Table 1 shows demographic, clinical and neuroradiological baseline characteristics of our cohort (63 patients). 88.9% received second ALEM-course and two patients did not for severe dysthyroidism and persistent disease activity after first cycle. Mean Annualized Relapse Rate (ARR), median Expanded Disability Status Scale (EDSS) and magnetic resonance imaging (MRI) activity at 24 and 36 months of follow-up are summarized in Figure 1. 49 patients had at least 24 months of follow-up and 53.1% reached No Evidence of Disease Activity (NEDA-3). 24.5% showed EDSS progression and 3 subjects underwent a third ALEM-course for disease activity. Table 2 shows ARR, EDSS and MRI activity at 24 and 36 months of follow-up in naïves. 18 had at least 24 months of follow-up and 72.2% reached NEDA-3. 25% showed mild/moderate infusion reactions and 2 subjects allergic reactions, which led to adoption of desensitization protocol for retreatment. 36.5% developed dysthyroidism, which needed...
radioiodine metabolic treatment in one case. Two patients developed Listeria Monocytogenes sepsis, one autoimmune hemophilia and one Fisher-Evans syndrome.

**Conclusions:** ALEM efficacy/safety profile in our cohort is comparable to clinical trials data. HA naïves with younger age, shorter MS history and lower EDSS score seemed to benefit more from ALEM. Further data and longer follow up are needed to confirm our observations.
CO-OCCURRENCE OF MULTIPLE SCLEROSIS AND AMYOTROPHIC LATERAL SCLEROSIS: A CASE REPORT

Paola Ajdinaj1,2,3, Marianna Gabriella Rispoli1,2, Laura Ferri1,2, Maria D’Apolito1,2, Deborah Farina2, Daniela Travaglini3, Giovanna De Luca3, Antonio Di Muzio2, Valentina Tomassini1,3
1University G. D’Annunzio of Chieti-Pescara, Department Of Neuroscience, Imaging And Clinical Sciences, Chieti, Italy, 2Centre for Neuromuscular Diseases, “ss Annunziata” Hospital, Chieti, Italy, 3MS Centre, Department Of Clinical Neurology, “ss. Annunziata” University Hospital, Chieti, Italy

Background and Aims:: Multiple Sclerosis (MS) is an immune-mediated, demyelinating and neurodegenerative disorder of the central nervous system. Amyotrophic Lateral Sclerosis (ALS) is a progressive neurodegenerative disorder that involves motor neurons in the cerebral cortex, brainstem and spinal cord. We report the co-occurrence of both MS and ALS within the same patient.

Methods:: Case report

Results:: A 52-year-old man was known by our Department of Neurology for MS diagnosed 21 years before, for which he was on treatment with Interferon-β. At the time of diagnosis, he presented left leg weakness and ataxic gait. Over the subsequent 20 years, his clinic-radiological findings were stable. In September 2019, he began to complain of worsening of weakness in his left leg, so he was treated with corticosteroids, without benefits. His lower limb weakness progressively worsened, eventually making him wheelchair-bound. In June 2020, fasciculations were evident on the tongue and the limbs that were also atrophic; there was paraplegia, hyposthenia on the left arm, dysarthria, dysphagia and dyspnea. The lesion burden was unchanged on MRI. Nerve conduction studies were normal, but there was widespread denervation on EMG, which confirmed a diagnosis of ALS. The genetic screening was negative. The patient rapidly deteriorated and died of respiratory failure within a month.

Conclusions:: Co-occurrence of MS and ALS has been reported in the literature for a few cases1 and a clear relationship has not been found as yet2-3. Searching for a link between the two conditions may shed light on their pathophysiologies, contributing to the development of more targeted therapeutic strategies.
BACKGROUND AND AIM:

Multiple sclerosis (MS) damage develops differently between the sexes. Here we investigate the relationship between cerebral grey matter (GM) hypoperfusion and white matter lesion volume and test whether this is different between the sexes. We hypothesize that there is a relationship between cerebral grey matter hypoperfusion and white matter damage and expect that this is affected by sex.

METHODS:

We recruited 94, clinically stable, relapsing remitting MS (RRMS) patients (M=27, F=67). In each patient, we calculated the proportion of T2-hyperintense lesion volume (T2LV) that is also hypointense on the T1-weighted images (T1LV), i.e., T1/T2 LV ratio. Global GM cerebral blood flow (CBF) was quantified using multi-inversion time pulsed ASL. For statistical analysis we used FSL tools, Pearson’s correlation and Wilcoxon test.

RESULTS:

CBF was negatively associated with T1LV ($r=-0.28$, $p=0.01$) and with T1/T2 LV ratio ($r=-0.39$, $p<0.001$) (Figure 1). There was no relationship between CBF and T2LV. There was no difference in T1LV and T2LV between men and women. T1/T2 LV ratio was different between the sexes ($p=0.005$), being higher in men. Women showed a correlation between CBF and T1/T2 LV ratio ($r=-0.3$, $p=0.01$) (Figure 2); this correlation was not significant in men ($r=-0.053$, $p=0.8$).
Conclusions:: Our results confirm a relationship between GM hypoperfusion and WM damage\(^5\) and suggest that an altered energy supply may play a role in the evolution of damage, and thus potentially in the progression of the disease, that is different in the two sexes.

Figure 2 (A) Sex differences in T1-hypointense and T2-hyperintense lesion volumes and in the T1/T2 ratio. (B) Correlations between CBF and T1/T2 ratio in women and men with MS.
Bladder Dysfunction in Multiple Sclerosis: A Preliminary Data from an Ongoing Hospital Based Study

Anomali Vidanagamage¹, Lakshan Seneviratne¹, Manjula Wijewardena¹, Ishani Rajapakshe², Chulika Makawita², Bimsara Senanayake²
¹National Hospital Colombo, Institute Of Neurology, Colombo, Sri Lanka,²National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

Background and Aims:: Bladder dysfunction in multiple sclerosis (MS) is common and is often overlooked. This could be due to dysfunction in bladder storage, voiding or both.

Methods:: Patients with MS diagnosed according to 2017 McDonald criteria who attend the MS clinic at the national hospital of Sri Lanka, with bladder symptoms were evaluated. Details on bladder symptoms, disease course and MRI were obtained. The Actionable questionnaire on quality of life in MS patients with bladder dysfunction was administered. An USS KUB with pre and post void bladder volumes and free flow uroflowmetry were performed. Treatment was commenced according to the type of bladder dysfunction with antimuscarinics and alpha blockers. The same questionnaire and QOL assessment were repeated after 10 weeks.

Results:: Out of eleven patients, three were (27%) males and 8 (72%) were females. The average EDSS of the group was 4. Three patients had hypotonic non-compliant bladder without outlet obstruction, five had hypotonic non-compliant bladder with outlet obstruction, two had normal detrusor with sensory urgency and one had bladder outlet obstruction only. Majority of the patients had bladders with no risk to upper tracts. The mean actionable symptom screening scores pre- and post-treatment were 16 and 9 respectively (P= 0.0014). 91% patients had demyelinating plaques in the cervical and dorsal spine on MRI.

Conclusions:: Bladder dysfunction in MS should be actively evaluated. Both storage and voiding dysfunction were observed in combination. Targeted treatment according to the type of bladder dysfunction significantly improved the symptoms and the quality of life.
CARDIOVASCULAR RISK IS ASSOCIATED WITH VERBAL LEARNING DYSFUNCTION IN MULTIPLE SCLEROSIS

Antonio Reia¹, Martina Petruzzo¹, Fabrizia Falco¹, Teresa Costabile¹, Matteo Conenna¹, Antonio Carotenuto¹, Maria Petracca¹, Giuseppe Servillo², Roberta Lanzillo¹, Vincenzo Brescia Morra¹, Marcello Moccia¹
¹Federico II University, Multiple Sclerosis Clinical Care And Research Centre, Department Of Neuroscience, Reproductive Science And Odontostomatology, Naples, Italy, ²Federico II University, Department Of Neuroscience, Reproductive Science And Odontostomatology, Naples, Italy

Background and Aims:: Cardiovascular comorbidities have been associated with cognitive decline in the general population. We evaluated the associations between cardiovascular risk and neuropsychological performances in MS.

Methods:: This is a cross-sectional study, including 69 MS patients. For all patients, we calculated the Framingham risk score, which provides the 10-year probability of developing macrovascular disease, using age, sex, diabetes, smoking, systolic blood pressure, and cholesterol levels as input variables. Cognitive function was examined with the Brief International Cognitive Assessment for MS (BICAMS), including the Symbol Digit Modalities Test (SDMT), the California Verbal Learning Test-II (CVLT-II), and the Brief Visuospatial Memory Test-Revised (BVMT-R).

Results:: Each point increase of the Framingham risk score was associated with 0.21 lower CVLT-II score. Looking at Framingham risk score components, male sex and higher total cholesterol levels were associated with lower CVLT scores (Coeff=-8.54; 95%CI=-15.51, -1.57; p=0.017; and Coeff=-0.11; 95%CI=-0.20, -0.02; p=0.015, respectively). No associations were found between cardiovascular risk and SDMT or BVMT-R.

Conclusions:: Cardiovascular risk is associated with verbal learning dysfunction in MS. Lifestyle and pharmacological interventions on cardiovascular risk factors should be considered carefully in the management of MS, given the possible effects on cognitive function.
PSYCHOLOGICAL CONSEQUENCES OF COVID-19 PANDEMIC ON PEOPLE WITH MULTIPLE SCLEROSIS: A META-ANALYTIC STUDY

Manuela Altieri1,2, Rocco Capuano1, Alvino Bisecco1, Alesandre D’Ambrosio1, Daniela Buonanno1, Gioacchino Tedeschi1, Gabriella Santangelo2, Antonio Gallo1

1University of Campania Luigi Vanvitelli, Department Of Advanced Medical And Surgical Sciences, Napoli, Italy, 2University of Campania Luigi Vanvitelli, Department Of Psychology, Caserta, Italy

Background and Aims:: Covid-19 pandemic had a relevant psychological impact on consequences in medical workers and general population (Luo et al., 2020). The aim of the present meta-analysis was to evaluate the psychological consequences of Covid-19 pandemic in people with Multiple Sclerosis (pwMS), who are at higher risk of psychological distress than age-matched healthy controls (HC) (Boeschoten et al., 2017).

Methods:: The literature search on three electronic databases yielded 86 studies (73 after the removal of duplicates). Six studies compared psychological variables between pwMS and HC during the pandemic and six studies evaluated the pre/during the pandemic differences in pwMS. The following outcomes were selected: depression, anxiety, physical QoL, mental QoL, stress, sleep. Mean weighted effect sizes (ES) were calculated using Hedges’ g, via Prometa3 software.

Results:: During the pandemic, pwMS showed higher levels of depression (g=0.58, p=0.001), anxiety (g=0.49, p=0.047), stress (g=0.51, p=0.016) and sleep disturbances (g=0.46, p<0.001) compared to HC. The comparison on psychological outcomes before and during the pandemic in pwMS revealed no significant increase during the pandemic on levels of anxiety (g=0.15, p=0.161), depression (g=0.04, p=0.535), mental QoL (g=-0.14, p=0.060), and physical QoL (g=0.00, p=0.986), whereas sleep quality deteriorated during the pandemic (g=0.52, p<0.001).

Conclusions:: In accordance with studies carried on before the pandemic, pwMS showed higher levels of psychological distress than HC also during the Covid-19 pandemic; however, longitudinal studies revealed that, in pwMS, the only psychological consequence was ascribed to a reduced sleep quality. More studies are needed to evaluate the long-term consequences of the pandemic on pwMS.
COVID-19 IN MULTIPLE SCLEROSIS: EXPERIENCE FROM NORTH INDIA

Dheeraj Khurana¹, Gurkeerat Kaur¹, Rajan Chellapa²
¹Postgraduate Institute of Medical Education and Research (PGIMER), Neurology, Chandigarh, India, ²Postgraduate Institute of Medical Education and Research (PGIMER), Physical Rehabilitation Medicine, Chandigarh, India

Background and Aims:: Background: Multiple Sclerosis (MS) patients on disease modifying therapies may be at risk of infection related to novel coronavirus disease (COVID-19) pandemic. Data on COVID 19 infections in Indian MS patients has not been well described Objective: To determine the clinical characteristics and outcome in MS patients on disease modifying therapies (DMTs) affected with COVID-19 and to assess the influence of COVID-19 infection on Multiple Sclerosis disease activity.

Methods:: Methods: Data was collected from our in-hospital MS registry between August to November 2020. Adult MS patients of any gender, subtypes with confirmed COVID-19 diagnosis based on a positive report of a SARS-CoV2 polymerase chain reaction were included. For each the Expanded Disability Status Score (EDSS), COVID-19 severity score and clinical outcome were assessed and patients followed up after a month.

Results:: Results: 5 Relapse RemittingMS (RRMS) patients with no comorbidities, on various DMTs with mean (SD) age 35.60(13.94), male: female ratio=3:2 and mean disease duration (years) 6.52 (3.42) were included in the study. 4 (80%) had COVID-19 severity score below 3. Median EDSS was 4 (range, 1-5.5). 1 (20%) was hospitalized. After one month of follow-up, median EDSS was 4.5 (range, 1-6), 1 (20%) had worsening of MS related symptoms (reported relapse) and 4 (80%) had positive COVID-19 IgG. No significant correlation was found between COVID-19 severity score, age, EDSS and disease duration (P>0.05).

Conclusions:: Conclusion: Indian MS patients were not at an additional risk of developing severe COVID 19 infection despite being on DMTs and COVID 19 did not influence MS disease course.
HHV-6 INFECTION AND ANTI-MOG ASSOCIATED MENINGOENCEPHALOMYELITIS IN AN IMMUNOCOMPETENT ADULT PATIENT

Nicola Zoppi¹, Stefano Masciocchi²,³, Irene Volonghi⁴, Loris Poli⁵, Alberto Benussi⁶, Alessandro Padovani⁷

¹Department of Clinical and Experimental Sciences - University of Brescia, Neurology Unit, Brescia, Italy, ²University of Brescia, Department Of Neurology, Brescia, Italy, ³University of Brescia, Italy, Neurology Unit, Department Of Clinical And Experimental Sciences, Brescia, Italy, ⁴ASST Spedali Civili di Brescia, Neurology Unit, Dept. Clinical And Experimental Sciences, University Of Brescia, Brescia, Italy, ⁵Neurology Unit, Department Of Clinical And Experimental Sciences, Brescia, Italy, ⁶University of Brescia, Neurology Unit, Department Of Clinical And Experimental Sciences, Brescia, Italy, ⁷University of Brescia, Dept. Clinical And Experimental Sciences, Brescia, Italy

Background and Aims:: A 42-year-old male patient was admitted with a clinical suspicion of acute transverse myelitis (TM). In about 24h he developed urinary retention, a lower thoracic (T8) sensory level and flaccid paraparesis.

Methods:: Routine blood laboratory showed mild lymphocytopenia and elevated inflammatory markers. Serum microbiological tests were negative for active infection (no IgM or DNA copies for CMV and EBV; all-encircling serological tests were all negative). Lumbar puncture showed 124 cells/uL (77% lymphocytes), high level of proteins (142 mg/dL, CSF Ig 10.7 mg/dL, liquor/serum albumin ratio 20.8, link index 0.6), with no OCB and a negative microbiological panel, except for isolation of HHV-6 (33851 copies/ml), with a lower serum viral titre (13414 copies/ml). MRI showed signs of meningoencephalomyelitis with a prominent medullary involvement.

Results:: Ganciclovir and dexamethasone (8mg bid) were started, with no benefit on clinical manifestations and CSF viral copies (33298 copies/ml) after 14 days. Meanwhile, further causes of TM were investigated and a dysimmune genesis was suspected. High dosage steroid was soon started and later Ig (0.4 g/kg/day) associated with prednisone (1 mg/Kg) was introduced, with progressive clinical improvement. Anti-MOG were found at high titer in serum and CSF, thus supporting our hypothesis. Genomic analysis of HHV-6 integration in hair samples confirmed an inherited chromosomally integrated viral genome.

Conclusions:: After 20 days, the patient recovered the ability to walk independently, with residual mild hypoesthesia in lower limbs and mild urinary symptoms (EDSS 2.5). After 6 months, MRI showed no signs of disease activity and the patient is clinically stable with maintenance therapy.
THE EVOLUTION OF COGNITIVE IMPAIRMENT IN MULTIPLE SCLEROSIS: A LONGITUDINAL STUDY

Rania Zouari¹, Nouha Farhat¹, Amira Maalej¹, Nadia Bouattour¹, Salma Sakka¹, Olfa Hdiji¹, Khadija Sonda Moalla², Sawsan Daoud³, Mariem Damak³, Chokri Mhiri³
¹Habib Bourguiba Hospital, Department Of Neurology, Sfax, Tunisia, ²habib bourguiba hospital, Neurological Department, sfax, Tunisia, ³habib bourguiba hospital, Neurology, sfax, Tunisia

Background and Aims:: Multiple sclerosis (MS) is the most significant cause of non-traumatic disability in young patients, due to the importance of its motor disability. Although neglected, cognitive impairment (CI) is a common feature that causes serious economic and social problems. We aimed to investigate the evolution of impairment within different cognitive domains in MS patients.

