachusetts General Hospital and Harvard Medical School, Department Of Psychiatry, Charlestown, United States of America, ⁴Magna Graecia University, Institute Of Neurology, Department Of Medical Sciences, Catanzaro, Italy, ⁵University Magna Graecia, Neuroscience Research Centre, Catanzaro, Italy

Background and Aims:: The purpose of this case-control study was to characterize the neuropsychological profiles of patients with ET and to delineate its neuroanatomical counterpart.
Methods:: We collected neuropsychological, and MRI data from 49 non-demented ET and 50 age-, sex-, and education matched healthy controls. We performed (i)direct comparison between groups; (ii)machine learning analysis with feature selection to obtain the best discriminant tests between groups. The tests showing differences and/or the best discriminating ability were inserted in a whole-brain voxel-based-morphometry (VBM) correlation model in MRI to evaluate the correlation between cognitive performances and the degree of brain atrophy in the ET group without a priori hypothesis.
Results:: ET patients performed worse than HC in tests evaluating cognitive control, verbal and working memory (FAB p:0.05, MCST-CA p:0.029, RAVLT-DR p:0.03, Digit-SpanB p:0.03). The same tests and those for language evaluation had the greatest discriminating ability (RAVLT-DR, FAB, COWAT, RAVLT-IR). Regardless of the test explored, the MRI analysis revealed a strong (p<0.05 FWE, whole brain) correlation between tests (FAB, RAVLT-IR, RAVLT-DR, COWAT) and widespread areas including cerebellum, thalamus, inferior and middle frontal cortices, cingulate cortices, hippocampus, parahippocampal gyri, temporal cortex.
Conclusions: Our results suggest that ET-related cognitive impairment involves attention/executive function, memory, and language. Heterogeneity in the cognitive presentation goes along with broad involvement of many cerebral areas that include cerebello-thalamo-cortical loop and spread outside this network (hippocampus, parahippocampal gyri, temporal and cingulate cortices). Therefore, ET patients may develop disease-related changes beyond the cerebellar network, leading to broad cognitive damage.

BETA-ADRENOCEPTOR ANTAGONISTS AND RISK OF PARKINSON’S DISEASE: META-ANALYSIS OF PHARMACOEPIDEMIOLOGICAL STUDIES

Ambrish Singh\textsuperscript{1}, Salman Hussain\textsuperscript{2}, Benny Antony\textsuperscript{1}
\textsuperscript{1}University of Tasmania, Menzies Institute For Medical Research, Hobart, Australia, \textsuperscript{2}Czech National Centre for Evidence-Based Healthcare and Knowledge Translation, Institute Of Biostatistics And Analyses, Faculty Of Medicine, Brno, Czech Republic

Background and Aims:: Parkinson’s disease (PD) is exhibited by intracellular accumulation of Lewy Bodies (α-synuclein) encoded by α-synuclein gene. A possible relationship between β-adrenergics and α-synuclein synthesis has been shown. Pharmacoepidemiological (PE) studies evaluating β-antagonist use and risk of PD have reported conflicting findings. We performed a meta-analysis of PE studies evaluating the association of β-antagonist use and risk of PD.

Methods:: PubMed, Embase were searched from inception to Oct-2020. Two reviewers screened records in duplicate; PE studies reporting relative risk (RR) of PD in β-antagonist-users, compared to non-users, were included. Newcastle-Ottawa scales (NOS) was used to assess study quality. We employed generic inverse variance method using RevMan(5.3.5) to estimate pooled adjusted RR (aRR) using random-effects model. Sub-groups were analyzed based on study design and type of β-antagonist.

Results:: Of 1054 records, eight studies (2:cohort;6:case-control) with 6,267,037 participants (74,189 PD cases), were included. Significant heterogeneity (I\textsuperscript{2}>92\%) was observed; majority (n=7) of the studies were of moderate/high quality. In the overall pooled analysis (n=7) including any β-antagonist-users, compared with non-users, the aRR for PD was 1.27 (95\%CI:1.02,1.57;P= 0.03). The risk of PD, in β-antagonist-users, was significant for cohort studies (n=2) (aRR:1.78;95\%CI:1.24,2.57;P=0.002), and non-significant (aRR:1.08;95\%CI:0.92,1.27;P=0.34) for the case-control studies (n=5). By β-antagonist type, risk of PD was significantly higher only for the propranolol (aRR:1.91;95\%CI:1.20,3.06;P=0.007) and not for metoprolol (aRR:1.05;95\%CI:0.88,1.24;P=0.61), carvedilol (aRR:0.87;95\%CI:0.79,0.96;P=0.006), bisoprolol (aRR:0.93;95\%CI:0.60,1.43;P=0.73), sotalol (aRR:1.03;95\%CI:0.69,1.52;P=0.90), and atenolol (aRR:0.97;95\%CI:0.92,1.02;P=0.28) users.

Conclusions:: An increased risk of PD was observed in β-antagonist users that was driven mainly by propranolol use and not the other β-antagonists’ use, possibly indicating a protopathic bias.
Background and Aims:: Considering the evidences of neuronal protective effects of curcumin in previous in vitro, experimental animal and clinical studies, this double-blind, randomized, placebo-controlled, and parallel-group trial would explore the possible nanomicelle curcumin (SinaCurcumin®. Nano-Micellar Soft gel)-mediated impact on sleep, fatigue, and quality of life (QoL) in patients with Parkinson's disease (PD).

Methods:: Fifty PD patients were recruited and randomly divided into experimental (25) and control groups (25). Measurement tools were as follows: Hoehn & Yahr scale for stage of disease progression, sleep quality based on the Pittsburgh Sleep Quality Index (PSQI), fatigue based on Fatigue Severity Scale (FSS), and QoL based on the Parkinson's Disease Questionnaire–39 (PDQ-39) at the beginning and the end of the study. The groups were treated for three months by 80 mg of Nano-Micellar Soft gel twice a day.

Results:: Nanomicelle curcumin significantly increased sleep quality and QoL compared with placebo (P-values= 0.0001 and 0.0002, respectively) in PD patients. This significant difference was not influenced by the variables of the duration of the disease, stage of disease progression, and the dose of levodopa. This supplement did not have a significant effect on the fatigue severity of patients compared to placebo.

Conclusions:: Based on the results of this study, it is recommended that the nanomicelle curcumin can be used to improve sleep quality and QoL in PD patients.
COLONIC TRANSIT TIME IN PROGRESSIVE SUPRANUCLEAR PALSY AND PARKINSON’S DISEASE

Ryuji Sakakibara¹, Hirokazu Doi², Fuyuki Tateno³, Yosuke Aiba³, Setsu Sawai⁴
¹Sakura Medical Center, Toho University, Neurology, Internal Medicine, Sakura, Japan, ²Sakura Medical Center, Toho University, Pharmaceutical Unit, Sakura, Japan, ³Neurology, Internal Medicine, Sakura Medical Center, Toho University, Neurology, Internal Medicine, Sakura, Japan, ⁴Chiba University, Neurology, Chiba, Japan

Background and Aims:: Gastrointestinal (GI) function in progressive supranuclear palsy (PSP) has not been reported, in contrast with extensive studies of GI function in Parkinson’s disease (PD). We aimed to investigate GI function in PSP and PD.

Methods:: A GI questionnaire for constipation and an objective colonic transit time (CTT) test were performed in 8 patients with PSP (6 men and 2 women; mean age, 74.6 years, mean duration of disease, 2.9 years), 36 patients with PD (19 men and 17 women; mean age, 75.6 years, mean duration of disease, 2.6 years) and 8 age-matched normal control subjects (4 men and 4 women; mean age, 73.6 years).

Results:: A GI questionnaire showed constipation in 2 (25%) PSP; 23 (64%) PD; and none (0%) control, without statistical significance. A CTT test showed total CTT of 63.2±33.9 hours in PSP; 69.6±42.8 hours in PD; and 45.2±40.3 hours in control, without statistical significance. In contrast, right CTT in PSP (p<0.05) and PD (p<0.01) was significantly prolonged from that in control.

Conclusions:: Subjective constipation is uncommon, but prolonged CTT is observed in PSP. This GI feature needs appropriate management and care, which might reflect PSP’s brainstem/sacral spinal cord pathology.
COMPREHENSIVE FUNCTIONAL EVALUATION OF THE SPECTRUM OF PROGRESSIVE NUCLEAR PALSY WITH 18F-FDG PET/CT AND 99MTC TRODAT-1 SPECT

Ritu Verma¹, Rajeev Ranjan², Nikhil Seniaray¹, Ethel Belho¹
¹Sir Ganga Ram Hospital, Department Of Nuclear Medicine And Pet Ct, NEW DELHI, India, ²Sir Ganga Ram Hospital, Department Of Neurology, NEW DELHI, India

Background and Aims:: To elucidate the patterns of characteristic hypometabolism on 18F-FDG PET/CT in various subtypes of PSP and correlation with the core clinical features.

Methods:: A retrospective analysis of 124 patients of clinically suspected PSP was done. All the subjects were clinically analyzed and rated using the Progressive supra nuclear palsy rating scale proposed by the Movement Disorder Society by the Neurologist and were further clinically segregated into five subtypes-PSP with Richardson’s syndrome, PSP with predominant parkinsonism, PSP with speech/language presentation, PSP with frontal presentation and PSP with predominant ocular presentation. All the subjects underwent 99mTc TRODAT-1 SPECT study and 18F-FDG PET/CT scan on two separate days. The scans were analyzed qualitatively (visually) and semi-quantitatively and the FDG uptake patterns were recorded and areas of hypometabolism that were two standard deviations from the mean were considered as abnormal.

Results:: 99mTc TRODAT-1 scan was abnormal in all the subjects, establishing degenerative Parkinsonism. The subjects of PSP with Richardson’s syndrome showed diffuse hypometabolism involving anterior cingulate and orbital frontal cortices with diffuse hypometabolism involving basal ganglia, thalami, mid brain and sensori-motor cortices. In subjects with PSP with speech/language and frontal presentation variable additional involvement of the anterior and medial frontal association, insular and anterior temporal cortices was seen.

Conclusions:: Dopamine transporter imaging agent 99mTc TRODAT-1 SPECT helps in confirmation of degenerative Parkinsonian disorders. Characteristic patterns of hypometabolism may help in differentiation of the subtypes of PSP in the presence of clinically overlapping symptoms.
Background and Aims:: Most patients diagnosed with PD show gastrointestinal symptoms as one of the earliest features. For example, PD patients often complain of gastrointestinal distress such as constipation and nausea. It is important to note that about 60% of PD patients suffer from constipation, which can begin 20 years before diagnosis and is one of the prodromal syndromes.

Methods:: This is an overview abstract including analysis of researches regarding gut microbiota and Parkinson's disease.

Results:: The human gut microbiome has been shown to complement the host with basic functions and affect the host's central nervous system via the gut-brain axis through modulation of neural pathways and GABAergic pathways and serotonergic signaling systems. The human gut microbiome subsequently divided into three enterotypes: Ruminococcus, Bacteroides and Prevotella. Next generation sequencing protocols are widely used to both identify and characterize these communities. The gastrointestinal microbiota has essential functions to maintain metabolic homeostasis such as direct inhibition of overgrowth of pathogenic microorganisms, development of intestinal defenses, vitamin biosynthesis, energy modulation, and immunological and xenobiotic effects.

Conclusions:: Unfortunately, the relationship between the microflora of the gastrointestinal tract and the brain is not well understood. There are relatively few studies that highlight the relationship between intestinal flora and PD; It can be concluded that the broader significance of the human microbiome is complex and requires further research to improve the current understanding of the mechanisms underlying Parkinson's disease.
CONNECTION BETWEEN OLFACTORY DYSFUNCTION AND SEVERITY OF TREMOR

Denis D Pokhabov¹, Vladislav Abramov², Maria Tunik¹, Michael Sadovsky³, Dmitry V Pokhabov¹
¹Krasnoyarsk state medical University, Neurological Diseases, Krasnoyarsk, Russian Federation, ²Siberian clinical center of FMBA, Neurology, Krasnoyarsk, Russian Federation, ³Siberian federal university, Bioinformation, Krasnoyarsk, Russian Federation

Background and Aims:: Neurological disorders it's a problem for a number of people worldwide. Parkinson's disease (PD) and essential tremor (ET) are among them. Tremor is the common symptom both for PD (rest tremor) and ET (postural-kinetic tremor). Olfactory dysfunction is stipulated to be the first manifest of PD preceding the movement disorders. It happens due to the neurodegenerative process starting in olfactory bulbs. Currently available data on the olfactory function in ET are insufficient and some of them are contradictory. Hence, our aim was to obtain tremor data of PD and ET patients and the data of their olfactory function to verify our scientific hypothesis on the inverse relation between tremor manifestation and olfactory function decay: milder tremor is accompanied with worse smell perception, and vice versa.

Methods::

- Image of test tubes with different colored caps, likely used for medical or scientific purposes, placed on a table.
We had three groups of patients: PD, ET and healthy people. An examination procedure of olfactory function was based on Sniffin’ sticks test. For tremor testing we used wireless device to monitor electrophysiological signals. We used an elastic map technique to cluster and analyze all data.

Results:
Combination of tremor data and smell perception provides clear and apparent distinction of PD patients from ET ones. Proven inverse relation between tremor level and olfactory function decay is the most sounding result of our work. Indeed, ET patients showed better olfactory function results accompanied by stronger tremor, as compared to PD patients.

**Conclusions:** The presented results could be implemented for early differential diagnostics of PD, ET, as well as for the improvement of individual therapy for such patients.
SUSTAINED RELEASE TRIPLE DRUG LOADED COLLOIDOSOMES FOR MANAGEMENT OF PARKINSON’S DISEASE

Saurabh Bhargava¹, Vishal Bhargava²
¹Signa College of Pharmacy, Pharmacy, Kanpur, India, ²GTB Hospital, R&d, Kanpur, India

Background and Aims:: Parkinson’s disease (PD) is well-known as a progressive and degenerative disease of nervous system. The degeneration of dopaminergic neurons in substantia nigra, and reduction in amount of neurotransmitter dopamine available in striatum relate symptoms of this disease. It is hypothesized that a drug delivery system that provides controlled and sustained release of PD drugs would afford better management of PD. Hollow microcapsules composed of PMMA (polymethyl methacrylate) and poly(caprolactone)(PCL) are prepared through a modified double-emulsion technique. They are loaded with three PD drugs, i.e., levodopa(LD), carbidopa(CD), and entacapone(ENT), at a ratio of 4:1:8.

Methods:: Microcapsules were prepared through a double emulsion(W1/O/W2) solvent evaporation method with modifications to produce hollow microspheres. Microcapsules were then spray coated along with ENT. Shape and surface morphology were studied using SEM & TEM. Average particle size and polydispersity index were determined by optical microscopy, drug entrapment, CLSM, Buoyancy tests and in-vitro drug release was studied.

Results:: LD and CD are localized in both hollow cavity and PMMA/PCL shell, while ENT is localized in PMMA/PCL shell. Release kinetics of hydrophobic ENT is observed to be relatively slow as compared to other hydrophilic drugs. It is further hypothesized that encapsulating ENT into PCL as a surface coating onto these microcapsules can aid in accelerating its release. Now, these spray-coated hollow microcapsules exhibit similar release kinetics, according to Higuchi’s rate, for all three drugs.

Conclusions:: Results suggest that multiple drug encapsulation of LD,CD, and ENT in gastric floating microcapsules could be further developed for in-vivo evaluation for management of PD.
Background and Aims:: Patients with essential tremor and adductor-type spasmodic dysphonia may manifest a prominent voice tremor. The diagnosis of voice tremor is currently based on perceptual and qualitative analysis. We have recently demonstrated in two independent studies that advanced voice analysis with machine learning objectively discriminates normal voices from those recorded from patients with essential tremor and dysphonia. The aim of this study is to achieve a direct and objective discrimination between voice samples recorded from patients with essential tremor and dysphonia both manifesting voice tremor.

Methods:: We investigated 33 patients with adductor-type spasmodic dysphonia (7 males, 65.6±11.7y), 36 patients with essential tremor and voice tremor (9 males, 72.4±8.6y), and 74 age-matched controls (20 males, 71.0±12.4y). We recorded voice samples during sustained vowel emission using a high-definition audio recorder. The classification of voice samples was achieved by means of a dedicated machine learning algorithm.

Results:: Receiver Operating Characteristic curves showed that machine learning objectively discriminated between controls and essential tremor (Accuracy: 96.1%; AUC: 0.95), controls and dysphonia (Accuracy: 97.5%; AUC: 0.97) and finally essential tremor and dysphonia (Accuracy: 97.5%; AUC: 0.97).

Conclusions:: Advanced voice analysis using machine learning objectively recognize voice tremor in patients with essential tremor and dysphonia discriminating the two forms of voice tremor with high accuracy. Our findings suggest that voice tremor differs in patients with essential tremor and spasmodic dysphonia. This finding points to different pathophysiological mechanisms underlying voice tremor in the two conditions.
BRAIN ACTIVITY IN THE IDIOPATHIC PARKINSON'S DISEASE

Jiří Bůřil¹, Petra Bůřilová², Andrea Pokorná², Martin Lamoš³, Marek Baláž¹
¹Masaryk University, Faculty of Medicine, Ist Department Of Neurology, Brno, Czech Republic, ²Masaryk University, Faculty of Medicine, Department Of Nursing And Midwifery, Brno, Czech Republic, ³Central European Institute of Technology, Centre For Neuroscience, Brno, Czech Republic

Background and Aims:: We used a high-density electroencephalography (HD EEG) to investigate changes in bioelectric potentials and potentially changes in connectivity between STN and IFC in patients with Parkinson's disease after deep brain stimulation (DBS).

Methods:: A prospective observational descriptive study in patients with DBS therapeutic intervention was chosen as a research design realised in the period between 2017 and 2020. A connectivity between subthalamic nucleus and inferior frontal cortex was observed during double-task cognitive non-motor task in patients with DBS stimulator turned off and on. The main examination method used was HD EEG with 256 channels.

Results:: A total of 32 patients were contacted during standard outpatient check-ups, eight (25 %) patients agreed to participate in the study. The average age of the patients was 66.7 years (range 57 – 76 years). At the end of the study decrement of the connectivity between IFC and STN for target stimuli after the DBS was switched ON in patients on dopaminergic medication was observed. This decrease may partly explain the negative effect on cognitive functions of the DBS STN therapeutic method in previously published studies.

Conclusions:: The decrease of connectivity between IFC and STN was identified. There was no difference in laterality of connectivity decrease. We therefore assumed that DBS stimulation during the medication ON state disrupted functional connectivity between IFC and STN. The study results forms new hypotheses in the field of brain connectivity in IPD patients. Further study is needed to confirm our hypotheses.
CLINICAL CHARACTERISTICS OF PARKINSON’S DISEASE IN SUDANESE PATIENTS ATTENDING DAOUD CHARITY CLINIC IN 2020-2021.

Radi Tofaha Alhusseini1, Abbasher Hussien2, Khabab Mohamed Ahmed3, Hussien Abbashar4, Amira Abdelgalil5, Faroug Mohammed6, Mohamed Malekaldar7, Rowaie Mohamed8, Fatimaaalzahra Abdelgadir9, Aziza Alrayah10, Roaa Sidahmed11, Munira Korsi12, Ahmed Hassan13, Mohajer Ismaiel14

Background and Aims:: Introduction: Parkinson’s disease (PD) is the second most common neurodegenerative disorder, after Alzheimer’s disease. Parkinson’s disease main four clinical features include muscle rigidity, tremors, and bradykinesia and gait. Also there is secondary features like depression, emotional change, dementia, constipation, postural hypotension, changes in speech, skin problem, and dysphagia. Objectives: To identify the clinical features of Parkinson disease in Sudanese Parkinson’s patients.

Methods:: A descriptive cross sectional clinic based study during the period of January 2020 to January 2021. Data was collected using unified Parkinson disease rating scale via trained doctors on interview based clinic setting with full medical history and physical examination.

Results:: This study includes 35 patients with Parkinson disease 25 (71, 4%) were male and 10 (28, 6%) were female. The most common age of the patients ranges from 61 to 70 years (34, 5%). Bradykinesia was found to be the most common symptoms (85, 7%) more than rigidity (82, 9%), tremor (74, 3%) and postural gait instability (71, 4%).

Conclusions:: This study has identified the most common clinical features of Parkinson’s disease. The present study confirms previous findings, notwithstanding the relatively limited sample, this work offers valuable insights into the clinical presentation of Parkinson disease in Sudanese
ASSESSMENT OF FRONTAL LOBE FUNCTIONS IN PARKINSONISM SYNDROMES

Jidhin Raj, Beena V, Jacob George
government medical college kottayam, Neurology, kottayam, India

Background and Aims:: Frontal lobe dysfunction is a predominant feature of progressive supranuclear palsy however it can be present in other parkinsonism syndromes also. The frontal assessment battery (FAB) is a brief tool developed to assess frontal lobe functioning at bedside Objective: To assess the frontal lobe functions in patients with Parkinsonism syndromes

Methods:: 110 study subjects who fulfilled the inclusion and exclusion criteria were included in the study over a period of 10 months They were clinically evaluated for frontal lobe dysfunction using the FAB battery during the ON and OFF period. Collected data was coded and entered in Microsoft Excel and data was analyzed using SPSS software version 20

Results:: Results: . The mean MMSE score of the population during the ON and OFF period was 25.09 +/-1.8 and 25.05+/-0.8. In terms of FAB scores, the mean value of the study population during ON and OFF periods were 11.18+/- 2.9 and 10.95+/- 2.8 respectively. The mean difference between the FAB scores during the ON and OFF period was 0.24 which was statistically significant (p=0.018). There was significant difference between the frontal lobe dysfunction during the ON and OFF period (p <0.05).

Conclusions:: Conclusion: Frontal lobe dysfunction during the ON period was found in 54.5% of the total study population In the OFF period 60% of the total study population had frontal lobe dysfunction. The maximum dysfunction was found in PSP and minimum in CBD during both ON and OFF period.
ASSESSMENT OF NON MOTOR SYMPTOMS IN PARKINSONISM SYNDROMES

Jidhin Raj, Beena V, Jacob George
government medical college kottayam, Neurology, kottayam, India

Background and Aims: BACKGROUND: James Parkinson described Parkinson’s disease in 1817. He described the motor and non motor findings in Parkinson’s disease. Despite this emphasis on motor symptomatology, several studies have shown that the non-motor symptoms of Parkinson’s disease, such as depression, psychosis, falls, and sleep disturbance, have greater significance when assessed by quality-of-life measures, institutionalization rates, or health economics. OBJECTIVE: To study the prevalence and duration of non motor symptoms in patients with parkinsonism syndromes

Methods: MATERIALS AND METHODS: 110 study subjects who fulfilled the inclusion and exclusion criteria were included in the study. Non Motor Symptom history was obtained using a questionnaire. Collected data was coded and entered in Microsoft Excel and data was analyzed using SPSS software version 20.

Results: RESULTS and DISCUSSION: - The prevalence of non motor symptoms was 97.3% of the total study population. The mean duration of Non Motor symptoms in the study population was 3.28 +/- 2.74 yrs. In IPD pts the mean duration was 4 +/- 3.5 yrs, in PSP was 2.13 +/- 1.88 yrs, in MSA was 2.16 +/- 1.83 yrs, and in CBD was 3 +/- 2.16 yrs and in vascular Parkinsonism it was 2.97 +/- 2.39 yrs. 23.6 % of the study population had postural hypotension.

Conclusions: CONCLUSION: - The most common symptom in the total population was gastroenterological symptoms and fatigue (60%) and the least common symptom was skin problems (0.9%). Skin and respiratory problems were least encountered non-motor symptoms.
METABOLIC CONCENTRATIONS, T2 VALUES PATIENTS WITH PARKINSON'S DISEASE (PD) AS BIOMARKERS OF THE LEVEL OF COGNITIVE IMPAIRMENT (CI)

Zinayida Rozhkova, Irina Karaban', Nina Karasevich
Institute of Gerontology of the Academy of Medical Sciences of Ukraine, Parkinson's Disease, Kyiv, Ukraine

Background and Aims:: To evaluate the level of CI in PD-patients we study the relaxation times and content of the main cerebral metabolites in the frontal lobe (FL) and in putamen (P).

Methods:: 18 PD-patients of 1st group (DPDG) with dementia (MMSE<25), 16 - 2nd (CIPDG) with mild CI (30≥MMSE≥25), 16-3rd (NPDG) with (MMSE≥30), 15 controls of 4th (CG) are studied by 1.5T SIGNA HDxt(GE). 1H spectra are obtained in FL and in P.

Results:: In FL the shortening of the T2M for all of the patients are found. T2M in FL: 67.1, 40.5, 98.6ms (DPDG); 145.2, 59.3, 207.5ms (CIPDG); 210.1, 185.3, 263.4ms(NPDG); 204.2, 198.0, 331.2ms(CG). These allow us to distinguish subjects of CG from PD-patients, but they are not specific for evaluation of the level of CI. T2M in P: 63.3, 56.5, 101.8ms(DPDG); 58.2, 49.0, 90.2ms(CIPDG); 134.1, 152.3, 233.1ms(NPDG); 215.0, 114.0, 320.1ms(CG). In P NAA/Cr ratios in DPDG and CIPDG are significantly lower than in the NPDG, Cho/Cr ratios higher than in NPDG. Content of NAA in P:(6.81+-1.8), (7.62+-1.4), (7.82+-1.3) in DPDG, CIPDG, and NPDG, and NAA/Cr decrease with the grade of CI. Concentrations of mIns in FL: (4.23+-0.79), (3.69+-0.62), (3.43+-0.83) in DPDG, CIPDG, and NPDG, and mIns/Cr increase with the grade of CI. Concentrations of Glx in FL is more pronounced, than other metabolites:(8.1+-1.9), (9.32+-1.6), (10.6+-1.8) in DPDG, CIPDG, NPDG, and Glx/Cr decrease with the grade of CI. Concentration of Glx in the BG: (6.34+-1.4), (7.93+-0.9), (9.46+-1.2) in DPDG, CIPDG, NPDG. We have found the progressive decreasing Glx-content in the FL and in P for the patient of NPDG, CIPDG, DPDG, that is associated with poorer cognitive function.

Conclusions:: T2M, concentration may be of CI.
Background and Aims:: Stiff Person Syndrome (SPS) is a rare autoimmune neurological disorder, characterized by axial and limb muscular stiffness and spasms, due to a loss of physiological GABAergic CNS inhibition. In 60%-80% of patients with classic SPS phenotype antibodies against glutamic acid decarboxylase (GAD) enzyme can be detected.

Methods:: All patients with a clinical diagnosis of SPS and GAD antibodies, evaluated at Ospedale Maggiore Policlinico, Milan, Italy, between 2013 and 2021, were retrospectively included. The presence of GAD antibodies was screened by quantitative assessment (either Chemiluminescent immunoassay-CLIA or Radioimmunoessay-RIA), and subsequently confirmed by qualitative assessment (Western Blot and immunohistochemistry.)