Methods:: A longitudinal study was conducted over 3 years recruiting MS patients from our department of neurology. Exhaustive neuropsychological assessment was performed, using the minimal assessment of cognitive function in MS (MACFIMS) and the French cognitive battery (BCcogSEP), at baseline and 3 years later, in order to evaluate the frequently affected cognitive domains and to determine the evolution of CI in MS.

Results:: Thirty MS patients were recruited (M/F=0,25). On average, the age at onset of the disease was 26,8 years, while the age at onset of CI was 30,6 years. Most patients (55%) were having 2nd line treatment, while 36% were treated with interferon. The information processing speed (IPS), working memory, and visuospatial functions were the most severely affected cognitive domains (93%). Less frequently, CI affecting attention skills (81%), executive functions (50%), and episodic memory (37%) were noted. Three years later, an alteration of the majority of the scores was observed, relating significantly to visuospatial functions, working memory, and IPS(p<0,05). These disturbances were significantly correlated to disability(p<0,05), but not correlated to MS treatment.

Conclusions:: We highlight the importance of early detection of CI in MS in order to improve care and minimize its impact on this young active population.
ACUTE DISSEMINATED ENCEPHALOMYELITIS ASSOCIATED WITH ANTI-MYELIN OLIGODENDROCYTE GLYCOPROTEIN (MOG-IGG) ANTIBODY IN A PATIENT WITH RECENT VACCINATION AGAINST SARS-COV-2

Anna Maria Simone, Giulia Monti, Stefano Amidei, Manuela Costa, Luca Vaghi, Massimiliano Devetak, Silvia De Pasqua, Enrico Fileccia, Mario Santangelo
AUSL Modena, Ramazzini Hospital, Internal Medicine, Neurology Unit, Modena, Italy

Background and Aims:: Vaccines are one of the greatest achievements of modern medicine and are safely administered, but they can give rise to autoimmune diseases which include Central Nervous System or trigger/exacerbate chronic diseases such as multiple sclerosis, neuromyelitis optic and Myelin Oligodendrocyte Glicoprotein Antibody Disease (MOGAD). The SARS-CoV 2 is a human respiratory virus with neuroinvasive and neurotropic capabilities. Several SARS-CoV-2 vaccines have been developed, some with messenger RNA and other with viral vectors.

Methods:: We describe a case of encephalomyelitis with anti-MOG-IgG antibody and recent SARS-CoV-2 vaccine

Results:: A 51-year-old woman with no significant medical history presented with acute urinary retention and bilateral hypoesthesia with a T10 sensory level two week after the SARS-CoV-2 vaccine with viral vector. Magnetic resonance imaging showed enhancing T2 hyperintense lesions in the spinal cord with longitudinal extension, in the midbrain and in the optic nerves bilaterally. Serum SARS-CoV-2 IgG anti spike protein was positive (titer was 86 and cutoff 50 UA/ml). Nasopharyngeal SARS-CoV-2 PCR was negative. Cerebrospinal fluid analysis showed lymphocyte pleocytosis (50 cells/μL), normal oligoclonal bands, normal synthesis rate and positivity for anti-MOG-IgG antibody. Borrelia IgM antibodies was positive in serum but Borrelia-PCR was negative in serum and CSF. High dose intravenous methylprednisolone induced clinical improvement.

Conclusions:: In our patient the SARS-CoV-2 vaccine may have triggered an autoimmune reaction involving the CNS with the production of MOG-IgG antibody, in a patient with genetic susceptibility and transient vaccine-induced immunosuppression. The clinical and strumental follow-up will be necessary to discriminate between a post-vaccination disease or a MOGAD.

Background and Aims:: In cerebrospinal fluid (CSF) of multiple sclerosis (MS) patients, the intrathecal synthesis (IS) of affinity-maturated IgG class antibodies secreted by transmigrated B cells, is considered as a hallmark of the disease. It is classically revealed by CSF isofocusing test (detection of IgG Oligoclonal bands (OCB) in CSF, considered as “the gold standard”), Total IgG Index and/or Reiber diagram. Our aim is to analyse the comparative performance of different CSF testing techniques for MS diagnosis.

Methods:: In our study, serum and CSF samples (n=1220) from 610 patients with suspicion of MS diagnosis were analyzed. IgG index was calculated and interpreted using Reiber diagram. IgG-OCB were analyzed by isofocusing test.

Results:: Patients were divided into « MS » (n =192) and « non MS » (n =418) groups according to their clinical and radiological criteria. Regarding MS patients, the mean value of IgG index (1.43) was significantly higher than non-MS group (0.69). Reiber diagram interpretation concluded to an intrathecal synthesis of IgG in 61 % of MS cases and a blood-brain barrier dysfunction in 16 % of cases. CSF isofocusing test revealed an OCB positivity in 87.5 % of MS cases. The specificity of OCB detection test for MS diagnosis was 78%, with a Negative Predictive Value of 93%.

Conclusions:: In routine practice, CSF isofocusing test appears as the most sensitive tool for MS diagnosis with a very high NPV. Quantitative tests (index, Reiberdiagram) are useful to provide faster results and to inform about the brain barrier status.
Background and Aims:: The concomitant presence of atrophy and microstructural abnormalities in multiple sclerosis (MS), as a result of the disease underlying physiopathology, is well documented. Nevertheless, the interplay between atrophy, iron and myelin changes remains elusive. Here we characterized their topography and their contribution to cognitive and motor disability.

Methods:: We analyzed volumetry, relaxometry and susceptibility in 117 MS patients, through voxel-based morphometry and voxel-based quantification analyses on longitudinal relaxation rate (R1) and susceptibility maps in grey matter (GM) and white matter (WM). Voxel-wise between-group differences and correlations between MR metrics and clinical parameters (global disability, cognitive and motor performance) were assessed.

Results:: While R1 decrease was extensive across GM and WM regions in MS patients, susceptibility showed substantially more limited modifications. Atrophy mainly involved deep GM, posterior and infratentorial regions. In several WM tracts R1 and susceptibility were both reduced. Cortex and deep showed a R1 reduction, associated with decreased susceptibility in the thalamus and small clusters of increased susceptibility in the caudate nucleus and cortical areas. Motor disability was associated with GM atrophy and susceptibility values in the cingulum and corona radiata, while cognition was associated with GM atrophy and focal demyelination.

Conclusions:: While demyelination is the prevalent microstructural abnormality in MS, atrophy and modifications of tissue susceptibility seem to have higher clinical relevance, with the former being an indirect marker of neurodegeneration and the latter possibly reflecting oligodendrocyte damage and subsequent reduction of the tissue repair capability.
Background and Aims:: Myelin oligodendrocyte glycoprotein antibodies (MOG-IgG) have been recently reevaluated as a biomarker of acquired demyelinating syndromes (ADS) of the central nervous system (CNS). Here, we describe the clinical and neuroimaging features, and the long-term outcome of children with ADS of the CNS associated with MOG-IgG.

Methods:: All patients underwent brain and spinal cord magnetic resonance imaging (MRI), lumbar puncture for cerebrospinal fluid (CSF) analysis and MOG-IgG and aquaporin-4 IgG (AQP4-IgG) testing.

Results:: Forty-eight pediatric patients were recruited. MOG-IgG were detected in 11/48 (25%) patients with the following clinical presentations: encephalomyelitis (EM), 8/11 (73%); optic neuritis (ON), 2/11 (18%); transverse myelitis (TM), 1/11 (9%). Patients negative for MOG-IgG were diagnosed with Multiple Sclerosis (MS) (n=15), EM (n=7), ON (n=7), neuromyelitis optica spectrum disorders (NMOSD) (n=5), TM (n=2) and encephalitis (n=1). MOG-IgG positive patients were younger at disease onset and they more frequently experienced encephalopathy and epileptic seizures compared with negative patients. EM and inflammatory lesions involving optic nerves on MRI imaging were more frequent in MOG-IgG positive patients. None of the patients with MOG-IgG became persistently seronegative during the follow-up, although a decrease in MOG-IgG titer was observed. Patients with MOG-IgG showed a good response to therapy and only two patients presented relapses during follow-up.

Conclusions:: This study supports the distinction of MOG autoimmune oligodendrocytopathy as a unique disease entity, with clinical features different from those of MS and AQP4-IgG-positive NMOSD.
**Background and Aims:** Syringomyelia (syrinx) is a chronic, progressive, and degenerative disorder of the medulla spinalis. The formation of syrinx can occur as a complication of various disease processes. Multiple sclerosis (MS) is a chronic disease with extensive clinical manifestations that presents as a multifocal area with the destruction of myelin from the CNS. The purpose of this case report is to present the clinical characteristics and MR imaging results of syringomyelia in a patient with multiple sclerosis.

**Methods:** The information is obtained through the patient’s history and medical record.

**Results:** A 20-year-old female patient with 2-year history of secondary progressive MS and bilateral blindness complained that both limbs are weak and cannot be moved progressively. Neurological examination revealed UMN-type inferior paraparesis, normal proprioception and sensory protopathic, and bilateral optic nerve neuropathy. Head MRI with contrast shows MS in the right juxtacortical parietal lobe and left posterior horn of the periventricle lateral area; spinal MRI with contrast shows MS of the spinal cord at C3-C4, C6, T2-T3, T3-T4 and syrinx formation is identified in the central canalis as high as C7 to T10.

**Conclusions:** Patients with a history of MS with demyelinating plaque in the spinal cord can progress and increase their risk of developing spinal syrinx formation.
FINGOLIMOD IN PEDIATRIC MULTIPLE SCLEROSIS: SIX CASE REPORTS

Michela Ada Noris Ferilli¹, Laura Papetti¹, Massimiliano Valeriani¹,²
¹Bambino Gesù Children’s Hospital, IRCCS, Neuroscience Department, Roma, Italy, ²Aalborg University, Center For Sensory-motor Interaction, Aalborg, Denmark

Background and Aims:: Treatment for pediatric-onset multiple sclerosis (POMS) currently reflects treatment for adult-onset MS, despite some differences in its clinical course. First-choice treatment of POMS generally consists of interferon β-1a or glatiramer acetate, with therapies such as natalizumab or fingolimod reserved for second-choice treatment. In cases of severe disease, both fingolimod and natalizumab can be considered first-choice therapy.

Methods:: This paper presents six case histories of patients with POMS and highlights the different uses of fingolimod within the POMS treatment algorithm.

Results:: Two cases are examples of escalation therapy, both in females aged 16 to 17 years, with fingolimod administering as second choice following disease progression. The other four cases are an example of using fingolimod as first-choice therapy.

Conclusions:: In all six cases, over a period of approximately 1 year after the initiation of fingolimod treatment, there was no further disease progression and no adverse events were recorded.
BILOBALIDE ALLEVIATES CPZ-INDUCED DEMYELINATION VIA SUPPRESSING THE POLERIZATION OF A1 ASTROCYTES

Wen-Yuan Ju¹,², Qing Wang¹, Li-Juan Song¹,², Dong Ma³, Min-Fang Guo⁴, Yu-Qing Yan⁴, Zhi Chai¹, Jie-Zhong Yu¹, Bao Guo Xiao⁵, Cun-Gen Ma¹,²,⁴
¹Shanxi University of Chinese Medicine, Research Center Of Neurobiology / The Key Research Laboratory Of Benefiting Qi For Acting Blood Circulation Method To Treat Multiple Sclerosis Of State Administration Of Traditional Chinese Medicine, Jinzhong, China, ²Shanxi Medical University, Physiology / Neurology, Taiyuan, China, ³General Hospital of National Medicine and Datong Coalmine, Neurosurgery, Datong, China, ⁴Shanxi Datong University, Institute Of Brain Science / Shanxi Key Laboratory Of Inflammatory Neurodegenerative Diseases, Datong, China, ⁵Fudan University, Institute Of Neurology-huashan Hospital-institutes Of Brain Science And State Key Laboratory Of Medical Neurobiology, Shang Hai, China

Background and Aims:: A1 astrocyte exerts neurotoxic effects and is a key factor of failure in nerve repair and myelin regeneration. Bilobalide (BB) is one of the active monomer component of Ginkgo biloba extract, which alleviates the demyelination in Cuprizone (CPZ) model and reduces the secretion of inflammatory cytokines by astrocyte. Our aim was to explore possible mechanisms of BB targeting astrocyte.

Methods:: Primary astrocyte was induced with LPS to establish In vitro inflammatory model, which was divided into normal group, LPS group and LPS+BB group. CPZ model was established in vivo and divided into normal group, CPZ group and CPZ+BB group. From the fourth weekend, CPZ+BB group received injection of BB (400mg/kg/day). The normal and CPZ groups were injected with saline in the same way. The expression of C3d was detected by immunofluorescence and PCR, and the secretions of IL-6, oxidative indexes (GSH-Px, RNS, and MDA) and BDNF, CNTF were detected by ELISA.

Results:: BB inhibited the polarization of A1 astrocyte, reduced the levels of GSH-Px, RNS and MDA, downregulated the secretion of IL-6, and promoted the release of BDNF and CNTF.

Conclusions:: BB can alleviate demyelination by reducing the release of oxidative product and inflammatory factors, and promoting the secretion of neurotrophic factors, which is related to the suppression of A1 polerization. (NNSF of China 81473577, Open Projects of The Key Laboratory of The Ministry of Education 2019004 and Leading Team of Medical Science and Technology, Shanxi Province 2020TD05, China Postdoctoral Science Foundation 2020M680912, Ma and Xiao are corresponding authors)
PATH FEEL SMART INSOLES ARE A RELIABLE TOOL TO ESTIMATE GAIT PARAMETERS FOR MONITORING MULTIPLE SCLEROSIS PATIENTS PROGRESSION.

Juan Manuel Völker¹, Ingvar Kiricenko¹, Nuala Burke²
¹Walk With Path, Data Science Group, København V, Denmark, ²Walk With Path, Clinical, Nørrebro, Denmark

Background and Aims:: Multiple sclerosis (MS) patients often exhibit impaired gait related to neurological disability. Light wearable sensors are an opportunity for gait analysis to identify, quantify and monitor gait changes in MS. Path Feel is a smart insole that estimates gait parameters using IMU and pressure sensors. Still, to be used in clinical conditions gait parameters must be reliable. The goal of this study was to investigate the reliability of this smart insole in healthy participants and the minimum detectable changes (MDCs) to describe if the insole is able to detect changes in MS patients.

Methods:: Six healthy participants (30 ± 3 years) participated in two experimental sessions separated by 5 ± 2 days. Participants walked in a 12 [m] walkway three times at their self-selected speed. Cadence, stride length, cycle duration, gait velocity and swing, were compared between sessions using the intraclass correlation coefficient (ICC-2,1) and Bland Altman (BA) plots analysis.

Results:: In total 658 steps were analyzed. Gait parameters showed an ICC > 0.75. BA showed no systematic bias between sessions in any parameter and Limits of Agreements (LoA) are narrow compared to the mean (LoA < 10% mean). Small MDCs were found in all parameters (normalized to mean values ranged from 2–12%).

Conclusions:: Reliability indicated the excellent performance of measuring gait parameters. MDCs are comparable to changes of gait in MS patients. Hence, Path Feel can be a useful tool to monitor MS progression and has the potential to support target-oriented rehabilitative management of MS patients.
THE INFLUENCE OF BIOLOGICAL SEX ON COGNITIVE PERFORMANCE IN PEOPLE WITH MULTIPLE SCLEROSIS

Manuela Altieri¹,², Gabriella Santangelo², Alvino Bisecco¹, Alessandro D’Ambrosio¹, Valentina Rippa², Rocco Capuano¹, Federica Giuliani¹, Federica Matrone¹, Simona Bonavita¹, Gioacchino Tedeschi¹, Antonio Gallo¹
¹University of Campania Luigi Vanvitelli, Department Of Advanced Medical And Surgical Sciences, Napoli, Italy, ²University of Campania Luigi Vanvitelli, Department Of Psychology, Caserta, Italy

Background and Aims:: Studies exploring the influence of sex on cognitive performance in people with Multiple Sclerosis (pwMS) are inconsistent and they did not evaluate the interaction effect between sex and clinical/sociodemographic variables (Donaldson et al., 2019; Savettieri et al., 2004). The aim of the study was to evaluate sex differences on cognitive performance and to explore possible interaction effect between sex and clinical/sociodemographic variables.

Methods:: 407 (147 males, 260 females) pwMS according to the latest McDonald criteria were recruited in the study. They underwent a neurological (EDSS) and neuropsychological evaluation (BRB-N). MANOVA and univariate analyses were performed to evaluate main effect of sex on cognitive performance and its interaction with disease duration, physical disability and education. Correction for multiple comparison was performed with Benjamini-Hochberg procedure.

Results:: The main effect of sex was significant on PASAT 3 scores (males>females, F₁,₄₀₆= 11.795, p = 0.001), PASAT 2” (males>females, F₁,₄₀₆=8.883, p = 0.003), SRT-D (females>males, F₁,₄₀₆=5.565, p= 0.019) and WLG (females>males, F₁,₄₀₆=12.697, p < 0.001). Moreover, the sex*education interaction was significant (high education females>low education females) on SPART scores (F₁,₄₀₆=11.486, p = 0.001), SDMT (F₁,₄₀₆=14.486, p < 0.001), SPART-D (F₁,₄₀₆= 6.106, p = 0.014), and STROOP (F₁,₄₀₆= 11.502, p = 0.001).

Conclusions:: The results revealed that biological sex has an impact on long-term verbal memory, attention, processing speed and verbal fluency. Moreover, educational attainment (a proxy of cognitive reserve) seems to have a protective effect only on females on spatial memory, processing speed and inhibitory control.
A CASE OF DELAYED POST-HYPOXIC LEUKOENCEPHALOPATHY FOLLOWING OPIOID INTOXICATION

Francesco Brovelli¹, Lorenzo Saraceno², Andrea Di Pietro³, Alessia Lanari², Cristina Erminio⁴, Carlo Ferrarese¹, Elio Clemente Agostoni²
¹University of Milan-Bicocca, Ospedale San Gerardo, Neurology, Monza, Italy, ²Grande Ospedale Metropolitano Niguarda, Neurology, Milano, Italy, ³University of Naples - Federico II, Neurology, Napoli, Italy, ⁴Grande Ospedale Metropolitano Niguarda, Neuroradiology, Milano, Italy

Background and Aims:: Delayed post-hypoxic leukoencephalopathy (DPHL) is a rare demyelinating syndrome characterized by cognitive and motor decline. It typically presents with a biphasic course after prolonged cerebral hypo-oxygenation.

Methods:: A 55 years old woman arrived at the emergency department due to a seizure-like episode, after presenting in the previous days a progressive cognitive-motor slowing. The brain CT and blood tests were normal. A month before, she was admitted to another hospital because of respiratory failure following a suicide attempt by medication overdose; she completely recovered in two weeks. After hospitalization in our department, the patient quickly became completely uncontactable and catatonic. The following tests were performed: blood test including screening for autoimmune/paraneoplastic, trombophilic and infective disease, EEG, brain MRI with gadolinium and spectroscopy.

Results:: The neurological examination showed akinetic mutism and catatonia with diffuse limb rigidity and fixed postures. Blood tests were negative; EEG demonstrated a global slowing of the activity. The brain MRI showed a symmetric T2, FLAIR and DWI hyperintensity of the white matter, confluent in the frontal regions. The findings were suggestive of an intramyelinic edema. Control MRI performed after 2 weeks, evidenced a progression of the demyelinating lesions in T2, FLAIR and DWI; spectroscopy demonstrated a decrease of creatine and NAA with an increase of lactate.

Conclusions:: The course of the patient's symptoms, her medical history of recent coma after drug intoxication and the EEG, MRI and spectroscopy findings, as well as the normal or non significant results of other tests for encephalopathies, were strongly supportive for a diagnosis of DPHL.
END OF DOSE INTERVAL (EDI) SYMPTOMS IN PATIENTS UNDERGOING TREATMENT WITH NATALIZUMAB

Giuseppe Magro, Antonio De Martino, Federico Tosto, Domenico Santangelo, Lucia Manzo, Pietro Bruno, Angelo Pascarella, Marilisa Pasquale, Stefania Barone, Antonio Gambardella, Paola Valentino
University Magna Graecia, Institute Of Neurology, Department Of Medical Sciences, Catanzaro, Italy

Background and Aims:: Many patients treated with Natalizumab experience End of Dose Interval (EDI) symptoms towards the end of the administration cycle. During the pandemic, due to the unknown effects of SARS-CoV-2 infection on patients undergoing treatment with Natalizumab (NTZ), we decided to shift patients on NTZ from a Standard Interval Dosing (SID of 4 weeks) to an Extended Interval Dosing (EID of 5-6 weeks). Our main objective was to study the prevalence and incidence of EDI symptoms in our MS center, along with its efficacy and safety.

Methods:: We reviewed 102 patients in our MS center treated with natalizumab for at least 12 months using EID. When tolerated/possible, patients were shifted from a SID of 4 weeks to an EID of 5-6 weeks. Patients were asked to report any worsening of their symptoms during the administration cycle, fatigue was assessed right before the administration of NTZ, with surveys and Fatigue Severity Scale (FSS).

Results:: Among the 102 patients, 41(40.19%) reported end of dose interval (EDI) symptoms, and the most common one was fatigue. Among those 41 patients: 26(63%) had a Relapsing Remitting (RR) course while 15(37%) had a Secondary Progressive (SP) course. Of note, 15(36.58%) patients reported a new onset of fatigue where none was present before the EID. Our data suggest that with EID efficacy is still preserved since only 6 patients showed new lesions on follow-up-MRI and with little clinical significance.

Conclusions:: Our study shows that when EID was adopted, fatigue was higher in the RR course group, with efficacy still preserved.
THE RELATIONSHIP BETWEEN DEPRESSION AND COGNITION IN MULTIPLE SCLEROSIS: A META-ANALYSIS

Manuela Altieri¹,², Francesco Cerciello², Antonio Gallo¹, Gabriella Santangelo²
¹University of Campania Luigi Vanvitelli, Department Of Advanced Medical And Surgical Sciences, Napoli, Italy, ²University of Campania Luigi Vanvitelli, Department Of Psychology, Caserta, Italy

Background and Aims:: Studies on the relationship between depression and cognition in people with Multiple Sclerosis (pwMS) are inconsistent (Arnett, 2005; Baumstarck-Barrau et al., 2011). The aim of the present meta-analysis was to evaluate the possible association between depressive symptomatology and cognitive performance on several cognitive domains in pwMS.

Methods:: The literature search on three electronic databases yielded 5402 studies (4333 after the duplicates removal). 29 studies compared depressive symptomatology (assessed with specific questionnaires) and cognitive performance (outcomes: global cognition, attention, processing speed, verbal, spatial and working memory, verbal fluency, executive functions). Positive ES were indicative of a negative relationship between depression and cognitive performance. A random-effect meta-analysis was performed and mean weighted effect sizes (ES) were calculated using Hedges’ g, via Prometa3 software. Meta-regression analysis served to explore the potential effect of clinical/sociodemographic variables of samples on outcomes.

Results:: Small ES were found in the meta-analysis exploring the relationship between depression and verbal memory (g=0.25, p=0.001), spatial memory (g=0.26, p<0.001), verbal fluency (g=0.30, p<0.001) and executive functions (g=0.33, p=0.002), whereas medium ES were found in the meta-analysis evaluating the possible relationship between depression and global cognition (g=0.53, p=0.016), attention (g=0.47, p<0.001), processing speed (g=0.50, p<0.001) and working memory (g=0.51, p=0.034). Meta-regression analysis revealed no effect of clinical and socio-demographical variables of primary samples on all outcomes.

Conclusions:: Depressed pwMS may show more difficulties in several aspects of cognition, especially those needed to retain, respond and process information in one’s environment, and to those needed be adequately stimulated in processing the relevant information.
ASSOCIATION BETWEEN SMOKING AND RELAPSE IN PATIENTS WITH RELAPSING-REMITTING MULTIPLE SCLEROSIS UNDER FINGOLIMOD TREATMENT

Eizo Tanaka, Mitsuru Watanabe, Takuya Matsushita, Noriko Isobe
Neurological Institute, Graduate School of Medical Sciences, Kyushu University, Department Of Neurology, Fukuoka, Japan

Background and Aims:: In relapsing-remitting multiple sclerosis (RRMS), smoking is a known risk factor of disease development and disability progression. However, little is known about the impact of smoking on the efficacy of fingolimod. Here we studied the relationship between smoking and relapses in patients with RRMS under fingolimod treatment.

Methods:: We retrospectively enrolled patients with RRMS who received fingolimod treatment in our hospital between January 2012 and December 2018. Smoking status during fingolimod treatment and clinical data were collected up to December 2019. We conducted survival analysis for clinical relapse during the observation period between smoker and non-smoker groups.

Results:: The study comprised 73 patients with RRMS under fingolimod treatment and 19 (26.0%) of them were smokers. Proportion of patients who relapsed during the follow-up period was higher in smokers than in non-smokers (36.8 vs 11.1%, p = 0.012). Time from the beginning of fingolimod to the clinical relapse was significantly shorter in smokers than the non-smokers (Log-rank test: p = 0.007; Cox proportional hazard model: hazard ratio 4.25 [95% CI 1.36–13.30], p = 0.013). Multivariate survival analysis also showed smoking was an independent risk factor of clinical relapse even after adjusting for sex, age at onset, disease duration, and number of relapses within two years before fingolimod treatment (hazard ratio 5.81 [95% CI 1.57–21.51], p = 0.009)

Conclusions:: Smoking remained a risk factor of disease activity in RRMS patients under fingolimod. Patients with RRMS should be advised to stop smoking even after initiation of high-efficacy drugs.
OUTCOME OF RITUXIMAB THERAPY IN REFRACTORY NEUROMYELITIS OPTICA

Sonu Kurian\textsuperscript{1,2}, Jawahar Marimuthu\textsuperscript{2}
\textsuperscript{1}Sree Chitra Thirunal Institute for Medical sciences and technology, Neurology, Trivandrum, India, \textsuperscript{2}Madras Medical College, Neurology, Chennai, India

Background and Aims:: BACKGROUND AND AIMS: Neuromyelitis optica (NMO) is a severe autoimmune disease targeting optic nerves and spinal cord. The monoclonal anti-CD20 B cell antibody Rituximab is a treatment option in refractory NMO. The prevalence of NMO in South India is around 2.6/lakh population. This study was conducted to evaluate the outcome of Rituximab over 12 months in refractory NMO.

Methods:: 23 patients of refractory NMO treated with Rituximab who attended the demyelination clinic from January 2017 were studied. Refractory NMO were cases of NMO with at least one relapse on immunosuppressive therapy. A fixed treatment scheme of total four doses of weekly Rituximab at 375mg/m2 and the same repeated every six months, or earlier based on CD19 levels, was given for refractory NMO. The mean annualized relapse rate (ARR) and the median Expanded disability status scale (EDSS) were analysed before treatment and after one year on Rituximab.

Results:: After a mean follow up of 13 months, we observed a significant reduction of median Annualized relapse rate from 2.9 to 0.14 and of the median EDSS score from 5.2 to 3.3. Two patients had relapse while on Rituximab, which was due to inadequate follow up doses of Rituximab. No serious side effects were noted in study group.

Conclusions:: The therapy with Rituximab, with proper follow-up, was found to significantly reduce the frequency of relapses, with subsequent stabilization or improvement in disability.
Patients with multiple sclerosis have poor quality of sleep and frequently suffer sleep related disorders.

Ismail Khatri, Esraa Arabi, Razan Alkhathlan, Abeer Alkhathlan, Ghaida Almusallam, Nazish Masud, Yaser Al Malik

1King Abdulaziz Medical City, MNGHA, Division of Neurology, Department of Medicine, Riyadh, Saudi Arabia, 2King Saud bin Abdulaziz University for Health Sciences, College of Medicine, Riyadh, Saudi Arabia

Background and Aims:: Multiple sclerosis (MS) causes physical as well as psychosocial disability in young adults. Various sleep disorders have been reported in patients with multiple sclerosis (pwMS). We determined the frequency of various sleep disorders in pwMS and correlated those with the quality of sleep.

Methods:: IRB approved study at King Abdulaziz Medical City, MNGHA, Riyadh, KSA. Various validated questionnaire were used to assess sleep disorders and quality of sleep.

Results:: Total of 169 patients were included; 116 (69%) were females. Mean age was 35 +/- 10 years, and mean BMI was 27.6 +/- 16.8 kg/m². Almost half (47%) of the patients were employed, most worked in day-shift (85%). Caffeinated beverages were used by 87%; 16% were smokers. Relapsing remitting MS was the commonest type in 93% patients; 82% were using disease modifying therapy. 18% used sleep related medications. EDSS disability was mild in 64%, moderate in 18%, severe in 18%. Poor quality of sleep was reported by 74% (mean PSQI 7.8 +/- 3.9). Circadian rhythm disorders were seen in 22%, psychiatric disorders in 18%, and parasomnias in 14%. 4% had sleep apnea. Psychiatric disorders (p=0.05) and movement disorders (p=0.05) were more frequently seen in women. Insomnia (p=0.03), circadian rhythm disorders (p=0.013) and psychiatric disorders (p=0.002) were associated with poor sleep quality. BMI, neck circumference, type of MS and current treatment did not affect the frequency of sleep disorders or quality of sleep.

Conclusions:: Sleep disorders were common in multiple sclerosis and most patients had poor quality of sleep. Women with multiple sclerosis may be more prone to sleep disorders.
Background and Aims: In the search for an MS diagnostic / prognostic biomarker, circulating microRNAs (miRs) have been in the spotlight. In the context of MS pathophysiological mechanism, several inflammatory miRs have been described as potential diagnostic tools but their prognostic usefulness is yet to be determined. We sought to quantify miR-26a and miR-145, serum levels in MS patients and analyse its diagnostic performance in different groups according to clinical features (MS course and disease activity).

Methods: MiR-26a and miR-145 serum levels were quantified in 90 patients with definitive MS diagnosis accordingly to 2017 McDonald’s Criteria (49F, 6 with Progressive MS, 15 in flare, 29% HLA-DRB1*15 positive, Expanded Disability Status Scale (EDSS) = 2.4 ± 2.1, Multiple Sclerosis Severity Score (MSSS) = 2.8 ± 2.7 Age Related MSSS (ARMSSS) = 3.6 ± 2.6). Twenty-four individuals without autoimmune and neurological pathologies were included in the control group.

Results: MS patients and control individuals had similar miR-26a and miR-145 circulating levels. Also, both miRs were not influenced by clinical form or relapses, nor by HLA-DRB1*15 presence. Noteworthy, miR-26a serum levels were inversely correlated with clinical outcome with lower levels associated with higher MSSS (ρ = -0.370, p = 0.002) and ARMS scores (ρ = -0.288, p = 0.017).

Conclusions: MiR-26a modulates TH17 cells differentiation and phenotype. An imbalance between anti and pro-inflammatory mechanisms could affect MS progression. Our preliminary results suggest that miR-26a could have a role on MS prognosis. Financial support: BIEM
Background and Aims:: There are several approaches to measuring education, such as measures of the time spent in education or the years of education associated with a legally recognized degree/diploma (Connelly et al., 2016). Since raw scores of several neuropsychological tests are corrected for educational attainment, the aim of the present study was to evaluate if different types of measures of education could be associated to possible differences in evaluating the cognitive performance of people with Multiple Sclerosis (pwMS).

Methods:: 412 (63.6% women) pwMS according to the latest McDonald criteria were consecutively recruited in the study. Rao’s BRB-N was administered. Education was calculated in two different ways: a) completed years of education (effective education, EE); b) years associated to a legally recognized degree/diploma (formal education, FE). Corrected and z-scores of BRB-N were calculated on the basis of the two educational approaches to allocate participants in cognitively preserved or impaired groups. Percentages and chi-square test were employed as appropriate.

Results:: Out of 412 pwMS, 91 showed a different number of years of education according to the two approaches. Among the 91 pwMS, 60.4% and 49.5% of pwMS were classified as cognitively impaired according to the EE and FE approaches, respectively. In all tests of BRB-N the significance testing for crosstabulation was significant (p<.001).

Conclusions:: The results revealed that the EE or FE approaches can have an impact on whether considering a pwMS as cognitively preserved or impaired. We suggest that, in future studies, the approach to measuring education should be made explicit.
FLUOXETINE SUPPRESSES TH17-CELLS FUNCTION VIA 5-HT2B-RECEPTOR IN MULTIPLE SCLEROSIS

Anastasiya Sviridova¹, Tatiana Solodova¹, Anna Lopatina¹, Mikhail Melnikov¹,², Alexey Boyko¹,²
¹Federal Center of Brain and Neurotechnology of Federal Medical-Biological Agency of Russia, Department Of Neuroimmunology, Moscow, Russian Federation, ²Pirogov Russian National Research Medical University, Department Of Neurology, Neurosurgery And Medical Genetics, Moscow, Russian Federation

Background and Aims:: Fluoxetine is a selective serotonin reuptake inhibitor, which also has an immunomodulatory effect. This study aimed to clarify the influence of fluoxetine on Th17-cells, which plays a crucial role in MS pathogenesis.

Methods:: Thirty MS patients and twenty controls were examined. To assess the effect of fluoxetine on Th17-cells, CD4⁺ T-cells were cultured in the presence of fluoxetine and stimulated with anti-CD3/anti-CD28-antibodies. To study the involvement of 5-HT2b-receptor in fluoxetine-mediated immunomodulation, CD4⁺ T-cells were pre-incubated with antagonists of or agonist of 5-HT2b-receptor, whereafter fluoxetine and anti-CD3/anti-CD28-antibodies were added to the cultures. To assess the direct effect of 5-HT2b-receptor activation on cytokine production, some samples of CD4⁺ T-cells were preincubated with a specific agonist of 5-HT2b-receptor and stimulated as described above. The levels of IL-17, IFN-γ, and GM-CSF in culture supernatants were assessed by ELISA.

Results:: Fluoxetine suppressed IL-17, IFN-γ, and GM-CSF production by stimulated CD4⁺ T-cells in both groups. Blockade of 5-HT2b-receptors decreased the inhibitory effect of fluoxetine on cytokine production in MS patients. Finally, 5-HT2b-receptor activation inhibits IL-17, IFN-γ, and GM-CSF production in both groups.