Results:: 9 patients were included, all of female gender. The mean age at onset was 42.7 years (25-61). The most common symptoms at onset were unexplained falls and dorso-lumbar pain. Three patients suffered from poorly controlled autoimmune diabetes; positivity to anti-thyroglobulin, anti-thyreoperoxidase and anti-parietal gastric cells was also detected. One patient had history of partial epilepsy, and other 3 patients had subclinical epileptic activity on EEG. All patients had a good response to symptomatic treatment with either clonazepam or baclofen (in one case with intrathecal pump), but were also treated with immunotherapy, with either plasma-exchange or IVIG in inpatient setting, and subsequently with second-line agents (Rituximab, Azatioprine, Methotrexate). Two patients underwent thymectomy, with identification of thymic hyperplasia vera, although with no symptomatic relief.
Conclusions: GAD associated SPS is a protean syndrome, with diverse neurological manifestations combined with autoimmune disorders. A patient-tailored combination of symptomatic drugs and immunotherapies is needed to improve the patients' quality of life.
CLINICAL UTILITY OF DOPAMINE TRANSPORTER SCAN (DAT SCAN) IN CLINICALLY SUSPECTED PARKINSONISM: A TERTIARY CARE CENTER EXPERIENCE

Walaa A. Kamel1,2, Jasem Al Hashel3, Samira Al Tailji4, Masoud Elgadafi35, Waleed Ahmed5, Ahmed Kodair5, Athar Iqbal5

Background and Aims:: The most sensitive imaging techniques for an early diagnosis of parkinsonian syndromes are SPECT and PET, with DaT scan reported to be widely used with effective management of PD. Aims and objectives: The objective of this study is to assess the impact of 123I-ioflupane SPECT i.e. (DaT SCAN) on the diagnosis and management along with assessing its safety profile in Kuwait

Methods:: We analyzed retrospectively the DaT scan referral forms, history data and official reports from the nuclear medicine department of Ibn Sina hospital in Kuwait between January 2018 to January 2020. All referring physicians were contacted in order to assess the impact of the scan on the diagnosis and management of those patients.

Results:: Table 1: Clinical utility

Conclusions:: Normal binding of 123I-Ioflupane to presynaptic transporters rules out, with a high diagnostic accuracy, the presence of IPD or other parkinsonian syndromes with high safety standards.
DYSAUTONOMIA IN IDIOPATHIC PARKINSON’S DISEASE: RELATIONSHIPS WITH DISTRIBUTION OF MOTOR SYMPTOMS AT ONSET

Domiziana Rinaldi, Michela Sforza, Lanfranco De Carolis, Marika Alborghetti, Edoardo Bianchini, Francesco Pontieri
Sapienza, University of Rome. Sant’Andrea Hospital, Nesmos, Rome, Italy

Background and Aims:: Dysautonomia is a common and disabling non-motor symptom (NMS) of Parkinson’s disease (PD), most frequently occurring in advanced patients. Some NMSs of PD, including cognitive and sleep disturbances, showed associations with lateralization of motor symptoms at onset. In this retrospective study, we investigated the relationships between motor features at onset and dysautonomia.

Methods:: Medical records from 308 PD patients referring to our Movement Disorder Service between 2015 and 2020 were screened for the presence of dysautonomia. This was defined as a score ≥2 in at least one of the “cardiovascular”, “genitourinary” or “gastrointestinal” items of the PD-Non Motor Symptoms Scale (NMSS). Lateralization of symptom onset was defined by at least 2-point left-right difference at the MDS-UPDRS-III score. Patients were divided according to the distribution of motor symptoms at onset as left side (LO, n=145), right side (RO, n=129) or bilateral (BO, n=34).

Results:: There were no demographic, clinical and therapeutic differences among the three groups. BO patients displayed higher prevalence of cardiovascular, gastrointestinal and urinary symptoms compared to LO and RO (41% vs. 21-24%, 59% vs. 52-43%, 71% vs. 50-47%, respectively). Moreover, BO patients displayed a higher prevalence of co-existence of all three dysautonomic domains (14%, p=0.008). There were no significant differences between LO and RO patients.

Conclusions:: PD patients devoid of clear lateralization of motor symptoms at onset are more prone to develop dysautonomic symptoms. This may contribute to determining stronger disability.
DEEP BRAIN STIMULATION IN HUNTINGTON'S DISEASE.

Roberta Bonomo¹, Antonio Elia², Giulio Bonomo³, Luigi Romito², Caterina Mariotti⁴, Grazia Devigili², Roberto Cilia², Riccardo Giossi⁵, Roberto Eleopra²
¹University of Milano-Bicocca, Experimental Neurology Unit, School Of Medicine And Surgery, Monza, Italy, ²Fondazione IRCCS Istituto Neurologico Carlo Besta, Department Of Clinical Neurosciences, Parkinson And Movement Disorders Unit, Milan, Italy, ³Fondazione IRCCS Istituto Neurologico Carlo Besta, Neurosurgery Department, Milan, Italy, ⁴Fondazione IRCCS Istituto Neurologico Carlo Besta, Unit Of Medical Genetics, Milan, Italy, ⁵Fondazione IRCCS Istituto Neurologico Carlo Besta, Neuroimmunology And Neuromuscular Diseases Unit, Milan, Italy

Background and Aims:: Huntington’s disease (HD) is an inherited neurodegenerative disorder clinically characterized by involuntary movements, cognitive decline, and behavioral changes. The complex constellation of clinical symptoms still makes the therapeutic management challenging. We evaluated the effects of deep brain stimulation (DBS) on patients affected by HD, providing a critical outlook on the achieved results and the possible developments.

Methods:: Articles describing the effect of DBS in patients affected by HD were selected from Medline and PubMed by the association of text words with MeSH terms as follows: “Deep brain stimulation”, “DBS”, and “HD”, “Huntington’s disease”, “Huntington”. Details on repeat expansion, age at operation, target of operation, duration of follow-up, stimulation parameters, adverse events, and outcome measures were collected.

Results:: Twenty eligible studies, assessing 42 patients with HD, were identified. The effect of GPI-DBS on Unified Huntington's Disease Rating Scale (UHDRS) total score revealed in 10 studies an improvement of total score from 5.4% to 34.5%, and in 4 studies an increase of motor score from 3.8% to 97.8%. Bilateral GPI-DBS was reported to be effective in reduction of Chorea subscore in all studies, with a mean percentage reduction of 21.4% to 73.6%.

Conclusions:: HD patients with predominant choreic symptoms may be the best candidates for surgery, but the role of other clinical features and of disease progression should be elucidated. For this reason, there is a need for more reliable criteria that may guide the selection of HD patients suitable for DBS. Accordingly, further studies which have functional outcomes as primary endpoint are needed.
A BRAINSTEM HYPERMETABOLISM IN A PATIENT WITH ESSENTIAL PALATAL TREMOR: A SIMULTANEOUS 18F-FDG-PET/3T-MRI STUDY

Oreste Marsico¹, Ilaria Sammarra², Pasquale Viola², Davide Pisani², Michele Trimbo³, Giuseppe Chiarella², Giuseppe Lucio Cascini³, Angelo Labate¹, Antonio Gambardella¹
¹Unit of Neurology, University Magna Graecia, Department Of Medical And Surgical Sciences, Catanzaro, Italy, ²Unit of Audiology, Magna Graecia University, Catanzaro, Italy, ³Unit of Nuclear Medicine, Magna Graecia University, Catanzaro, Italy

Background and Aims:: Essential palatal tremor (EPT), previously referred as palatal myoclonus, is a rare movement disorder characterized by rhythmic and continuous jerks of soft palate [1]. While symptomatic palatal tremor (SPT) is typically caused by brainstem or cerebellar lesions [2], pathogenetic mechanism underlying EPT remains debated [1]. Here we reported a simultaneous brain fluorine-18-fluorodeoxyglucose-positron emission tomography (18F-FDG-PET)/3T- magnetic resonance imaging (MRI) study in a woman with EPT.

Methods:: A 54-year-old woman presented to our Neurological Department reporting as isolated manifestation a bilateral ear clicking started at the age of 20 years. She referred the “click” was perceived constantly, except during sleep, and worsened by stressful situations. The neurological examination revealed palatal movements lifting posterior soft palate, including the uvula, synchronous to an audible outside clicking noise, resembling a clockwork mechanism.

Results:: Oropharyngeal evaluation revealed rhythmic and brief contraction of posterior soft palate. Video-laryngoscopy recorded soft palatal lifting movements and myoclonic contractions of tensor veli palatini. EEG, multimodal evoked potentials, blink reflex study and 3T brain MRI were all unremarkable. Lack of inferior olive nuclei change signal or enlargement on MRI ruled out SPT [2]. Therefore, a diagnosis of EPT was made. The simultaneous 18F-FDG-PET/3T-MRI study showed an area of increased glucose uptake in the lower brainstem, nearby the inferior olive nuclei bilaterally, more on the right side.

Conclusions:: This is the first application of simultaneous 18F-FDG-PET/3T-MRI in EPT. Our results illustrate that lower brainstem encompassing the inferior olivary nuclei might be the underlying generator in case of EPT.
UNUSUAL CAUSE OF LATE-ONSET CHOREA: ERDHEIM CHESTER DISEASE

Furqan Khan, Dhaval Dave, Satish Nirhale, Shalesh Rohatgi, Prajwal Rao, Pravin Naphade, V.V. Sravya Kotaru, Sahil Gupta, Advait Gitay, Prashant Dubey
Dr. D. Y. Patil Medical College, Pimpri, Pune., Neurology, Pune, India

Background and Aims: Erdheim-Chester disease (ECD) is a rare non-Langerhans cells histiocytosis. First described in 1930 by Jacob Erdheim and William Chester, till date since 1930 only 650 cases have been reported. Although tissue infiltration can occur in almost every organ, skeleton, retroperitoneum (mainly the kidney and aorta) and orbit involvement is common. Neurological involvement is seen in less than 50 % of patients. When patients have central nervous system involvement, they are often symptomatic, with diabetes insipidus and ataxia syndromes being the most common presentations.

Methods: A 60-year-old male presented with a history of insidious onset gradually progressive generalized choreo-athetoid movements since 6 years, cerebellar ataxia since 4 years. Detailed workup including genetic study was negative for inherited/genetic, structural, paraneoplastic, autoimmune, toxin/drug-induced, & metabolic causes of progressive choreoathetosis with the pan-cerebellar syndrome.

Results: MRI-brain showed pituitary macroadenoma, T2, & Flair hyperintensity in the midbrain, pons, & bilateral dentate nucleus. 18F-FDG-PET Scan showed, increased FDG activity in the midbrain, pons, pituitary fossa, in the superior mediastinum along the origin & proximal portion of left subclavian artery, perinephric soft tissue, bilateral renal sinuses, bilateral adrenal glands, along the wall of the aorta. Histopathology of the biopsy of perinephric soft tissue show CD68 positive aggregates of foamy macrophages, lymphocytes, plasma cells & eosinophils with areas of diffuse & dense fibrosis suggestive of ECD.

Conclusions: ECD is a rare cause of late-onset chorea. Only 3 cases have been reported who presented with chorea as the initial manifestation. A high degree of suspicion is required, PET CT can help in the diagnosis of ECD.
THE VIDEO HEAD IMPULSE TESTS IN THE PARKINSONIAN DISORDERS

Sunghee Kim
Ewha Womans University, Mokdong Hospital, Neurology, Seoul, Korea, Republic of

Background and Aims:: Recent studies have revealed significant abnormalities in the head-impulse test (HIT) in patients with cerebellar ataxia. We anticipated that the quantitative study of the VOR may help to detect cerebellar impairment in multiple systemic atrophy (MSA) and therefore to perform the differential diagnosis between idiopathic Parkinson’s disease (IPD) and other parkinsonian disorders.

Methods:: A retrospective analysis was performed in patients who presented with gait disturbance. The diagnosis of each parkinsonian disorder was based upon the clinical and laboratory data. The secondary parkinsonian disorders including normal pressure hydrocephalus and vascular parkinsonism were excluded. The VOR gain was calculated as the ratio between the integrated velocities of the eye relative to the head divided by the integrated velocities of the head during a time window from 0 to 20 ms after head impulse start.

Results:: A total of 77 patients with the primary parkinsonian disorders were included; IPD, MSA, and progressive supranuclear palsy. There were no statistically significant differences of age, MMSE score, and m-UPDRS motor score between disorders. The Kruskal-Wallis test showed that there was no significant difference of the VOR gain values and the gain asymmetry of each semicircular between the disorders. Pearson’s Chai-Square test showed that there was only a significantly higher occurrence rate of the CUS during vHITs in non-IPD patients than in IPD.

Conclusions:: These results suggest that the vHIT alone cannot discriminate between patients with primary parkinsonian disorders but only provide an ancillary information for distinguishing IPD from non-IPD.
MOTOR AND NON-MOTOR FLUCTUATIONS IN MEN AND WOMEN CITIZEN UZBEKISTAN WITH PARKINSON’S DISEASE

Dilyora Pulatova
Tashkent medical academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: To identify the frequency and characteristics of the motor and non-motor fluctuations in men and women with Parkinson's disease (PD) and to establish their impact on the quality of life of patients.

Methods:: We examined 42 men and 56 women with PD stages 2.5–4.0. The degree of clinical manifestations was determined using the Unified Parkinson's Disease Rating Scale and the Hoehn and Yahr scale. The 9-Symptom Questionnaire (patient self-assessment diary) was used to assess fluctuations. Quality of life was assessed using Parkinson's Disease Quality of Life Questionnaire 39 and the second part of the European Quality of Life Questionnaire.

Results:: Among motor fluctuations, the on-off phenomenon prevailed, which occurred in 69.8% of men and 73.7% of women. Vegetative fluctuations were observed in 86.0% of men and 93.0% of women. Certain autonomic disorders were found statistically significantly more often in women than in men. Mental fluctuations were found in 79.1% of men and 75.4% of women. Apathy was recorded statistically significantly more often in men than in women. Among sensory fluctuations observed in 55.8% of men and 50.9% of women, pain syndrome was statistically significantly more common in women.

Conclusions:: Gender influences the prevalence of certain non-motor fluctuations in PD patients.
THE ASSOCIATION OF COGNITIVE IMPAIRMENT AND OTHER NON-MOTOR SYMPTOMS AMONG THAI PARKINSON’S DISEASE PATIENTS

Chayasak Wantaneeyawong¹, Kittithatch Booncharoen², Kanokwan Wattana¹, Orawan Ronran¹, Siwadhol Chaimano¹, Chutithep Teekapat², Sataporn Bhakeechee², Suchada Sangpetch², Chatchanon Gumtorntip², Angkana Nudsasarn¹, Surat Tanprawate²
¹Chiang Mai University, The Northern Neuroscience Centre, Chiang Mai, Thailand, ²Chiang Mai University, Internal Medicine, Chiang Mai, Thailand

Background and Aims:: Cognitive impairment is a common non-motor symptoms of Parkinson’s disease. This problem frequently impairs patients’ quality of life and cause disability to the patients. Our aims are to investigate the prevalence of cognitive impairment and the association of other non-motor symptoms in Parkinson’s Disease patients.

Methods:: Prospective cross-sectional study was carried in Chiang Mai University Hospital from November 2019 to June 2021. Data collection was done by data extraction checklist, Unified Parkinson’s Disease Rating Scale (UPDRS) examination and related questionnaires. The association between cognitive impairment and other non-motor symptoms was analyzed by multivariable logistic regression.

Results:: A total of 103 eligible Parkinson’s Disease patients were recruited during the study period. 49.5% of participants were male and mean age of all participants was 65.0 ± 9.4 years. Prevalence of cognitive impairment (defined by MoCA score Thai version < 26) and overall non-motor symptoms were 68.9% and 99.0% respectively. Non-motor symptom subtype of urinary symptoms was significantly associated cognitive impairment (aOR 8.42, 95%CI 1.32-53.87). For subitems of non-motor symptoms which significantly increased probability of cognitive impairment after adjustment were nocturia, unexplained weight change, anxiety, hallucination and salivary dribbling.

Conclusions:: This study emphasizes high prevalence of cognitive impairment and non-motor symptoms in Parkinson’s Disease patients. Parkinson’s Disease patient with problems of urinary symptoms especially nocturia, unexplained weight change, anxiety, hallucination or salivary dribbling should be screened for cognitive impairment.
ATYPICAL PARKINSONIAN SYNDROMES: ABOUT A SERIES OF 20 CASES

Hakim Si Ahmed, Smail Daoudi
CHU TIZI-OUZOU, Department Of Neurology, Chu Tizi Ouzou, Tizi-Ouzou, Algeria

Background and Aims:: The aim of this study was to define the clinical and radiological characteristics of patients presenting atypical PS, as well as their evolution under dopa therapy.

Methods:: This is a retrospective and observational study of 20 patients presenting atypical PS who had their follow up within the Neurology department in Tizi-Ouzou University Hospital (Algeria) over a period of 10 years (2009-2019).

The included Patients were diagnosed with MSA, PSP and CBD.

For each patient, we analysed the symptoms and clinical signs at the onset, brain MRI data and evolution under dopa therapy.

Results:: The most frequent occurrence was PSP (60%), followed by MSA (25%), contrary to the data in the literature (ref. 5), the average consultation time was short (one year), which we allowed a good appreciation of the input modes and the data of the initial examination. The mode of entry into MSA does not differ from the data in the literature; postural instability with falls and dysautonomia signs were almost constant (ref.1). The parkinsonian syndrome was variable depending on the pathology. In MSA, it was most often akineto-rigid in the limbs, atypical. In PSP, the axial site was predominant.

For dopa therapy, the beneficial effect was only observed in certain AMS, which is most often described (ref. 2). For suggestive radiological abnormalities; they are inconstant (ref. 5), which is the case in our patients.

Conclusions:: The differential diagnosis of parkinsonian syndromes remains a challenge for neurologists despite the improvement in clinical and pharmacological criteria and the development of visual analysis.
"PSEUDO INO" IN PROGRESSIVE SUPRANUCLEAR PALSY

Vaibhav Mathur, Dinesh Khandelwal
SMS Medical College and Hospital, Dept Of Neurology, Jaipur, India

Background and Aims:: A 65 year old male, with 2 years presented with history of slowness of daily activities, occasional backward falls, apathy & behavioral complaints, and double vision.

Methods:: • Oculomotor findings were slow vertical and horizontal sacchades, supranuclear vertical > horizontal gaze paresis, bilateral lateral > medial gaze restriction with abduction nystagmus (not true INO, but INO-like) in presence of preserved convergence and bilateral VOR. No history of fatiguability, diminution of vision, cerebellar symptoms, autonomic symptoms. • Frontal assessment battery score 10/18 in form of subcortical frontal affection. Speech was hypophonic and slurred. Increased tone with Axial > Limb rigidity observed. Bilateral brisk DTR with mute plantar responses. Sensory examination was normal for all modalities. Cerebellar signs were absent, and patient had a slow, short stepped, extrapyramidal gait.

Results:: In our patient, a diagnosis of PSP was evident given the clinical scenario and MRI findings. • While True INO (caused by a MLF lesion) causes restricted medial gaze in ipsilateral eye, and corrective abduction nystagmus in other eye, our case had an Inter-nuclear ophthalmoparesis caused by unequal supranuclear denervation of lateral > medial recti causing diplopia as well as abduction nystagmus.
Conclusions:: • Previous descriptions of bilateral INO (WEBINO) and horizontal oculomotor findings in PSP have been published, however we present INO-like (Pseudo INO) disparity of intra-ocular horizontal movements (Lateral > Medial restriction) likely due to differential supranuclear denervation causing diplopia, and abduction nystagmus in presence of normal duction, convergence and bilateral VOR.
MANAGEMENT OF CRANIAL MOVEMENT DISORDERS WITH BOTULINUM TOXIN

Massinissa Lounis¹, Smail Daoudi²
¹Nedir Moahammed Teaching Hospital, Neurology, Tizi ouzou, Algeria, ²CHU TIZI-OUZOU, Department Of Neurology, Chu Tizi Ouzou, Tizi Ouzou, Algeria

Background and Aims:: Botulinum toxin (BT) has truly revolutionized the management of movements disorders, although the marketing authorization is limited to cervical dystonia and blepharo-spasm. Its mechanism of action as well as its efficacy and tolerance profile allow recurrent use. Its use has grown considerably in recent years following the demonstration of remarkable efficacy in other indications, that we will discuss in this communication.

Methods:: Movement disorders that affect the neck, face, jaw, tongue or palate are a frequent neurological problem. These disorders can be limited to the cranial muscles or manifest as part of a more generalized movement disorder and Botulinum toxin is an effective symptomatic treatment in most focal cranial movement disorders. We will discuss through video clinical cases the management by Botulinum toxin of involuntary movements that affect the neck, face, jaw and tongue.

Results:: Clinical cases will be approached through videos to highlight clinical expression of cranial movement disorders before and after treatment, such as blepharospasm, eyelid apraxia, hemifacial spasm, face Tics, facial dyskinesia, synkinesis, cervical dystonia, head tremor, oromandibular dystonia, jaw tremor, edentulous dyskinesia, lingual dystonia and palatal tremor.

Conclusions:: Considerable advances have been made in the past two decades, but we still need to improve our knowledge of the diagnosis and treatment of cranial movement disorders. The clinical characteristics seem to be well delineated; however, the differential diagnosis and management of these disorders can be complex owing to the similarities in patterns of muscle involvement and activation profiles in different disorders.
EMG-GUIDED INJECTION OF BOTULINUM TOXIN A IN THE TREATMENT OF PISA SYNDROME: A CASE REPORT OF A TAILORED MULTILEVEL APPROACH

Valentina Rossi, Simone Bolla, Stefania Pistoni, Alessandra Lai, Lorenzo Sampietro
ASL3 Sistema Sanitario Regione Liguria, Dipartimento Cure Primarie, Genova, Italy

Background and Aims:: Pisa syndrome (PS) is a disabling, medication-resistant, postural abnormality that may affect 7-10% of patients with Parkinson's disease (PD). In this case report, we evaluate the efficacy of botulinum toxin Electromyography-guided injections in PD-associated PS using a tailored multilevel approach.

Methods:: We describe the case of a 72-year-old man with diagnosis of PD with a severe axial-lateral flexion of the trunk to the left side. Surface Electromyography (SEMG) bilateral recordings of paraspinal muscles, latissimus dorsi, levator scapulae and obliqui externi were performed in walking and sitting posture. Right paraspinal muscles T7-T8 showed a pattern of continuous muscle activity. We decided to treat with incoBTX-A these hyperactive muscles. After incoBTX-A injections, the patient was involved in a customized rehabilitation program to improve the muscle activity of the left side: exercises were identified using SEMG recordings. After 6 months, SEMG evaluation revealed a pattern of hyperactivity of the T10-T11 paraspinal muscles which were treated with incoBTX-A. The patient was evaluated at baseline, at 6 and 12 months, measuring the angle of trunk inclination in standing position using a goniometer.

Results:: At 6 and 12 months after the beginning of combined treatment, the patient showed an improvement of 10° angle of trunk inclination. The procedure was well tolerated, without side effects or complications.

Conclusions:: These results suggested that a tailored multilevel approach using botulinum toxin injections combined with a rehabilitation program could be a useful therapeutic strategy for PD subjects with PS for improving axial posture and trunk mobility.
MOVEMENT SMOOTHNESS IMPAIRMENT IN IDIOPATHIC CERVICAL DYSTONIA

Anna Castagna1, Pietro Arcuri2, Ilaria Carpinella3, Alberto Marzegan4, Tiziana Lencioni5, Marina Ramella6, Alessandro Crippa7, Denise Anastasi2, Marco Rabuffetti5, Maurizio Ferrarin5, Antonio Caronni8

4IRCCS Fondazione Don Gnocchi, Polo Tecnologico/safl, Milano, Italy.
5IRCCS Fondazione Don Gnocchi, Polo Tecnologico, Milano, Italy.
6IRCCS Fondazione Don Gnocchi, Dat, Milano, Italy.
7IRCCS Fondazione Don Gnocchi, Larice/safl, Milano, Italy.
8IRCCS Fondazione Don Gnocchi, Neuro-rehabilitation, Milano, Italy.

Background and Aims:: Voluntary movement is characterized by accuracy, speed and smoothness. Although phenomenology of idiopathic cervical dystonia (ICD) is typically defined by abnormal postures (with head deviation at rest) plus dystonic twisting or tremulous movements, also head voluntary movements and motor control can be impaired. This complex impairment leads to disability in peripersonal space exploration in daily life activities. The current work is aimed at evaluating if smoothness of voluntary head rotations is reduced in ICD.

Methods:: Participants (18 ICD patients with torticollis and 18 controls) completed discrete rightward and leftward head rotations in an optoelectronic movement analysis laboratory (Smart D, BTS, Italy). Patients head movements were analyzed in the case of the rotation in the opposite direction to the torticollis (AwayDys). Amplitude and angular velocity were measured and indices from angular jerk and the arc length of the spectrum of the angular speed (i.e. SPARC, arbitrary units) were chosen as smoothness measures (the higher, the smoother). Generalised linear mixed effects models were used for statistics.

Results:: Controls’ movements (49.2 °/s, 41.9-56.9 °/s) were faster than AwayDys (28.9 °/s, 22.9-35.5 °/s). Net of any difference in amplitude and speed, SPARC (but not jerk) showed reduced smoothness in patients’ AwayDys (1.46, 1.35-1.61) compared to controls (1.86, 1.72-2.03).

Conclusions:: Poor smoothness is an independent and clinically relevant motor disturbance in ICD. SPARC is a valid measure of movement smoothness to differentiate HC and ICD patients and possibly a synthetic index in monitoring treatments like botulinum neurotoxin injections and adjunct motor learning programs.
CREUTZEL-JAKOB DISEASE MIMICS A RICHARDSON SYNDROME, SPECTRUM OF SUPRANUCLEAR PROGRESSIVE PALSY

Background and Aims:: The clinical spectrum of Creutzfeld-Jakob disease (CJD) is extensive. CJD in the sporadic variant could be debut as prominent ataxic (10%) or thalamic (2%) of cases) symptoms. In a patient with rapidly cognitive impairment in less than six months, the probability of diagnosis is high. We presented a man with six months of evolution con cerebellar syndrome, ocular supraversion limited and symmetrical parkinsonism with multiple cognitive impairments that simulated a Richardson spectrum of Supranuclear progressive Palsy.

Methods:: March 2020
The patient initially presented extreme behavioural changes, obsessive-compulsive, alterations in the sleep pattern (parasomnias), in addition to only sleeping five hours a day, irritability, frequent mood changes, feelings of hopelessness and anxiety were observed. October 2020
Weight loss of 13 kg in four months. January 2021, he starts impairment in episodic, working and semantic memory. Errors in the execution, planning, and sequence of previously learned actions were typical. February 2021
He presented insidiously with gait disturbance consisting of indistinct lateropulsion and a broad base of support. Alterations in eye movements due to patient's inability to fix the gaze in the horizontal and vertical plane), intention tremor, changes in the voice (fluency has become slow, he drags the words and tends to separate in syllables).

Results::
Ocular movements
Gait
### Conclusions:: Table 1.

MESENCHYMAL STEM CELL THERAPY FOR PARKINSON'S DISEASE: SYMPTOMS DURING THE SIX MONTHS POST-TRANSPLANT PERIOD COMPARED WITH PLACEBO

Veranika Chyzhyk, Vladimir Ponomarev, Aliaksandr Boika, Natallia Aleinikava
State Educational Establishment «Belarusian Medical Academy of Postgraduate Education», Department Of Neurology And Neurosurgery, Minsk, Belarus

Background and Aims:: Treatment of patients with Parkinson disease (PD) using autologous mesenchymal stem cells (MSCs) is a promising method to influence the pathogenesis of the disease. However, this method of PD treatment isn't a fully understood process and requires a long follow-up in the post-transplant period and assessment of the possible placebo effect on the recovery process. Our study has started in January 2019 and now included 22 PD patients in the post-transplant period and 13 PD patients that received placebo. The aim was to assess the results of the introduction of MSCs and placebo on the dynamics of motor and non-motor symptoms during the six months post-transplant period.

Methods:: MSCs were transplanted to 22 patients with PD intravenous and tandem (intranasal + intravenous) injections. Placebo therapy (isotonic saline) was performed to 13 patients with PD via tandem injection. Effectiveness of the therapy was evaluated 7 days, one, three and six months post-transplantation according to the dynamics of non-motor symptoms by scoring the following scales: Hamilton Depression Rating Scale, The Pittsburgh Sleep Quality Index, Non-Motor Symptoms Scale, The 39-item Parkinson's Disease Questionnaire. The severity of motor symptoms was evaluated on the basis of Section III of the Unified Parkinson's Disease Rating Scale.

Results:: The severity of motor and non-motor symptoms in the post-transplant period decreased in contrast to the control group.

Conclusions:: Our results of the introduction of MSCs on the intensiveness of the motor and non-motor symptoms exceed the placebo effect and allow us to consider MSCs transplantation as a disease-modifying therapeutic strategy in PD.
TWO DISTINCT AND CONSECUTIVE BRAINSTEM DEMYELINATING LESIONS POST-IRRADIATION OF CRANIAL NERVE SCHWANNOMA: WHICH DIAGNOSIS?

Valentina Tontini¹, Francesca Brazzale¹, Lucia Zinno², Irene Florindo²
¹Neurosciences Unit, Department Of Medicine And Surgery, University Of Parma, Parma, Italy, ²Neurosciences Unit, Department Of Medicine And Surgery, University Of Parma, Parma, Italy

Background and Aims:: Demyelination is a known neurological side effect of radiation therapy (RT). Moreover, radiation has been discussed as a potential causative factor for Multiple Sclerosis (MS). We report the case of a 38-year-old female radio-treated for right jugular foramen schwannoma, after which she developed two consecutive symptomatic brainstem demyelinating lesions.

Methods:: MRI were recorded at the admission and during hospitalization. CSF analysis was performed.

Results:: 5 months after RT, the patient developed a right medulla T2-Flair hyperintense lesion, with moderate contrast-enhancing, symptomatic for controlateral brachio-crural sensitive-motor syndrome, ipsilateral deviation of the tongue and dysphagia. Supposing a post-irradiation neurotoxicity, she was treated with oral corticosteroids for 3 months; complete remission followed. Seven months later, she developed diplopia and headache, with appearance of a similar lesion in right pons-peduncular cerebellum on MRI. Medullary MRI was negative, CSF analysis showed mononuclear pleocytosis and presence of liquoral oligoclonal bands, differential diagnostics tests for other demielinating syndromes including anti-MOG and AQP-4 Ab were negative. She was treated with high-dose steroids i.v. with initial clinical and radiological improvement. Follow-up is ongoing.
Conclusions: It has been suggested that RT could alter the nervous tissue in radiation clinical target volume, making it vulnerable to a pre-existing autoimmune attack predisposition. Even if only few cases of MS following RT have been reported so far, this case underlies that caution should be used in patients with demyelinating lesions post-RT, especially young women with relapsing course, keeping in mind the differential diagnoses in order to avoid mistakes or treatment delays.
LONG-TERM EFFICACY AND SAFETY OF ECULIZUMAB IN AQUAPORIN-4 IMMUNOGLOBULIN G-POSITIVE NEUROMYELITIS OPTICA SPECTRUM DISORDER

Dean Wingerchuk¹, Achim Berthele², Kazuo Fujihara³⁴⁵, Celia Oreja-Guevara⁶, Ho Jin Kim⁷, Michael Levy⁸⁹, Ichiro Nakashima³¹⁰, Jacqueline Palace¹¹, Shulian Shang¹², Marcus Yountz¹³, Larissa Miller¹⁴, Sean Pittock¹⁵

Background and Aims:: In PREVENT, eculizumab reduced relapse risk in patients with aquaporin-4 immunoglobulin G-positive (AQP4+) NMOSD by 94.2% vs placebo. We present the long-term efficacy and safety data from PREVENT (NCT01892345) and its open-label extension (OLE; NCT02003144). Eculizumab is not reimbursed for neurology indications in Italy as of April 2021.

Methods:: During PREVENT, adults with AQP4+ NMOSD received eculizumab or placebo with/without immunosuppressive therapy (IST), after which, patients could receive eculizumab in the OLE. Eculizumab data from PREVENT and its OLE were combined for this analysis.

Results:: Overall, 137 patients received eculizumab for a total of 362.3 patient-years. At 192 weeks, 94.4% (95% CI: 88.6–97.3%) of patients were relapse free. The adjudicated annualised relapse rate was 0.025 (95% CI: 0.013–0.048); the annualised relapse-related hospitalisation rate (ARRHR) was 0.03/patient-year (95% CI: 0.017–0.055). Rates of AEs and serious AEs (SAEs)/100 patient-years were 732.5 and 33.7, respectively. Common SAEs, excluding NMOSD relapses, were pneumonia (3.6%), urinary tract infection (2.9%) and acute cholecystitis (2.9%). One patient died (pulmonary empyema) and one developed disseminated Neisseria gonorrhoeae infection. Overall, 25/137 patients (18.2%) developed a serious infection vs 6/47 (12.8%) receiving placebo (none meningococcal). During the OLE 42% of patients changed IST; most (88%) stopped or decreased IST use.

Conclusions:: The proportion of relapse-free patients remained high (94%) through 192 weeks. Eculizumab was well tolerated and AEs were consistent with the established safety profile. ARRHR was low and most patients reduced or stopped concomitant IST. This study was funded by Alexion Pharmaceuticals, Inc.
CONSTRUCTION OF A RESOURCE FOR ADVANCE CARE PLANNING IN MULTIPLE SCLEROSIS (CONCURE-SM): RESULTS OF COGNITIVE DEBRIEFING WITH USERS

Ludovica De Panfilis, Simone Veronese, Luca Ghirotto, Michela Bruzzone, Marta Cascioli, Andrea Giordano, Maria Grazia Grasso, Paola Kruger, Leigh Manson, Alessandra Lugaresi, Eugenio Pucci, Alessandra Solari

Lucia Foundation, Multiple Sclerosis Unit., Rome, Italy, 8The European Patients’ Academy (EUPATI), The European Patients’ Academy (eupati), Roma, Italy, 9Health Quality & Safety Commission New Zealand, Health Quality & Safety Commission New Zealand, Nelson, New Zealand, 10IRCCS Istituto delle Scienze Neurologiche di Bologna, Uosi Riabilitazione Sclerosi Multipla, Bologna, Italy, 11Università di Bologna, Dipartimento Di Scienze Biomediche E Neuromotorie, Bologna, Italy, 12ASUR Marche, Uoc Neurologia, Fermo, Italy

Background and Aims:: ConCure-SM is a mixed-methods research project for developing and testing an advance care planning (ACP) intervention for people with progressive multiple sclerosis (pwPMS) in Italy. It consists of a booklet to be used during the ACP conversation (the focus of this presentation) and a training program for MS healthcare professionals (HPs). Aims: To assess the acceptability and comprehensibility of the ConCure-SM booklet.

Methods:: An interdisciplinary panel translated and adapted to the Italian legislation and to the MS context a booklet developed by the National ACP programme for New Zealand. The booklet was then probed via individual cognitive interviews with pwPMS and caregivers, and a focus group meeting (FGM) with MS HPs.

Results:: We conducted 13 interviews (September-January 2021) which lasted between 36 and 80 minutes. Participants were 10 pwPMS and 3 caregivers; 8 were men, median age was 54 years. Twelve HPs participated in the FGM (7 neurologists, 3 psychologists, one nurse and one physiotherapist), which lasted 105 min. Thematic analysis identified 4 overarching themes: comprehensibility and clarity; content acceptability and emotional impact; images and layout; suggestions for improvement. Interviews revealed that the booklet was useful and informative, though pwPMS found it emotionally taxing. The FGM was well participated; few experiential data on ACP emerged, lack of training and time constraint emerging as major reasons.

Conclusions:: Cognitive debriefing was key to refine the ConCure-SM booklet. Interview and FGM results corroborated use of the booklet within the ACP conversation, and the challenge of appraisal as a stand-alone tool.
CLINICAL RELEVANCE OF MULTIPARAMETRIC MRI ASSESSMENT OF CEREBELLAR DAMAGE IN MULTIPLE SCLEROSIS

Raffaello Bonacchi\textsuperscript{1,2}, Alessandro Meani\textsuperscript{3}, Elisabetta Pagani\textsuperscript{3}, Olga Marchesi\textsuperscript{2}, Massimo Filippi\textsuperscript{2,4,5}, Maria Rocca\textsuperscript{1,2,4}
\textsuperscript{1}IRCCS San Raffaele Scientific Institute, Neurology Unit, Milano, Italy, \textsuperscript{2}IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Division Of Neuroscience, Milan, Italy, \textsuperscript{3}IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Milano, Italy, \textsuperscript{4}Vita-Salute San Raffaele University, Na, Milan, Italy, \textsuperscript{5}IRCCS San Raffaele Scientific Institute, Neurology Unit, Neurorehabilitation Unit And Neurophysiology Service, Milan, Italy

\textbf{Background and Aims::} To quantify in-vivo cerebellar damage and identify MRI predictors of physical disability and cognitive dysfunction in multiple sclerosis (MS) patients, and to characterize patients with cerebellar disability in terms of MRI findings.

\textbf{Methods::} One-hundred and sixty-four (89 relapsing-remitting and 75 progressive) MS patients and 53 healthy controls underwent brain and cervical cord 3Tesla MRI with sequences for assessing lesions and atrophy in brain and cervical cord, and diffusion-tensor metrics of cerebellar peduncles. Subjects underwent neurological examination and neuropsychological assessment. MRI predictors of clinical variables were identified with random forest models. Hierarchical clustering was applied on MRI metrics in patients with cerebellar disability.

\textbf{Results::} In MS patients, informative predictors were lower cord grey matter (GM) area, higher cord GM lesion volume (LV), lower brain volume, lower brain GM volume (GMV), higher brainstem LV, lower cord global area, lower brain cortical GMV, lower cerebellum lobules I-IV and vermis GMV for higher Expanded Disability Status Scale score (out-of-bag-R\textsuperscript{2}=0.83); higher supratentorial and superior cerebellar peduncle LV, lower brain volume, lower thalamus volume, lower cerebellum lobule VIIIb GMV, lower basal ganglia volume, lower brain GMV and lower cerebellum Crus II GMV for lower cognition z-score (out-of-bag-R\textsuperscript{2}=0.25). In patients with cerebellar disability, we found three MRI-clusters: high brain LV (including cerebellar peduncles), marked cerebellum GM atrophy, and severe cord damage.

\textbf{Conclusions::} Damage to cerebellum GM and connecting structures has a relevant role in explaining cognitive dysfunction and physical disability in MS. The identification of three MRI-subtypes of patients with cerebellar disability is a step forward in MRI-clinical correlations.
REVEALING STRUCTURAL AND CLINICAL HETEROGENEITY IN THE SPECTRUM OF NEUROMYELITIS OPTICA WITH UNSUPERVISED MACHINE LEARNING

Laura Cacciaguerra¹,², Maria Rocca¹,²,³, Elisabetta Pagani², Marta Radaelli³, Sarlota Mesanos⁴, Vittorio Martinelli², Andrea Falini¹,⁵, Jovana Ivanovic⁴, Massimo Filippi¹,⁶,⁷
¹Vita-Salute San Raffaele University, Na, Milan, Italy, ²IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Division Of Neuroscience, Milano, Italy, ³IRCCS San Raffaele Scientific Institute, Neurology Unit, Milano, Italy, ⁴University of Belgrade, Clinic Of Neurology, Faculty Of Medicine, Belgrade, Italy, ⁵IRCCS San Raffaele Scientific Institute, Neuroradiology Unit, Milan, Italy, ⁶IRCCS San Raffaele Scientific Institute, Neurology Unit, Neurorehabilitation Unit And Neurophysiology Service, Milan, Italy, ⁷IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Divisione Of Neuroscience, Milano, Italy

Background and Aims:: The spectrum of neuromyelitis optica (NMOSD) includes different phenotypes and serotypes. Understanding disease heterogeneity is fundamental for targeted treatment. We aimed to unravel differences among NMOSD patients using unsupervised machine learning.

Methods:: We obtained MR images and clinical data from 140 patients with NMOSD (n=105, 88 aquaporin-4-IgG [AQP4]-positive, 17 AQP4-negative) or AQP4-negative NMOSD-like manifestations (n=35, 17 recurrent myelitis [RM] and 18 recurrent optic neuritis [RON]) and 151 healthy controls. CNS damage (brain, optic nerve [ON] and cervical cord) was assessed in terms of lesions, normalized volumes, and cortical thickness. We computed between-group differences with age-, sex- and site-adjusted linear models. Based on structural measures, we ran unsupervised clustering analysis among NMOSD/NMOSD-like patients.

Results:: Except for RM, NMOSD and NMOSD-like patients had diffused cortical atrophy (p<0.008), which was worse in the cingulate (AQP4-positive NMOSD, p=0.001), parietal (AQP4-negative NMOSD, p=0.008) and occipital lobes (RON, p=0.022). AQP4-positive NMOSD had reduced normalized brain volume (p<0.006) and cervical cross-sectional area (p=0.02). AQP4-negative NMOSD and RON had ON atrophy (p<0.03), the latter with additional optic chiasm atrophy (p<0.001). Clustering analysis identified three groups of NMOSD/NMOSD-like patients, with similar ON and cord lesion volume/length, number of optic neuritis/myelitis and phenotypes. Cluster-1 included patients with higher brain lesion volume (p<0.048), cluster-2 included patients with worse ON and cord atrophy (p<0.048) and cluster-3 included patients with greater cortical atrophy, milder disability, and higher rate of oligoclonal bands (p<0.037).

Conclusions:: The heterogeneity of NMOSD spectrum goes beyond clinical manifestations and serostatus, possibly mirroring different pathophysiological substrates.
DYNAMIC FUNCTIONAL CONNECTIVITY ANALYSIS IN THALAMIC SUB-REGIONS SHOWS DIVERGENT PATTERNS IN MULTIPLE SCLEROSIS PHENOTYPES

Antonio Carotenuto¹, Paola Valsasina¹, Milagros Hidalgo De La Cruz², Laura Cacciaguerra¹,³,⁴, Paolo Preziosa¹,⁴, Olga Marchesi⁵, Massimo Filippi¹,³,⁶, Maria Rocca¹,³,⁷

¹IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Division Of Neuroscience, Milan, Italy, ²IRCSS Ospedale San Raffaele, Neuroimaging Research Unit, Division Of Neuroscience, Milan, Italy, ³Vita-Salute San Raffaele University, Na, Milan, Italy, ⁴IRCCS San Raffaele Scientific Institute, Neurology Unit, Milan, Italy, ⁵IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Division Of Neuroscience, Milan, Italy, ⁶IRCCS San Raffaele Scientific Institute, Neurology Unit, Neurorehabilitation Unit And Neuropsychology Service, Milan, Italy, ⁷IRCCS San Raffaele Scientific Institute, Neurology Unit, Milano, Italy

Background and Aims:: In multiple sclerosis (MS), thalamic sub-regions (frontal, motor, occipital, post-central and temporal) show distinct resting state (RS) functional connectivity (FC) abnormalities. Besides RS FC, thalamus also showed dynamic FC (dFC) abnormalities in MS. Here, we explored sub-regional thalamic dFC in MS.

Methods:: Eighty-nine MS patients (49 relapsing-remitting [RR]; 40 progressive [P]MS) and 53 healthy controls (HCs) performed RS fMRI, clinical and neuropsychological assessment. Thalamic sub-regional dFC was calculated as the standard deviation of FC assessed through sliding-window seed-voxel analysis. Between-group comparisons and correlations were assessed with voxel-wise ANOVA, t-Tests and linear regressions.

Results:: MS patients, especially RRMS, showed a lower dFC between most of thalamic sub-regions and fronto-temporo-occipital areas vs HCs. In addition, PMS also displayed higher dFC vs HCs and RRMS between posterior thalamic sub-regions and occipito-parietal cortices and basal ganglia. Cognitive impairment was associated with higher dFC between motor, temporal and occipital thalamic sub-regions and cortical areas belonging to the sensorimotor and default-mode networks. Higher clinical disability was associated with lower dFC between post-central thalamic sub-regions and frontal cortex in RRMS and with higher dFC between post-central and left frontal thalamic sub-region and left occipital/right insular cortices in PMS.

Conclusions:: RRMS patients experienced reduced dFC vs HCs. On the other hand, PMS patients and patients with more severe clinical and cognitive disability also displayed higher thalamo-cortical dFC. Higher dFC may reflect adaptive mechanism at early stages and maladaptive mechanisms at later stages of the disease. Funding: Antonio Carotenuto is supported by a MAGNIMS/ECTRIMS research fellowship.
MICROCHIMERISM IN MULTIPLE SCLEROSIS: THE IMPACT OF SEX-RELATED DIFFERENCES IN FETAL-MATERNAL CROSS-TALK ON THE CLINICAL AND RADIOLOGICAL PHENOTYPE IN WOMEN WITH MULTIPLE SCLEROSIS

Giglio", U.o.c Neurologia E Centro Regionale Hub Sclerosi Multipla, Cefalù (PA), Italy

Background and Aims:: Multiple Sclerosis (MS) is a chronic autoimmune disorder characterised by inflammation and neurodegeneration. Persisting fetal microchimeric cells seem to contribute to autoimmune diseases pathogenesis. The aim of the study is to investigate the impact of microchimerism on the clinical, radiological, and laboratory features of MS.

Methods:: We recruited 101 consecutive MS patients: 43 nulliparous subjects (age: 36.1 ± 9.5, disease duration: 10.4 ± 8.7, median EDSS: 2.5), 40 patients with at least one male son (age: 42.3 ± 10.0, disease duration: 11.4 ± 8.5, median EDSS: 2.5), and 18 patients with only daughters (age: 47.2 ± 10.5, disease duration: 17.6 ± 12.6, median EDSS: 3.75). Demographic, clinical, radiological, and paraclinical data at baseline and follow-up were collected. MRI protocol included 3D-T2w FLAIR FatSat and 3D-T1w FSPGR.

Results:: Patients with at least a male son had a significantly higher age at onset (p<0.001) and a highest frequency of pyramidal onset (p<0.001). The same group had a shorter time-gap from onset to EDSS 4 and to EDSS 6 when compared with the group with only female daughters (respectively, 113.4 ± 17.5 vs 201.7 ± 44.3, p=0.039; 98.8 ± 25.2 vs 203.2 ± 49.4, p=0.058). Finally, patients with at least a male son had a lower chiasm volume when compared with the nulliparous patients (p=0.023) and with the only-daughter group (p=0.019).

Conclusions:: In a multifactorial background, the microchimeric XY fetal cells could modulate the inflammatory and neurodegenerative mechanisms underlying the MS, influencing the disease features.
DEVELOPMENT OF AN APP (ABOUTCOME) FOR EVALUATION IN MULTIPLE SCLEROSIS

Rachele Di Giovanni¹, Erica Grange¹, Andrea Tacchino², Marcella Spirito², Claudio Solaro³
¹“Mons. Luigi Novarese” Hospital, Moncrivello, Dept. Of Rehabilitation, Moncrivello, Italy, ²Italian Multiple Sclerosis Foundation (FISM), Scientific Research Area, Genova, Italy, ³“Mons. Luigi Novarese” Hospital, Moncrivello, Department Of Rehabilitation, Moncrivello, Italy

Background and Aims:: Data collection represents fundamental component of clinical research and practice, allowing analysis of collected data. The aim of the study is to implement data collection through creation and validation of the app ABOUTCOME, to allow data storage and facilitate patients to fulfil questionnaires.

Methods:: ABOUTCOME has been developed for people with Multiple Sclerosis (PwMS). It consists of standardized tests and self-administered measures. Measures included: Disability of the Arm Shoulder and Hand (DASH), Abilhand, Manual Ability Measure-36 (MAM-36), Fatigue Severity Scale (FSS), Modified Fatigue Impact Scale (MFIS), Modified Ashworth Scale (MAS), 9-Hole Peg Test (9-HPT), Hand Grip Strength (HGS), Expanded Disability Status Scale (EDSS), Brief International Cognitive Assessment Multiple Sclerosis (BICAMS). ABOUTCOME is multilanguage (Italian and English), with available users’ manual.

Results:: 16 PwMS [10 female, mean age 58.2 years (DS=7.71), mean EDSS 6.5 (DS=0.98), 3 relapsing remitting MS, 13 progressive MS] completed 5 self-administrated scales (DASH, Abilhand, MAM-36, FSS, MFIS) on paper and tablet version. An ad hoc questionnaire has been created to evaluate necessary commitment to complete questionnaires, mental fatigue and frustration level due to paper and tablet implementation.

Conclusions:: 14 MS subjects preferred and considered less challenging tablet compilation. The possibility to use a simple finger tap rather than pencil pinch has proved to be good alternative, reducing subjects effort and time employed. Data export and database creation directly from ABOUTCOME resulted easier and more immediate, removing paper transcription errors. ABOUTCOME is available on Android systems and can be implemented including other evaluation measures.
VITAMIN D LEVELS INFLUENCE RADIOLOGICAL AND LABORATORY OUTCOMES OF MULTIPLE SCLEROSIS PATIENTS TREATED WITH OCRELIZUMAB

Giuseppina Miele¹, Gianmarco Abbadessa¹, Antonio De Martino², Paola Valentino², Girolama Marfia³, Simona Bonavita¹
¹University of Campania "Luigi Vanvitelli", Department Of Advanced Medical And Surgical Sciences, Napoli, Italy, ²Institute of Neurology, University "Magna Graecia", Catanzaro, Italy, Department Of Medical And Surgical Sciences, Catanzaro, Italy, ³Multiple sclerosis center, Tor Vergata Hospital, Rome, Neurology, ROme, Italy

Background and Aims:: Several observational studies showed an association between low circulating levels of 25-hydroxy-vitamin D (25-OH-VitD) and an increase of inflammatory activity in Multiple Sclerosis (MS). The aim of our study is to evaluate disease activity and CD19 kinetic in Ocrelizumab-treated MS patients, and their associations with 25-OH-VitD levels.

Methods:: Retrospectively collected data on new T2 or Gd+ lesions at magnetic resonance imaging (MRI), and laboratory measures including 25-hydroxy-vitamin D levels. According to CD 19 B lymphocytes count after 6 months of treatment (cut-off: <0,1%), patients were divided into two groups: with fast (FR) and slow (SR) repopulation rate. The independent samples t-test and Spearman correlation coefficient were used to test differences between means and association between 25-OH-VitD levels, radiological outcomes, and laboratory measures.

Results:: 94 MS patients with a mean follow-up of 14 months were enrolled. On MRI, new T2 and/or Gd+ lesions were seen in 11,8 % (12 out of 101 scans). Seasonally adjusted 25-OH-VitD levels in samples drawn close to all magnetic resonance images with new T2 and/or Gd+ lesions were lower compared to the remainder (18,72 vs. 31,71 ng/ml; p = 0.0367). Moreover, the FR rate group showed lower levels of 25-hydroxy-vitamin D compared to LR group (19,74 ng/ml vs. 29,42 ng/ml p = 0,0142). Levels of 25-hydroxy-vitamin D were associated with CD19 cells number at 6 months(r² = -0.5449; p = 0.0013).

Conclusions:: Higher 25-OH-VitD levels were associated with LR rate and better radiological outcomes.
NODDI MICROSTRUCTURAL ABNORMALITIES IN NORMAL-APPEARING GRAY MATTER AND WHITE MATTER CONTRIBUTE TO COGNITIVE IMPAIRMENT IN MULTIPLE SCLEROSIS

Paolo Preziosa1,2, Lorenzo Conti1, Elisabetta Pagani1, Olga Marchesi1, Maria Rocca1,2,3, Massimo Filippi1,3,4
1IRCSS Ospedale San Raffaele, Neuroimaging Research Unit, Division Of Neuroscience, Milano, Italy, 2IRCCS San Raffaele Scientific Institute, Neurology Unit, Milano, Italy, 3Vita-Salute San Raffaele University, Na, Milan, Italy, 4IRCCS San Raffaele Scientific Institute, Neurology Unit, Neurorehabilitation Unit And Neurophysiology Service, Milan, Italy

Background and Aims:: Heterogeneous processes contribute to multiple sclerosis (MS)-related cognitive impairment. Using neurite orientation dispersion and density imaging (NODDI), we explored the associations between microarchitecture abnormalities of focal lesions and normal-appearing (NA) tissues and cognitive impairment in patients with MS (PwMS).

Methods:: One hundred and fifty-two PwMS and 48 healthy controls (HC) underwent a brain 3T acquisition. PwMS with ≥1 abnormal test in ≥2 domains of Rao’s battery were defined as cognitively impaired (CI). A cognitive impairment index (CII) was also derived. NODDI-derived intracellular (ICV_f) and extracellular volume fractions (ECV_f) and orientation dispersion index (ODI) were assessed in cortical and white matter (WM) lesions, thalamus, NA-cortex and NAWM.

Results:: Fifty-two (34.2%) PwMS were CI. CI and cognitively preserved (CP) PwMS vs HC showed significantly decreased NA-cortex, thalamic and NAWM-ICV_f (p<0.001) and NA-cortex-ODI, and increased NAWM-ECV_f (p<0.003). CI PwMS showed also a significantly decreased thalamic-ODI and increased NAWM-ODI (p<0.018). CI vs CP PwMS had significantly decreased NA-cortex-, thalamic- and NAWM-ICV_f and thalamic-ECV_f, and increased NAWM-ECV_f and ODI (p<0.016). No lesional microstructural differences were found in CI vs CP PwMS. NA-cortex-ICV_f and NAWM-ICV_f and ODI were significantly correlated with CII (r from -0.24 to 0.30 p from 0.006 to 0.047).

Conclusions:: NA-cortex, thalamic and NAWM neuro-axonal loss, together with NAWM inflammation, gliosis and loss of tissue coherence, are associated with cognitive impairment in MS. NODDI could disentangle in vivo the complex processes determining cognitive dysfunctions. Funding: This study was partially supported by Fondazione Italiana Sclerosi Multipla (fellowship: FISM2019/BS/009 and grant: FISM2018/R/16).
PREDICTORS OF OCRELIZUMAB EFFECTIVENESS IN PATIENTS WITH MULTIPLE SCLEROSIS

Maria Cellerino¹, Giacomo Boffa¹, Caterina Lapucci², Francesco Tazza¹, Elvira Sbragia¹, Elisabetta Mancuso⁷, Nicolo Bruschi⁷, Simona Minguzzi², Federico Ivaldi³, Ilaria Poire³, Alice Laroni¹, Gian Luigi Mancardi¹, Elisabetta Capello², Giovanni Novi³, Matilde Inglese¹
¹University of Genoa, Dinogmi, Genova, Italy, ²IRCCS Ospedale Policlinico San Martino, Genoa, Italy, ³Laboratory Of Experimental Neurosciences, Genova, Italy, ⁴Ospedale Policlinico San Martino-IRCCS, Genoa, Italy, Department Of Neurology, Genova, Italy

Background and Aims:: We aim to provide effectiveness and safety data of ocrelizumab in patients with relapsing-remitting (RR-) and progressive multiple sclerosis (P-MS) and to evaluate clinical and immunological predictors of early treatment response.

Methods:: Demographic characteristics, effectiveness outcomes (time-to-confirmed disability worsening, time-to-first relapse, time-to-first evidence of MRI activity and time-to-first evidence of disease activity), clinical and immunological predictors of early treatment response and incidence of adverse events (AEs) were recorded at baseline and throughout follow-up (FU).

Results:: 153 subjects were included [93 RR-MS, 43 primary-P-MS (PP-MS), 17 secondary-P-MS (SP-MS); 60% females; baseline mean(SD) age 41.9(11.4) years; mean(SD) disease duration 10.3(9.9) years; mean(SD) annualized relapse rate 0.5(0.7); median(IQR) EDSS 3.5(2-5.5)]. At 2 years, disability worsening-free survival was 90.5%, 64.7% and 68.8% for RR-MS, PP-MS and SP-MS patients, respectively. At 2 years, 67.1%, 72.7% and 81.3% of patients with RR-MS, PP-MS and SP-MS were free of MRI activity, with NEDA-3 percentages of 62.1%, 54.6% and 55.1%, respectively. A lower baseline EDSS was independently associated with reduced risk of disability worsening HR(95%CI)=1.45(1.05-2.00), p=0.024, while previous treatment exposure with increased probabilities of radiological activity [HR=2.53(1.05-6.10), p=0.039]. At 6 months, CD8+ cell decrease was less pronounced in patients with inflammatory activity (p=0.022). Upper respiratory tract infections were the most frequently AEs.