Conclusions:: These data suggest an anti-inflammatory role for fluoxetine in MS, which could be mediated by the activation of 5-HT2b-receptors. The study was supported by the Russian Foundation for Basic Research grant 18-315-00436.
ALEXITHYMIA IN PATIENTS WITH MULTIPLE SCLEROSIS

Mouna Ben Abdallah¹, Nouha Farhat², Imen Baati¹, Olfa Hdiji³, Mariem Damak², Jawaher Masmoudi¹, Chokri Mhiri³
¹CHU Hedi Chaker hospital Sfax Tunisia, Psychiatry, Sfax, Tunisia, ²CHU habib bourguiba Sfax, Neurology, sfax, Tunisia, ³Universal Hospital Habib Bourguiba, Neurology, SFAX, Tunisia

Background and Aims:: To study the prevalence of alexithymia in patients with multiple sclerosis (MS) and to determine the factors related to it.

Methods:: We conducted a cross-sectional, descriptive and analytical study, which took place in the neurology department, at the Habib Bourguiba University Hospital in Sfax. It involved MS patients in remission phase (Mc Donald criteria 2017). Data collection was done using a form exploring sociodemographic, clinical and radiological data. We used the Toronto Alexithymia Scale (TAS-20) and the Expanded Disability Status Scale (EDSS).

Results:: Our study included 93 patients followed for MS. The mean age of our patients was 36.59 ± 10.69 years with a sex ratio (M/F) of 0.45. The participants were married in 57% of cases. The total number of relapses ranged from 1 to 30, with a median of 5. The EDSS score ranged from 0 to 8, with a median of 3.5. A temporal lesion on brain imaging was found in 29% of cases. Alexithymia was found in 54 MS patients (58.1%). It was more frequent in unmarried (single and divorced) patients (p = 0.028). Among clinical and radiological factors, the number of relapses and the EDSS score were higher (p = 0.035 and p = 0.000, respectively) and temporal lesion on brain imaging was more frequent in alexithymic patients (p = 0.045).

Conclusions:: Our study shows that alexithymia affects more than half of the patients followed for MS. Therefore, we propose to develop training programmes for neurologists to detect and manage alexithymic patients at an early stage.
INFLAMMATORY OPTIC NEUROPATHY FOLLOWING SARS-COV-2 MRNA VACCINE: DESCRIPTION OF TWO CASES

Valentina Barone¹, Federico Camilli¹, Michela Crisci², Cinzia Scandellari², Piero Barboni³, Alessandra Lugaresi¹,²
¹Università di Bologna, Dipartimento Di Scienze Biomediche E Neuromotorie, Bologna, Italy, ²IRCCS Istituto delle Scienze Neurologiche di Bologna, Uosi Riabilitazione Sclerosi Multipla, Bologna, Italy, ³Studio Oculistico D’Azeglio, Studio Oculistico D’azeglio, Bologna, Italy

Background and Aims:: A wide range of immune mediated inflammatory events have been temporally associated with vaccinations, and usually appear within weeks after the immunization, although more rarely the delay is longer. Among inflammatory events, optic neuritis is known to be the most common isolated inflammatory syndrome of the central nervous system (CNS) following vaccinations. It has still to be clarified whether optic neuritis will remain an isolated episode or it may represent the first clinical manifestation of a chronic autoimmune disease.

Methods:: Description of clinical history, examination, neuroimaging and treatment of two patients with optic neuritis closely following SARS-CoV-2 mRNA vaccination.

Results:: Two patients aged 48 and 31 years presented with acute optic neuritis a few days after SARS-CoV-2 mRNA vaccination (Fig. 1). The first patient had a typical presentation of unilateral retrobulbar optic neuritis and was treated with intravenous methylprednisolone with partial recovery. Magnetic resonance imaging (MRI) was unremarkable (Fig. 2). The second patient had a transient loss of vision after exposure to high temperature (Uhthoff’s phenomenon) followed by persistent monocular dyschromatopsia and central scotoma.
Conclusions: The two cases we report might represent a rare adverse reaction to SARS-CoV-2 mRNA vaccination. Given the low risk of inflammatory CNS disease following vaccinations and the risk of onset or relapse of CNS demyelination after infections, vaccination benefits outweigh risks. The relationship between mRNA vaccination and later development of CNS demyelinating diseases has still to be ascertained. Clinical and radiological follow up of patients will help clarify this controversial association.
BALANCE DISORDERS IN MULTIPLE SCLEROSIS: THE USE OF POSTURAL TEST IN FUNCTIONAL CLINICAL ASSESSMENT

Diletta Zardi1, Valentina Barone1, Federica Pinardi2, Loredana Sabattini2, Stefania Pozzi3, Alessandra Lugaresi1,2
1Università di Bologna, Dipartimento Di Scienze Biomediche E Neuromotorie, Bologna, Italy, 2IRCCS Istituto delle Scienze Neurologiche di Bologna, Uosi Riabilitazione Sclerosi Multipla, Bologna, Italy, 3DATER Riabilitazione Ospedaliera Azienda USL di Bologna, Uosi Riabilitazione Sclerosi Multipla, Bologna, Italy

Background and Aims:: Multiple sclerosis (MS) is a demyelinating disease of the central nervous system (CNS). A high prevalence of balance disorders has been reported in persons with MS (PwMS), even in the early stages and with minimal disability. Posturography is the current gold standard for balance assessment. Aim of this study was to analyse instability in a cohort of PwMS through postural tests and static posturography and to investigate their correlation with the Extended Disability Status Scale (EDSS) score.

Methods:: We performed a retrospective analysis on 72 PwMS prospectively recruited from 1 May 2015 to 31 October 2019. An in-house standardized postural test and conventional static posturography were performed in every patient. Posturographic data were processed using the Equilibrium software. We used Spearman's rank correlations to relate disability and clinical data obtained from postural tests.

Results:: 48/72 PwMS (66.6%) were female. Mean age was 46.8 (11.6) years, median EDSS 3.5 (IQR 2.5-4.5). The majority (81%) of stabilometric tests were altered. Patients with higher EDSS showed the worst performances. Postural tests, including asymmetric bipodal load, demonstrated high sensitivity but moderate specificity in capturing postural instability when compared to stabilometric measures.
Conclusions: Balance disorders in PwMS still represent a clinical and therapeutic challenge. This study proposes a novel postural test as a useful, non-invasive, quick-and-easy-to-administer screening clinical tool in the diagnosis and follow-up of postural instability in MS. Early detection of balance impairment, especially in patients with low disability, is critical to devise the best rehabilitation strategy to delay functional disability.
BIPOLAR DISORDER IN PATIENTS WITH MULTIPLE SCLEROSIS

Mouna Ben Abdallah¹, Nouha Farhat², Imen Baati¹, Sawsan Daoud², Mariem Damak³, Jawaher Masmoudi¹, Chokri Mhiri⁴
¹CHU Hedi Chaker hospital Sfax Tunisia, Psychiatry, Sfax, Tunisia, ²CHU habib bourguiba Sfax, Neurology, sfax, Tunisia, ³Universal Hospital Habib Bourguiba, Neurology, SFAX, Tunisia, ⁴Habib Bourguiba university hospital, Neurology, Sfax, Tunisia

Background and Aims:: To study the prevalence of BD in patients followed for MS and to determine the factors related to it.
Methods:: This was a cross-sectional, descriptive and analytical study, which took place in the neurology department at the Habib Bourguiba University Hospital in Sfax. It focused on MS patients in remission phase (Mc Donald criteria 2017). The questionnaire included sociodemographic, clinical and therapeutic data and two psychometric tools: the Mood Disorder Questionnaire (MDQ) and the Expanded Disability Status Scale (EDSS).
Results:: Our study included 93 patients. The mean age was 36.59 ± 10.69 years, with a sex ratio (M/F) of 0.45. The socio-economic level was high in 47.3% of cases. The patients presented a relapsing-remitting form in 94.6% of the cases. Of the neurological functions affected according to the EDSS, cerebellar function was affected in 33.5% of cases. The total dose of corticosteroids prescribed during relapses ranged from 0 to 100 g, with a median of 15 g. At the time of the study, 79 patients (84.9%) were being treated with disease-modifying therapy for MS: first-line therapy (27.8%) and second-line therapy (72.2%). According to the MDQ, 13 MS patients had BD. The clinical factors associated with BD were the presence of cerebellar function impairment (p = 0.011). Furthermore, no correlation was found between BD and socio-demographic factors or therapeutic factors.
Conclusions:: Our study confirmed the frequency of BD in MS, independent of sociodemographic and therapeutic factors. This link could be secondary to biological, immuno-inflammatory and genetic factors, according to the literature.
EVALUATION OF SUICIDAL IDEATION IN MULTIPLE SCLEROSIS PATIENTS

Mouna Ben Abdallah¹, Nouha Farhat², Imen Baati¹, Nadia Bouattour³, Mariem Damak², Jawaher Masmoudi¹, Chokri Mhiri³
¹CHU Hedi Chaker hospital Sfax Tunisia, Psychiatry, Sfax, Tunisia, ²CHU habib bourguiba Sfax, Neurology, sfax, Tunisia, ³Universal Hospital Habib Bourguiba, Neurology, SFAX, Tunisia

Background and Aims:: The aims of our work were to assess suicidal ideation in patients with multiple sclerosis (MS) and to determine the factors associated with it.

Methods:: Our study, descriptive and analytical, took place in the neurology department of the Habib Bourguiba University Hospital in Sfax. It focused on patients with MS in remission (Mc Donald criteria 2017). A pre-established form was used to collect sociodemographic, clinical and radiological data. We also used the Beck Suicide Scale (BSS) and the Hospital Anxiety and Depression Scale (HADS).

Results:: Our study included 93 patients followed for MS. The socio-economic level was high in 47.3% of cases. The duration of MS ranged from 1 to 276 months (median = 72 months). Spinal cord injury and brain atrophy were found on imaging in 71% and 15.1% of cases, respectively. At the time of the study, ten patients (10.8%) reported suicidal ideation. The BSS score ranged from 0 to 21 (median = 0). The BSS score was associated with low to moderate socioeconomic status (p = 0.021) and the presence of spinal cord injury (p = 0.045) and brain atrophy on imaging (p = 0.015). The duration of the disease was also correlated with the suicidal ideation score (p = 0.022). This score was higher in depressed patients (p = 0.000).

Conclusions:: Several psychosocial, clinical and radiological factors could explain the occurrence of suicidal ideation in MS patients. Early detection of suicidal ideation is important in this vulnerable population, especially in the presence of depressive symptoms.
FACTORS ASSOCIATED WITH ANXIETY IN PATIENTS WITH MULTIPLE SCLEROSIS

Mouna Ben Abdallah\textsuperscript{1}, Nouha Farhat\textsuperscript{2}, Imen Baati\textsuperscript{1}, Khadija Sonda Moalla\textsuperscript{3}, Mariem Damak\textsuperscript{2}, Jawaher Masmoudi\textsuperscript{1}, Chokri Mhiri\textsuperscript{4}
\textsuperscript{1}CHU Hedi Chaker hospital Sfax Tunisia, Psychiatry, Sfax, Tunisia, \textsuperscript{2}CHU habib bourguiba Sfax, Neurology, sfax, Tunisia, \textsuperscript{3}Universal Hospital Habib Bourguiba, Neurology, Sfax, Tunisia, SFAX, Tunisia, \textsuperscript{4}Universal Hospital Habib Bourguiba, Neurology, SFAX, Tunisia

**Background and Aims::** To study the prevalence of anxiety in patients with MS and to determine the factors related to it.

**Methods::** This is a cross-sectional, descriptive and analytical study in the neurology department at the CHU Habib Bourguiba in Sfax, among MS patients in remission phase (Mc Donald criteria 2017). The questionnaire included sociodemographic and clinical data and two measurement tools: the Hospital Anxiety and Depression Scale (HADS) and the Expanded Disability Status Scale (EDSS).

**Results::** The 93 patients included in the study had a mean age of 36.59 ± 10.69 years and a sex ratio (M/F) of 0.45. The participants were married in 57% of cases. Eighteen patients (19.4%) smoked, with a daily number of cigarettes between 4 and 25 (median = 12.5). The duration of the disease ranged from 1 to 276 months (median = 72 months). The EDSS score ranged from 0 to 8 (median = 3.5). MS patients had anxiety in 38.7% of cases. Factors correlated with anxiety were: being unmarried (single or divorced) (p = 0.028), high number of cigarettes consumed per day (p = 0.046) and high EDSS score (p = 0.01). We did not find an association between anxiety and gender, nor did we find an association with the duration of the disease.

**Conclusions::** Anxiety is a frequent psychiatric comorbidity in our MS patients, according to the literature. It influences daily functioning by decreasing quality of life, which implies special attention to patients with personal and clinical risk factors to detect anxiety early and treat it in time.
COMORBIDITY IN PEOPLE WITH MULTIPLE SCLEROSIS. A CROSS-SECTIONAL STUDY IN TWO ITALIAN AREAS

Giulia Mallucci1, Michela Ponzio2, Paola Borrelli3, Maria Cristina Monti4, Sara Fusco1, Eleonora Rigoni1, Dabila Amicizia5, Giampaolo Brichetto2, Pietro Perotti5, Mario Battaglia7, Maria Francesca Piazza5, Santino Silva6, F Ansaldi9, Cristina Montomoli4, Roberto Bergamaschi1

1IRCCS Mondino Foundation, Multiple Sclerosis Research Centre,, Pavia, Italy, 2Italian Multiple Sclerosis Foundation, Scientific Research Area, Genova, Italy, 3University "G. d'Annunzio" Chieti-Pescara,, Department Of Medical, Oral And Biotechnological Sciences, Laboratory Of Biostatistics, Chieti, Italy, 4University of Pavia, Department Of Public Health, Pavia, Italy, 5Liguria Health Authority A.li.sa, Genova, Italy, 6Health Protection Agency, Ats, Pavia, Italy, 7University of Siena, Department Of Life Sciences, Siena, Italy, 8Health Protection Agency, Pavia, Pavia, Italy, 9University of Genoa, Department Of Health Sciences, Genova, Italy

Background and Aims:: The reported prevalence of comorbidities in people with multiple sclerosis (pwMS) varies widely depending on specific comorbid conditions, population evaluated and socio-demographic factors. Our aim is to estimate the prevalence of major comorbidities and to analyze demographic factors related to presence of comorbidity in pwMS.

Methods:: Comorbidity in pwMS was assessed in the period 2012-2017 using a specific algorithm currently used for monitoring prevalence of chronic diseases by Italian Local Health Authorities. The data refer to two study areas of Northern Italy (Pavia, PV and Genoa, GE provinces) where the MS person were identified through a validated administrative MS case definition. Logistic regression models were used to evaluate the risk of having at least a comorbidity considering age class, sex, and study area.

Results:: The MS cases identified were 2984. The 59.5% of pwMS had at least one comorbidity (50.5% GE and 78.6% PV, p<0.001), 64.5% were females (p>0.05) and MS GE population was slightly older (GE median=50 vs PV median=49 years, p=0.005). The most prevalent comorbidities were: depression (32.8%), cancer (29.2%), hypertension (18.0%), heart disease (7.8%), hyperlipidaemia (7.3%) and cerebrovascular diseases (7.1%). Presence of comorbidities were significantly less likely among males (OR 0.8, p=0.008) and more likely in PV area (OR=4.57, p<0.001) and among older age groups (ORs from 1.31 to 9.58 considering the different age classes, p<0.001).

Conclusions:: Our study shows the importance of considering population-based characteristics when evaluating comorbidities in MS as prevalence may vary based on age, sex and residence geographic area.
THE LINK BETWEEN MULTIPLE SCLEROSIS AND DEPRESSION

Mouna Ben Abdallah, Nouha Farhat, Imen Baati, Salma Sakka, Mariem Damak, Jawaher Masmoudi, Chokri Mhiri

1CHU Hedi Chaker hospital Sfax Tunisia, Psychiatry, Sfax, Tunisia,
2CHU habib bourguiba Sfax, Neurology, sfax, Tunisia,
3UNIVERSITY HOSPITAL CENTER HABIB BOURGUIBA, Neurology, SFA, Tunisia,
4Universal Hospital Habib Bourguiba, Neurology, SFAX, Tunisia

Background and Aims:: To study the prevalence of depression in patients with MS and to determine the factors related to it.

Methods:: Our study, descriptive and analytical, focused on patients followed for MS at the neurology department, Habib Bourguiba University Hospital in Sfax. In addition to collecting sociodemographic, clinical and radiological data, we used the Hospital Anxiety and Depression Scale (HADS) and the Expanded Disability Status Scale (EDSS).

Results:: The 93 patients included in the study had a low to medium socio-economic level in 52.7% of cases. The duration of MS ranged from 1 to 276 months (median = 72 months). The EDSS score ranged from 0 to 8 (median = 3.5). Urinary function was affected in 37.6% of cases. On imaging, frontal and spinal cord lesions were found in 47.3% and 71.1% of cases respectively. MS patients had depression in 26.9% of cases. Patients with a low to medium socio-economic level were more depressed (p = 0.006). The clinical factors of MS associated with depression were: the duration of the disease (p = 0.031), the severity of disability (p = 0.000) and the impairment of urinary function (p = 0.027). As for radiological factors, the presence of a frontal lesion and a spinal cord lesion on MRI was associated with depression (p = 0.001 and p = 0.028, respectively).