Conclusions:: Ocrelizumab is a good treatment option in RR-MS and P-MS patients, with a manageable safety profile. Better outcomes were observed in treatment-naive patients and in patients with a low baseline disability. Depletion of CD8+ cells could underlie early therapeutic effects of ocrelizumab.
**FIRST-LINE THERAPIES IN LATE ONSET MULTIPLE SCLEROSIS: AN ITALIAN REGISTRY STUDY**

Emanuele D'Amico¹, Aurora Zanghì¹, Carlo Avolio², Maria Pia Amato³, Massimo Filippi⁴, Maria Trojano⁵, Francesco Patti¹

¹University of Catania, Italy, G.f. Ingrassia, Catania, Italy, ²University of Foggia, Neurology, Foggia, Italy, ³University of Florence, Neurology, Italy, ⁴IRCCS San Raffaele Scientific Institute, Neurology, Milan, Italy, ⁵University “Aldo Moro” of Bari, Italy, Department Of Basic Medical Sciences, Neurosciences And Sense Organs, Bari, Italy

**Background and Aims:** Late-onset (≥50 years) relapsing remitting Multiple Sclerosis (LORRMS) is associated with adverse prognosis but established marker(s) of such poor prognosis are still lacking in the clinical practice. The aim of the study is to compare effectiveness of injectable and oral first line disease modifying therapies (DMTs) in a cohort of patients with LORRMS for time to first relapse, time to confirmed disability progression (CDP), and, additionally, for time to discontinuation.

**Methods:** This is a multicenter, observational, retrospectively acquired cohort study on LORRMS-naïve patients from the Italian MS Register who started either injectable or oral first line DMTs between January 1, 2013 and December 31, 2017. LORRMS were divided into two groups, namely the injectable group (IG) and oral group (OG). Cox models adjusted with inverse probability weighted propensity score were built for the investigated outcomes.

**Results:** Of a cohort of 3,989 patients, 302 were enrolled (203 in the IG and 99 in the OG). The two cohort did not differ for baseline characteristics. Time to first relapse did not show any difference between the two groups (HR = 1.10; CI 95% 0.50-2.46, p=.797). Furthermore, no differences were found between the two groups with respect to the risk of CDP (HR = 1.04; CI 95% 0.35-3.06, p = .939), nor for the risk of DMT discontinuation (HR = 0.90; CI 95% 0.17-2.08, p = .425).

**Conclusions:** Real-world data from the Italian MS Register suggested that both injectables and oral first line DMTs controlled similarly the investigated outcomes in LORRMS.
EMOTION AND MULTIPLE SCLEROSIS: A FUNCTIONAL TRANSCRANIAL DOPPLER STUDY

Elio Troisi, Caterina Albensi, Sheila Catani, Luca Pace, Giorgia Presicce, Francesco Rizzi, Carlo Caltagirone, Maria Grazia Grasso

1 S. Lucia Foundation IRCCS Rome, Neurorehabilitation, Rome, Italy, 2 IRCCS S. Lucia Foundation, Multiple Sclerosis Unit, Rome, Italy

Background and Aims:: Multiple sclerosis (MS) manifests itself mostly as white matter demyelination and associated axonal damage. Emotional and mood changes are very frequent in MS patients. However, recent studies indicate that the MS patients show signs of impaired emotional reactivity. The aim of the study was to investigate the neuropsychology of emotions in MS patients by transcranial Doppler ultrasonography.

Methods:: For this reason, blood flow velocity changes were investigated in both middle cerebral arteries during a rest condition and when viewing non-emotional and emotional slide sequences. The study included 19 MS patients and 20 healthy subjects.

Results:: The negative emotional task was accompanied by a significantly higher increase in the right than in the left MCA in the control group alone. MS patients showed a bilateral, symmetrical increase in MFV. To determine whether there was a dysfunction in cerebrovascular reactivity and a deficit in the ability to activate both hemispheres in response to non-emotion-related stimuli in MS patients, the protocol study included a cerebrovascular reactivity test to apnea, a motor task and a cognitive task performed by both patients and controls. The pattern of MFV changes during these tasks was not statistically different in experimental groups.

Conclusions:: This study shows the possibility of obtaining specific functional information by means of bilateral transcranial Doppler ultrasonography and suggests a emotional processing deficit in MS patients. This finding points to a disruption of the neural circuits that link the prefrontal, posterior parietal, superior temporal and limbic cortices to subcortical structures in MS patients, as well as a possible interhemispheric disconnection.
IDENTIFY UNANSWERED QUESTIONS IN MULTIPLE SCLEROSIS. A COCHRANE STRATEGY TO PRIORITIZE FUTURE RESEARCH.

Maria Grazia Celani¹, Teresa Cantisani¹, Francesco Nonino², Elisa Baldin², Kathryn Mahan³, Massimiliano Orso⁴, Graziella Filippini⁵

¹Azienda Ospedaliera di Perugia, Neurofisiopatologia, Perugia, Italy, ²IRCCS, Istituto delle Scienze Neurologiche di Bologna, Epidemiology And Statistics Unit, Bologna, Italy, ³Cochrane Neurological Sciences Field, Regione Umbria, Perugia, Italy, ⁴Azienda Sanitaria, Istituto Zooprofilattico Sperimentale Dell'umbria E Delle Marche “togo Rosati”, Perugia, Italy, ⁵Cochrane Multiple Sclerosis and Rare Diseases of the CNS, Neurological Sciences, Milano, Italy

Background and Aims: In an ever-increasing world of scientific knowledge, capabilities, and expectations, the extent of uncertainty is rarely discussed. Identifying, not neglecting, unanswered questions in medicine can enable research to determine which questions matter most, thus deserving priority attention. Since 2006, Cochrane has progressively implemented prioritization mechanisms for key review topics, now within the “Cochrane Methods priority setting Group”. Cochrane Groups in neurology field launched their priority setting exercises with the aim of identifying pressing questions to make sure that neurological systematic reviews will be as useful as possible to the people who need them. Recently Cochrane Multiple Sclerosis Group, in collaboration with Cochrane Neurological Sciences Field, decided to start an international consultation process aimed at identifying five new topics for upcoming Cochrane reviews on MS.

Methods: An online survey, translated in 12 languages, was run asking respondents (researchers, clinicians, patients and carers) to identify and rank 5, out of 16, high priority questions of potential uncertainty in five core areas (diagnosis, health communication and participation, pharmacological treatments, rehabilitation and social support interventions), selected by members of a Steering Group made up of different stakeholders. Participants could add an additional free-text priority research topic.

Results: 1372 participants from 50 countries prioritized the following: Magnetic Resonance Imaging in predicting disability worsening, comparison of benefits and harms of disease modifying drugs, psychological health, role of multidisciplinary care teams, benefits and harms of exercise.

Conclusions: Top priorities for the future research agenda in Multiple Sclerosis have been identified by equal partners with different perspectives and cultural viewpoints.
EVALUATION OF A COOLING VEST DESIGNED FOR DAILY USE IN IMPROVING PHYSICAL PERFORMANCE OF MULTIPLE SCLEROSIS PATIENTS

Fulvio Pasquin¹, Alex Buoite Stella¹, Shawnda Morrison², Maria Elisa Morelli¹, Alessandro Dinoto¹, Alessio Bratina¹, Antonio Bosco¹, Arianna Sartori³, Fabiola Giudici³, Paolo Manganotti¹
¹University of Trieste, Neurology Unit, Department Of Medical, Surgical And Health Sciences, Cattinara University Hospital, Asugi, Trieste, Italy, ²University of Ljubljana, Faculty Of Sport, Ljubljana, Slovenia, ³University of Trieste, Statistics Unit, Department Of Medical, Surgical And Health Sciences, Cattinara University Hospital, Asugi, Trieste, Italy

Background and Aims:: Fatigue is a common symptom in Multiple Sclerosis (MS) and has a significant impact on patients’ life. This disabling condition and other symptoms are often worsened by high environmental temperature and increase of body temperature (e.g. during physical exercise) limiting patients’ physical activity. In order to improve the quality of life of PwMS (patients with MS), a wide range of cooling methods were tested, all of which showed to improve physical endurance and to prevent symptoms worsening. Aim of this study is to evaluate the efficacy of a cooling vest specifically designed for patients’ daily use.

Methods:: A cross-over study was conducted in a group of PwMS comparing their physical performance (distance and walking time to exhaustion) while wearing the cooling vest and in normal condition. As secondary outcomes heart rate, thermal sensation, skin back, and chest temperature were considered.

Results:: Ten patients were recruited. While wearing the vest, patients walked farther (1879±539m vs 1302±318m, p<0.001) and longer (1896±602s vs 1399±404s, p<0.001). At the end of the test, skin back and chest temperature were lower (-3.9±1.8 °C, p=0.001 and -2.7±1.8 °C, p<0.01 respectively), while no difference was observed for heart rate and thermal sensation.

Conclusions:: Studied cooling vest demonstrated to increase physical performance of PwMS. More studies on this topic are needed, but this preliminary result shows a possible way to improve patients' daily quality of life.
MULTIMORBIDITY IN MULTIPLE SCLEROSIS: IMPACT ON DISABILITY, QUALITY OF LIFE AND HEALTH STATUS

Matilde Leonardi¹, Erika Guastafierro¹, Maria Teresa Pugliese¹, Alberto Raggi¹, Claudia Toppo¹, Carlo Antozzi², Laura Brambilla², Paolo Confalonieri², Valentina Torri Clerici², Renato Mantegazza²
¹Fondazione IRCCS Istituto Neurologico Carlo Besta, Neurology, Public Health, Disability, Milan, Italy, ²Fondazione IRCCS Istituto Neurologico C. Besta, Neuroimmunology Unit, Milan, Italy

Background and Aims: Multiple Sclerosis (MS) can be associated to different comorbidities, and presence of multimorbidity (i.e. the joint presence of two or more condition in addition to MS) may impact on hospitalization, relapse and mortality. Little is known on multimorbidity impact on disability, quality of life and general health status in MS.

Methods: We consecutively enrolled MS patients and addressed multimorbidity with the Structured Comorbidity Questionnaire (SCQ). Measures of disability, QoL, anxiety, depression and cognitive functioning were also administered.

Results: A total of 151 patients (93 females, average age 51.6±5.8, average EDSS 2.6±1.6) were enrolled, and 77 of them (51%) scored positively for multimorbidity. Multimorbidity was associated to higher disability and lower QoL (both p<.001), higher symptoms of depression (p=.004), higher state and trait anxiety levels (p=.003 and p=.013, respectively). No differences were found for age, disease duration, EDSS, progressive course and cognitive functioning. In a multivariable regression model, depression, trait anxiety and SCQ score predicted both disability (R2=.524) and QoL (R2=.411) variation.

Conclusions: More than half of MS patients herein enrolled had multimorbidity according to the SCQ, and showed worse disability, QoL, anxiety and depression. Moreover, disability and QoL were predicted by depression, trait anxiety and SCQ score. Identification and treatment of common mental health symptoms, such as depression and anxiety, might positively impact on disability and QoL improvement.
Multiple Sclerosis Functional Composite Predicts Thalamic Atrophy in Multiple Sclerosis

Rocco Capuano¹, Alvino Bisecco¹, Alessandro D’Ambrosio¹, Manuela Altieri¹, Renato Docimo¹, Mario Cirillo¹, Francesca Trojsi¹, Antonio Russo¹, Chiara Marzi¹, Stefano Diciotti², Gioacchino Tedeschi¹, Antonio Gallo¹
¹University of Campania Luigi Vanvitelli, Department Of Advanced Medical And Surgical Sciences, Napoli, Italy, ²University of Bologna, Department Of Electrical, Electronic And Information Engineering, Bologna, Italy

Background and Aims:: In people with multiple sclerosis (pwMS) thalamic atrophy is strongly associated with cognitive functions while inconsistent results have been shown with the expanded disability status scale (EDSS). This might depend on the fact that EDSS is too much weighted for motor deficits. To overcome these EDSS limitations, it was developed the Multiple Sclerosis Functional Composite (MSFC) which includes the assessment of: i) leg function (Timed 25-Foot Walk/T25FT), ii) arm function (9-Hole Peg Test/9-HPT), iii) attention (Paced Auditory Serial Addition test/PASAT). Due to the well-known limitations of the PASAT, an alternative MSFC with the “Symbol Digit Modalities Test”(SDMT) instead of the PASAT, has also been proposed (MSFC-SDMT). The aim of this study is to investigate/compare the relationship between thalamic volume and disability measures (EDSS/MSFC/MSFC-SDMT) in pwMS.

Methods:: We enrolled 115 relapsing-remitting pwMS who underwent clinical (EDSS/MSFC/MSFC-SDMT) and 3T–MRI assessment. Thalamic volumes were calculated using FIRST tool of the FMRIB Software Library. Spearman correlations and linear regression models were applied to investigate the relationship between thalamic volumes and EDSS/MSFC/MSFC-SDMT or their subcomponents.

Results:: The MSFC-SDMT was the only significant independent predictor of the thalamic volume (Adj.R²=0.29;β=0.67;t=4.16;p<0.001). Replacing MSFC and MSFC-SDMT with their components (9HPT, T25FW, PASAT and SDMT) in the linear regression model, the SDMT was the only significant predictor of the thalamic volume (Adj.R²=0.28;β=0.47;t=3.95;p<0.001).

Conclusions:: Between most commonly used composite disability scales, MSFC-SDMT is the only independent predictor of thalamic volume. Moreover, this study further confirms that thalamic volume is more associated with cognitive than physical disability.
EFFICACY OF COMPUTER BASED COGNITIVE REHABILITATION IN MULTIPLE SCLEROSIS ACCORDING TO FREQUENCY OF TRAINING SESSIONS

Valentina Ignatova¹, Lyubomir Haralanov¹, Lyudmila Todorova²
¹MHAT National Cardiology Hospital, Clinic Of Neurology, Sofia, Bulgaria, ²Bulgarian Academy of Sciences, Institute Of Biophysics And Biomedical Ingeneering, Sofia, Bulgaria

Background and Aims:: The cognitive impairments affect up to 75% from persons with multiple sclerosis (MS) and lead to significant disability in parallel with or independently of physical deficiency. Aim: to follow up the effect of computer based rehabilitation on cognition in MS patients according to the frequency of training sessions

Methods:: The cognitive rehabilitation was made through computer based module RilaCogniSoft which included training of the speed of information processing, visuo-spatial orientation, verbal learning and executive functions. Fifty subjects with definite MS at mean age 45.6±11.8 years (33 female, 17 male) were enrolled in the study. An individual rehabilitation program was composed with mean duration of the sessions 20 minutes. The patients were divided into 2 groups: 1) Group A, who made training sessions at every 5±3 days, 2) Group B who performed training at every 10±3 days. The period of cognitive rehabilitation lasted 3 months. The cognition was tested twice - before and after the rehabilitation period through a brief cognitive screening.

Results:: Persons from Group A showed significant improvement on cognition (p<0.05), while the persons from Group B increased their cognitive skills non substantially.

Conclusions:: Computer-based rehabilitation is recommended to be performed at least once a week in order to stimulate the cognitive brain reserve. The results from our study support the concept of inclusion of the cognitive rehabilitation to the overall therapeutic approach to persons suffering from MS. This research is supported by the Bulgarian National Science Fund under Grant Ref. No. KP-06-N22/1/2018 "Theoretical research and applications of InterCriteria Analysis".
PATIENT REPORTED OUTCOMES OF NEW BRAND-GENERIC PRODUCT OF TERIFLUNOMIDE (TEBAZIO®) IN PATIENTS WITH RELAPSING-REMITTING MULTIPLE SCLEROSIS: PRELIMINARY ANALYSIS

Roya Abolfazli¹, Seyed Massood Nabavi², Amir Reza Azimi³, Mohammad Ali Nahayati⁴, Koroush Gharegozli⁵, Monireh Ghazaeian⁶, Shahrzad Shahrokhi⁷, Sara Samadzadeh⁸

¹Tehran university of medical sciences-Amiralam Hospital, Department Of Neurology, Tehran, Iran, ²Shahed University of Medical Sciences, Department Of Neurology, Tehran, Iran, ³Multiple Sclerosis Research Center, Sina Hospital, Tehran University of Medical Sciences., Department Of Neurology, Tehran, Iran, ⁴Mashhad University of Medical Sciences, Department Of Neurology, Mashhad, Iran, ⁵Shahid Beheshti University of Medical Sciences, Department Of Neurology, Tehran, Iran, ⁶Mazandaran University of Medical Sciences - Faculty of Pharmacy, Department Of Clinical Pharmacy, Sari, Iran, ⁷Zistdaru Danesh Pharmaceutical company, Medical Department, Tehran, Iran, ⁸Tehran university of medical sciences, Department Of Neurology, Tehran, Iran

Background and Aims:: This study aimed to evaluate the patients’ treatment satisfaction after switching to a brand-generic Teriflunomide product (Tebazio®, 14 mg tablet) produced by Zistdaru Danesh biopharmaceutical company and report the tolerability and safety concerns during the period of the treatment.

Methods:: The study was conducted on 100 patients with confirmed diagnosis of MS with a EDSS 0 to 5.5 from Nov 2019 to Nov 2020. Study outcomes included patients’ satisfaction was measured by Treatment Satisfaction Questionnaire for Medication [Version 1.4] (TSQM) at baseline and week 24, disability status measured by EDSS score at baseline and week 24 after starting of Teriflunomide 14 mg, safety and tolerability evaluated over 6 months.

Results:: Patients reported significant improvements in treatment satisfaction scores of convenience and side effects domains of TSQM scores at week 24 following the switch to teriflunomide regardless of the reason for treating with teriflunomide (disease worsening: baseline, 66.53, Week 24, 68.97; convenience: baseline, 66.31, Week 24, 78.97; intolerance: baseline, 67.13, Week 24, 75.60; Global Satisfaction: baseline, 63 Week 24, 65.42; P < 0.001 in all comparisons). The most common adverse drug reactions were hair thinning (36%), dermatologic (17%), gastrointestinal (23%), liver function test dysfunction (11%) which all were mild to moderate and rarely caused treatment discontinuation.

Conclusions:: Patients reported significant satisfaction regarding TSQM scores after switching to Tebazio at week 24 which can be impressive to increase patient compliance. The 14 mg brand-generic Teriflunomide product was well tolerated in Iranian RRMS patients and no new alarming signal was detected during the study period.
ASSOCIATIONS BETWEEN MULTIPLE SCLEROSIS AND SKIN LESION: ABOUT FIVE CASES

Mariem Elfekih, Hajer Derbali, Bissene Douma, Mariem Messelmani, Malek Mansour, Jamel Zaouali, Ridha Mrissa
CHU, Military Hospital Of Tunis, tunis, Tunisia

Background and Aims:: Vitiligo, Psoriasis and alopecia areata, a common chronic inflammatory disease, increases the risk of developing multiple sclerosis (MS), but evidence for this outcome is still unclear. This relation does not appear to be more common in patients with MS or their relatives. It may also be a rare side effect of treatment Related complication of MS.

Methods:: We conducted a retrospective study including one hundred patients followed for MS at the Neurology Department of the Main Military Hospital of Tunis (HMPIT) over a 16-year period from 2001 to 2020. The inclusion criterion was a definite diagnosis of MS meeting the criteria of Mc Donald 2017.

Results:: We collected 5 patients with MS and skin lesions. The mean age of onset was 34 years old. We reported an association of MS and psoriasis in three cases, vitiligo in one case and alopecia areata in one case. The mean duration between the diagnosis of skin lesion and the onset of MS was 17 years. Two patients developed psoriasis few months after initiation of Interferon-B therapy.

Conclusions:: Although there are some common genetic linkages in skin lesion and MS, psoriasis does not appear to be more common in patients with MS or their relatives. Further studies are warranted to establish the mechanisms underlying this relationship and its potential clinical consequences.
PSEUDOTUMORAL FORMS OF MULTIPLE SCLEROSIS: ABOUT 6 CASES

Mariem Elfekih, Hajer Derbali, Bissene Douma, Mariem Messelmani, Malek Mansour, Jamel Zaouali, Ridha Mrissa
CHU, Military Hospital Of Tunis, tunis, Tunisia

Background and Aims:: Multiple sclerosis (MS) is the most common chronic disabling disease of the central nervous system (CNS) in young adults. It is characterized by the presence of multiple demyelinating inflammatory lesions disseminated in the CNS. Pseudotumoral lesions (PL) are rarely observed in patients with MS. The aim of this study is to describe characteristics of PL in patients with MS.

Methods:: We conducted a retrospective study including one hundred patients followed for MS at the Neurology Department of the Main Military Hospital of Tunis over a 16-year period from 2001 to 2020. The inclusion criterion was a definite diagnosis of MS meeting the criteria of Mc Donald 2017.

Results:: 6 patients (5 female, 1 male), with a mean age of 30 years, were identified. All of them suffered from a relapsing-remitting form of MS. 5 patients had symptomatic PL. one patient presented atypical clinical manifestations such as epileptic seizures. Full recovery was found in all our patients. After a mean follow-up of 43 months, recurrent PL episodes were not observed, the annualized relapse rate was 0.95 and the mean final EDSS score was 1.5. The majority of PL (5 patients) were supratentorial, coexisted with typical demyelinating plaques and showed the ring-like morphology and the ring pattern of contrast enhancement. One patient had an aspect of cystic mass.

Conclusions:: The PL of MS often represent a diagnostic problem. Our findings contribute to a better characterization of PL in patients with MS. However, larger studies are required to define this atypical entity more exactly.
FAMILIAL AND SPORADIC FORMS OF MS IN ALGERIA: ARE THERE DISTINCTIVE CLINICAL AND GENETIC FEATURES?

Nassima Hecham1, Meriem Tazir2, Mohamed Lotfi Boudjella3, Malika Benhalima3, Lamia Ali Pacha2
1Laboratory of Research in Neurosciences, University of Algiers, Department of Neurology Mustapha Bacha hospital, Neurology, Algiers, Algeria, 2Medical school of Algiers, Neurology, ALGIERS, Algeria, 3Department of immunology Mustapha Bacha hospital, Immunology, Algiers, Algeria

Background and Aims:: Multiple sclerosis (MS) is a multifactorial disease implicating environmental factors and genetic susceptibility. The objective of this study is to describe the clinical and genetic characteristics of familial forms of MS and comparing them to sporadic forms.

Methods:: A cohort of 116 patients was studied, we identified two groups: 36 Familial MS (fMS) with history of first or second-degree relative affected by MS and 80 sporadic MS (sMS) with no family history of MS. All patients were genotyped for HLA class II alleles by PCR-SSP technique.

Results:: MS patients with familial form had an older age at onset compared to sMS group but statistically there is no significant difference (32.3 versus 30.8; p= 0.53). Relapsing form were predominant in the two groups (89% in group 1 and 95% in group 2; p= 0.41). Mean EDSS scores (3.1 versus 3.1), Median time to reach EDSS 4 (10 versus 9; p= 0.19) and MSSS scores (4.2 versus 4.3; p=0.91) were similar in the 2 groups. HLA-DRB1*1501 gene was present in 33% of fMS and in 36% of sMS (p=0.79). The severity of the disease was similar among most affected family members, especially in the siblings who share the same haplotype.

Conclusions:: As described in previous studies, we have not reported major differences between familial and sporadic forms of MS. Concordance in disease course and severity between family members has been found in most studies. HLA studies in siblings with MS reveal more common haplotypes than would be randomly expected.
ITALIAN TRANSLATION AND VALIDATION OF THE ABILHAND-26 AND ITS CORRELATION WITH UPPER LIMB OBJECTIVE AND SUBJECTIVE MEASURES IN MULTIPLE SCLEROSIS SUBJECTS

Erica Grange1,2 Davide Marengo3 Rachele Di Giovanni2 Margit Mueller4 Giampaolo Brichetto4 Andrea Tacchino4 Rita Bertoni5 Francesco Pappalardo6 Angelo Pappalardo6 Luca Prosperini7 Letizia Castelli8 Rosalba Rosato3 Davide Cattaneo5 Claudio Solaro9

Of Rehabilitation, Moncrivello, Italy 3University of Turin, Department Of Psychology, Torino, Italy 4Italian Multiple Sclerosis Foundation (FISM), Scientific Research Area, Genova, Italy 5IRCSS Fondazione Don Carlo Gnocchi, Larice Lab, Milano, Italy 6University of Catania, Department Of Medical And Surgical Sciences And Advanced Technologies "g.f. Ingrassia", Catania, Italy 7S. Camillo-Forlanini Hospital, Dept. Of Neurology, Roma, Italy 8Fondazione Policlinico Universitario A. Gemelli IRCCS, --, Roma, Italy 9"Mons. Luigi Novarese" Hospital, Moncrivello, Department Of Rehabilitation, Moncrivello, Italy

Background and Aims:: Upper limb (UL) function affected in about 50% of people with MS (PwMS). In the last decade, Patient Reported Outcome Measures (PROM) are playing an important role in clinical trial and practice. ABILHAND-26 is a PROM that assess self-perceived manual ability defined as the capacity to manage daily activities using the upper limbs. The aim of the study is to translate the ABILHAND-26 into Italian, to explore its psychometric properties examining the associations with demographics, clinical variables, 9-Hole Peg Test (9-HPT) and Manual Ability Measures-36 (MAM-36).

Methods:: Subjects were recruited in five Italian neurological centers. They were evaluated through ABILHAND-26, 9-HPT and MAM-36. Confirmatory factor analysis and Rasch analysis were adopted to investigate the psychometric properties of the ABILHAND-26.

Results:: Two hundred and forty-five patients were recruited. Rasch analyses showed adequate functioning and supported the unidimensionality of the scale. ABILHAND-26 negative correlations with age and disease duration, moderate negative correlation with EDSS and the 9-HPT scores for both arms and strong positive associations (ρ ≥ .84) with the MAM-36. Difference in ABILHAND scores only emerged when comparing patients with higher disability (EDSS ≥ 6) with both the other groups (p < .01)

Conclusions:: The Italian version of the ABILHAND-26 in now available. It shows adequate reliability of the score, good convergent validity, moderate criterion validity and strong convergent validity. ABILHAND-26 is a valid assessment for self-perceived ability to perform manual activity, especially for PwMS with moderate-to-high level of disability.
CORRELATION BETWEEN MANUAL ABILITY MEASURE-36 AND THREE UPPER LIMB OBJECTIVE MEASURES IN PEOPLE WITH MULTIPLE SCLEROSIS

Claudio Solaro¹, Rachele Di Giovanni², Erica Grange², Giampaolo Brichetto³, Margit Mueller³, Andrea Tacchino³, Rita Bertoni⁴, Francesco Patti⁵, Angelo Pappalardo⁶, Luca Prosperini⁶, Letizia Castelli⁷, Rosalba Rosato⁸, Davide Cattaneo⁹, Davide Marengo⁸
¹"Mons. Luigi Novarese" Hospital, Moncrivello, Department Of Rehabilitation, Moncrivello, Italy, ²"Mons. Luigi Novarese" Hospital, Moncrivello, Dept. Of Rehabilitation, Moncrivello, Italy, ³Italian Multiple Sclerosis Foundation (FISM), Scientific Research Area, Genova, Italy, ⁴IRCSS Fondazione Don Carlo Gnocchi, Larice Lab, Milano, Italy, ⁵University of Catania, Department Of Medical And Surgical Sciences And Advanced Technologies "g.f. Ingrassia", Catania, Italy, ⁶S. Camillo-Forlanini Hospital, Dept. Of Neurology, Roma, Italy, ⁷Fondazione Policlinico Universitario A. Gemelli IRCCS, --, Roma, Italy, ⁸University of Turin, Department Of Psychology, Torino, Italy

Background and Aims:: Upper limb (UL) function is often affected in people with Multiple Sclerosis (PwMS) and it is usually assessed through objective measures: Nine Hole Peg Test (9-HPT), Box and Block Test (BBT), Hand Grip Strength (HGS). However, subjective self-perceived manual ability should be assessed through Manual Ability Measure-36 (MAM-36). The study aims to evaluate correlations between 9-HPT, BBT, HGS and MAM-36 to understand impact of UL dysfunction in MS.

Methods:: The multicenter study included 5 Italian neurological centers. Subjects were assessed through 9-HPT, BBT, HGS, MAM-36 and Spearman correlations were computed in the whole sample, by EDSS and disease course.

Results:: 199 PwMS were included: 128 females, mean age 50.69 (13.05) years, 119 relapsing-remitting, 31 primary and 49 secondary progressive MS, mean disease duration 13.97 (10.41) years, mean EDSS 4.58 (1.97).

Results in the whole group showed 9-HPT had small-to-moderate significant negative correlations with the MAM-36, while BBT and HGS showed small-to-moderate positive associations with the MAM-36. As regards the correlation computed in the different EDSS subgroups: 9HPT: significant associations between the 9HPT and MAM-36 scores in severe disability group (EDSS ≥ 6).

HGS: moderate positive associations with MAM-36 in mild and moderate groups.
BBT: small-to-moderate positive correlation with MAM-36 in severe disability group.

Conclusions:: Correlations between objective measures and MAM-36 were overall small-to-moderate, meaning that subjective perception is not covered by objective measures. In particular, 9HPT and BBT showed significant association with MAM-36 in severe disability group with HGS in mild and moderate disability groups.
THE TRAJECTORY OF FUNCTIONAL DISORDERS IN EARLY DIAGNOSED PEOPLE WITH MULTIPLE SCLEROSIS: 1-YEAR FOLLOW-UP STUDY

Claudio Solaro¹, Elisa Gervasoni², Denise Anastasi², Rachele Di Giovanni³, Giampaolo Brichetto⁴, Ilaria Carpinella⁵, Paola Confalonieri⁵, Cristina Grosso², Luca Prosperini⁶, Andrea Tacchino⁴, Marco Rovaris², Davide Cattaneo²
¹"Mons. Luigi Novarese" Hospital, Moncrivello, Department Of Rehabilitation, Moncrivello, Italy, ²IRCSS Fondazione Don Carlo Gnocchi, Larice Lab, Milano, Italy, ³"Mons. Luigi Novarese" Hospital, Moncrivello, Dept. Of Rehabilitation, Moncrivello, Italy, ⁴Italian Multiple Sclerosis Foundation (FISM), Scientific Research Area, Genova, Italy, ⁵IRCCS Foundation “Carlo Besta” Neurological Institute, Research, Milano, Italy, ⁶S. Camillo-Forlanini Hospital, Dept. Of Neurology, Roma, Italy

Background and Aims:: There are limited research aimed at understanding the multidimensional trajectory of functional disorders overtime in early diagnosed People with Multiple Sclerosis (PwMS). The study aims to investigate progression of disability, walking endurance, fatigue, manual dexterity and cognition in a cohort of PwMS in early disease stage.

Methods:: Eighty-two subjects were assessed at baseline (BL) and 46 PwMS (age:39.5±10.6 years, Expanded Disability Status Scale (EDSS)≤2.5, disease duration≤5 years) were assessed and followed prospectively over 1-year period (FU). Data collected: EDSS, Six-Minutes Walking Test (6MWT), Fatigue Severity Scale (FSS), Multiple Sclerosis Walking Scale-12 (MSWS-12), Nine Hole Peg Test (NHPT), Symbol Digit Modality Test (SDMT).

Results:: Percentages of abnormal scores:6MWT: BL=28%, FU=32%; FSS: BL=23%, FU=17%; MSWS-12: BL=51%, FU=58%; NHPT: BL=27%, FU=27%; SDMT: BL=10%, FU=2 %. Changes at FU: 6(13%) out of 46 subjects deteriorated at the EDSS using a cut-off of 0.5 points increment. A higher percentage was observed for 6MWT (n=8, 18%,cut-off≤55m), followed by MSWS-12 (n=7, 15%,cut-off≤4 points), FSS (n=6, 15%,cut-off≤2 points), SDMT(n=4, 9%,cut-off≤10%), NHPT(n=2, 4%,cut-off≤20%). Weak correlations (from-.01 to .25) between changes at EDSS and changes in functional scales were observed. Correlations among changes in functional scales ranged between .04 to .55.

Conclusions:: Walking impairments measured by 6MWT and MSWS-12 progressed faster than manual dexterity and cognitive disorders. Changes at EDSS did not correlate with changes in functional tools suggesting that EDSS is not sensitive enough to detect deterioration in functional disorders. Walking impairments should be assessed in this population using specific tools to early detect functional disorders and set up tailored preventive interventions.
MILIARY DISTRIBUTION OF MRI RING-ENHANCING BRAIN LESIONS: AN ATYPICAL PRESENTATION OF MULTIPLE SCLEROSIS

Domenico Fiorillo¹, Arianna Braccia¹, Francesca Carta¹, Ginevra Tecilla¹, Valeria Tognoli², Luisa Maria Caniatti², Eleonora Baldi²
¹University of Ferrara, Sant’Anna Hospital, Clinical Neurology, Ferrara, Italy, · Ferrara Hospital, Neurology, Ferrara, Italy

Background and Aims:: Ring-enhancing lesions are one of the most frequently encountered abnormalities on neuroimaging and can be expression of infectious, neoplastic, vascular or inflammatory disease. In particular, they are currently considered a possible radiological pattern of Multiple Sclerosis (MS) [1]. We report a case of Multiple Sclerosis with atypical ring-enhancing lesions: clinicians should be aware of the possible unusual radiological presentation of this very common inflammatory disease.

Methods:: A 27-year-old woman presented to Emergency Department with left brachio-crural weakness. MRI showed diffuse, “miliary”, T2-FLAIR hyperintense, T1-hypointense, ring-enhancing white matter lesions, attempting supratentorial brain regions, cerebellum and spinal cord. Cerebral Spinal Fluid (CSF) profile revealed moderate lympho-plasmacellular pleiocytosis. Patient started intravenous Desamethasone, with good response.
Results: Autoimmune, neoplastic and infectious diseases were ruled out. Anti aquaporin-4 and anti-MOG antibodies resulted negative. We finally found multiple CSF IgG clonal bands, so the diagnosis of definite MS was posed. Patient underwent two more disease relapses responsive to corticosteroids and finally started Ocrelizumab, showing radiological and clinical improvement (actual moderate residual paraparesis).

Conclusions: Ring-enhancing lesions are considered a possible MS radiological pattern, usually appearing as single or a few, open ring-enhancing lesions [2]. This case was unusual because brain MRI showed a great amount of very little lesions (< 12 mm diameter) with closed ring-enhancement, mimicking infectious or neoplastic disease. Negativity of all investigations, good response to steroidal therapy and CSF finding of multiple IgG clonal bands supported diagnosis of MS, sometimes very challenging for
A GENE-SET ANALYSIS SUGGESTS THE POSSIBLE INVOLVEMENT OF IRON HOMEOSTASIS IN NEURODEGENERATION IN PROGRESSIVE MULTIPLE SCLEROSIS

Antonino Giordano1,2, Silvia Santoro2, Melissa Sorosina2, Ferdinando Clarelli2, Laura Ferrè1,2, Miryam Cannizzaro1,2, Elisabetta Mascia2, Massimo Filippi1,3, Federica Esposito1,2
1IRCCS San Raffaele Scientific Institute, Neurology Unit, Neurorehabilitation Unit And Neurophysiology Service, Milan, Italy, 2IRCCS San Raffaele Scientific Institute, Laboratory Of Human Genetics Of Neurological Disorders, Milan, Italy, 3IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Division Of Neuroscience, Milan, Italy

Background and Aims:: Advanced neuroimaging has revealed that slowly expanding lesions with a paramagnetic iron rim are the most common lesion type in progressive multiple sclerosis (pMS) and correlate with disability. Iron accumulation in the activated microglia and macrophages at the edge of these lesions is governed by inflammatory pathways and may contribute to the pathogenesis of pMS. We investigated whether genetic variants in genes involved in iron metabolism may have an impact on pMS.

Methods:: After selecting a set of 312 genes deemed relevant for iron homeostasis from KEGG and Gene Ontology sources, we performed an association analysis to test the impact of single-nucleotide polymorphisms (SNPs) in these genes on the development of pMS, comparing relapsing-remitting (RR) MS patients who did not experience disease progression after 20-years from disease onset versus primary progressive (PP) MS patients.

Results:: We included 830 patients (RR:243, PP:508) and 4,594 SNPs mapping to the selected genes, retrieved from available whole-genome data. One SNP, rs16902359, passed the threshold for a significant association with the progressive course (p=2.19e-05; OR=0.48). Rs16902359 lies within CASC11 (Cancer Susceptibility-11), a long non-coding RNA gene, implicated as transcriptional activator in glial and neural tumorigenesis. In addition, rs16902359 has an expression- and methylation-Quantitative-Trait-Loci effect on the adjacent MYC gene, a key player in iron homeostasis, apoptosis and neurodegeneration, involved in the pathogenesis of other neurodegenerative diseases.

Conclusions:: CASC11 and MYC genes, that are involved in iron metabolism and neurodegeneration, appear to have a role in the development of pMS. These results need to be confirmed in larger and independent cohorts.
Background and Aims: NMOSD is an immune-mediated disorder which is characterized by relapsing episodes of optic neuritis and myelitis. Brain stem related symptoms such as intractable vomiting are not usually considered as the initial presentation and misdiagnosis has been frequently observed. Almost 4% of NMOSD cases are pediatric. Early differentiation of NMOSD from other childhood disorders including ADEM, MS, infections and mass lesions is critical.

Methods: An 11 years old girl presented with intractable vomiting and received several types of gastrointestinal treatments during one month. After that diplopia occurred and also she suffered vertigo. In this stage Brain MRI showed isolated edematous intramedullary lesion with heterogeneous enhancement. Patient received corticosteroid therapy with diagnosis of brain stem mass and the symptoms improved. She was candidate for biopsy to decide for radiation or chemotherapy but her parents didn’t accept. After three months she developed central facial nerve palsy, the brain MRI showed the same lesion. Anti AQP4 ab was positive, so the appropriate treatment started with final diagnosis of NMOSD.

Results: Only about 30% of patients presents with brainstem involvement. It is difficult to diagnosis of NMOSD with presentation of acute brainstem or cerebral or diencephalic syndromes for physicians who are not familiar with its clinical features and diagnostic criteria. Involvement of the area postrema can lead to the initial presentation of sometimes intractable nausea and vomiting with associated intramedullary lesions on MRI in 16% to 43% of patients.

Conclusions: NMOSD should be considered in differential diagnosis of isolated brain stem lesions to avoid from invasive surgical interventions. Early diagnosis is critical for proper treatment.
TREATMENT WITH NATALIZUMAB DURING THE COVID-19 PANDEMIC IN MULTIPLE SCLEROSIS PATIENTS

Judit Díaz-Díaz, Clara Isabel Ramirez, Marta Ortiz-Pica, Elena García-Yusta, Irene Gómez-Estevez, Celia Oreja-Guevara
University Hospital Clínico San Carlos, Neurology. Multiple Sclerosis Center, Madrid, Spain

Background and Aims:: Multiple sclerosis patients treated with highly active treatments (natalizumab, ocrelizumab) have an increased risk of infections. Natalizumab discontinuation can produce a rebound effect, consisting of severe disease reactivation. We aim to study the management and safety of MS patients on natalizumab during the Covid-19 pandemic.

Methods:: Prospective study of MS patients on natalizumab during COVID-19 pandemic. We evaluate demographic features, time on natalizumab, dose interval, and COVID-19 symptoms. RT-PCR COVID-19 tests from nasopharyngeal sample were performed before every natalizumab infusion.

Results:: We analyzed 69 patients: 71% women, mean age: 43. The mean treatment duration was 68 months (range: 2-141). In 32% of patients natalizumab was changed from every 4 weeks to every 6w to decrease visits to the hospital. From March to April 2020, 5 patients had COVID19 (tables 1-2). On May 2020 we started Covid-19 screening before natalizumab infusion. From May 2020 to March 2021, 553 nasal swab PCR COVID-test were performed. Fourteen patients showed a positive result and natalizumab was stopped; test was repeated 1-2 weeks later with a negative result and natalizumab was restarted. In summary: 28% of patients had COVID19, 90% asymptomatic or mild symptoms and only 2 patients required specific treatment (tables 1-2). There were no statistically significant differences in the age (p0.158), dose interval (p0.962) or treatment duration (p0.298) between patients with COVID19 and non-COVID19.

**Conclusions:** Natalizumab treatment seems to be safe in MS patient during COVID-19 pandemic. Most patients were asymptomatic and no patient required mechanical ventilation.
Background and Aims:: Myelin oligodendrocyte glycoprotein associated disease (MOGAD) features may overlap with relapsing-remitting multiple sclerosis (RRMS). Little is known about brain atrophy occurrence in MOGAD. This study compares rates of brain volume change over time in MOGAD and RRMS patients.

Methods:: 18 adult MOGAD patients (10 females) were selected from a multicentric observational study in which they had been previously enrolled. 33 RRMS patients (17 females), matched for age and sex to the MOGAD cases were recruited in the Verona MS centre. Availability of two brain MRI scans performed in an interval of 6-30 months and a clinical follow-up ≥6 months were mandatory for each patient. The same MRI protocol and scanner at both timepoints was used for each patient. Annualised percentage brain volume change (PBVC/y) between the two MRI timepoints, baseline global brain, grey and white matter (WM), and regional volumes were compared between groups.

Results:: Mean PBVC/y was lower in MOGAD than in RRMS in a subgroup of patients aged <60 years and with a disease duration ≤10 years (p=0.046). Overall, mean global brain volume was higher in MOGAD (p=0.021) as well as mean WM volume (p<0.001); mean putaminal volume was lower in MOGAD (p=0.003). Median T2-lesion volume at timepoint 1 was lower in MOGAD (p<0.001); T2-lesion volume increased between the 2 MRI timepoints in RRMS (p<0.001) but not in MOGAD (p=0.11).

Conclusions:: MOGAD displays less global brain and WM atrophy than RRMS, as well as less brain volume loss and lesion load over time, suggesting different neuropathogenic mechanisms underlining the two diseases.
ITALIAN MULTICENTER OBSERVATIONAL STUDY ON REAL-LIFE EXPERIENCE WITH ALEMTUZUMAB IN NAÏVE PATIENTS WITH AGGRESSIVE MULTIPLE SCLEROSIS

Background and Aims:: Alemtuzumab(ALEM) is an anti-CD52 monoclonal antibody approved for the treatment of active Multiple Sclerosis(MS) which showed high efficacy also in the subgroup of highly-active patients. We aimed to evaluate efficacy/safety profile of ALEM-treatment in a population of aggressive MS naïve-patients.

Methods:: We conducted a multicenter prospective observational study in a cohort of aggressive naïve-patients treated with ALEM. Clinical and neuroradiological parameters were collected from clinical records in 29 Italian MS Centers from October 2015 to February 2021.

Results::

33 naïve-patients were included. Basal characteristics are shown in Table1. Efficacy data were analyzed after the end of the complete therapeutic cycle (2 ALEM-courses) because presence of disease activity between the two courses is not indicative of a therapeutic failure. Follow-up data at 24 and 36 months were available for 99/133 and 61/133 subjects, respectively. NEDA-3 at 24 and 36 months was reached by 89.2% and 69.4% of patients, respectively. At 24 and 36 months mean ARR were 0.06 and 0.1; median EDSS were 2.0 and 1.5, respectively. At the same time-points, mean increase in T2 lesions was
0.2 and 0.48 respectively. 5.3% of patients needed a third cycle of therapy. Overall 74.4% of patients reported adverse events (Table2).

Conclusions:: These results highlight that aggressive naïve-patients are an ideal candidate for immune system resetting, likely due to young age, short disease duration and low disability. Furthermore, absence of previous immunomodulating/immunosuppressant drugs altering the immune system play a key role in determining effectiveness of this powerful drug. Longer FU is needed to confirm our data.
EFFECTS OF INTERMITTENT APPLICATION OF TRANSCRANIAL DIRECT CURRENT STIMULATION COMBINED WITH STATIONARY BICYCLE IN IMPROVING GAIT IN MULTIPLE SCLEROSIS

Sarvenaz Rahimibarghani¹,², Mohaddeseh Azadvari², Seyede Zahra Emami-Razav¹, M. Hossein Harirchian³, Shahram Rahimi-Dehgolan², Hamid R Fateh²
¹TUMS, Physical Medicine And Rehabilitation, Tehran, Iran, ²Tehran University of Medical Sciences, Physical Medicine And Rehabilitation Department, Tehran, Iran, ³Tehran University of Medical Sciences, Iranian Center for Neurological Research, Neurology, Tehran, Iran

Background and Aims:: The exercise therapy program has proved to be safe and well-tolerated for multiple sclerosis (MS) patients. Recently, physical therapy combined with transcranial direct current stimulation (tDCS) has been shown to reinforce the therapeutic effects in neurorehabilitation. The present study aimed to evaluate the therapeutic efficacy of tDCS along with a stationary bike in improving gait among MS patients.

Methods:: This randomized double-blinded controlled trial (RCT) was conducted on 50 eligible individuals with MS. A total of 39 participants completed the study. 21 in the active and 18 in the sham group. The subjects were randomly assigned to receive exercise along with anodal tDCS, or exercise alone utilizing stationary bike plus a sham-tDCS protocol. The study goal was to determine and compare walking performance tests, [2-minute walk test (2MWT), 5-Meter Walk Test (5MWT), and Timed Up and Go test (TUG)]. Manual muscle test (MMT), fatigue severity scale (FSS), and multiple sclerosis quality of life-54 (MSQOL-54) questionnaires.

Results:: In terms of the observed changes in 2MWT and 5MWT, all the post-treatment values were better for the interventional group than the exercise-alone group. After intervention and one month later, the mean TUG value statistically decreased significantly in the combinational-treatment group (P=0.002) than the control group. On the other hand, there was no preference between the two groups in terms of FSS score, MSQOL-54, and MMT improvement.

Conclusions:: Intermittent application of anodal tDCS combined with cycling can lead to better results in walking speed of MS subjects comparing to exercise alone.
CONTINUOUS USE OF INTERFERON BETA-1B IN MULTIPLE SCLEROSIS PATIENTS WITH CANCER

Background and Aims:: There is limited available data regarding the use of disease modifying therapies (DMT) in multiple sclerosis (MS) patients with newly developed malignancies and there are currently no accepted guidelines for the management of such patients. We are presenting two cases of continuous use of DMTs in patients with MS and cancer.

Methods:: From our clinic’s MS database, we retroactively selected the few cases in which the use of DMTs was not interrupted in MS patients who developed cancer.

Results:: A 31 years old patient diagnosed with relapsing remitting multiple sclerosis (RRMS) (EDSS=1.5) and treated with Interferon beta 1b, developed desmoplastic nodular medulloblastoma 7 years later. The DMT was not interrupted during or after radiotherapy and the surgical removal of the tumor. Currently, 14 years after the MS diagnosis, the patient has an EDSS score of 6 and is cancer free on multiple MRI scans. Another 45 years old patient was treated with Interferon beta 1b for 5 years for RRMS (EDSS=1.5) prior to her developing cervical cancer. The DMT was not interrupted during or after radiotherapy and removal of the tumor. Now, 15 years after the cancer diagnosis, the patient has EDSS score of 4.5 and is cancer free.

Conclusions:: Although the current guidelines make no recommendations for the use of DMTs on active cancer patients, it was our patients’ wish to continue the treatment. For 15 and respectively 7 years after the cancer diagnosis, the patients continue using Interferon beta 1b, experiencing no cancer relapses.
FASUDIL PROMOTED REMYELINATION IN CPZ-INDUCED MICE BY REGULATING THE FUNCTION OF ASTROCYTES

Zhi-Bin Ding¹,², Qing-Xian Han¹, Yang-Yang Chen¹, Wen-Yuan Ju¹, Qing Wang¹, Li-Juan Song¹,², Zhi Chai¹, Jie-Zhong Yu³, Min-Fang Guo³, Jian-Jun Huang⁴, Bao-Guo Xiao⁵, Cun-Gen Ma¹,²,³

Background and Aims:: Fasudil, a ROCK inhibitor, has been exhibited its advantageous roles in demyelinating diseases. Previous researches have shown that Fasudil performs multiple functions including immunomodulation, neurotrophy, neuro-axonal regeneration and myelin protection. Our aim was to observe the myelin protection and potential mechanisms of Fasudil in Cuprizone (CPZ)-induced mice model.

Methods:: Male C57BL/6 mice were divided into three groups: Control group was fed with standard diet, while CPZ demyelinating model was fed with 0.2% CPZ diet for 6 weeks, which were divided into model and Fasudil treatment group. Fasudil treatment group received intraperitoneal injection (i.p.) of Fasudil (40mg/kg/d) in the last two weeks, while Control and model mice were injected with saline (i.p.).

Results:: Fasudil improved anxiety/depression-like behaviors. Immunofluorescence staining showed that Fasudil increased the phagocytosis of myelin debris by GFAP+ astrocytes and the number of BDNF+GFAP+ astrocytes in the corpus callosum of CPZ mice. Fasudil also enhanced the expression of Sox2 by GFAP+ astrocytes and induced astrocytes to express a marker of OPCs (NG2), implying that Fasudil may promote the transformation of astrocytes into OPCs.

Conclusions:: Fasudil may increase astrocytes to phagocytize myelin debris and induce astrocytes to express neurotrophic BDNF as well as translation factor Sox2 and promote astrocytes to differentiate into myelinogenic cells, therefore, improving behaviors and promoting the remyelination of CPZ mice. (NNSF of China 81473577, Open Projects of The Key Laboratory of The Ministry of Education 2019004 and Chinese Academy of Sciences 2020-MDB-KF-09, China Postdoctoral Science Foundation 2020M680912, Ma and Xiao are corresponding authors)
REAL WORLD EXPERIENCE WITH CLADRIBINE AT S.ANDREA HOSPITAL OF ROME

Elena Barbuti¹, Antonio Ianniello¹,², Riccardo Nistri¹, Serena Ruggieri², Giovanna Borriello², Carlo Pozzilli¹,²
¹MS Center, Sant'andrea Hospital, Rome, Italy, ²Sapienza University, Department Of Human Neurosciences, Rome, Italy, ³NCL, Institute Of Neuroscience, Rome, Italy

Background and Aims:: Among drugs used for Multiple Sclerosis (MS), Cladribine (Mavenclad) is the most recent commercially available in Italy. Here, we report the real world experience from patients treated with Cladribine in our MS Center.

Methods:: Clinical data included Expanded Disability Status Scale (EDSS) scores and relapses. Confirmed disability improvement (CDI) and confirmed disability worsening (CDW) was defined by a 1 point increase or decrease in the EDSS score respectively. MRI findings were also recorded.

Results:: We collected data from 60 patients (11 males; 49 females). Fifty-six patients had a relapsing remitting course (RRMS), 4 patients had a secondary progressive phenotype (SPMS). Mean age at baseline was 35,40 +/- 8,79. Mean and median EDSS at baseline was 2,8 and 2,5 (range 1-5.5) respectively. Prior to Cladribine, 29 patients received 2 or more disease modifying treatments (DMTs), 13 patients had 1 DMT and 18 patients were naïve. The mean follow-up was 16 months +/-9.38. CDI was found in 6 patients and CDW in 2 patients. Four patients had relapses. Follow-up MRIs was available up to now in 34 patients, 10 of them show at least one new MRI lesion. No adverse events were reported except for 1 case of recurrent cystitis and 1 of lymphopenia grade 3. Only one patient was shifted to another DMT for lack of efficacy.

Conclusions:: These data provide information on routine use of Cladribine while the most existing knowledge about the use of Cladribine comes from phase 3 clinical trials.
CSF CXCL13 AND CHITINASE 3-LIKE-1 CONCENTRATIONS PREDICT DISEASE COURSE IN RELAPSING MULTIPLE SCLEROSIS

Matteo Lucchini1, Valeria De Arcangelis1, Geny Piro2, Viviana Nociti1, Assunta Blanco1, Chiara De Fino1, Gabriele Di Sante3, Francesco Ria3, Paolo Calabresi2, Massimiliano Mirabella1
1Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Neurology, Rome, Italy, 2Università Cattolica del Sacro Cuore, Oncology, Rome, Italy, 3Università Cattolica del Sacro Cuore, Pathology, Rome, Italy

Background and Aims:: Several biomarkers from MS patients' biological fluid have been evaluated to support a more precise diagnosis, to predict disease course, and to evaluate treatment response. We investigated the diagnostic and prognostic value of CSF concentration of target biomarkers in both relapsing (RMS=107) and progressive (PMS=18) MS patients and in other inflammatory (OIND=10) and non-inflammatory (ONIND=15) neurological disorders.

Methods:: We evaluated the CSF concentration of APRIL, BAFF, CHI3L1, CCL-2, CXCL-8, CXCL-10, CXCL-12, CXCL-13 through a Luminex Assay. MS patients were prospectively evaluated, and clinical and radiological activity were recorded.

Results:: CHI3L1 and CXCL13 CSF levels were significantly higher in both MS groups compared to both control groups while CCL2, BAFF, and APRIL concentrations were lower in RMS patients compared to PMS and OIND. Higher concentrations of CHI3L1, CXCL10, CXCL12, and CXCL13 were registered in patients with single demyelinating event who convert to clinically defined MS. RMS patients in the CXCL13 and CHI3L1 high concentration group have a significantly higher risk of relapse (HR 12.61 and 4.57,p<0.001), MRI activity (HR 7.04 and 2.46,p<0.001), and of any evidence of disease activity (HR 12.13 and 2.90,p<0.001) during follow-up.

Conclusions:: CSF CXCL13 e CHI3L1 levels represent very good prognostic biomarkers in RMS patients and therefore can guide the treatment choice. Higher CSF concentrations of neuro-inflammatory biomarkers were associated with a higher risk of conversion to CDMS in patients with a first clinical demyelinating event. Differential CSF BAFF and APRIL levels between RMS and PMS suggest a different modulation of B-cells pathways in the different phases of the disease.
PATTERNS OF USE AND EFFECTIVENESS OF ANALGESICS AND CANNABINOIDS FOR PAIN RELIEF AMONG IRISH PATIENTS WITH MULTIPLE SCLEROSIS.

Danielle Daly¹, Brian Sweeney²
¹University College Cork, Medicine, Cork, Ireland, ²Cork University Hospital, Neurology, Cork, Ireland

Background and Aims:: Pain is an often-reported symptom in Multiple Sclerosis (MS); however, pain management is often described as being inadequate. Emerging evidence suggests that cannabinoids may be effective in the treatment of MS related pain. This research aimed to determine the prevalence and patterns of use of medications and cannabinoids for pain relief in a sample of Irish patients with MS.

Methods:: This was a cross-sectional survey. 101 individuals attending neurology outpatient appointments at Cork University Hospital completed questionnaires measuring demographics, severity of disability, nociceptive pain, neuropathic pain, use of medications, use of cannabinoids and degree of depression.

Results:: 59% (95% CI 48-67.7%) of patients had experienced MS related pain, while 26% (95% CI 17–34%) had experienced neuropathic pain. Prescription medication had been used by 73% (95% CI 62-84%) of participants with pain. 30% (95% CI 18–42%) of patients experiencing pain had used cannabinoids. Patients who had used cannabinoids compared to non-users were more likely to experience neuropathic pain, be of a younger age and to use cannabinoids recreationally (p< 0.05). In addition, the type of cannabinoids participants used appeared to influence how effectively they rated it as a pain reliever; with cannabis/hash being rated as more effective than CBD oil or a Sativex spray (p< 0.05).