Conclusions:: The results of our study showed that depression was common in MS patients. It would be wise to develop a multidisciplinary approach with collaboration between neurologists and psychiatrists to improve the management of this psychiatric comorbidity.
ADMINISTRATIVE DATA TO ESTIMATE THE BURDEN OF MAJOR COMORBIDITIES IN MULTIPLE SCLEROSIS. A CROSS-SECTIONAL STUDY IN TWO ITALIAN AREAS

Maria Cristina Monti1, Giulia Mallucci2, Michela Ponzio3, Paola Borrelli1,4, Eleonora Rigoni2, Sara Fusco2, Dabiela Amicizia2,5, Giampaolo Brichetto3, Maria Francesca Piazza5, Pietro Perotti6, Santino Silva7, F Ansaldi8, Mario Battaglia9, Cristina Montomoli1, Roberto Bergamaschi10

1University of Pavia, Department Of Public Health, Pavia, Italy, 2IRCCS Mondino Foundation, Multiple Sclerosis Research Centre, Pavia, Italy, 3Italian Multiple Sclerosis Foundation, Scientific Research Area, Genova, Italy, 4University “G. d’Annunzio” Chieti-Pescara, Department Of Medical, Oral And Biotechnological Sciences, Laboratory Of Biostatistics, Chieti, Italy, 5Liguria Health Authority, A.l.i.s.a, Genova, Italy, 6Health Protection Agency, Ats, Pavia, Italy, 7Health Protection Agency, Pavia, Pavia, Italy, 8University of Genoa, Department Of Health Sciences, Genova, Italy, 9University of Siena, Department Of Life Sciences, Siena, Italy, 10IRCCS Fondazione Mondino, Centro Sclerosi Multipla, Pavia, Italy

Background and Aims:: Although comorbidity is important in Multiple Sclerosis (MS), there are few validated methods for its assessment. Our aim is to estimate the burden of major comorbidities in people with MS (pwMS) in two Northern Italy study areas (Pavia, PV and Genoa, GE), using routinely collected healthcare data.

Methods:: We estimated prevalence of comorbid conditions in pwMS in the period 2012-2017 using a specific algorithm currently used for monitoring prevalence of chronic diseases by Italian Local Health Authorities (BDA system). Direct healthcare costs were defined by regional and governmental contracts; the aggregated healthcare expenditure was compared between pwMS with/without comorbidities and by sex, age class and area of study.

Results:: The MS cases identified were 2984, 2035 in GE and 949 in PV and 59.5% of pwMS had at least one comorbidity. The mean direct healthcare costs of MS were substantially higher for individuals with comorbidity (36,135 € vs 25,796 €, p<0.001), showing 40% of additive costs.

Conclusions:: Our study provides evidence of the burden of comorbidities in MS. Comorbidity is common in MS and produce additive costs. The use of administrative data for tracking the MS comorbidity could help to improve knowledge’ gaps. Moreover, when an additivity situation is involved, preventive policies could lead to monetary savings.
Background and Aims:: The pathogenesis of multiple sclerosis (MS) is multifactorial, being controversial whether there is a relationship between this disease and cancer. A recent study reported an increased risk of primary central nervous system cancer (PCNSC) but a decreased overall risk of other cancer (OC) in MS patients.

Methods::

Table 1. Demographic characteristics of patients with diagnosis of MS and cancer. PCNSC: primary central nervous system cancer. OC: other cancer. *Mean / median. SD: standard deviation. IQ: interquartile range 25-75.

Methods: We performed an observational, analytic, retrospective, case-control study at National Medical Center “Siglo XXI”, in Mexico City. All patients whom got cancer diagnosis after MS diagnosis criteria were include. Our list includes type of cancer, immunomodulatory (IM) drugs used and gender.

Results::
11 patients were included, while only 2 (18.1%) got PCNSC. Incidence in women was higher than in men [9 (81.8%) versus 2 (18.1%); P < .05]. Breast cancer was present in four patients (36.3%), while 2 was treated with glatiramer acetate, and 2 with fingolimod. Other IM used in patients with cancer were interferon and mitoxantrone, with no statistically significant evidence of relationship between IM and an specific type of cancer. The Odds Ratio (OR) for getting cancer diagnosis after MS being woman was 20.25 with 95% confident interval of 1.24-16.25 (p value 0.0028).

**Conclusions:** Being woman is by itself a risk factor for the development of cancer after MS treatment and breast cancer was the most frequent type. We have not reported an increased risk of brain cancer after long-term exposure to IM. No data support an increase in cancer risk among MS patients treated with IM.

RESULTS OF LONG-TERM FOLLOW-UP AFTER HIGH-DOSE IMMUNOSUPPRESSIVE THERAPY AND AUTOTRANSPLANTATION OF HEMATOPOIETIC STEM CELLS (ATHSC) IN PATIENTS WITH A SECONDARY PROGRESSIVE MULTIPLE SCLEROSIS (SPMS).

Sergey Makarov, Anna Nikolaeva, Oksana Berezhnaya
Center for Bone Marrow Transplantation of the Samara Regional Clinical Hospital named after V. D. Seredavin, Hematology, samara, Russian Federation

Background and Aims:: Most authors evaluate ATHSC as an effective treatment method for remitting and rapidly progressing MS. The question of the feasibility of using ATHSC in the SPMS remains poorly understood.
To evaluate the long-term results of ATHSC based on clinical and radiological data in patients with SPMS.

Methods:: We analyzed data from 14 MS patients aged 29 to 47 years, who were observed in the center for more than 5 years with a good clinical response to transplantation. Pretransplantation conditioning was performed according to the standard protocol: BEAM+ALG.

Results:: The duration of the disease before transplantation is from 9.0+ 5.1years, EDSS - from 4.5 to 6.5 points. The duration of follow-up after ATHSC is from 60 to 148 months. After ATHSC, there was an improvement in the condition in 6 patients with a decrease in EDSS by 0.5 points. The condition was stabilized in 8 patients with no signs of activity according to MRI data. After two years, the condition was stabilized in 11 patients, 3 patients showed deterioration with further accumulation of disability. The five-year progression-free survival rate was 35 %.

Conclusions:: SPMS is of a clinical and immunological heterogeneous nature, where inflammatory activity may persist. The best results after ATHSC were observed with the duration of the disease up to 10 years, the level of EDSS no more than 6.5 points, a low index of disease progression, as well as episodes of exacerbation disease in the anamnesis.
INVESTIGATION OF FATIGUE AND ANXIETY IN PATIENTS WITH MULTIPLE SCLEROSIS DURING COVID-19

Furkan Bilek¹, Ferhat Balgetir², Caner Demir²
¹Firat University, Department Of Physiotherapy And Rehabilitation, Elazığ, Turkey, ²Firat University, Department Of Neurology, Elazığ, Turkey

Background and Aims: People with MS (PwMS) have a higher burden of neuropsychiatric comorbidities and are known to undertake maladaptive coping strategies in stress conditions. The aim of this study was to understand the effects of the COVID-19 epidemic process and epidemic measures on anxiety and fatigue in MS patients.

Methods: The study was designed as a prospective, cross-sectional survey study. The early stage of COVID-19 outbreak (ESO) data were collected on January, 2020 and the peak stage of COVID-19 outbreak (PSO) data were collected on April, 2020. Individuals who were being followed with a diagnosis of RRMS or SPMS and an EDSS score of ≤4.0 were included in the study. Participants' depression states were evaluated with the Beck Anxiety Inventory (BAI) and fatigue states were evaluated with the fatigue effect scale (FIS).

Results: The study included 61 PwMS (Female: 83.60%). The average age of the participants was 29.4±7.24. BAS levels of the patients showed a significant increase in PSO compared to ESO (p<0.01). In FSI measurements, the cognitive subscale scores and the total FIS score were significantly at PSO compared to ESO (p<0.05 for all), whereas no significant difference was found with regard to the physical and social subscale scores (p>0.05).

Conclusions: The results of this study show that the anxiety levels and fatigue of MS patients continue to increase together during the COVID-19 process. As the COVID-19 outbreak continues to widen, our findings will provide vital advice for the development of a psychological support strategy and priority areas in areas affected by the outbreak.
ANCESTRALITY AND FAMILIAL RECURRENCE RATES OF MULTIPLE SCLEROSIS IN BRAZIL

Fabiana Pereira¹, Raphael Guimarães², Regina Alvarenga³
¹UNIVERSIDADE FEDERAL DO ESTADO DO RIO DE JANEIRO, Neurology, Rio de Janeiro, Brazil, ²Escola Politécnica, Fundação Oswaldo Cruz, Public Health, Rio de Janeiro, Brazil, ³Universidade Federal do Estado do Rio de Janeiro, Neurology, Rio de Janeiro, Brazil

Background and Aims:: Familial multiple sclerosis is defined as multiple sclerosis cases occurring in at least two family members, and there is no data on the recurrence risk of familial multiple sclerosis in the Brazilian population, which is characterized by a high frequency of afrodescendants as a result of the miscegenation occurred between European settlers and African slaves. Objective: To estimate the multiple sclerosis recurrence risk in patient families in Rio de Janeiro (RJ) and investigate the relationship with Caucasian and African ancestry.

Methods:: A cross-sectional study was conducted in Rio de Janeiro (Brazil), with 197 patients followed by a RJ specialized outpatient clinic. Recurrence risks were calculated by relative multiple sclerosis patient categories through age-adjusted Crude recurrence risks.

Results:: Familial multiple sclerosis frequency (7.10%) was identified in the RJ study population. The risk of Age-adjusted recurrence (ARR) was high among grandparents, at 2.72 (95% CI 2.16 - 3.28). Sibling ARR was calculated as 1.41 (95% CI 1.22 - 2.08), and Caucasian ancestry conferred a risk of 1.96. Concerning the parent relationship, ARR was of 1.57 (95% CI 1.36 - 1.78) and increased to 1.76 (95% CI 1.41 - 2.11) in the presence of a European ancestor. Among uncles/aunts, a significant increase from 1.42 (95% CI 1.01 - 1.83) to 2.91 (95% CI 2.28 - 3.54) risk in individuals with Caucasian ancestry was observed, and to 2.65 (95% CI 2.02 - 3.27) in individuals with African ancestry.

Conclusions:: A higher risk among individuals with Caucasian ancestry was observed compared to Afro descendant ancestry.
THE PREVALENCE OF COVID-19 INFECTION IN PATIENTS WITH MULTIPLE SCLEROSIS (MS): A SYSTEMATIC REVIEW AND META-ANALYSIS

Mahsa Ghajarzadeh1, Abdorreza Naser Moghadasi2, Omid Mirmosayyeb3, Mahdi Barzegar3, Mohammad Ali Sahraian2

1Multiple sclerosis research center, neuroscience institute, tehran university of medical sciences, tehran, Iran, Neurology, tehran, Iran, 2multiple sclerosis research center, neuroscience institute, tehran university of medical sciences, Neurology, tehran, Iran, 3Isfahan Neurosciences Research Center, Isfahan University of medical sciences, Isfahan, Iran, Neurology, isfahan, Iran

Background and Aims:: There prevalence of COVID-19 is different in studies conducted in different countries. The aim of this systematic review and meta-analysis is to estimate pooled prevalence of COVID-19 in MS patients.

Methods:: Two independent researchers independently searched PubMed, Scopus, EMBASE, Web of Science, and google scholar along with gray literature up to 23th of October 2020. The search strategy included the MeSH and text words as (((coronavirus OR Wuhan coronavirus OR novel coronavirus OR coronavirus disease OR COVID-19 OR 2019 novel coronavirus infection OR 2019-nCoV OR severe acute respiratory syndrome coronavirus 2 OR SARS-CoV-2) AND (Multiple Sclerosis OR Sclerosis, Multiple) OR Sclerosis, Disseminated) OR Disseminated Sclerosis) OR MS (Multiple Sclerosis) OR Multiple Sclerosis, Acute Fulminating).

Results:: We found 1460 articles by literature search, after deleting duplicates 1023 remained. Twelve articles remained for meta-analysis. Totally 16577 patients were evaluated and total number of possible/confirmed cases was 570. Mean age ranged from 35-54 years. Totally 4 patients died. The pooled prevalence of COVID-19 in MS patients was 4% (95% CI: 2%-5%) (I^2=95%, P <0.001). The pooled prevalence of hospitalization in infected cases was 15% (95% CI: 8%-23%) (I^2=92%, P<0.001). The pooled prevalence of death in infected cases was 0% (I^2=0, P=0.9).

Conclusions:: Hospitalization rate is higher among MS patients based on COVID-19 while the pooled infection rate estimated as 4%.
PREVALENCE OF COVID-19 INFECTION IN PATIENTS WITH NEUROMYELITIS OPTICA SPECTRUM DISORDER (NMOSD): A SYSTEMATIC REVIEW AND META-ANALYSIS.

Neuromyelitis optica spectrum disorder (NMOSD) is an inflammatory disease of the central nervous system (CNS) which predisposes cases to increased risk of infection based on immunosuppressive treatments.
Conclusions:

The pooled estimate of COVID-19 infection in NMSD patients was 2% (95% CI: 0.7%-7.0%) (I2=80.6%, p<0.001).

Conclusions: Prevalence of COVID-19 infection is rare in NMSD patients.

Methods:

We systematically searched PubMed, Scopus, EMBASE, Web of Science, and Google Scholar and also gray literature up to the included studies. The search strategy included the MeSH and text words as ((coronavirus OR Wuhan coronavirus OR novel coronavirus OR coronavirus disease OR COVID-19 OR 2019 novel coronavirus infection OR 2019 CoV) AND (Neuromyelitis optica spectrum disorder OR NMOSD OR Devic syndrome OR Neuromyelitis optica spectrum disorder)).

STMATA (Version 13.0; Stata Corp LP, College Station, TX, USA) was used for data analysis. Inconsistency (I2) was calculated for heterogeneity evaluation.

Results:

The literature revealed 54 articles. Totally, 3458 patients with NMOSD were evaluated. The pooled estimate of COVID-19 infection in NMOSD patients was 2% (95% CI: 0.7%-7.0%) (I2=80.6%, p<0.001).

Conclusions: Prevalence of COVID-19 infection is rare in NMOSD patients.
PSYCHOMETRIC PROPERTIES OF CROATIAN VERSION OF THE MULTIPLE SCLEROSIS INTIMACY AND SEXUALITY QUESTIONNAIRE-15

Zvonimir Uzarevic¹, Anamarija Soldo Koruga²,³, Ivana Kampic², Zeljka Popijac², Silva Butkovic Soldo²,³ ¹Faculty of Education-University of Osijek, Department Of Natural Sciences, Osijek, Croatia, ²Clinical Hospital Centre Osijek, Department Of Neurology, Osijek, Croatia, ³Faculty of Medicine-University of Osijek, Department Of Neurology, Osijek, Croatia

Background and Aims:: Multiple sclerosis (MS) is a chronic demyelinating inflammatory progressive disease of the central nervous system that results in a wide range of clinical manifestations and has a great impact on patient quality of life. The aim of this study was to determine the psychometric properties of Croatian version of the multiple sclerosis intimacy and sexuality questionnaire-15 (MSISQ-15).

Methods:: A cross cultural adaptation of the MSISQ-15 into Croatian and a psychometric analysis of the translated version of the MSISQ-15 was carried out in MS patients. The MSISQ-15 includes three subscales: primary - MS related neurologic changes that may directly affect sexual feelings and/or sexual response; secondary - MS related physical changes that affect the sexual response indirectly; and tertiary - referred to the psychosocial and cultural aspects of MS that affect sexuality. The data was descriptively analysed and Cronbach’s alpha assessed internal consistency. Pearson’s correlation was performed on the MSISQ-15 total scale and subscale scores. The level of significance was set to p<0.05.

Results:: Eighty-two MS patients were assessed (mean age 42.6±11.9 years, 62.2% females). The means score for the MSISQ-15 total scale, primary, secondary and tertiary subscales were 33.35±13.00, 12.01±5.38, 11.31±4.47 and 10.04±5.37, respectively. Cronbach’s alpha for the MSISQ-15 total scale was 0.93 (range for subscales: 0.84-0.92). The total MSISQ-15 scale significantly correlated with all subscale scores (Pearson correlation range: 0.77-0.91).

Conclusions:: The Croatian version of the MSISQ-15 can be a valid and reliable instrument for multiple sclerosis intimacy and sexuality problems in Croatian-speaking MS patients.
DIFFERENCES IN MS CLINICAL AND EPIDEMIOLOGICAL CHARACTERISTICS IN ASHKENAZI AND NON ASHKENAZI JEWISH PATIENTS IN ISRAEL – A RETROSPECTIVE SINGLE CENTER STUDY

Keren Regev1,2, Gil Ben Noon2
1Tel Aviv Sourasky Medical Center, Neurology, Tel Aviv, Israel, 2Sourasky Tel Aviv Medical Center, Neurology, Tel Aviv, Israel

Background and Aims:: Background: The prevalence and severity of Multiple Sclerosis (MS) are diverse across different ethnicities, with a tendency to a more severe phenotype in Non-Caucasian populations. Objective: Our objective was to evaluate the differences in disease phenotype between Ashkenazi and Non-Ashkenazi Jewish patients in Israel.

Methods:: We conducted a retrospective cohort study based on clinical charts. Subjects were assigned to Ashkenazi or Non-Ashkenazi groups according to self-reported ancestry and disease severity was assessed using the expanded disability status (EDSS), MS severity score (MSSS), progression index (PI) and MRI metrics.