Conclusions:: Pain is a significant problem for patients with MS which the current therapeutic options have failed to control. A substantial number of patients used cannabinoids to manage their pain, however further research into the efficacy and long-term side effects of this substance is necessary.
PREVALENCE OF SARS-COV-2 ANTIBODIES IN MULTIPLE SCLEROSIS: THE HIDDEN PART OF THE ICEBERG

Nicola Capasso¹, Raffaele Palladino², Emma Montella³, Francesca Pennino¹,², Roberta Lanzillo¹, Antonio Carotenuto¹, Maria Petracca¹, Rosa Iodice¹, Aniello Iovino⁴,⁵, Francesco Aruta¹, Viviana Pastore², Antonio Riccardo Buonomo⁶, Emanuela Zappulo⁶, Ivan Gentile⁶, Maria Triassi², Vincenzo Brescia Morra¹, Marcello Moccia¹

Background and Aims:: We compared the prevalence of SARS-CoV-2 IgG/IgM in multiple sclerosis (MS), low-risk, and high-risk populations and explored possible clinical correlates.

Methods:: In this cross-sectional study, we recruited MS patients, low-risk (university sta from non-clinical departments), and high-risk individuals (healthcare sta from COVID-19 wards) from 11 May to 15 June 2020. We used lateral flow immunoassay to detect SARS-CoV-2 IgG and IgM. We used t-test, Fisher’s exact test, chi square test, or McNemar’s test, as appropriate, to evaluate between-group differences.

Results:: We recruited 310 MS patients (42.3 ± 12.4 years; females 67.1%), 862 low-risk individuals (42.9 ± 13.3 years; females 47.8%), and 235 high-risk individuals (39.4 ± 10.9 years; females 54.5%). The prevalence of SARS-CoV-2 IgG/IgM in MS patients (n = 9, 2.9%) was significantly lower than in the high-risk population (n = 25, 10.6%) (p < 0.001), and similar to the low-risk population (n = 11, 1.3%) (p = 0.057); these results were also confirmed after random matching by age and sex (1:1:1). No significant differences were found in demographic, clinical, treatment, and laboratory features. Among MS patients positive to SARS-CoV-2 IgG/IgM (n = 9), only two patients retrospectively reported mild and short-lasting COVID-19 symptoms.

Conclusions:: MS patients have similar risk of SARS-CoV-2 infection to the general population, and can be asymptomatic from COVID-19, also if using treatments with systemic immunosuppression.
THE “NO EVIDENCE OF DISEASE ACTIVITY” (NEDA) CONCEPT IN MS: IMPACT OF SPINAL CORD MRI

Elena Di Sabatino, Lorenzo Gaetani, Andrea Mancini, Angela Borrelli, Silvia Sperandei, Lucilla Parnetti, Massimiliano Di Filippo
University of Perugia, Santa Maria della Misericordia Hospital, Section Of Neurology, Department Of Medicine And Surgery, Perugia, Italy

Background and Aims:: Measures to define treatment response, such as no evidence of disease activity (NEDA), are routinely used in multiple sclerosis (MS) clinical practice. Although spinal cord involvement in MS is frequent and strongly correlated with future disability accrual, its magnetic resonance imaging (MRI) monitoring, in the absence of spinal cord symptoms, is not routinely performed. This study aimed to assess the impact of spinal cord imaging and specifically, the impact of missing asymptomatic spinal cord lesions, in the definition of NEDA status in a cohort of MS patients treated with disease-modifying therapies (DMTs).

Methods:: We selected for the study 115 patients treated with first line DMTs undergoing clinical and MRI routine monitoring, for whom MRI was extended at least to the study of the cervical spinal cord. We retrospectively analyzed for the presence or absence of NEDA in the whole cohort, either considering or not spinal cord monitoring data for the definition of MRI disease activity.

Results:: When considering only clinical and brain MRI measures, 97 out of 115 patients (84.3%) satisfied the criteria for NEDA. In this same cohort, the percentage of patients who showed NEDA decreased to 76.5% (88 out of 115 subjects) when considering also spinal cord imaging data.

Conclusions:: These findings suggest that, in routine clinical practice, spinal cord MRI monitoring in patients under first line DMTs, leads to a slight but significant change in the proportion of subjects classified as clinically and radiologically stable according to the definition of NEDA.
MR NEUROGRAPHY UNRAVELS MYSTERY OF COLD ABSCESS

Alisha Saxena, Birinder Paul
Dayanand Medical College and Hospital, Neurology, Ludhiana, India

Background and Aims:: This is a case report of a 24-year-old migrant laborer who came to neurology outpatient clinic with weakness of hypothenar and lumbrical muscles of left hand associated with painless swelling above the medial epicondyle.

Methods:: Complete neurological examination including assessment of peripheral neuropathy was done. Nerve electrophysiologic study and ultrasonography along with MR neurography was performed.

Results:: On examination there was palpable firm swelling in the medial lower part of left arm with hypopigmented patch over his left face. Neurological examination revealed only left ulnar neuropathy which was confirmed on electrophysiological studies. Left ulnar nerve ultrasound revealed round hypoechoic area above the thickened ulnar nerve and fusiform thickening extending up to the axilla. MR neurography of bilateral upper limb revealed hyperintense thickened left ulnar nerve through out its course (8.8 mm) with loss of fascicular architecture, proximally extending to involve inferior trunk of brachial plexus and medial cord while distal thickening till cubital tunnel. Forearm part of ulnar nerve was normal. There was associated hyperintense collection 2.2 X 1.4 cm communicating with the ulnar nerve 6 cm proximal to the elbow joint. Skin smear and aspiration of the collection confirmed the diagnosis of tubercular leprosy.

Conclusions:: This is the first case report highlighting the MR imaging characteristics of thickened ulnar nerve with extension till brachial plexus and communicating abscess in a patient of tubercular leprosy. Another unique finding in our patient was isolated involvement of single nerve with development of nerve abscess in the absence of any prior treatment for leprosy.
BEYOND THE DISABILITY, WHAT IS THE QUALITY OF LIFE IN ALGERIAN PATIENTS WITH MULTIPLE SCLEROSIS?

Nassima Hecham¹, Meriem Tazir², Lamia Ali Pacha²
¹Laboratory of Research in Neurosciences, University of Algiers, Department of Neurology Mustapha Bacha hospital, Neurology, Algiers, Algeria, ²Medical school of Algiers, Neurology, ALGIERS, Algeria

Background and Aims:: Multiple sclerosis (MS) is the most common chronic progressive and disabling neurological disease of the CNS. It has many impacts on social, family and professional life. These repercussions have often been discussed in terms of quality of life. The purpose of this study is to assess quality of life, fatigue, and depression in MS patients.

Methods:: The clinical types, quality of life (Multiple Sclerosis Quality of Life-59), two depression scales (MADRS and HDRS) and fatigue levels (Fatigue Severity Scale - FSS) were carried out in 66 patients.

Results:: The mean age of the patients was 38.4 ± 2.4 years, and the mean disease duration was 8.1 ± 6.2 years. The mean EDSS was 3.66 ± 2.18. 93.9% of patients had relapsing-remitting MS. All dimensions of quality of life seemed to be impaired, 33.3% of patients had limitations related to physical activity, 34.8% of patients had memory problems, the fatigue was found in 68.2% of cases. Sexual disorders were present in 56.3% of men, and in 40% of women. Mood disorders and depression in 10% of cases

Conclusions:: Quality of life measures are bound to develop, with the aim of improving the quality of care. For the practitioner, the results of a quality of life questionnaire can be a valuable aid in detecting important problems and facilitating communication with the patient. Living as normally as possible is one of the challenges raised by multiple sclerosis.
BALO’S CONCENTRIC SCLEROSIS MIMICKING AN INTRACRANIAL SPACE OCCUPYING LESION IN A NIGERIAN ADULT MALE: A CASE REPORT

Francis Campbell, Bibiana Oti, Ned Ndafia, Idawarifagha Hart, Okwuoma Okwunodulu, Chika Ndubuisi, Samuel Ohaegbulam
Memfys hospital for Neurosurgery, Department Of Neurosurgery, ENUGU, Nigeria

Background and Aims:: Baló’s concentric sclerosis (BCS) is a rare demyelinating disease often classified as a variant of multiple sclerosis. Typically, brain MRI shows concentric lamellae of demyelination alternating with normal zones of myelin preservation. Given its presentation with mass effect, it may be mistaken for other intracranial space occupying lesions (ICSOL), especially in our sub-region where neuroimaging facilities are scarce or not easily affordable. To the best of the authors’ knowledge, this is the first reported case of BCS in sub-Saharan Africa. Aims: We report the management and early outcome of a young Nigerian man managed for BCS in our hospital.

Methods:: Case report

Results:: The patient presented with behavioral changes, focal seizures, cranial neuropathy, long tract signs and cerebellar dysfunction causing severe disability and functional impairment with modified Rankin score (mRS) of 4. Brain MRI showed multiple heterogeneous lesions in the right cerebral hemisphere, brainstem and cerebellum with features in keeping with BCS. Cerebrospinal fluid oligoclonal bands were negative and C-reactive protein was normal. He received high doses of intravenous steroid therapy and was subsequently maintained on oral steroids and immunosuppressive therapy. He made gradual neurological improvement and significant symptom resolution and was able to return to work after about a year (mRS 1). He has been followed up for 18 months without relapse.

Conclusions:: Although BCS is a rare entity, it should be considered a differential diagnosis of ICSOL in our sub-region and high index of suspicion and prompt neuroimaging is required for early diagnosis.
TRIGEMINAL NEURALGIA ASSOCIATED WITH A SOLITARY DEMYELINATING PONTINE LESION: A CASE REPORT

Domenico Plantone¹, Eugenio Distaso¹, Mariangela D'Onghia¹, Claudia Dell'Aquila¹, Antonio Giannini², Giuseppe Rinaldi¹
¹ASL Bari - Di Venere Teaching Hospital, Neurology Institute, Bari, Italy, ²ASL Bari - Di Venere Teaching Hospital, Radiology Institute, Bari, Italy

Background and Aims: Trigeminal neuralgia associated with brainstem lesions is currently considered as a rare condition and only few patients have been reported so far in literature. Tohyama and colleagues recently proposed the nosological entity of trigeminal neuralgia associated with solitary pontine lesion, trying to categorize it as a new clinical syndrome on its own. Based on this description, trigeminal neuralgia associated with solitary pontine lesion patients have an identical clinical presentation compared to other patients with trigeminal neuralgia but have a solitary pontine lesion. The nature of the pontine lesion has been attributed to several etiologies, including ischemia, demyelination or previous pontine viral neuritis. In those patients with a putative demyelinating lesion, a definite diagnosis of multiple sclerosis cannot be made due to the lack of dissemination in space. Very little is known in relation to the cerebrospinal fluid characteristics of this population of patients.

Methods: Case report

Results: We present a case of a 42-year-old man suffering of trigeminal neuralgia associated with solitary pontine lesion with a likely demyelinating etiology. The patient herein described had an atypical trigeminal neuralgia associated with a single pontine lesion comparable to those described by Tohyama and colleagues. The MRI characteristics of the lesion, along with the presence of oligoclonal bands in the cerebrospinal fluid, suggested a demyelinating etiology. Trigeminal neuralgia associated with solitary pontine lesion may be categorized as a possible manifestation of solitary sclerosis.

Conclusions: Future research need to reveal which features can predict the risk of conversion to clinically defined multiple sclerosis and which treatments modify this risk.
ICARIIN INHIBITS DEMYELINATION BY TARGETING THE PHAGOCYTIC ACTIVITY OF MICROGLIA IN CPZ-INDUCED DEMYELINATING MICE

Qing-Xian Han¹; Zhi-Bin Ding¹,², Qiang Miao¹, Ru-Heng Wei¹, Qing Wang¹, Li-Juan Song¹,², Zhi Chai¹, Jie-Zhong Yu¹,³, Jing-Wen Yu², Jian-Jun Huang⁴, Bao-Guo Xiao⁵, Cun-Gen Ma¹,²,³ ¹Shanxi University of Chinese Medicine, Research Center Of Neurobiology / The Key Research Laboratory Of Benfiting Qi For Acting Blood Circulation Method To Treat Multiple Sclerosis Of State Administration Of Traditional Chinese Medicine, Jinzhong, China, ²Shanxi Medical University, Physiology/neurology, Taiyuan, China, ³Shanxi Datong University, Institute Of Brain Science / Shanxi Key Laboratory Of Inflammatory Neurodegenerative Diseases, Datong, China, ⁴General Hospital of National Medicine and Datong Coalmine, Neurosurgery, Datong, China, ⁵Fudan University, Institutes Of Brain Science And State Key Laboratory Of Medical Neurobiology, Shanghai, China

Background and Aims:: The phagocytosis of myelin debris by microglia may be the key step to the treatment of multiple sclerosis (MS). Our aim was to investigate whether the neuroprotective effect of Icariin (ICA) is achieved by promoting phagocytosis of myelin debris of microglia.

Methods:: Mice were fed with a diet containing cuprizone (CPZ) for 4 weeks to induce demyelination. Then, the debris of myelin marked by CFSE were injected into the unilateral corpus callosum in mice. Then, the mice were injected with ICA for two weeks. BV2 and bone marrow-derived macrophages were inoculated on the 6-well plate. After cell adherence, CFSE-labeled myelin debris and ICA were incubated. Relevant cytokines and proteins were detected by western blot, Immunofluorescence and ELISA.

Results:: Compared with normal mice, CPZ-fed mice showed extensive demyelination, which was inhibited by ICA treatment. The presence of CFSE-labeled myelin debris in microglia was observed under immunofluorescence, and the phagocytosis of myelin debris by microglia was enhanced by ICA intervention. Microglia mediated TREM2 receptors to promote phagocytosis, and partially affected the TLR4/NF-κB and Nrf2/HO-1 signaling pathways, reducing neuroinflammation and oxidative stress in the brain. The same result was verified in the in vitro BV2/BMDMs experiment, thereby promoting the repair of myelin sheath.

Conclusions:: ICA effectively promotes the phagocytosis of myelin debris by microglia, and reduces oxidative stress and inflammation, thereby inhibiting the loss of myelin. (NNSF of China 81473577, 81471412, 82004028; Natural Fund Project of Shanxi Province 201901D111334, 201901D211538; Shanxi University of Chinese Medicine 2018TD-012. Ma and Xiao are corresponding authors)
THE PSYCHOLOGICAL EFFECT OF COVID19 PANDEMIC ON NEUROMYELITIS OPTICA SPECTRUM DISORDER PATIENTS AND THEIR ATTITUDE CHANGE DURING THE PANDEMIC, AFTER A YEAR.

Roshanak Mehdipour¹, Fereshteh Ashtari²
¹Isfahan Neuroscience Research center, Isfahan University of Medical science, Kashani Hospital MS clinic, Neurology, Isfahan, Iran. ²Isfahan Neuroscience Research Center, Kashani Research Institute, Isfahan University of Medical Science, Isfahan, Iran

Background and Aims:: Coronavirus 2019 is a new coronavirus that created a pandemic with high mortality. NMOSD patients are more affected by psychological effects of COVID19 pandemic such as anxiety since they may be worried to be prone to infection (due to the nature of disease and its treatment by immunosuppressants).

Methods:: The aim of study was to evaluate the anxiety and fear due to COVID19 infection 3 and 12 months after beginning of epidemic. Study was done in patients of NMOSD Clinic of Kashani hospital, Isfahan. We asked them if they are anxious or afraid of the pandemic subjectively. To investigate the objective level of anxiety, Hospital Anxiety and Depression Scale questionnaire was filled. Also we asked them about respecting general cautions and sanitary protocols to prevent infection. The steps repeated after nine months.

Results:: 120 patients (96 female) with mean age of 36.37±9.69 and mean duration of disease about 8.49±5.35 years enrolled. 96 patients (80%) experienced anxiety during the first 3 months of pandemic. The point is that their level of anxiety decrease significantly with the prolongation of pandemic and just 66 patients (55%) showed anxiety on the second survey. Respecting preventive majors increase in the same period (wearing mask from 86.66% to 100%, social distancing from 75% to 90%, hand washing from 85% to 91.66%).

Conclusions:: Along with pandemic prolongation, level of anxiety had been decreased gradually. But the level of alertness and attention is almost high because they respect the sanitary rules and preventive disciplines more. It should be considered that awareness must be preserved till the end of epidemic.
ANTI-HBS TITERS ARE NOT DECREASED AFTER TREATMENT WITH ORAL CLADRIBINE IN PATIENTS WITH MULTIPLE SCLEROSIS VACCINATED AGAINST HEPATITIS B VIRUS

Doriana Landi¹, Carolina Nicoletti¹, Giovanni Di Mauro¹, Gaia Cola¹, Alfonso Grimaldi¹, Giorgia Mataluni¹, Girolama Marfia²
¹University of Tor Vergata, Multiple Sclerosis Clinical And Research Unit, Department Of Systems Medicine, Rome, Italy, ²IRCCS Neuromed, Unit Of Neurology, Pozzilli (IS), Italy

Background and Aims:: Oral cladribine is a novel treatment for Multiple Sclerosis (MS). It is a purine nucleoside antimetabolite analogue that incorporates into the DNA, resulting in single-strand breaks in DNA and apoptosis of replicating lymphocytes. Specifically, Cladribine induces limited depletion of CD4 and CD8 T subsets and a more marked depletion of memory B cell subsets. Therefore, natural and acquired humoral response against pathogens may be potentially impaired. The aim of this study was to assess longitudinal variation of antiHBs titers in patients with MS treated with Cladribine.

Methods:: Patients with MS treated with 1 cycle of Cladribine (3,5 mg/kg) and previously vaccinated against Hepatitis B virus (HBV) were enrolled. Anti-HBs titers were compared pre and after 12 months from Cladribine treatment. Total lymphocyte count was also analysed.

Results:: Among the 14 RMS patients (11 F, mean age 33,7 SD 7) enrolled, all had anti-HBs titers >10 mg/dl at baseline. Anti-HBs titer dropped below the reference value (<10 mg/dl) at 12 months after Cladribine only in 1 case. Pre-post Cladribine mean anti-HBs values were not significantly different considering the whole cohort (Wilcoxon-Mann-Whitney Test p=0,76). Four patients had grade 1 and 1 patient grade 2 lymphocytopenia at 12 months.

Conclusions:: Cladribine does seem to reduce humoral immune responses in subjects previously vaccinated against HBV, even in case of drug-induced lymphocytopenia. These results, if confirmed in larger populations, appear reassuring also for other vaccinations (i.e. COVID19). The low impact of Cladribine on plasma cells may explain such findings.
GINKGO K PROMOTES THE PHAGOCYTOSIS OF MYELIN DEBRIS BY ASTROCYTES VIA REBALANCING TLR4 AND ABCA1 SIGNALING PATHWAYS

Xiao-Hui Li¹, Qiang Miao¹, Ru-Heng Wei¹, Min-Fang Guo², Jing-Wen Yu², Guo-Bin Song², Qing Wang¹, Li-Juan Song¹,³, Jian-Jun Huang⁴, Dong Ma⁴, Bao-Guo Xiao⁵, Cun-Gen Ma¹,²,³
¹Shanxi University of Chinese Medicine, Research Center Of Neurobiology / The Key Research Laboratory Of Benefiting Qi For Acting Blood Circulation Method To Treat Multiple Sclerosis Of State Administration Of Traditional Chinese Medicine, Jinzhong, China, ²Shanxi Datong University, Institute Of Brain Science / Shanxi Key Laboratory Of Inflammatory Neurodegenerative Diseases, Datong, China, ³Shanxi Medical University, Physiology/urology, Taiyuan, China, ⁴General Hospital of National Medicine and Datong Coalmine, Neurosurgery, Datong, China, ⁵Fudan University, Institutes Of Brain Science And State Key Laboratory Of Medical Neurobiology, Shanghai, China

Background and Aims:: Ginkgolide K (GK), a novel compound extracted from Ginkgo biloba, showed the ability to protect myelin sheath via promoting the phagocytosis of myelin debris by astrocytes, but the potential mechanisms are unknown. Our aim was to investigate the cellular and molecular mechanisms of GK on the phagocytosis of myelin debris by astrocytes.

Methods:: Primary astrocytes were cultured, and purified from newborn mouse. After incubation with CFSE-labeled myelin debris under the presence or absence of GK (50 μg/ml) for 24 hours, phagocytosis of myelin debris by astrocytes was detected with SpectraMax iD3. Then, pretreated with LPS or glibenclamide for 2 hours, astrocytes were incubated with CFSE-labeled myelin debris under the presence or absence of GK again. Relevant cytokines and proteins were detected by ELISA, western blot and immunohistochemistry, respectively.

Results:: The results showed that astrocytes contained CFSE-labeled myelin, which triggered the activation of TLR4 and inflammation response. GK treatment improved the phagocytosis of myelin by astrocytes, accompanied by an inhibition of inflammatory cytokines and TLR4 signaling, but an enhancement of neurotrophic molecules and ABCA1 signaling. Pretreatment with LPS or glibenclamide resulted in decline of the phagocytosis of myelin by astrocyte, and GK treatment promoted myelin uptake by astrocytes after a pretreatment with LPS, but had no influence on myelin uptake after a pretreatment with glibenclamide.

Conclusions:: GK could effectively promoted the phagocytosis of myelin debris by astrocytes via rebalancing TLR4 and ABCA1 signaling pathway. (NNSF of China 81473577, 81971194. Ma and Xiao are corresponding authors).
FULMINANT ACUTE DEMYELINATING ENCEPHALOMYELITIS (ADEM) WITH COEXISTING CEREBRAL VENOUS SINUS THROMBOSIS (CVT) IN PREGNANCY – AN UNUSUAL PRESENTATION

Kasun Udenika, Bimsara Senanayake
National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

Background and Aims:: Acute demyelinating encephalomyelitis (ADEM) is commoner in children than in adults. Pregnancy, a pro-thrombotic state is known to cause cerebral venous sinus thrombosis (CVT). ADEM is rare in pregnancy and its diagnosis can be challenging. Both ADEM and CVT occurring simultaneously in pregnancy are rare. We report such an unusual case.

Methods:: A 20 year old female presented in the second trimester of her pregnancy with headache, right hemiparesis, seizures and rapidly deteriorating level of consciousness. Examination revealed right side hemiparesis with a Glasgow coma scale of 8 out of 15. MRI brain showed bilateral asymmetrical signal changes involving cortical and subcortical regions of the brain with no clear evidence of cerebral venous sinus thrombosis. She deteriorated over the ensuing days and a repeat NCCT brain showed diffuse cerebral oedema. As most of her routine investigations including blood, serum, urine, inflammatory markers, CSF studies, autoimmune encephalitis antibody panel and anti-phospholipid antibody screening were normal she was subjected to a craniotomy with brain biopsy.

Results:: She was treated with intravenous antibiotic, acyclovir, steroid and anti-coagulated with low molecular weight heparin. Because of the deteriorating clinical state her pregnancy was terminated. She finally succumbed to her illness in spite of all interventions. Post-mortem revealed extensive cerebral venous thrombosis and histology of the brain revealed features consistent with ADEM.

Conclusions:: Fulminant ADEM in pregnancy is rare and the clinical presentation can vary. High degree of suspicion and advanced imaging are needed for an early diagnosis. When fulminant ADEM occur simultaneously with CVT the prognosis is poor.
Background and Aims:: Neurofibromatosis type 1 (NF1) is an autosomal dominant neurocutaneous disease which confers an increased risk of malignant tumour. NF1 is one of the most common autosomal dominant genetic disorders. Relapsing remitting multiple sclerosis (RRMS) is an inflammatory demyelinating disease of the central nervous system. The coexistence of multiple sclerosis and NF1 is rare but has been reported. We describe the case of a man with NF1 and RRMS successfully treated with natalizumab.

Methods:: The coexistence of RRMS and NF1 is very rare but has been described in the literature. The patient was studied with contrast enhanced brain and spine MRI as well as lumbar puncture. Treatment option discussed.

Results:: MRI imaging showed multiple supra- and infra-tentorial demyelinating lesions. In addition, multiple focal alterations with both centromedullary and peripheral distribution in C1, C2, C5 and D3 in the cervical and dorsal spinal cord were seen. The CSF analysis showed presence of oligoclonal IgG bands. A formal diagnosis of MS was made. After a course of metilprednasonolone 1000mg i.v. for 5 days, therapy with intravenous natalizumab 300 mg every 6 weeks was started (JCV index above 1.5).

Conclusions:: Natalizumab therapy resulted in an excellent disease control with a 2 point reduction in the disability, while minimizing the risk of possible oncogenic effects on NF1 triggered by immunosuppressants. No relapses were detected at 24 months. Due to the elevated JCV index, a DMT shift may be needed in the short-term. This will expose patients to risk of MS rebound and challenge the physician decision-making process.
PREVALENCE OF INSULIN RESISTANCE AND DYSLIPIDEMIA IN MULTIPLE SCLEROSIS AND ITS CORRELATION WITH DISEASE ACTIVITY

Saravana Sukriya1, Dheeraj Khurana2, Sanjay Bhadad3, Paramjit Singh4, Sucharita Ray5
1Postgraduate Institute of Medical Education and Research (PGIMER), Neurology, Chandigarh, India, 2PGIMER, CHANDIGARH, Neurology, CHANDIGARH, India, 3PGIMER, Endocrinology, CHANDIGARH, India, 4Post Graduate Institute of Medical Education and Research, Radiodiagnosis And Imaging, Chandigarh, India, 5PGIMER, Chandigarh, Neurology, Chandigarh, India

Background and Aims:: BACKGROUND Insulin resistance (IR) and dyslipidemia have been described as comorbidity in multiple sclerosis (MS) contributing to disease progression and disability. AIMS To study the prevalence of IR and dyslipidemia in a North Indian cohort of MS patients and its correlation with disease activity.

Methods:: METHODS Fifty relapsing remitting MS patients aged 15 – 55 years fulfilling the 2017 modified Mc Donald criteria and fifty age- and sex-matched healthy controls were recruited. Fasting blood glucose, insulin, glycated hemoglobin and lipid levels were done at baseline for all participants and at one year follow-up for patients. IR was calculated by Homeostatis Model Assessment (HOMA - IR). The disease activity and disability were assessed by magnetic resonance imaging (MRI) of brain and spinal cord using the demyelination disease protocol, and Expanded Disability Status Score (EDSS), respectively at baseline and after one year follow-up. Descriptive statistics was used.

Results:: RESULTS The mean age of patients was 32.3±7.9 years and mean BMI was 24.8±2.8 kg/m². The mean baseline EDSS was 2.8±1.4. The prevalence of IR and dyslipidemia were 70% and 92% of patients respectively. Low HDL was the most common abnormality seen in 82.6%(38/46) followed by raised levels of LDL seen in 60.9% (28/46) of patients. IR and dyslipidemia did not correlate with EDSS and MRI lesion load at baseline and at one-year follow-up.

Conclusions:: CONCLUSION Insulin resistance and dyslipidemia were prevalent among MS patients and did not correlate with disease activity.
OCRELIZUMAB TREATMENT IN MULTIPLE SCLEROSIS: PROSPECTIVE REAL WORLD OBSERVATIONAL MULTI-CENTER STUDY IN CAMPANIA, ITALY

Background and Aims:: We aimed at exploring potential impact of early ocrelizumab introduction and its efficacy on disability accrual in multiple sclerosis patients.

Methods:: We included relapsing remitting or active secondary progressive MS patients treated with Ocrelizumab. Including patients with at least one-year follow-up we assessed the association between baseline clinical features and treatment efficacy through multilevel-mixed analysis.