Results:: We identified 330 Ashkenazi and 207 Non-Ashkenazi patients. Non-Ashkenazi patients were younger at evaluation (43.0 years vs. 49.4 years) and at disease onset (32.7 years vs. 35.7), with a lower proportion of females (62.3% vs. 73.3%). MSSS was higher in Non-Ashkenazi patients (3.29 vs. 2.91) when adjusted to covariates using propensity score analysis and in patients with relapsing remitting MS (RRMS) when analyzed separately (2.47 vs. 1.90).

Conclusions:: Non-Ashkenazi Jewish patients scored higher in disease severity scores, were diagnosed at an earlier age and demonstrated a narrower sex gap as compared to Ashkenazi Jewish patients. These findings might contribute to prognosis evaluation and motivate further epidemiological and genetic investigation.
CLINICAL AND PARACLINICAL FINDINGS IN A CASE SERIES OF MOGAD: EXPLORING THE PRESENCE OF PERIVENULAR BRAIN WHITE MATTER LESIONS

Antonio Farina¹, Alice Mariotti², Federica Azzolini², Claudia Mechi³, Anna Maria Repice², Alessandro Barilaro³, Luca Massacesi¹

¹University of Florence and Careggi University Hospital, Department Of Neurosciences Drugs And Child Health And Department Of Neurology 2, FIRENZE, Italy, ²Careggi University Hospital, Department Of Neurosciences Drugs And Child Health And Department Of Neurology 2, Firenze, Italy, ³Careggi University Hospital, Department Of Neurology 2, Firenze, Italy

Background and Aims:: Clinical and histopathological manifestations of the MOG associated disease (MOGAD) may overlap with those of multiple sclerosis (MS) and of NMO spectrum disorders (NMOSD), and histopathological findings consistent with MS pattern II lesions have been reported. To further explore clinical and radiological phenotype of MOGAD, evaluating for the first time the presence of perivenular brain white matter lesions (PVL).

Methods:: We retrospectively reviewed the records of a single Neurology clinic for MOGAD cases, analyzing clinical and paraclinical findings.

Results:: In the patients included (n= 11), median age 27 (range 19-52), the most frequent clinical manifestation at onset was optic neuritis (73%), bilateral in 62% of the cases. Intrathecal oligoclonal IgG production in CSF was never observed. Over a median follow-up of 16 months, 36% of patient experienced a clinical relapse. At last follow-up, 36% of the patients met the 2015 NMOSD diagnostic criteria and none of them fulfilled the 2017 McDonald criteria for MS. At baseline MRI, 6 out of the 10 patients with an available scan had at least one brain lesion, that resulted located in a “MS typical” site in 4/10 cases. Corticospinal tract lesions were present in 2/10 cases. Several PVLs were observed in the case showing evaluable lesions.

Conclusions:: Our case series displays several clinical and paraclinical specific features of MOGAD, despite a few brain MRI findings overlapped with MS. The observation PVLs in one case warrants further studies investigating the potential clinical value of the central vein sign for the differential diagnosis between MS and MOGAD.
Background and Aims:: Peripheral nervous system in form of nerve or a radicle can also be involved in NMOSD and MOGAD. Kim et al postulated that CNS-PNS transition zone i.e the radicles are main target as they contain AQP4.

Methods:: This was a prospective observational study done for 15 months. Inclusion criteria: Patients with age >13y who satisfy IPND NMOSD diagnostic criteria or MOGAD. Exclusion criteria: Patient who have past history of neuropathy or any disease which can cause peripheral nerve involvement. Eg:- T2DM & Vasculitis. All patients underwent sensory and motor nerve conduction studies including F wave.

Results:: 95 patients were included in study. Mean age was 33.99 ± 13.8 years. Male: Female =1:3. Isolated optic neuritis (ON) was the presentation in 57(60%), isolated myelitis in 25 (32.6%), myelitis with ON in 12(12.6%), brainstem syndrome in 1(1.1%), diencephalic syndrome in 1(1.1%) and area postrema syndrome in 6(6.3%) 30% patients had neuropathic symptoms. AQP4 antibody was positive in 37% patients, Anti MOG was positive in 15% and both were negative in 52%. NCS was abnormal in 41 (43.2%). Among which demyelination pattern was seen in 16(39%) and axonal pattern was seen in 25(61%). Abnormal NCS was found the least in patients of age 12-20 years (p=0.00).
Conclusions: We hypothesize that presence of Aquaporin-4 at extracranial site would lead to complement mediated inflammation and axonal nerve damage. Our study showed significant association of peripheral demyelination in dual antibody negative patients. So, we think there could be association of other antibodies in these disorders which would cause demyelination in the peripheral nervous system.
GUILLAIN BARRÉ SYNDROME DURING THE ZIKA PANDEMIC FROM 2016 TO 2019 IN VERACRUZ, MEXICO.

Luis Del Carpio-Orantes¹, Sergio García-Méndez², Ishar Solís-Sánchez¹, Miguel Arnulfo Perfecto-Arroyo³, Jesús Salvador Sánchez-Díaz¹, Nancy Patricia Moreno-Aldama³
¹Instituto Mexicano del Seguro Social, Internal Medicine, Veracruz, Mexico, ²Hospital Regional de Alta Especialidad de Oaxaca, Internal Medicine, Oaxaca, Mexico, ³Instituto Mexicano del Seguro Social, Neurology, Veracruz, Mexico

Background and Aims:: During the Zika pandemic in southeastern Mexico, there was an increase in Guillain Barré cases initially attributable to viral neurotropism demonstrated in other latitudes

Methods:: We conducted a descriptive, retrospective, and longitudinal study in Veracruz, Mexico, where follow-up of cases of Guillain Barre Syndrome (GBS) occurred during 2016 to 2019. The central point of the study is to look for the etiological association of GBS with the presence of acute zika infection. Secondly, other known neurotropic agents, both viral and bacterial were searched. The diagnosis techniques used were PCR-RT (blood and urine) and IgM/IgG for Zika; serum PCR-RT and IgM/IgG for Dengue and Chikungunya; IgM/IgG for TORCH; PCR-RT in CSF for Herpes and Enterovirus; serological panel of Hepatitis B and C; PCR-RT in rectal swab for Campylobacter.

Results:: A cohort of 40 patients has been formed over 4 years of study, of which only 2 cases were identified by PCR-RT in urine; others were identified such as: Dengue, Chikungunya, Enterovirus, Herpes and Hepatitis B; however, the identification of Campylobacter was even more remarkable, also highlighting that only four patients had diarrhea. Regarding the treatment, 38 patients received IVIG, 1 patient received plasmapheresis and 1 patient received both. The prognosis was good in 35 patients (basal Hugues from 4–5 to 2), 5 had poor functional prognosis and died.
Conclusions: During the Zika pandemic in southeast Mexico, the main agent of Guillain Barré syndrome cases was Campylobacter, the incidence of Zika and other viruses with neurotropic potential was low, so campylobacter should always be considered.
FREQUENCY AND EFFECT OF DONEPEZIL ON COGNITIVE DYSFUNCTION IN PATIENTS WITH MS OF UZBEK NATIONALITY

Dilafruz Mirzaeva
Medical Sanitary Unit, Emergency Department, Zarafshan, Uzbekistan

Background and Aims:: About half of all MS patients experience problems with memory and other cognitive functions. Because there have been limited trials of donepezil in MS and the results have been mixed, the current evidence of the efficacy of donepezil on cognitive function in people with MS is unclear. Donepezil is a cholinesterase inhibitor. It is thought to work by inhibiting an enzyme which breaks down acetylcholine, which is a chemical in the central nervous system that acts as a neurotransmitter - carrying messages from nerve to nerve. Therefore, donepezil increases levels of acetylcholine.  
Methods:: This study included 16 (100%) admitted Uzbek patients with a diagnosis of MS who applied to the local Family Hospital during the period 2017-2020. In 7 (43.75%) patients, cognitive impairment was observed as a decreased memory and thinking. 3 of them (18.75%), by their consent, took the drug Alzancer (Donepezil) in a dose of 10 mg, 1 tab daily for 120 days.  
Results:: Of the 3 (18.75%) patients taking donepezil, only 2 (12.5%) noted a slight improvement in memory 90-100 days after the start of the drug. 1 (6.25%) patient, comparing the periods before and after taking the drug, did not indicate any (positive or negative) changes in memory and thinking.  
Conclusions:: The number of patients with cognitive impairment was 7 (43.75%). Taking donepezil 10 mg, 1 tab daily for 120 days did not have a significant positive effect on the cognitive impairment of patients with MS in the local family clinic.
MULTIPLE SCLEROSIS ENVIRONMENTAL RISK FACTORS AT BEJAIA, AN ALGERIAN STUDY.

Saddek Khellafter1, Asma Sait2, Loubna Zemmouchi2, Ouahiba Ait Amokrane1, Rafika Mersel1, Anissa Bayou1, Hakim Deba1
1Bejaia University Hospital, Internal Medicine, Bejaia, Algeria, 2Bejaia University Hospital, Faculty Of Medicine, Bejaia, Algeria

Background and Aims:: Multiple Sclerosis (MS) is an inflammatory and degenerative disease of central nervous system. This condition involves multiple genetic and environmental factors. The aim of our study is to evaluate environmental related risk factors.

Methods:: A cross-sectional study carried out during 2020 at the University Hospital of Bejaia in Algeria. Data were collected using a risk factors questionnaire inspired from the international ENVIMS study.

Results:: We collected 35 cases of MS with an F/M sex ratio of 1.9. Mean age of disease onset was 28±6.62 years. Analysis objectified low vitamin D levels in 51.42% of cases, overall reduced physical activity (82.9%), irregular sun exposure during childhood (35%) and adolescence (71.4%), high body mass index (BMI) values (48.6%), active (25%) and passive smoking habits (54%). We have found significant associations, between high relapses frequency and each of high BMI, vitamin D deficiency and low sun exposure during childhood. On the other hand, low relapses frequency was correlated with regular physical activity and long breastfeeding period. Low initial EDSS was related with normal BMI and infant breastfeeding too.

Conclusions:: Vitamin D deficiency, reduced sun exposure in childhood, smoking and insufficient physical activity during adolescence, appear to be risk factors of developing MS in adulthood.
MORPHO-FUNCTIONAL ALTERATIONS IN AUTOSOMAL-DOMINANT LEUKODYSTROPHY (ADLD): THE INTRIGUING ROLE OF THE ASTROCYTES

Stefano Ratti¹, Isabella Rusciano¹, Sara Mongiorgi¹, Irene Neri¹, Gabriella Teti¹, Alessandra Cappellini¹, Mirella Falconi¹, Pietro Cortelli², Lucio Cocco¹, Lucia Manzoli², Giulia Ramazzotti¹
¹Alma Mater Studiorum - University of Bologna, Department Of Biomedical And Neuromotor Sciences, Bologna, Italy, ²IRCCS-Istituto di Scienze Neurologiche, Dibinem- University Of -bologna, Bologna, Italy, ³Alma Mater Studiorum - University of Bologna, Department Of Biomedical And Neuromotor Sciences, bolgna, Italy

Background and Aims:: Autosomal Dominant Leukodystrophy (ADLD) is a rare and fatal adult-onset neurodegenerative disorder that affects the central nervous system. It is characterized by Lamin B1 (LMNB1) gene duplication or deletion upstream the gene, but the molecular mechanisms responsible for driving the onset and development of this pathology are not clear yet. Considering the pivotal role that glial cells as oligodendrocytes and astrocytes, and Leukemia Inhibitory Factor (LIF)-activated signaling pathways have in the myelination process, this work aims to analyze the specific alterations in different cell populations

Methods:: Specific morpho-functional aspects of ADLD patients' primary cells and engineered cellular models overexpressing Lamin B1 have been analyzed.

Results:: Cells from ADLD patients and astrocytes overexpressing LMNB1 show several nuclear alterations, not present in oligodendrocytes overexpressing LMNB1. Moreover, the accumulation of Lamin B1 in astrocytes induces a reduction in LIF and in LIF-R levels with a consequential decrease in LIF secretion, leading to the downregulation of Jak/Stat3 and PI3K/Akt axes, downstream of LIF/LIF-R in both the cellular models. Administrating exogenous LIF, the toxic effects, induced by LMNB1 accumulation, may be partially reverted with differences between astrocytes and oligodendrocytes. In addition, it was observed that astrocytes are undergoing apoptosis, highlighting that LMNB1 overexpression drastically affects astrocytic function reducing their fundamental support to oligodendrocytes in the myelination process. Finally, it has been shown the activation of proinflammatory mechanisms and increase of reactive oxygen species (ROS) in ADLD patients’ cells.

Conclusions:: Our studies point out, for the first time, that astrocytes may be pivotal in the development of the
disease.
PROSPECTIVE LONG-TERM TOCILIZUMAB RESPONSES IN RELAPSING MYELIN OLIGODENDROCYTE GLYCOPROTEIN IGG-ASSOCIATED DISEASE AND FACTORS ASSOCIATED WITH POST-TOCILIZUMAB RELAPSE-FREEDOM

Fan Cheng¹,², Jiawei Wang², Jing Chen³, Hui Pan⁴, Jingtao Yang⁴, Fei Chen⁵, Yuling Duan⁶, Ker Tang¹
¹Hull University Teaching Hospitals NHS Trust, Department Of Neurology, Kingston upon Hull, United Kingdom, ²Peking Union Medical College Hospital, Department Of Neurology, Beijing, China, ³The First Affiliated Hospital of Sun Yat-Sen University, Department Of Neurology, Guangzhou, China, ⁴Chongqing General Hospital, University of the Chinese Academy of Sciences, Department Of Neurology, Chongqing, China, ⁵Zhongshan Hospital of Xiamen University, Department Of Neurology, Xiamen, China, ⁶Xiangya Hospital, Central South University, Department Of Neurology, Changsha, China

Background and Aims:: Tocilizumab (TCZ), an anti-interleukin-6 receptor antibody, shows promise in treating myelin oligodendrocyte glycoprotein-associated neurological disease (MOGAD). However, large prospective studies are lacking, while determinants for post-biologic disease response remain unclear. We prospectively evaluated long-term TCZ-responses in relapsing MOGAD and associated-factors for post-TCZ relapse-freedom.

Methods:: 195 aquaporin-4 antibody-negative adult MOGAD patients with relapses despite ≥3 immunosuppressants (5 highly-specialised neurology-centres) received intravenous TCZ (8mg/kg 4-weekly) for 4years (2017–2021). We characterised pre- and post-TCZ annualised relapse rates (ARR), Expanded Disability Status Scale (EDSS) scores, radiological progression, adverse events (AE), features of those with and without post-TCZ relapses, and elucidated factors for relapse-freedom and odds ratios (OR) by logistic regression.

Results:: Mean age, MOGAD onset-age and disease duration were 47.9, 42.1 and 5.8years, with 566 pre-TCZ clinical demyelinating-episodes (mean 2.9/patient). 63.1% previously used rituximab. Post-TCZ initiation, 21.0% relapsed over 4years (86.1weeks to first relapse). TCZ reduced cumulative ARR (1.81 to 0.11, p<0.0001) and median ARR 18months pre- and post-initiation (2.0 to 0.0, p=0.0009). Previous rituximab-users had lower ARR during TCZ-treatment than rituximab (0.11 vs 0.53, p=0.0007). TCZ mildly-improved EDSS (3.36 to 2.87, p=0.004). 84.6% and 61.0% showed no post-TCZ EDSS or radiological progression. Post-TCZ 4-year survival was 90.8%. 81.0% developed AEs (43.1% infections, 5.1% severe). Post-TCZ relapse-freedom independently-associated with 1 pre-TCZ relapse (OR4.38, p=0.003), pre-TCZ MOGAD duration<2years (OR2.19, p<0.001), onset-age<40 (OR1.83, p=0.001), and no autoimmune comorbidities (OR3.52, p=0.002).

Conclusions:: TCZ reduces MOGAD relapse and disability over 4years. 1 pre-TCZ relapse, pre-TCZ MOGAD duration<2years, onset-age<40 and no autoimmune comorbidities heralded superior responses, identifying those likely to show greater TCZ-response. Efficacy of TCZ-initiation after first relapse warrants further investigation.
EFFICACY OF FINGOLIMOD IN THE 2ND LINE TREATMENT OF ACTIVE RELAPSING-REMITTING MULTIPLE SCLEROSIS: ABOUT A TUNISIAN COHORT OF 50 PATIENTS

Zakaria Saied, Ichrak Ghachem, Fatma Nabli, Emine Rachdi, Cyrine Jeridi, Samir Blel, Samia Ben Sassi
Institut nationale de neurologie, Faculté De Médecine, Tunis, Tunisia

Background and Aims:: Fingolimod (FING) is the first oral immunomodulatory treatment approved for the 2-line disease-modifying treatment of active relapsing-remitting (RR) forms of multiple sclerosis (MS). Observational post-marketing studies are important for clarifying the efficacy and safety of the product in current medical practice. The Aim of our study is to assess the effectiveness of FING in patients with RR-MS followed at the National institution of neurology in Tunis.

Methods:: An observational study on 50 patients with MS, older than 18 years, treated with FING for the first time for a period of ≥ 3 months between 2015 and 2019 and followed up at the National institution of neurology in Tunis.

Results:: FING was initiated at a mean age of 41.3 years (± 10). The mean duration of progression of MS before the initiation of FING was 11.42 years. The mean annualized relapse rate (APR), under the first-line treatments was 1.11, with a significant decrease in APR before and after treatment with FING (from 1.11 to 0.38 under FING, relative risk reduction of 65.76% (p <10^{-3}). 42.6% of patients became free from relapses on FING after an average duration of treatment with FING of 32.1 months. 26 patients (57%) did not present with progression of disability under FING. In multivariate analysis, the duration of the progression of MS at FING introduction was the predictive factor of progression of MS with FING (OR= 2.24, p= 0.018).

Conclusions:: Earlier introduction of FING as soon as the failure of the first-line treatment could improve its effectiveness and the control of relapses.
IMPACT OF THE SARS-COV 2 PANDEMIC ON PATIENTS WITH MULTIPLE SCEROSIS : A TUNISIAN STUDY

Mouna Naguez¹, Samia Younes²
¹fattouma bourguiba university hospital ,department of neurology,Monastir,Tunisia, Department Of Neurology,monastir,tunisia, monastir, Tunisia, ²Department of neurology,Mahdia,Taher Sfar university hospital ,Tunisia, Department Of Neurology, Mahdia, Tunisia

Background and Aims:: In the context of SARS-COV2 pandemic, patients with multiple sclerosis (MS) constitute a vulnerable population due to the assumptions made about the risk of severe infection and the limitation of access to health care. We aim to study the sanitary and therapeutic impact of the SARS-cov2 outbreak on patients with MS.

Methods:: We conducted a cross-sectional study including patients followed for MS. The study period was divided into two: pre-pandemic (October to March 2020) and pandemic (March to June 2020). The diagnosis of MS was selected according to the criteria of Mc Donald (2017). Added to collecting data from medical files, we carried out a telephone questionnaire regarding therapeutic compliance, aggravation or installation of new neurological symptoms.

Results:: Seventy-two patients (mean age =32.6 years, mean EDSS =3.8) were included. During confinement, 16 patients stopped their basic treatment because of the non-authorization of inter urban travel and the fear of contamination by SARS-cov2 upon arrival at hospitals. Compared to the pre-pandemic period during which 24 patients (50% discontinuing treatment) had a relapse, 20 patients (16 without basic treatment) reported worsening of neurological symptoms and the use of corticosteroid therapy in consulting (50 %) and hospitalized patients. Multivariate statistical analysis showed that non compliance and relapses’ frequency did not differ before and during pandemic and that the occurrence of relapses is correlated with non-adherence to therapy.

Conclusions:: It is necessary to make informed decisions about MS treatment management in order to minimize the health impact of this pandemic.
STATUS EPILEPTICUS INAUGURATING MULTIPLE SCLEROSIS: “ONE TRAIN HIDES ANOTHER”: A CASE REPORT

Ichrak Ghachem¹, Sabra Riahi¹, Sana Ben Hmida¹, Asma Allaya¹, Samia Younes²
¹Département de neurologie Taher Sfar Mahdia, Faculté De Médecine, Mahdia, Tunisia, ²Department of Neurology, Mahdia, Taher Sfar university hospital, Tunisia

Background and Aims: The prevalence of epilepsy is 4.5 to 6 times higher in patients with multiple sclerosis (MS) than in the general population. Only few cases have proven a direct causal relationship with MS. Is this just a frequent combination or symptomatic attacks of MS? Are these attacks the result of an acute flare-up of the disease?

Methods: We report the case of a patient followed in our neurology department in Mahdia for MS, inaugurated by status epilepticus.

Results: A young mother of 26 years, presented a status of epilepticus, made of focal motor tonicoclonic right hemi-bodily seizures with secondary bilateralisation. The neurological examination outside of the seizures was without abnormality, except for the presence of sharp tendon reflexes in the 4 limbs without Babinski's signs. Cerebral-medullary MRI revealed multiple demyelinating lesions of the white matter, with the presence in particular of nodular juxta-cortical lesions and a small left upper frontal cortical lesion. Note the absence of spinal cord injuries and signs of activity. The diagnosis of MS was retained in view of young age, female sex, spatial dissemination on brain MRI, the presence of oligoclonal bands in the CSF, the absence of red flags. The patient received a 5-day bolus of solumedrol and put on Levet 500 mg 1cp * 2/d and interferonB. We note the recurrence of seizures after 4 months due to non-adherence to antiepileptic drug. A control MRI showed the increased lesion burden.

Conclusions: Epilepsy may be the only symptom of MS. An exhaustive etiological assessment is obligatory. “One train hides another”
MULTIPLE SCLEROSIS INCIDENCE UPDATE IN PROVINCE OF FERRARA, NORTHERN ITALY, DURING COVID19 ERA.

Michele Laudisi, Elena Vannini, Annibale Antonioni, Ilaria Casetta, Maura Pugliatti, Eleonora Baldi, Enrico Granieri
University of Ferrara, Dept. Of Neuroscience And Rehabilitation, Interdepartmental Research Centre For The Study Of Multiple Sclerosis And Inflammatory And Degenerative Disease Of The Nervous System, Ferrara, Italy

Background and Aims:: Previous descriptive surveys on multiple sclerosis (MS) in the province of Ferrara carried out by our own epidemiological research group in the previous decades, pointed out that this area was not at low-medium risk for MS. We aim to confirm the above assumption and to update MS frequency estimates in this area

Methods:: We used a complete enumeration approach by reviewing all the possible sources of case collection available in Ferrara for 2016 through 2020. We included all patients with definite and probable MS according to the Poser criteria

Results:: The incidence cases were 84, 22 men and 62 women. The mean incidence for the period 2016-2020 was 4.86 per 100,000 (95 % CI, 1.66-4.01), 6.91 for women and 2.65 for men. The adjusted incidence to the European population was 6.01 per 100,000/year. The incidence temporal trend in 1965-2020 is shown in Figure 1.

Conclusions:: In the province of Ferrara MS appears to occur more frequently than suggested by the geographic-related distribution model. The slowly incremental incidence trend cannot be solely attributed to improvement in diagnostic capability, but – likely - to variation of exposure to exogenous risk factors in genetically predisposed individuals. The incidence rate over the study period remained relatively stable compared what previously observed (1965-2015), and a not significant decrease in 2019 and 2020 (Figure 2) was recorded, likely representing an underestimation in relation to the contingent COVID19 pandemic and the consequent difficulty in accessing health
Background and Aims:: The diagnosis of Neuromyelitis Optica spectrum disorder (NMOSD) can be challenging especially in patients with atypical presentations and unknown serostatus for aquaporin-4 antibodies (AQP4-Ab). We present three cases with different onset variations and relapsing episodes and aims to present and compare the clinical, radiological and evoked potential findings.

Methods:: This is a prospective serial case of three patients. A 20-year-old female presenting with acute myelopathy with a history of optic neuritis and a 26-year-old female presenting with bilateral optic neuritis with a history of myelopathies, both cases shown optic nerve involvement in head MRI. The third case was a 46-year-old female presenting with acute myelopathy and history optic neuritis with a normal MRI finding. They were no distinctive lesion for Multiple sclerosis (MS) in all cases, yet they were treated as MS and results in more frequent episodes of relapse and disabilities. A Visual evoked potential help evaluate the optic nerve involvement in all three cases and the diagnosis was concluded by presence of a lesion that extends three or more adjacent vertebral segments.

Results:: In all three cases, they were treated as NMO with prednisone and azathioprine and there were no relapse for two years follow up.

Conclusions:: It is important for clinicians to distinguish the cause of the clinical picture, and radiological imaging criteria that was beneficial in the establishment of patient’s diagnosis whether is an NMOSD or MS. Because the two diseases have different treatments with different prognoses.
THE IMPORTANCE OF OPTICAL COHERENCE TOMOGRAPHY IN THE DIAGNOSIS OF SUBCLINICAL OPTIC NEURITIS

Yumin Huang-Link1, Ge Yang2, Helena Gauffin1, Greta Gustafsson3, Hans Link4, Pierfrancesco Mirabelli5
1Linköping University Hospital, Neurology, Linköping, Sweden, 2Sun Yat-sen University, State Key Laboratory Of Ophthalmology, Guangzhou, China, 3Linköping University Hospital, Neurophysiology, Linköping, Sweden, 4Karolinska Institutet, Neurology, Stockholm, Sweden, 5Linköping University Hospital, Ophthalmology, Linköping, Sweden

Background and Aims:: Optic neuritis (ON) is an inflammatory condition of the optic nerve. ON is often associated with development of demyelinating diseases of the central nervous system (CNS), such as multiple sclerosis (MS) or neuromyelitis optica spectrum disorders (NMOSD). CNS lesions visualized by magnetic resonance imaging (MRI) and finding of oligoclonal bands (OB) in the cerebrospinal fluid (CSF) are used to stratify risk of MS after "first" episode of ON, so-called clinically isolated syndrome (CIS). However, diagnosis of ON in the absence of typical clinical manifestations can be challenging.

Methods:: Here we present 3 cases of changes in the optic nerve and its neuron in the retina over disease course.

Results:: 1) A 34-year old female with history of migraine and hypertension had suspect amaurosis fugax (transient vision loss) in the right eye. This patient developed MS 4 years later. Optical coherence tomography (OCT) showed dynamic changes of the thickness of peripapillary retinal nerve fiber layer (RNFL) and macular ganglion cell-inner plexiform layer (GCIPL) over time. 2) A 29-year old male with spastic hemiparesis and lesions in the brain stem at onset. Six years later he had bilateral subclinical ON identified using OCT. The patient fulfilled diagnosis of antibody-negative NMOSD. 3) A 23-year old female with overweight and headache had bilateral optic disc swelling. With OCT, idiopathic intracranial hypertension (IIH) was excluded. Further investigation showed positive antibody for myelin oligodendrocyte glycoprotein (MOG).

Conclusions:: These three cases illustrate importance of using OCT to facilitate quick, accurate diagnosis of subclinical ON, and thus proper therapy.
APOE GENOTYPE AND COGNITIVE IMPAIRMENT IN MULTIPLE SCLEROSIS; IS THERE A LINK?

Amirreza Naseri†, Saeed Sadigh-Eteghad‡, Farshid Mashayekhi§, Milad Asadi‖, Negin Abbasi Garravand¶, Mahnaz Talebi‡

†Tabriz University of Medical Sciences, Student Research Committee, Tabriz, Iran, ‡Tabriz university of Medical Sciences, Neurosciences Research Center (nsrc), Tabriz, Iran, §Tabriz University of Medical Sciences, Immunology Research Center, Tabriz, Iran, ¶University of Tabriz, Faculty Of Educational Sciences And Psychology, Tabriz, Iran

Background and Aims:: Cognitive impairment (CI) is one of the prevalent, but neglected symptoms of multiple sclerosis (MS). Apolipoprotein E (ApoE) is one of the genetic factors associated with human cognition. We investigated the role of the ε4 isoform of ApoE (ApoE4) in CI in MS patients.

Methods:: After obtaining informed consent, adult (18+) mildly disabled (EDSS score<4) relapsing-remitting MS (RRMS) patients, based on 2017 revised MacDonald criteria, were assessed by the approved Persian version of minimal assessment of cognitive function in MS (MACFIMS) battery. After determining the genotype of ApoE, patients were divided into two groups of ApoE4 positive and negative, and the frequency of CI was compared. CI was defined as was at least 1.5 standard deviations below the mean normative value in the Iranian population.

Results:: 71 patients, including 54 ApoE4-positive cases, were participated in this study. There was no significant difference between study groups in demographic factors. At least one impaired test in MACFIMS battery was observed in 64.70% of patients in the ApoE4 positive and 29.62% of the ApoE4 negative group (p<0.01). The rate of overall CI, which was defined as a failure in ≥2 tests, was not different between groups of the study (p=0.75). In a detailed investigation of the components, failure in Paced Auditory Serial Addition Test (p=0.01) was the only difference.

Conclusions:: MS ApoE4 positive patients are susceptible for CI and should be followed up strictly with MS-specific cognitive tests. The existing controversies between the studies, highlight a need for future well-designed studies with larger sample sizes.
Background and Aims:: Distinguishing Vegetative from Minimally Conscious State (VS; MCS) is a challenge due to the difficulty in relating observed behaviors with underlying brain activity. The visual responses in the visual subscale of the Coma Recovery Scale-revised (CRS-r) are informative of the change from VS to MCS; however, few studies explored the functional and structural integrity of the visual system in these patients.

Methods:: Forty-two DoC patients showing visual blink, and twelve showing visual pursuit were enrolled in the study. All of the patients had a diagnosis of VS except for the visual subscale of the CRS-r. For each participant, we collected flash Visual Evoked Potentials (fVEPs), structural Magnetic Resonance Imaging (MRI) of the visual system, and Positron Emission Tomography with 2-deoxy-2-[fluorine-18]fluoro-D-glucose (FDG-PET) variables to explore difference between groups.

Results:: Patients manifesting visual pursuit showed a better fVEPs response, greater integrity at the level of right V1 and optic radiation, and a difference for the cluster localized in the right calcarine cortex and lingual gyrus.

Conclusions:: Despite the role of V1 in conscious visual processing is still controversial, our results highlighted the importance of primary visual areas for conscious visual behaviors. The lateralization of neuroimaging results is supported by the right-hemisphere dominance for top-down modulation in visuospatial processing. The fVEPs results indicated how differences can be detected even by easily applicable exams, as our fVEPs data were not able to detect higher-order visual processing. In concluding, multimodal measures would be adopted as they can help clinicians for diagnostic purposes.
PERSONALLY - EMOTIONAL SPHERE IN PATIENTS WITH MILD TRAUMATIC BRAIN INJURY

Rustambek Matmurodov, Nargiza Mirzaeva, Ibadulla Qilichev
Tashkent medical academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: One of the earliest and most significant disorders in traumatic brain injury (TBI) is a violation of the emotional and personal sphere. To study the degree of anxiety and depression in patients with mild traumatic brain injury.

Methods:: We examined 83 patients with TBI (42 men and 41 women aged 47.8±9.5 years) and 10 healthy individuals matched by sex and age. To check for anxiety Spielberg-Hanin scale, to check the depression rate - Tsung scales were used.

Results:: We tested the levels of anxiety and depression in patients to assess their personal emotional state. 73 (87.9%) of patients who underwent mild TBI had anxiety with an average of 44±9.7 points on the Spielberg-Hanin scale. This condition was associated with moderate to severe anxiety (31-45 points). All patients had higher personal anxiety rates rather than reactive anxiety, 65.4% and 34.6% accordingly. When patients with BC had light and moderate anxiety levels, patients with TBI and TE had all types of anxiety. When compared the levels of anxiety in patients with mild TBI according to time, there was a critical difference between early and late recovery periods (p<0.05).

Conclusions:: Personally - emotional disorders are not unique to the acute phase of the injury, but may increase levels of depression as a result of impaired serotonin metabolism in the dynamics. It is therefore advisable to assess the levels of anxiety and depression in the dynamics.
INTERRACRANIAL PRESSURE IN ADOLESCENT CHRONIC POST-TRAUMATIC HEADACHE AND ITS TREATMENT

Ryosuke Takagi1, Kiyoshi Takagi2, Shuichiro Asano3, Kazuyoshi Kato4, Takashi Kawahara5, Masamichi Atsuchi5

1Yokohama Minami Kyosai Hospital, Department Of Neurosurgery, Yokohama, Japan, 2Abiko Seijinkai Hospital, Nph Center, Abiko, Japan, 3Kashiwatanaka Hospital, Department Of Neurosurgery, Kashiwa, Japan, 4Abiko Seijinkai Hospital, Department Of Surgery, Abiko, Japan, 5Jifukai Atsuchi Neurosurgical Hospital, Nph Center, Kagoshima, Japan

Background and Aims:: Although chronic post-traumatic headache (CPTH) is a life disturbing disorder for adolescence, it is usually attributed to neurosis or somatoform disorders. We have reported the possibility of increased intracranial pressure (ICP) in adult CPTH (Eur J Med Res 2007; 12: 246-54)). The purpose of this study is to investigate the ICP in adolescent CPTH.

Methods:: We retrospectively investigated ICP measured by lumbar spinal tap in 17 patients less than 20 yo with CPTH for over 3 months. Body mass index (BMI) was also calculated. Causes of trauma, disease period, and characteristic of the headache were also investigated. Data were demonstrated in median (IQR). All patients received epidural saline and oxygen injection (ESOI) (Acta Neurochir Suppl 2013; 118: 293-6).

Results:: Age was 14 years (IQR; 13, 16.5). There were 11 males and 6 females. The ages were 13 yeas (11, 17) and 14 (13.75, 16.25). All patients complained headache with orthostatic nature. ICP was 168 (141.5, 230) and BMI was 19.2 (17.55, 23.6). Disease period was 8 months (4.5, 15). All patients improve by ESOI and 3patients were completely cured.