Results:: We included 89 relapsing and 294 progressive patients (205 Female, mean age: 45.8 ± 11.2, disease duration: 12.7 ± 11.6 years), with 217 patients followed up for more than 12 months. Both relapsing and progressive patients showed an increased EDSS at baseline compared to the year before ocrelizumab start (coeff. = 0.18, 95%CI=0.30 – 0.34, p=0.02; coeff. = 0.28, 95%CI=0.18 – 0.37, p<0.001) while no further increase was observed after 1 year. Patients naive to DMTs showed a decreased EDSS one year after ocrelizumab treatment compared with EDSS at baseline (relapsing: coeff. = -0.29, p=0.02; progressive: coeff. = -0.33, p=0.01). Patients with a time from conversion shorter than 5 years showed an increased EDSS between one year before ocrelizumab start and baseline (coeff. = 0.42, 95%CI=0.12 – 0.72, p=0.005), with no EDSS increase in the following year (p=0.38).

Conclusions:: We observed that better responders to ocrelizumab were naïve patients and those with a time from conversion shorter than 5 years. The present study highlighted the need to treat patients as early as possible to be able to affect disease trajectory in the therapeutic window.
TRANSCUTANEOUS SPINAL CORD STIMULATION (TSDCS) IN MULTIPLE SCLEROSIS

Simona Mrakic-Sposta¹, Roberta Ferrucci², Alessandra Vezzoli¹, Stefano Floro², Maurizio Vergari³, Milena Deriz⁴, Marta Parazzini⁵, Alberto Priori²

¹National Research Council, Institute Of Clinical Physiology (cnr-ifc), Milan, Italy, ²III Clinical Neurology Unit, Polo Universitario Ospedale San Paolo, ASST Santi Paolo e Carlo, Department Of Health Sciences, University Of Milan, Milan, Italy, ³Foundation IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy, U.O. Neurophysiology, Milan, Italy, ⁴Foundation IRCCS Ca’ Granda Ospedale Maggiore Policlinico, U.O. Of Neurology, Milan, Italy, ⁵National Research Council, Institute Of Electronics, Computer And Telecommunication Engineering (ieiit), Milan, Italy

Background and Aims:: Multiple Sclerosis (MS) is a multifactorial disease of the Central Nervous System in which both inflammatory and neurodegenerative processes occur simultaneously. Over the past few years, several studies suggest positive effects of non-invasive neuromodulation in MS. We therefore aim to investigate in patients with MS the clinical effects of transcutaneous spinal direct current stimulation (tsDCS) and potential mechanisms of action on neuroinflammation through the assessment of biomarkers for oxidative stress and inflammation.

Methods:: 7 subjects (5 men; aged 42-70), with MS and spasticity were studied. We delivered anodal and sham tsDCS (2mA, x 20 minutes) once a day, for 5 days consecutively. One electrode was positioned over the spinal process of the tenth thoracic vertebra and the other above the right shoulder. In each session, clinical and biochemical measures were administered before the treatment (baseline), on day five (T1) and after 1 month (T2).

Results:: After anodal tsDCS our results showed a decrease of ROS production rate (umol.min⁻¹; p<0.05; -6%) and an increase in antioxidant Capacity (TAC; mM; p<0.05; +4%), while sham tsDCS failed to induce changes. Besides, an increase in total and reduced Glutathione (GSH; umol.L⁻¹) can suggest an antioxidant effect of DC current. At T2 Ashworth scale improved by about 42% and MS spasticity scale about 17%.

Conclusions:: Anodal tDCS, over the spinal process, seems to induce an antioxidant effect, in MS patients. This pilot study has demonstrated a possible therapeutic role of tsDCS. However, to confirm our data, a larger sample size is needed.
CLINICAL PREDICTORS OF THE BENIGN COURSE OF MULTIPLE SCLEROSIS IN A MEDICALLY UNDERSERVED POPULATION

Alina Ivaniuk, Tetiana Marusich, Iuliia Solodovnikova, Tetiana Muratova
ONMedU, Neurology And Neurosurgery, Odessa, Ukraine

Background and Aims: Benign multiple sclerosis (MS) is characterized by little disability accumulation over the disease course. The majority of contributions to understanding the predictors of benign MS come from high-income areas; it is unknown whether the same predictors can be derived from the resource-limited populations that have limited access to proper diagnostics and management. We aimed to study clinical predictors of benign MS in individuals with relapsing-remitting (RR) course coming from underserved areas.

Methods: This retrospective study used clinical data of 55 residents of underserved areas with RR-MS with a minimal disease duration of 10 years. The benign course was defined as EDSS ≤ 3.0 after 10 years from MS onset. Binominal logistic regression was used to study the association between the benign course of MS and sex, smoking, diagnostic errors at disease onset, time to the establishment of the diagnosis, disease-modifying therapy, and EDSS, symptoms and age at MS onset.

Results: Of 55 patients (average disease duration 28.47±9.5 years), 16 (29%) had a benign course. Lower EDSS at onset was the only factor associated with benign RR-MS (OR 0.56, 95%CI 0.35-0.8, p=0.005).

Conclusions: EDSS at the disease onset was the only determinant of benign RR-MS course in our cohort; while this predictor is consistent with the available literature data, other factors turned to be nonpredictive, which may be explained by a small sample. Further studies are needed to address this question.
MRI CHANGES IN EARLY STAGES OF NMOSD AMONG THE POPULATION OF UZBEKISTAN

Shokhijakhon Shokhimardonov, Kuzieva Shakhnoza
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: Early diagnosis of Neuromyelitis optica spectrum disorders (NMOSD) is critical. Unlike multiple sclerosis, NMOSD episodes are normally quite severe. These episodes can lead to irreversible consequences. The diagnosis of NMOSD is based on the presence of evidence of optic neuritis and transverse myelitis. Study additional findings in early MRI scans could play important role in early diagnosing and treatment course.

Methods:: We retrospectively analyzed the results of MRI scanning among 45 patients in the Tashkent Medical Academy Neurology Department with a diagnosis NMOSD.

Results:: The results of MRI study demonstrated a high incidence of involvement of the brain stem (44%) and hemispheres periventricular white matter (21%) at the time of disease clinical debut. Lesions involving corticospinal tracts and diencephalic region was find only in one patient (2.2%).

Conclusions:: This study confirms that early MRI diagnosing results among patients with NMOSD in Uzbekistan usually demonstrate involve-ment of the brainstem and hemispheres periventricular white matter.

Of Neuroscience And Rehabilitation, Interdepartmental Research Center For The Study Of Multiple Sclerosis And Inflammatory And Degenerative Diseases Of The Nervous System, Ferrara, Italy

Background and Aims:: Little is known about the environmental risk determinants in POMS, although evidences support an increased susceptibility related to a gene-environment interaction. An Italian multicenter case-control study (the PEDIGREE study) has been launched to investigate the environmental component and the PEDIGREE Questionnaire (PEQ-IT) aims to collect relevant information on past exposures in POMS. To better understand the role played by environment in determining POMS, a new validated tool is presented.

Methods:: PEQ-IT was developed through translation and adaptation of a questionnaire used in POMS U.S. studies and was tested for relevance, acceptability, feasibility and reliability through a pilot study. This phase was conducted in a population of pediatric subjects and their parents recruited from pediatric clinics and general population from five Italian participating sites.

Results:: PEQ-IT achieved good level of relevance, excellent levels of acceptability and feasibility, and reliability was rated as at least moderate in all sections.

Conclusions:: PEQ-IT represents an effective vehicle for collecting information on a potentially highly informative disease as to the role of environmental exposures in generating susceptibility to MS. Our results suggest that PEQ-IT should be administered through interview or in presence of the researcher, so as to ensure good quality of data. We believe that the development, pilot testing and dissemination of research tools could optimize efforts and ensure greater comparability of evidence in epidemiological research. The study received funds from the Italian Multiple Sclerosis Foundation (Fondazione Italiana Sclerosis Multipla, FISM, Genoa, Italy), grant n. Prot. N. 12/18/F14 (P.I. Angelo Ghezzi).
THE COVID-19-RELATED QUALITY OF LIFE CHANGES IN PATIENTS WITH MULTIPLE SCLEROSIS

Khryystyna Duve, Svitlana Shkrobot
Ternopil National Medical University, Neurology, Ternopil, Ukraine

Background and Aims:: Multiple sclerosis (MS) is a chronic disease affecting the central nervous system. The aim of the study was to evaluate the quality of life (QOL) of patients with relapsing-remitting MS, who suffered from Covid-19 disease.

Methods:: Methods. We examined 48 patients (31 - women and 17 – men). The QOL was evaluated by the questionnaire SF-36. The mean age was 38 ± 18 years. The average disease duration was about 8.32 ± 11.54 years and the EDSS score was 3,1 ± 1.7. Confirmed Covid-19 was diagnosed in 27 of patients (PCR or retrospective IFA-test). The QOL results of those who had Covid-19 were compared to those who were not infected (control group).

Results:: Results. The SF-36 results were the following: physical functioning - (33,30 ± 2,33) points against (53,00 ± 3,67) in the control group (p <0,01), physical role functioning - (15,25 ± 2,57) and (61,73 ± 5,84) (p <0,01), bodily pain - (34,26 ± 1, 85) scores and (51,25 ± 5,48) (p <0,05), general health - (21,91 ± 1,36) points against (41,80 ± 2,64) ( p <0,05), vital activity - (41,43 ± 1,64) scores and (65,50 ± 2,34) (p> 0,05), social functioning - (52, 12 ± 1,80 points and (68,14 ± 3,81) (p> 0,05), emotional role functioning - (26,81 ± 3,08) and (48,02 ± 7, 42) scores (p <0,05), mental health - (31,54 ± 1,55) points against (51,44 ± 2,65) (p <0,05).

Conclusions:: Conclusions. Thus, a significant quality of life decrease was observed in all subscales except vital activity and social functioning.
Background and Aims:: Fatigue is recognized as a common symptom reported by patients with multiple (MS). His presence has created a new challenge in the management of these patients. Our objective was to assess the impact of fatigue on the various spheres of daily functioning, in particular the physical, cognitive and psychosocial spheres, and to demonstrate the relationship between fatigue and Expanded Disability Status Scale (EDSS).

Methods:: A retrospective study of 60 patients with MS was conducted at the Neurology Department of the Military Hospital of Tunis over a period of 14 years (2015-2019). The form of MS and the Expanded Disability Status Scale (EDSS) were collected. Fatigue was measured using the Fatigue Severity Scale (FSS). The physical, cognitive and psychosocial impact was assessed by the Fatigue Impact Scale (EMIF-SEP).

Results:: Among the 60 patients, 39 suffering from fatigue, with an average FSS score of 4.67. The mean score of EMIF-SEP is 65.36 / 100. Higher EMIF-SEP total scores were associated with higher EDSS. There were also higher physical and psychological subscale scores of EMIF-SEP linked to higher EDSS.

Conclusions:: Fatigue can interfere in daily functioning of patients with MS. This impact justifies the particular interest given to this symptom to find various management strategies.
Background and Aims:: Background and goals. The immune system dysfunction in MS patients are accompanied by the production of autoantibodies to neurotransmitters. The relationship between the level of AT to serotonin (ATC), norepinephrine (ATH), and histamine (ATG) and the clinical signs of MS was evaluated.

Methods:: The level of AT in the blood serum in conventional units (CU) of optical density was measured by a sensitive electro-optical method. Were examined 38 MS patients, control group (CG) of 20 patients with non-autoimmune diseases of the nervous system and 20 donors (D).

Results:: The level of ATG in MS patients was Me -0.452 CU, which is significantly higher than in the CG and D groups (p< 0.05). There was a significant increase in ATG to Me- 0.497+0.002 CU as a possible marker of inflammation in the period of recovery from exacerbation in the remitting course of MS. There was a statistically significant increase in the level of ATN in patients with MS Me-27.0 CU, in comparison with CG and D. The lowest ATN indicators are characteristic of: the stage of remission of MS Me-24.5 CU and in the group of MS with stress-inducing mechanisms of development Me-23.0 CU. The level of ATC in MS patients was Me-18.3 CU, which is 4.0-4.4 times higher than in CG and D. There was an increased level of ATC in MS patients with severe damage to the sensory system.

Conclusions:: The results indicate the significance of neuroimmunopathological disorders in MS and may be an additional marker of the clinical features of MS.
DISTURBANCE OF SEROTONERGIC REGULATION OF HEMATOPOIETIC STEM CELLS (HSCS CD 34+) AND BLOOD MONONUCLEAR CELLS (BMCS) IN PATIENTS WITH MULTIPLE SCLEROSIS (MS),

Sergey Makarov, Oksana Berezhnaya, Anna Nikolaeva
Center for Bone Marrow Transplantation of the Samara Regional Clinical Hospital named after V. D. Seredavin, Hematology, Samara, Russian Federation

Background and Aims:: Background and goals. Serotonin is involved in the mechanisms of regulation of the function of immunocompetent cells through the receptor apparatus. The aim of the study was to evaluate the expression capacity (EC) of BMCs and HSCs under the influence of serotonin - creatine sulfate at a dose of $10^{-4}$ M in the "in vitro" test system (TS). Violation of the receptor apparatus of cells serotonin led to a change in their quantitative registration.

Methods:: We studied BMCs by enzyme immunoassay and ELISA in 86 patients with MS and HSCs in 12 patients. The control group included 16 donors, 12 patients with autoimmune diseases and hemoblastosis (AD).

Results:: In contrast to MS patients, donors showed an increase in the EC of CD3+ and CD8+ cells under the influence of serotonin. In TS, there was a smaller increase of CD16+ cells (p<0.002) with a decrease in their expression capacity, and the number of CD20+ and CD56+ decreased. In TS, patients with AD had lower quantitative values in comparison with MS: CD3+, CD4+, CD8+ cells (p<0.05) MS, except for CD54+ cells. This may indicate the resistance of individual populations of MNCs in MS patients to serotonergic regulation, regardless of clinical signs. Similar phenomena were observed in the HSCs of MS patients. The calculated deviation coefficient in the HSCs test system was 0.12+0.15 at MS, -0.59+0.23 at AD (p<0.05), −0.25+0.4 in donors.

Conclusions:: The observed changes indicate a defect in the serotonergic regulation of BMCs and HSCs in MS and are probably systemic in nature.
THE ROLE OF D2-LIKE DOPAMINERGIC RECEPTORS IN DOPAMINE-MEDIATED MODULATION OF TH17-CELLS IN MULTIPLE SCLEROSIS.

Anna Lopatina¹, Tatiana Solodova¹, Anastasiya Sviridova², Mikhail Melnikov¹, Alexey Boyko²
¹Pirogov Russian National Research Medical University, Department Of Neurology, Neurosurgery And Medical Genetics, Moscow, Russian Federation, ²Federal Center of Brain and Neurotechnology of Federal Medical-Biological Agency of Russia, Department Of Neuroimmunology, Moscow, Russian Federation

Background and Aims:: Dopamine participates in multiple sclerosis (MS) pathogenesis by modulating immune cell activity. This study aimed to clarify the role of dopaminergic receptors in dopamine-mediated modulation of Th17-cells in MS.

Methods:: Thirty-four MS patients and twenty-three controls were examined. To assess the effect of dopamine on Th17-cells, CD4+ T-cells were cultured in the presence of dopamine and stimulated with anti-CD3/anti-CD28-antibodies. To study the involvement of dopaminergic receptors in dopamine-mediated immunomodulation, CD4+ T-cells were pre-incubated with antagonists of D₁- or D₂-like dopaminergic receptors, whereafter dopamine and anti-CD3/anti-CD28-antibodies were added to the cultures. To assess the direct effect of D₂-like dopaminergic receptor activation on cytokine production, some samples of CD4+ T-cells were preincubated with a specific agonist of D₂-like dopaminergic receptors and stimulated with anti-CD3/anti-CD28-antibodies. The levels of IL-17, IFN-γ and GM-CSF in supernatants were assessed by ELISA.

Results:: The production of cytokines was comparable between the groups. Dopamine suppressed cytokine production in both groups (p<0.0001). Blockade of D₁-like dopaminergic receptors did not affect the influence of dopamine on cytokine production, while blockade of D₂-like dopaminergic receptors decreased dopamine-mediated suppression of IL-17, IFN-γ and GM-CSF production in MS patients (p<0.05). Finally, activation of D₂-like dopaminergic receptors reduced cytokine production in both groups (p<0.05).

Conclusions:: These data suggest an inhibitory effect of dopamine on Th17-cells in MS, which could be mediated by the activation of D₂-like dopaminergic receptors. This study was supported by grant from the Russian Science Foundation (project №19-75-00075).
PAROXYSMAL SYMPTOMS IN MULTIPLE SCLEROSIS

Narjes Gouta¹, Mariem Mhiri², Mouna Aissi², Mahbouba Frih²
¹Fattouma Bourguiba hospital in Monastir, Neurology, sousse, Tunisia, ²Fattouma Bourguiba Hospital in Monastir, Neurology, Monastir, Tunisia

Background and Aims:: paroxysmal symptoms are common manifestations of multiple sclerosis (MS). When established as the first clinical manifestation, they can easily be mistaken for transient ischemic stroke. The nature of these paroxysmal phenomena depends on their site of origin, which is usually in the brainstem or spinal cord. Our aim is: To diagnose multiple sclerosis based on atypical manifestations.

Methods:: A 23 year old male was admitted for dystonic movements that date back to 2 years before. The episodes consisted of sustained and involuntary muscular contraction of the right hemibody without facial involvement responsible for an abnormal attitude. A 32 year old female, with a history of postpartum thrombophlebitis of the lower limb, complained of heaviness of the lower limbs and dizziness occurring 1 to 10 times a day and lasting less than a minute. These episodes occurred since 6 months and disappeared after a month.

Results:: for the first patient: Brain MRI showed multiple lesions of the white matter, supra and subtentorial encompassing the corpus callosum, in periventricular and sub cortical regions, with ovoid and radial form, with hyper signal on FLAIR sequences. for the second patient, The brain MRI showed multiple lesions on the supra and infratentorial lesions in addition to the cervical medulla in which there was a gadolinium enhancement. for both, The MS was the most probable diagnosis.

Conclusions:: Establishing new criteria for diagnosing MS in the face of paroxysmal and infrequent symptoms is a dilemma for neurologists, especially for therapeutic management, which remains a paradigm.
Background and Aims:: Multiple Sclerosis (MS) may co-occur in subjects with coeliac diseases (CD). If MS belongs to the CD spectrum is not clear, equally if it shows specific clinical features.

Methods:: We retrospectively analyzed clinical, radiological and genetic variables in 18 MS+CD patients positive for serological, histological and genetic CD markers and 17 MS patients with risk factors for CD (CRF) such as being CD first-degree relatives or complaining CD symptoms, compared to 18 MS and 8 Neuromyelitis optica spectrum disorder (NMOsd) patients.

Results:: Optic neuritis (ON) and myelitis were the most common presentations at disease onset among MS+CD (38.89% and 50%) MS+CRF (24% and 41%) NMOsd patients (50% and 50%), compared to MS (11% and 28%). Using Kruskal-Wallis test and Bonferroni correction, a similar pattern was observed along the disease course for MS+CD compared to MS (84% vs 50%, p<0.011 for myelitis, 50% vs 22%, p=0.227 for ON). Predictive numbers of spinal cord lesions at MRI onset were higher in MS+CD and NMOsd compared to MS patients (p<0.001). Considering the whole population, using a Poisson distribution, HLA DQ2/DQ8 genotypes were significantly associated with myelitis (p<0.002).

Conclusions:: ON and myelitis characterize the clinical phenotype of MS+CD and MS+CRF patients. Screening for CD should be included in differential diagnosis work-up in case of newly diagnosed MS patients predominantly showing these clinical features. Further studies will clarify if MS associated with CD should be considered a new disease entity.
Background and Aims:: Multiple sclerosis is a chronic immune mediated demyelinating disorder involving the central nervous system. The familial recurrence rate is estimated at about 15% and rare in Asia. To the best of our knowledge MS occurring in a mother-son pair has not been reported before either from Sri Lanka or South Asia.

Methods:: Son: A 26 years old male presented with progressive difficulty in walking for 1 year. Examination revealed bilateral spastic paraparesis without sensory involvement and left cerebellar signs. Mother: A 43 years old lady had progressive limb weakness, gait instability and left side visual impairment for 10 years. Both son and mother fulfilled MAGNIMS 2016 MRI criteria and McDonalds 2017 criteria for the diagnosis of MS. Both son and mother were diagnosed with primary progressive MS. MRI of son (Figure 1), MRI of mother (Figure 2) and all other investigations (Table 1) are summarized.
Figure 1: MRI brain and spine of son; (A) T2 sagittal, (B) T2 FLAIR axial, (C) T1 axial images demonstrates numerous T2 high signal T1 low signal white matter lesions arranged perpendicular to the bilateral lateral ventricles suggesting Dawson’s fingers. Lesions involve the corpus callosum, callosal-septal interface and the posterior fossa.

T2 axial image of the orbits (D) shows right optic neuritis.

Cervical spine T2 sagittal (E) and axial (F) images demonstrate multiple short segment T2 high signal lesions without significant spinal cord edema and expansion. Lesions are not contrast enhancing.
Results:: MS is a chronic disabling disease, common among women and median age of onset is 28 to 31 years. Exact cause of MS is yet to be determined and several etiological factors including viral infections like EBV and genetic factors especially variation involving the HLA-DRB1 loci has been postulated. Familial MS is variable in some geographic locations and absent in some ethnic groups.

Conclusions:: MS is thought to be less prevalent in Sri Lanka and the true prevalence is yet to be determined. This case highlights the importance of obtaining a family history in MS and the possibility of MS to running in families.
WUZI YANZONG PILLS RELIEVE CPZ-INDUCED DEMYELINATION BY IMPROVING THE MICROENVIRONMENT IN THE BRAIN

Zhi Chai¹, Hui Jie Fan¹, Meng Ying Sun¹, Yan Rong Li¹, Wu Shuai Xiao¹, Wei Hang¹, Lu Jia¹, Qing Wang¹, Jian Jun Huang², Jie Zhong Yu³, Bao Guo Xiao⁴, Cun Gen Ma¹,³
¹Shanxi University of Chinese Medicine, The Key Research Laboratory Of Benefitting Qi For Acting Blood Circulation Method To Treat Multiple Sclerosis Of State Administration Of Traditional Chinese Medicine And Scientific And Technological Innovation Team Of Integrated Chinese And Western, Jinzhong, China, ²General Hospital of Datong Coalmine Group, General Hospital Of Datong Coalmine Group, Da Tong, China, ³Shanxi Datong University, Institute Of Brain Science- Shanxi Key Laboratory Of Inflammatory Neurodegenerative Diseases, Da Tong, China, ⁴Fudan University, Institute Of Neurology-huashan Hospital-institutes Of Brain Science And State Key Laboratory Of Medical Neurobiology, Shanghai, China

Background and Aims:: Wuzi Yanzong Pills(WYP) can be used to treat neurological diseases, but its therapeutic effect on multiple sclerosis(MS) is still unclear. To explore the effect of WYP on improving demyelination and its mechanism in the microenvironment.

Methods:: The male C57BL/6 mice were randomly divided into control group, model group and WYP group. The model group and WYP group were fed with 0.2% CPZ feed for 6 weeks, and WYP group was gavaged with WYP(16g·kg⁻¹·d⁻¹) at the end of second weekend, twice a day for 28 consecutive days. Luxol fast blue staining detected the degree of demyelination of the corpus callosum. Western blot detected the protein expression levels of Arg-1 and iNOS in the brain. ELISA detected the content of IL-6, IL-1β, IL-10 and TGF-β in the brain.

Results:: Compared with the control group, the average integral optical density of model group decreased(P<0.0001), the levels of iNOS, IL-6, IL-1β increased(P<0.05,P<0.01, P<0.001), while the levels of Arg-1, IL-10, TGF-β decreased(P<0.05, P<0.01).Compared with the model group, the average integral optical density of WYP group increased(P<0.0001), the levels of Arg-1, IL-10, TGF-β increased(P<0.05, P<0.0001), while the levels of iNOS, IL-6, IL-1β decreased(P<0.05,P<0.01, P<0.001).

Conclusions:: WYP can significantly improve CPZ-induced demyelination, its mechanism may be related to reducing the inflammatory environment in the central nervous system.(Grants: NNSF of China 81102552 and 81703978,Central Government Guided Local Funding Projects for Science and Technology Development YDZX20201400001483,Key Research and Development Projects of Shanxi Province 201803D31209,Shanxi University Science and Technology Innovation Project 2019L0724. *corresponding authors: Prof. C.G. Ma or Prof. H.J. Fan)
Background and Aims:: The clinical spectrum of MOG-IgG-associated disease has expanded from pediatrics with acute disseminated encephalomyelitis to adult patients presenting as NMO-SD. It is characterized by significant optic nerve damage and steroid responsiveness. Indian data on this new disease is insufficient. It is important to correctly diagnose it as its treatment strategy is different from other demyelinating diseases, particularly MS.

Methods:: 19 adult (Age >12 years) patients who presented to KEM hospital, Mumbai from August 2017 to January 2020 with NMO-SD and were seropositive for MOG-IgG antibodies were prospectively evaluated for clinical and radiologic spectrum and response to treatment.

Results:: 19 patients had 36 attacks. 61.1% (11/18) were males while 38.9% (7/18) were females. 50% (9/18) belonged to age group 20 years to 40 years, 38.9% (7/18) were from 12 years to 20 years age group and only 11.1% (2/18) patients were above 40 years of age. 22.2% (4/18) had only optic neuritis, 16.7% (3/18) presented with only LETM, 5.5% (1/18) with brainstem demyelination and 27.8% (5/18) with cortical lesions. 22.2% (4/18) had LETM and optic neuritis. 61.1% (11/18) had monophasic and 38.9% (7/18) had a relapsing course. 55.6% (10/18) patients had optic neuritis either alone or in combination with others. 22.2% (4/18) patients had bilateral optic nerve involvement. Patients with h/o recurrent episodes had no further episode on immunosuppression at mean follow up of 12 months.

Conclusions:: MOG-IgG associated disease is a novel NMO-SD. Optic neuritis is the most common presentation. Monophasic illness is more common than relapses suggesting better prognosis compared to other demyelinating diseases.
AN INTRIGUING CASE OF COMBINED CENTRAL AND PERIPHERAL DEMYELINATION

Shruti Agrawal¹, Sangeeta Ravat¹,², Neeraj Jain¹, Piyush Anshu³, Gajanan Panandikar¹, Karan Desai¹
¹Seth GSMC and KEM hospital Mumbai, Neurology, Mumbai, India, ²Professor Seth GS Medical College and KEM Hospital, Neurology, Mumbai, India, ³KEM HOSPITAL, Department Of Neurology, Mumbai, India

Background and Aims:: It is extremely rare to see combined central and peripheral nervous system demyelination. We are reporting this case of central demyelination in a case of multifocal acquired demyelinating sensorimotor neuropathy (MADSAM). After thorough review of literature, it is the first case report from India.

Methods:: A 28 years old male presented with 1.5 months history of progressive right upper and lower limb tingling and weakness followed by left hand tingling. There was no history of bladder or cranial nerve involvement. On examination patient had distal more than proximal weakness of right upper and lower limb with right hand wasting. All the DTRs were diminished and bilaterally plantars were extensor. Bilateral greater auricular, ulnar and radial nerves were thickened. He had positive Rhomberg’s with no cerebellar signs. Gait was normal.

Results:: NCS was suggestive of asymmetric multifocal demyelinating sensorimotor polyneuropathy affecting all four limbs. CSF showed 124 mg% protein with no cells. MRI Brain and spine was done in view of extensor plantar response. There were T2/Flair hyperintense lesions in periventricular white matter and mildly contrast enhancing lesions in left occipital, cerebellum, pons, patchy in cervical and thoracic cord. CSF OCB was negative, IgG index was normal. Serum NMO antibody was negative. Patient improved with IV pulse steroid followed by 3 months course of oral steroids and is stable on azathioprine.

Conclusions:: This is an intriguing case of classical MS- like central demyelinating disease presenting with peripheral demyelination i.e. MADSAM. The pathophysiology needs to be determined.
SAFETY AND EFFECT OF DIMETHYL FUMARATE ON WHITE AND GREY MATTER PATHOLOGY IN PATIENTS WITH MULTIPLE SCLEROSIS

Damiano Marastoni, Francesco Crescenzo, Anna Pisani, Carmela Zuco, Gian Marco Schiavi, Marco Pitteri, Francesca Pizzini, Massimiliano Calabrese
University of Verona, Department Of Neurosciences, Biomedicine And Movement Sciences, Verona, Italy

Background and Aims: To evaluate the safety and efficacy of dimethyl fumarate (DMF), a disease-modifying drug for the treatment of relapsing-remitting multiple sclerosis (RRMS), on both white and cortical and deep grey matter (GM) pathology.

Methods: A 2-year prospective study was performed on 177 RRMS patients treated with DMF and 47 untreated age and sex-matched patients. Patients underwent clinical evaluations, including Expanded Disability Status Scale (EDSS) assessment and a 3T-MRI at baseline, after 12 and 24 months. White and grey matter lesion load, brain volume change (PBVC), global and regional cortical thickness and deep grey matter volume changes were calculated.

Results: One-hundred forty-seven patients treated with DMF completed the follow-up. No severe reactions occurred; 4 patients developed severe, not confirmed, lymphopenia (<500/mm³). DMF led to lower incidence of relapses (14% vs 40%, p < 0.001), disability accumulation (EDSS change 0.1 ± 0.4 vs 0.4 ± 0.5, p < 0.001) and reduced white matter (0.4 ± 0.9 vs 2.6 ± 1.9, p < 0.001) and cortical lesions (CL) accumulation (0.2 ± 0.6 vs 1.9 ±1.6, p < 0.001). Among treated patients, 71% reached the NEDA-3 status and 18% the NEDA-4 status (cut-off for PBVC of 0.4%), with a mean annual PVBC of -0.55 ± 0.21%. Global and regional thickness and volumes changes were lower in treated patients (p < 0.001). Cox regression analysis showed younger age (HR 0.96[0.93-0.99], p 0.03) and higher EDSS (OR 1.32[1.06-1.66], p 0.01) as predictors of disease activity. CL number associated with annualized PBVC (β-1.46x10^-4, p 0.0343).

Conclusions: A significant effect of DMF on the progression of both focal and diffuse GM damage was noticed.
Background and Aims:: WYP has a potential therapeutic effect on EAE Mice, but the mechanism is not clear. To investigate the therapeutic effect of WYP on EAE mice and its effect on ERS.

Methods:: Mice were randomly divided into normal, model and WYP groups. EAE model was established by MOG\textsubscript{35-55}. From the third day after immunization, 25 days of drug intervention. The neurological function scores were recorded daily. On the 28th day after immunization, the spinal cord samples of mice were collected. The infiltration of inflammatory cells and the degree of demyelination in spinal cord tissues were observed by hematoxylineosin staining and Luxol fast blue staining method. The expressions of GRP78, GRP94, p-PERK, p-IRE1\textalpha, p-JNK, Caspase-12 and CHOP were detected by Western blot. The expressions of ATF6\textalpha was detected by fluorescence PCR.

Results:: The model group of the neurological function score increased (P<0.05), the degree of inflammatory infiltration and demyelination increased (P<0.01), the expressions of GRP78, GRP94, p-PERK, p-IRE1\textalpha, ATF6\textalpha, p-JNK, Caspase-12 and CHOP increased (P<0.05, P<0.01). The WYP group of the neurological function score decreased (P<0.05), the degree of inflammatory infiltration and demyelination decreased (P<0.05, P<0.01), the expressions of GRP78, GRP94, p-PERK, p-IRE1\textalpha, ATF6\textalpha, p-JNK, Caspase-12 and CHOP decreased (P<0.05, P<0.01).

Conclusions:: The effect of Wuzi Yanzong Pill on EAE may be related to reduce the activation of ERS-mediated pro-apoptotic pathways by down-regulating sustained ERS response. (Grants: NNSF of China 81102552 and 81703978, Central Government Guided Local Funding Projects for Science and Technology Development YDZX20201400001483. *corresponding authors: Prof. C.G. Ma or Prof. H.J. Fan)
MICROBIOME SIGNATURE IN MULTIPLE SCLEROSIS IN NORTH INDIA

Gurkeerat Kaur1, Dheeraj Khurana1, Ranjana Minz2, Usha Dutta3, Pallab Ray4, Paramjeet Singh5, Poonam Khanna6, Rajesh Pandey7, Deepak Sharma8
1Postgraduate Institute of Medical Education and Research (PGIMER), Neurology, Chandigarh, India, 2Postgraduate Institute of Medical Education and Research (PGIMER), Immunopathology, Chandigarh, India, 3Postgraduate Institute of Medical Education and Research (PGIMER), Gastroenterology, Chandigarh, India, 4Postgraduate Institute of Medical Education and Research (PGIMER), Medical Microbiology, Chandigarh, India, 5Postgraduate Institute of Medical Education and Research (PGIMER), Radio-diagnosis & Imaging, Chandigarh, India, 6Postgraduate Institute of Medical Education and Research (PGIMER), Community Medicine And School Of Public Health, Chandigarh, India, 7CSIR-Institute of Genomics and Integrative Biology (CSIR-IGIB), Integrative Genomics Of Host-pathogen (ingen-hope) Laboratory, New Delhi, India, 8CSIR-Institute of Microbial Technology (CSIR-IMTECH), G. N. Ramachandran Protein Centre (gnrpc), Chandigarh, India

Background and Aims:: Background: Gut microbiome dysbiosis has been associated with many disorders including Multiple Sclerosis (MS) through bi-directional gut-brain axis. In western studies, characterization of gut microbiota in MS is well established but the differential effect of Indian diet in disease process of MS is yet to be explored. This ongoing study aims to study the gut microbiome in North Indian MS patients. Objective: To characterize the gut microbiota in North Indian MS patients and correlate it with disease activity.

Methods:: Relapse remitting MS (RRMS) patients (both naïve and on-treatment with disease modifying therapies), 18-60 years of age are being recruited. Major inclusions are RRMS patients with an Expanded Disability Status Score (EDSS) < 5.5 and exclusions are progressive forms of MS and no associated comorbidities. Stool samples have been stored at -80°C for further processing for DNA isolation and microbiome characterisation by 16S rRNA sequencing. 10 ml blood sample for serum Neurofilament light chain (NfL) assessment and isolation of DNA for HLA (human leukocyte antigen) DR typing.

Results:: 74 RRMS patients and 43 healthy controls have been recruited for the study. Out of total, 61 (82.4%) are RRMS and 13 (17.6%) are Aggressive RRMS patients. The mean (SD) age is 34.50 (8.10) and male:female ratio is 1:2 for recruited RRMS patients. The interim results of this ongoing study will be presented.

Conclusions:: Conclusion: The results of the study will characterize the gut microbiota of North Indian MS patients and its association with Aggressive MS if any.
MYELIN OLIGODENDROCYTE GLYCOPROTEIN (MOG) ANTIBODY TITRES AND RETINAL DEGENERATION IN MOG-ASSOCIATED DISEASE: A SINGLE CENTRE ITALIAN STUDY

Eleonora Rigoni, Silvia Colnaghi, Matteo Gastaldi, Diego Franciotta, Elisabetta Zardini, Silvia Scaranzin, Elena Colombo, Marina Ranzani, Giacomo Greco, Roberto Bergamaschi

1I.R.C.C.S. Mondino Foundation, Multiple Sclerosis Centre, Pavia, Italy, 2I.R.C.C.S. Mondino Foundation, Pavia, Laboratory Of Neuro-otology And Neuro-ophthalmology, Pavia, Italy, 3IRCCS Mondino Foundation, Neuroimmunology Laboratory, Pavia, Italy, 4IRCCS Ospedale Policlinico San Martino, Immunology Laboratory, Genova, Italy, 5University of Pavia, Department Of Brain And Behavioral Sciences, Pavia, Italy, 6IRCCS Fondazione Mondino, Centro Sclerosi Multipla, Pavia, Italy, 7IRCCS Mondino Foundation, Multiple Sclerosis Research Centre, Pavia, Italy

Background and Aims:: Optical Coherence Tomography(OCT) features in patients with Myelin Oligodendrocyte Glycoprotein-antibody associated disease(MOG-AD) are poorly explored. We investigated MOGab titres and OCT features in a cohort of MOG-AD patients.

Methods:: We obtained OCT scans from MOG-AD patients referring to IRCCS Mondino Foundation(Pavia). Patients were divided in two groups, according to MOGab titres at disease onset: low-titre-LT(≤1:640) and high-titre–HT(≥1:1280). We retrospectively collected clinical characteristics at disease onset and compared retinal nerve fiber layer(RNFL) and ganglion cell layer(GCL) thicknesses among the two groups.

Results:: Our cohort was made up of 7 patients(male/female: 1/6). Mean age was 36 years(SD 10.2). At disease onset, optic neuritis(ON) occurred in 5/7 patients, and 2 patients experienced myelitis. Four/7 patients belonged to LT group. OCT was performed at a mean follow-up time of 5 years(SD 3.6) from disease onset. Mean RNFL thickness was similar between LT and HT(92.5 µm vs 92.1, respectively), while mean GCL was lower in the HT group(72 µm) vs. LT(81 µm). Considering 5 eyes with history of ON, mean RNFL and GCL thicknesses were lower in HT(RNFL 82.5 µm, GCL 70 µm) than in LT(RNFL 86 µm, GCL 77 µm). Among 7 unaffected eyes, RNFL thickness was similar between groups(96 µm in LT vs. 98 µm in HT), while GCL thickness was lower in HT(74 µm) than in LT group(84 µm).

Conclusions:: MOGab titres at disease onset are related to retinal damage, even in patients without history of optic neuritis, thus reflecting a subclinical neuronal degeneration. GCL parameter could be considered more reliable than RNFL in assessing retinal damage.
Background and Aims:: In Multiple sclerosis (MS) the “rebound” of disease is a well known phenomenon occurring after the withdrawal of sequestering therapies as Natalizumab or Fingolimod. Until now, we don't know if other treatments acting on B cells as Rituximab or Ocrelizumab, for the specific mechanism of action, could give a reactivation of the disease after the suspension. Here we present a case of MS patient that present a strong reactivation of disease at Rituximab withdrawal.

Methods:: A 51-year-old female patient diagnosed with multiple sclerosis in 2011 with right hemiparesis, sensory and bladder disturbances. Over time, disease activity required several therapeutic switches until arriving in March 2018 at rituximab with clinical stability. In January 2019 we have scheduled a switch from rituximab (off-label treatment) to ocrelizumab (on-label treatment) monitoring the recovery of CD20, usually slow. Surprisingly the CD20 B cells increased rapidly from December to January 2019 (3% to 8%) with clinical (difficulty walking, numbness of the breast line and urinary retention) and radiological (new MRI cervical T2 lesions with gadolinium enhancement) worsening. After pulse steroid therapy, she started ocrelizumab treatment with clinical and instrumental stability.

Results:: To date, no cases of multiple sclerosis rebound in patients treated with anti-CD20 after discontinuation of Rituximab due to rapid immunoreconstitution have been described in the literature.

Conclusions:: Further studies are needed to better understand and predict CD20 immunoreconstitution after discontinuation of Rituximab and Ocrelizumab.
POST PARTUM PSYCHOSIS AS THE INITIAL PRESENTATION OF MULTIPLE SCLEROSIS: A CASE REPORT

Rim Smaoui, Salma Sakka, Emna Smaoui, Khadija Sonda Moalla, Sawsan Daoud, Nadia Bouattour, Nouha Farhat, Mariem Damak, Chokri Mhiri
Universal Hospital Habib Bourguiba, Neurology, SFAX, Tunisia

Background and Aims:: Psychotic disorders (PD) with multiple sclerosis (MS) is rare and occurs with rates of 2–3% and they usually develop after the neurological signs of MS. They are mostly linked to the side effects of treatment with interferon beta-group immune modifiers. MS revealed with an episode of psychosis is a rare entity mainly post partum psychosis (PPP).

Methods:: A case report of an uncommon presentation of MS revealed by a post partum psychosis.

Results:: We report a case of a 35 years old woman with no history of psychiatric disorder or drug abuse who developed psychiatric symptoms 15 days after she gave born to a child starting with delusional ideas, behavioral dysfunction, auditory and visual hallucinations associated to headache and insomnia. The neurological examination was normal and the psychiatric origin was initially retained. She was treated with neuroleptics without any improvement. Cerebro-spinal MRI was then performed which showed periventricular and short cervical T2 and Flair white matters. Some lesions were enhanced after gadolinium injection. The immunological study of the CSF showed IgG oligoclonal bands and there was no clinical or biological sign for systemic disease. MS was then retained according to the criteria of MacDonald 2017 and she received methylprednisolone and interferon therapy, which resulted in improvements in her clinical conditions.

Conclusions:: PPP is a severe, but treatable form of mental illness that can happen ‘out of the blue’ to women without previous experience of mental illness but sometimes it can be a manifestation revealing an organic illness such as MS.
DIFFICULT DIFFERENTIAL DIAGNOSIS BETWEEN NEUROMYELITIS OPTICA SPECTRUM DISORDER (NMOSD) AND WERNICKE ENCEPHALOPATHY (WE). CASE REPORT.

Francesca Carta¹, Arianna Braccia², Domenico Fiorillo¹, Ginevra Tecilla², Eleonora Baldi³, Luisa Maria Caniatti³, Valeria Tugnoli³
¹University of Ferrara, Sant’Anna Hospital, Clinical Neurology, Ferrara, Italy, ²Clinical Neurology, University Of Ferrara, Ferrara, Italy, ³Ferrara Hospital, Neurology, Ferrara, Italy

Background and Aims:: NMOSD and WE could share similar clinical and neuroradiological manifestations. Differential diagnosis is difficult when NMOSD occurs with area postrema syndrome or mental status changes and when T2 hyperintense lesions involve thalamus, hypothalamus, periventricular and periaqueductal regions [1,3]. The involvement of mammillary bodies in NMOSD is rare [2].

Methods::
We describe the case of a 67-year-old woman, with story of daily alcohol abuse, admitted to Neurology Unit with altered mental state, ataxia and progressive loss of consciousness. In the previous days she reported nausea and vomiting. MRI showed symmetric T2 hyperintensity in the periventricular regions of the third and fourth ventricles and mamillary bodies with contrast enhancement. CSF profile revealed lymphocytic pleocytosis without oligoclonal bands. The laboratory test showed hyponatremia and anti-ENA antibody (anti-RO-52, anti-RO-60 and anti-La). We suspected WE and started intravenous thiamine and sodium supplementation with good improvement in consciousness and ataxia, but residual anterograde amnesia, disorientation and disinhibited behavior.

Results:
18 months later she developed rapid progressive flaccid tetraplegia, dysphagia and respiratory failure. MRI demonstrated a T2-hyperintense lesion from medulla to C6 with ring enhancement and in the chiasm and optic tracts. The presence of AQP4-IgG in her serum confirmed the diagnosis of NMOSD.

**Conclusions:** This is an atypical case of NMOSD because the involvement of mammillary bodies is rarely seen in this disease, being instead a usual location for WE. Pleiocytosis in CSF and presence of anti-ENA antibody might suggest NMOSD. Early detection of AQP4 could be essential for a correct diagnosis, before a relapse occurs.

CASE SERIES: MULTIPLE SCLEROSIS CLINICAL ONSET AND RELAPSE AFTER SARS-COV-2 INFECTION.

Antonia Pignolo¹, Maria Aprile¹, Cesare Gagliardo¹,², Giovanni Giammanco³, Marco D'Amelio¹, Paolo Aridon¹, Giuseppe La Tona¹, Giuseppe Salemi¹, Paolo Ragonese¹
¹Università di Palermo, Department Of Biomedicine, Neuroscience And Advanced Diagnostics (bind), Palermo, Italy, ²University of Palermo, Department Of Biomedicine, Neuroscience, And Advanced Diagnostics, Palermo, Italy, ³Università di Palermo, Department Of Health Promotion, Mother And Child Care, Internal Medicine And Medical Specialties (promise), Palermo, Italy

Background and Aims:: SARS-CoV-2 infection has been associated with several neurological disorders including encephalitis, stroke, demyelinating disorders. We report three patients with multiple sclerosis (MS) onset or with a relapse of MS, temporally correlated with SARS-CoV-2 infection. We hypothesize that SARS-CoV-2 infection, as previously reported for other viruses, could drive active inflammatory response that can contribute either to the onset of MS or its relapse.

Methods:: We tested anti-SARS-CoV-2 Spike Ags IgG and IgM and a cerebrospinal fluid (CSF) PCR for SARS-CoV 2. Patients underwent also to brain and spinal cord magnetic resonance imaging (MRI). In patients with MS onset, we also performed lumbar puncture, autoimmunity testing, virological screening and multimodal evoked potentials (EPs).

Results::

Two patients tested negative for SARS-CoV-2 PCR in CSF, while three tested positive for anti-SARS-CoV-2 Spike Ags IgG, and negative IgM, supporting recent infection. The MRI performed in two patients with MS onset, showed widespread bilateral subcortical and periventricular active lesions and cervical lesions. MRI performed in MS relapse, showed diffuse encephalic new lesions with contrast enhancement. EPs, virological and immunity testing resulted normal.

Conclusions:: Viral infections are possible factors associated to MS pathologic mechanisms or triggers for MS. Extracellular vesicles are involved in cell-to-cell communication, also in blood-brain barrier (BBB) and macrovesicles (MVs) and exosomes in viral infection and antiviral response. Exosomes in SARS-CoV-2 infection, transfer ACE2 receptor to cells, supporting virus internalization. MVs promote BBB damage through co-involvement of tumor necrosis factor-α and interleukin-6. Resulting therefore,
plausible that SARS-Cov2 infection could drive the inflammatory response causing demyelinating disease.
BEHAVIOR OF LYMPHOCYTARY SUBPOPULATIONS DURING TREATMENT WITH DIMETHYL FUMARATE IN PATIENTS WITH MULTIPLE SCLEROSIS

Minerva Mañez Sierra¹, Agustín Rodriguez Belli¹, Virginia Delgado Gil², Francisco Padilla Parrado¹
¹University Hospital Virgen de la Victoria, Neurology, Málaga, Spain, ²HOSPITAL VIRGEN DE LA VICTORIA, Neurología, Málaga, Spain

Background and Aims:: The appearance of Progressive multifocal leukoencephalopathy (PML) is a known risk associated with the use of Tecfidera, already described in its technical data. Its incidence is very low, but it is a disease with an unfortunate clinical course that can lead to death or produce severe disability of the patient.

Methods:: Dimethyl fumarate (DMF) is indicated as a disease-modifying treatment for patients with relapsing-remitting multiple sclerosis (MS R-R). It is a highly effective drug widely used among patients with R-R MS. Due to its mechanism of action DMF can cause lymphopenia.

Results:: To date, the risk of developing PML with the use of DMF was only associated with lymphocyte values below 0.5 x 10⁹ / L (severe lymphopenia) for a prolonged period (minimum 6 months). However, cases of PML with lymphocyte values > 0.5 x 10⁹ / L have been reported. In these cases, the absolute lymphocyte count may be close to normal, suggesting that other specific changes may occur in the T-CD4⁺ and specially in T-CD8⁺ lymphocyte subpopulations that favor the appearance of PML.

Conclusions:: This review attempts to update the scientific evidence about lymphopenia and the behavior of lymphocyte subpopulations in patients receiving DMF and whether there is a relationship with PML cases. It could be reasonable to particularize some cases and proceed to monitor lymphocyte subpopulations in patients with a higher risk of developing PML, such as: elderly patients, patients with lower lymphocyte counts since the start of treatment and patients previously treated with Natalizumab.
LYMPHOPENIA IN PATIENTS WITH MULTIPLE SCLEROSIS TREATED WITH DIMETHYL FUMARATE: A SINGLE-CENTER EXPERIENCE.

Alessandro Dinoto, Arianna Sartori, Marta Cheli, Fulvio Pasquin, Sara Baldini, Alessio Bratina, Antonio Bosco, Paolo Manganotti
University of Trieste, Neurology Unit, Department Of Medical, Surgical And Health Sciences, Cattinara University Hospital, Asugi, Trieste, Italy

Background and Aims:: Lymphopenia is a common side effect of treatment with dimethyl fumarate (DMF) in patients with multiple sclerosis (PwMS). The real prevalence and predictive factors of this side effect are still matter of debate.

Methods:: We retrospectively recruited PwMS that were treated for at least one month with DMF and collected clinical, demographic data and absolute lymphocyte count (ALC) during follow-up. Lymphopenia was graded according to CTCAE. We divided patients according to the grade of lymphopenia (all grades) and severe lymphopenia (grade II-IV). Characteristics of patients with/without lymphopenia and patients with/without severe lymphopenia were analyzed in order to highlight any statistical differences, then a logistic binary regression was performed to elucidate any predictive factor of lymphopenia and severe lymphopenia.

Results:: 98 patients treated with DMF were included: 46.9% of them developed lymphopenia, and 27.6% severe lymphopenia. Lymphopenia was associated with basal ALC (p<0.001), treatment duration (p=0.01), % of reduction at third month (p=0.001) Severe lymphopenia was associated with basal ALC (p=0.003).

Conclusions:: Lymphopenia is a common side effect of DMF. Basal ALC seems to be the most relevant predictive factor.
META-ANALYSIS OF METABOLIC BIOMARKERS FOR MULTIPLE SCLEROSIS IDENTIFIES NOVEL UPSTREAM REGULATORS

D'Annunzio of Chieti-Pescara, Department Of Innovative Technologies In Medicine & Dentistry, Chieti, Italy

Background and Aims:: Metabolomics holds promise as a non-invasive tool for revealing biochemical pathways implicated in multiple sclerosis (MS) (1). Specifically, Ingenuity Pathway Analysis (IPA) can be used to identify pathways associated with proteins and metabolites of relevance in MS as biomarkers or targets of intervention (2).

Methods:: We compared metabolite levels from biological fluids between MS patients and controls by performing Core Analysis in IPA. We included metabolites described as potential MS biomarkers in the literature. Each metabolite was associated with a 10-fold increase, when upregulated in MS, with a 10-fold decrease, when downregulated, or was considered unchanged, when found with conflicting or uncertain activation states.

Results:: Although no canonical pathway was significantly up- or down-regulated, several pathways likely play a role in MS, including those involved in the overproduction of free radicals, glutamate excitotoxicity and mitochondrial dysfunction (Figure). In the upstream analysis, which identifies molecular regulators of metabolite expression, huntingtin emerged as an upregulated upstream regulator, while curcumin appeared as an inhibited upstream regulator.

Conclusions:: Our findings indicate that metabolic pathways of huntingtin and curcumin may be relevant in MS pathogenesis. Upregulated huntingtin may have a pleiotropic role both in neuroinflammation, by regulating macrophage function and its response to stress (3), and in prevention of neurodegeneration, being involved in neuronal function and survival (4). The curcumin pathway, downregulated in MS, is typically involved in the antioxidant response to xenobiotics and stressful agents (5). We suggest that several metabolic processes remain to be explored in MS that may help to develop new, targeted treatment
strategies.
MULTIMODAL EVOKED POTENTIALS INFLUENCE MULTIPLE SCLEROSIS PHENOTYPE AND DISABILITY ACCRUAL

Saloua Mrabet, Amira Souissi, Amina Nasri, Imen Kacem, Mouna Ben Djebara, Amina Gargouri-Berrechid, Riadh Gouider
Razi University Hospital, Neurology And Lr18sp03, Mannouba, Tunisia

Background and Aims:: Previous studies have suggested that Evoked Potentials (EPs) correlate with Multiple Sclerosis (MS) phenotype and disability rate. The goal of this study is to investigate whether multimodal EPs have distinct features between primary progressive (PPMS) and relapsing MS (RRMS) and are predictors of disability accrual.

Methods:: A comparative study was conducted in the department of Neurology of Razi Hospital including patients diagnosed with MS. Patients were relapse free at the time of neurophysiological assessment. They were divided into two groups: RRMS versus PPMS, matched according to disease duration. Data regarding visual (VEP), somatosensory (SSEP) and brainstem (BEP) evoked potentials were compared. Disability accrual was measured by the MS severity score (MSSS). P value<0.05 was considered as statistically significant.

Results:: Sixty-four patients were included (32 RRMS, 32 PPMS (sex-ratio=2.2)) and matched according to disease duration (9 years; p=0.9). VEP were impaired among 24/32 patients in PPMS versus 21/32 in the RRMS group (p=0.4). An axonal damage on optic nerve was found in three cases (PPMS=2; RRMS=1). SSEP were impaired in 21/22 cases in PPMS versus 12/24 in the RRMS group (p=0.001) with a predominant alteration in lower limbs (30/46). BEP were normal among 12/12 patients with PPMS versus 12/14 in the RRMS group (p=0.1). MSSS were significantly higher for patients with abnormal SSEP (2.2 versus 6.2; p=0.000) regardless of phenotype.

Conclusions:: Somatosensory pathways alterations are common during PPMS and are associated with disability accrual. This finding is due to a higher frequency of spinal cord lesions affecting the long tracts during this condition.
GWAS-ASSOCIATED VARIANTS, NON-GENETIC FACTORS, AND TRANSIENT TRANSCRIPTOME IN MULTIPLE SCLEROSIS ETIOPATHOGENESIS: A COLOCALIZATION ANALYSIS

Background and Aims:: A clinically actionable understanding of multiple sclerosis (MS) etiology goes through GWAS interpretation, prompting research on new gene regulatory models. We previously suggested a stochastic etiologic model where small-scale random perturbations could reach a threshold for MS development. The recently described mapping of the transient transcriptome (TT), including intergenic and intronic RNAs, seems appropriate to verify this model through a rigorous co-localization analysis.

Methods:: Through Phyton and R, we performed a colocalization analysis of: (1) 601Multiple Sclerosis associated variants from GWAS Catalog; (2) selected MS-relevant human and EBV transducer DNA Binding Regions (DBRs), namely EBNA2, EBNA3C, AID, VDR; and (3)more than 4,5 million genomic intervals plausibly coding for transient RNAs (TrRNAs), including enhancers and super enhancers, sorted by the cell type and other experimental settings used in wet experiments from databases.

Results:: We show that genomic regions coding for the transient transcriptome are significantly enriched for MS-associated GWAS variants and DNA binding sites for molecular transducers mediating putative, non-genetic, etiopathogenetic factors for MS (vitamin D deficiency, Epstein Barr virus latent infection, B cell dysfunction).

Conclusions:: Our results suggest a model whereby TT-coding regions are hotspots of convergence between genetic ad non-genetic factors of risk/protection for MS (and plausibly for other complex disorders). We also set-up a freely available data resource at www.mscoloc.com for future research on transcriptional regulation in MS.
USE OF ALEMTUZUMAB IN A REAL-WORLD CLINICAL SETTING: THE EXPERIENCE FROM SAN RAFFAELE HOSPITAL

Background and Aims:: Multiple sclerosis (MS) is an inflammatory disease of the central nervous system. Alemtuzumab (ALEM) is an immunosuppressant for highly-active (HA) MS. We present efficacy/safety profile of ALEM in a real-world setting.

Methods:: Data were collected from clinical records at San Raffaele Hospital.

Results::

Treatment characteristics

| T2-weighted lesion count pre ALEM start, number (percentage) | >9 lesions = 50 (79,4%) |
| Previous treatments, mean (min-max) | 2,5 (1.6-6) |
| Switch from 1st line DMDs, number (percentage) | 16 (38,1%) |
| Switch from 2nd line DMDs, number (percentage) | 28 (61,9%) |

| Number of patients with Gadolinium-enhancing lesion pre ALEM start, number (percentage) | 48 (76,2%) |

| Retreatment (II cycle), number (percentage) | 56 (88,9%) |
| Follow-up (y), mean ± stand dev (min-max) | 3,7 ± 1,6 (0,1-6,3) |