Conclusions:: Although the headache had orthostatic nature suggesting low ICP, ICP in adolescent CPTH was high that cannot be attributed to obesity. The result of this study indicates the importance of measuring ICP inb adolescent CPTH. Epidural saline and oxygen injection is a promising therapeutic modality.
MODIFIED SPINAL CORD STIMULATION (MSCS) PROMOTED TO AWAKEN THE PATIENTS WITH CHRONIC UNCONSCIOUSNESS

Jian-Jun Huang¹, Yong Wang¹, Yong-Wen Bai¹, Guo-Qing Zhang¹, Dong Ma¹, Guo-Tao Zhuang¹, Guang-Yuan Han², Ke-Xin Liu², Jie-Zhong Yu²,³, Jian-Chun Liu², Li-Juan Song²,⁴, Cun-Gen Ma²,³,⁴
¹General Hospital of National Medicine and Datong Coalmine, Neurosurgery, Datong, China, ²Shanxi University of Chinese Medicine, Research Center Of Neurobiology / The Key Research Laboratory Of Benfiting Qi For Acting Blood Circulation Method To Treat Multiple Sclerosis Of State Administration Of Traditional Chinese Medicine, Jinzhong, China, ³Shanxi Datong University, Institute Of Brain Science / Shanxi Key Laboratory Of Inflammatory Neurodegenerative Diseases, Datong, China, ⁴Shanxi Medical University, Physiology/neurology, Taiyuan, China

Background and Aims:: Chronic patients with unconsciousness after brain injury often require long-term monitoring and treatment, which is expensive and usually leads to heavily psychological and economic burden. Our aim was to analyze the applicable value and economic effect of the modified spinal cord stimulation (MSCS) for the treatment of unconsciousness in chronic patients.

Methods:: In this study, we used real-world research methods (Non-randomized concurrent standard control study and historical control study). Sixty chronic patients with unconsciousness from August 2020 to August 2022 in General Hospital of National Medicine and Datong Coalmine were divided into experiment group (n=30) , standard control group (n=20) and historical control group (n=10) . The patients in experimental group were treated with early implementation of MSCS, the patients in standard control group were treated with routine clinical treatment and the patients in historical control group were treated with clinical routine treatment before 2020. We carried out awareness assessment and intuitive-quantitative electrophysiological examinations to evaluate the applicable value of MSCS at four time points: pre-operaton, and 1, 3 and 6 months after surgery.

Results:: The recovery rate and consciousness level of patients in experimental group were significantly higher than those of other two groups with a significantly lower medical cost and shorter length of hospitalization stay.

Conclusions:: MSCS is clinically applicable and economically valuable, which is worth spreading in the treatment of unconsciousness due to chronic illness. (Funding for Key Laboratory of Prevention and Treatment of Neurological Diseases, 2020SYS20, Huang is corresponding author)
NEUROAID USE IN TRAUMATIC BRAIN INJURY (TBI)

Ramesh Kumar¹, Farizal Fadzil², Soon Bee², Palani Kamalanathan², Ainul Jaffar², Sanmugarajah Paramasvaran², Toh Jeng², Jegan Thanabalan², Azizi Bakar², Peh Shawn²
¹University Kebangsaan Malaysia Medical Centre, Division Of Neurosurgery, Department Of Surgery, Kuala Lumpur, Malaysia, ²University Kebangsaan Malaysia, Division Of Neurosurgery, Department Of Surgery, Kuala Lumpur, Malaysia

Background and Aims: The ongoing NeuroAiD Safe Treatment (NeST) Registry (ClinicalTrials.gov Identifier NCT02536079) examined NeuroAiD safety and efficacy in a cohort of traumatic brain injury (TBI) subjects from Malaysia. MLC601/MLC901 (NeuroAiD) is a formulation of natural products shown to aid neurological recovery after injury, especially ischemic stroke. Its evidence still remains limited in TBI.

Methods: The online NeST Registry prospectively collected data at baseline and visits (V) 1, 2, and 3, included demographics; medical conditions; clinical assessments of Glasgow Coma Scale (GCS), modified Rankin Scale (mRS), and Short Orientation Memory Concentration Test (SOMCT); compliance; concomitant medications; and adverse events.

Results: This analysis included 23 subjects, of whom 18 had data until V3. Median age was 36 years (range 15-64), with 17% (4) female. Median GCS at baseline was 11 (moderate TBI). Median time from injury to NeuroAiD administration was 20 days (range 7-40). All clinical assessments showed improvement over time. At baseline, only 30%(7) had GCS of 13-15, improving to 83%(15) by V3. For functional independence per mRS, none had mRS 0-1 at baseline, improving to 33%(6) by V3. For cognitive function per SOMCT score, 61%(14) had severe cognitive impairment at baseline, decreasing to only 22% (4) by V3. There were 2 subjects with deterioration of GCS score (only 1- and 2-point decrease) but their level of functional independence per mRS was preserved. No other adverse events were noted.

Conclusions: MLC601/MLC901 is demonstrated to be a safe adjunctive therapy for aiding recovery in TBI. Larger studies should further assess its safe use in enhancing TBI recovery.
REDUCTION IN HYPERMETABOLIC STATE ON MIDAZOLAM STEWARDS ANTICONVULSIVE TREATMENT FOR INTERICTAL PATTERNS IN SEVERE ACUTE BRAIN INJURY: A PILOT MR PERFUSION STUDY.

Mohamed Elashwal¹,², Gregory Kapinos³
¹King’s County Hospital, Neurology, Brooklyn, United States of America, ²Alfaisal University, Medicine, Riyadh, Saudi Arabia, ³King’s County Hospital, Neurocritical Care, Brooklyn, United States of America

Background and Aims:: Small Cohorts have utilized PET and SPECT scans as complementary markers of metabolic activity in status epilepticus in patients with ictal-interictal EEG patterns (IIC). While some rhythmic/periodic discharges mandate termination, other IIC patterns reflect underlying stable brain lesions with no superimposed cerebral injury. We realize that perfusion mapping is not the greatest surrogate; however, it is more readily available. We suggest severe brain injury patients be treated with aggressive anticonvulsive treatment only when they fulfill all the following criteria: 1) altered mental status, 2) IIC EEG patterns, 3) periodic/rhythmic discharges colocalizing with hypermetabolism detected by loco-regional hyperperfusion and 4) significant decrease in hyperperfusion during a midazolam (MDZ) test.

Methods:: A cohort of neuro-ICU patients with criteria 1 and 2 underwent MRI with a repeat run of arterial spin labeling, assessing the response of hyperperfusion foci to brief anticonvulsive therapy with 2mg of MDZ.

Results:: Our pilot study established the frequency of IIC patterns that coincide hyperperfused foci. We are now doing the analysis to quantify the hyperperfusion and how much it decreased during the MDZ test. Outcome measures will include incidence of subsequent seizures, new FLAIR lesions, and degree of neurologic disability.

Conclusions:: Subsequent studies will compare the effect of treating only patients with criteria 1&2, v-s 1-3, vs. 1-4. Our study is limited by the use of perfusion as a surrogate for metabolism, the absence of simultaneous EEG during the imaging study and deficiency in standardized quantification for hyperperfusion during the ictal processes. These are slightly addressed by patient specific analysis and pharmacological challenge.
TAILORED NEUROPHYSIOLOGY: QUANTITATIVE EEG UNCOVERS SUBCLINICAL ISCHEMIA/OLIGEMIA AND REDEFINES PENUMBRA AMENABLE TO BLOOD PRESSURE OPTIMIZATION.

Mohamed Elashwal¹,², Gregory Kapinos³
¹King’s County Hospital, Neurology, Brooklyn, United States of America, ²Alfaisal University, Medicine, Riyadh, Saudi Arabia, ³King’s County Hospital, Neurocritical Care, Brooklyn, United States of America

Background and Aims:: Continuous quantitative EEG (cqEEG) is used in critical care for prognosing coma, or to identify non-convulsive seizures and early injury secondary to ischemia. We report on our expansive utilization of cqEEG in a neuro-ICU for 1) enhanced detection of widespread subclinical ischemia/oligemia, 2) defining oligemia with positive response to mild hemodynamic augmentation (HDA), a.k.a. perfusion optimization-responding syndrome (PORS) and 3) optimization of blood pressure (BP) for penumbral salvage.

Methods:: In ten subarachnoid hemorrhage (SAH) patients, cqEEG was used because of other modalities presaging vasospasm. In 3 other patients, 1 with acute ischemic stroke (AIS) and 2 in vasospasm after SAH, we used cqEEG to ascertain the need for HDA for penumbral salvage. In these 3 patients, PORS was confirmed and cqEEG was continued to assess our induced adjustments in BP.

Results:: Relative alpha variability (RAV), alpha-delta ratio (ADR) and alpha power (AP) by quadrant, hemispheric suppression ratio (HSR), these EEG findings together provide enhanced revelation of subclinical ischemia. PORS was identified by an increase in AP or decrease in HSR. PORS enabled us to recognize those patients who required escalation in HDA. Once started, fine-tuning of BP goals was based on quadrant AP & ADR, allowing for more accurate adjustments, compared to adjustments guided by clinical parameters alone.

Conclusions:: cqEEG is an invaluable modality in identifying the need for “pressing” a patient and in gauging induced hypertension. cqEEG should not be used only in coma but in parallel with clinical examinations in all brain injured patients who are at risk for secondary ischemia.
Background and Aims:: Traumatic brain injury (TBI) is one of the leading causes of death and disability worldwide with an African incidence estimated at around 8 million cases per year. We report this study to describe the socio-demographic, clinical, paraclinical and evolutionary characteristics.

Methods:: This is a descriptive retrospective study lasting one (1) year from March 2020 to February 2021, carried out at the Neurology Unit of the National Reference Teaching Hospital in N’Djamena. Our study included complete records of patients hospitalized for suspected or documented TBI. Sociodemographic, clinical, paraclinical, therapeutic and evolutionary data were collected and analyzed using SPSS 2.0 software.

Results:: Out of 219 files examined, 24 (22 men) had met the selection criteria. The mean age of our patients was 37.5 ± 16.1 years old. The 25 to 34 age group was the most affected with 29.2% of cases. Traders and motorcycle drivers (Clandoman) were the most represented with 25% (n = 6) for each. Road accidents were the most common causes with 79.2% (n = 19). 45.8% of patients had a Glasgow Coma Scale (GCS) ≥13; 29.2% had a GCS between 12 and 9 then 25% had a GCS ≤ 8. Fifteen patients had performed a brain scan. Hemorrhagic or edema-hemorrhagic contusions were found in 53.3% of patients. The mean time to hospitalization was 7.7 ± 4 days. The outcome was favorable in 87.5% (n = 21) of cases, the death rate was 12.5% (n = 3).

Conclusions:: TBI is a major public health problem, especially in low- and middle-income countries.
INTRODUCING THE WCN CONSCIOUSNESS SCALE: A COMPREHENSIVE TOOL TO ASSESS CONSCIOUSNESS IN THE CRITICAL CARE SETTING.

Mohamed Elashwal1,2, Gregory Kapinos3
1King’s County Hospital, Neurology, Brooklyn, United States of America, 2Alfaisal University, Medicine, Riyadh, Saudi Arabia, 3King’s County Hospital, Neurocritical Care, Brooklyn, United States of America

Background and Aims: Different specialties use different neurologic terminology, scales and flowsheets when it comes to the assessment of unconscious patients in critical care units, and no agreement identifies slight decreases in the degree or content of consciousness. Mild decrements in consciousness without full deterioration can be assessed with a simple clinical examination to assess nuanced domains of consciousness more accurately than AVPU, JCS, GCS, FOUR, RASS, CAM-ICU or NIHSS.

Methods: We systematically reviewed commonly used consciousness scales, and obtained criteria for arousability and alertness from each scoring system. Sensitivity and specificity of GCS, RASS, FOUR and NIHSS item 1 were tested against our proposed compound scale during neuro-ICU rounds.

Results: Scoring alertness before/after stimuli, attention span, processing speed, gauging of the arousing stimulus and quality of the response, period at peak alertness, all carry more value than arousa or attention alone, such as measured by GCS or RASS; respectively. Our combined assessment is considerably more consistent and valuable than degree of orientation (“AOx3”). We noted that trainees from different residencies and neurosciences nurses had more consistent assessments of consciousness. Furthermore, identification of deterioration was earlier. Contrasted to standard charting, our tool is conducive of more accurate terminology, better clinical documentation, and keener inter-professional communication.

Conclusions: The WCN Consciousness Scale better establishes arousability, alertness, and attention. It likely outperforms GCS and RASS. We urge neurologists, neurosurgeons and critical care experts to join forces and establish a sensitive basic scale of consciousness to allow easier communication as well as utilize it in research to readjust trial endpoints.
SMOKING ASSOCIATED WITH INCREASED ODDS OF POST-CONCUSSIVE SYNDROME IN LARGE CROSS-SECTIONAL STUDY

Monika Johal¹, Narayan Kuleindiren², Hamzah Selim³, Mohammad Mahmud⁴, Aaron Lin⁵, Itai Palmon⁶, Sam Clothier⁷, Ross Greenhalf⁸, James Allardice⁹, Raphael Rifkin-Zybutz¹⁰
¹Imperial College London, Medicine, London, United Kingdom, ²Imperial College London, Department Of Chemistry, London, United Kingdom, ³University College London, Medicine, London, United Kingdom, ⁴Imperial College London, Department Of Brain Sciences, London, United Kingdom, ⁵University of Birmingham, Medicine, Birmingham, United Kingdom, ⁶University of Michigan, Medicine, Ann Arbor, United States of America, ⁷University College London, Department Of Neuroscience, London, United Kingdom, ⁸Lancaster University, Department Of Computer Science, Lancaster, United Kingdom, ⁹University of Birmingham, Department Of Computer Science, Birmingham, United Kingdom, ¹⁰University Hospitals Bristol and Weston, South Bristol Academy, Bristol, United Kingdom

Background and Aims:: Post-concussion syndrome (PCS) affects 30% of those who suffer a concussion, with symptoms such as memory difficulties and mood changes. The evidence between smoking and PCS in humans is unclear. Some studies correlate smoking with slower neurocognitive recovery whilst others merely demonstrate a higher symptom severity in those who do not recover.

Methods:: A cross-sectional study of 1,563 users of Mindset4Dementia, an application developing screening tests for dementia, was performed. The Rivermead Post-Concussion Symptoms Questionnaire (RPQ) was used to assess PCS symptoms. Lifestyle factors and scores from two modified cognitive tests, the Stroop and Symbol Digit Modality Test, were also collected. Regression models were used to assess the effect of concussions on cognitive tests scores and the correlation of lifestyle factors to RPQ scores.

Results:: 360 individuals had suffered at least one concussion with 318 Individuals completing the RPQ. Individuals with previous concussions performed worse on the Stroop Test (beta = -0.08, p<0.001) with a trend to worse performance on the Symbols Digit Modality Test (beta = -0.04, p = 0.063). Smoking (beta = 0.23, p = 0.001) but not alcohol (beta = -0.05, p =0.2) was strongly associated with an increase in the odds of PCS (OR 3.03, CI 1.44 - 6.42, p = 0.003) as assessed by a cut-off of 16 on the RPQ-13.

Conclusions:: Although the cross-sectional nature of the study makes causation difficult to establish, this study provides preliminary evidence that smoking is associated with the development of PCS.
EFFICACY AND SAFETY OF ANDEXANET ALFA FOR FACTOR XA INHIBITORS USE ASSOCIATED INTRACRANIAL BLEEDING: A SYSTEMATIC REVIEW AND META-ANALYSIS

Dhan Shrestha¹, Pravash Budhathoki², Ayush Adhikari³, Sudat Shrestha⁴, Nirajan Khati⁵, Tilak Joshi⁶, Anuj Shrestha⁷

¹Mt. Sinai Hospital, Internal Medicine, CHICAGO, United States of America, ²Bronxcare Health System, Internal Medicine, Bronx, United States of America, ³Tribhuwan University Teaching Hospital, Anesthesia And Critical Care, Kathmandu, Nepal, ⁴Patan Academy of Health Sciences, Surgical Intensive Care Unit, Lalitpur, Nepal, ⁵Bishnudevi Hospital, Kirtipur, Emergency Medicine, Kirtipur, Nepal, ⁶Mount Sinai Hospital, Internal Medicine, CHICAGO, United States of America, ⁷University of Missouri-Kansas City School of Medicine, Hematology/oncology, Kansas City, United States of America

Background and Aims:: Direct oral anticoagulants use has been significantly expanded from atrial fibrillation, deep vein thrombosis and pulmonary embolism to use in cancer patients, and some surgical patients in the last decade. Favored pharmacokinetics and pharmacodynamics, predictable effects, few drug interactions favors oral Factor Xa inhibitors over traditional Vitamin K antagonists. However, fatal bleeding as unfavored event are also reported with its use. In May 2018, FDA approval use of Andexanet Alfa (AA) in patients treated with rivaroxaban and apixaban, in the setting of life-threatening or uncontrolled bleeding. This systematic review and meta-analysis was conducted to analyze the effectiveness and safety profile of AA in bleeding caused by Factor Xa inhibitors to fully appraise the role of AA.

Methods:: PubMed, Pubmed Central, Scopus, Embase and Cochrane library were searched for relevant studies. Covidence was used for screening of literatures based on inclusion and exclusion criteria. RevMan 5.4 was used for quantitative synthesis. Odds ratio (OR) and mean difference (MD) was used to estimate the outcome with a 95% confidence interval (CI).

Results:: 1245 studies were identified after a thorough database search and three studies were included for analysis. Analysis using fixed effect model showed AA resulted in lower odds of mortality compared to 4F-PCC (OR, 0.37; 95% CI, 0.20-0.71) among patients with intracranial hemorrhage. There was no difference in thrombotic events, length of hospital stay, and ICU stay were seen between patients receiving AA and 4F-PCC.

Conclusions:: AA reduced in-hospital mortality in patients who had bleeding due to Factor Xa inhibitors compared to 4F-PCC.
ROLE OF DEXAMETHASONE IN CHRONIC SUBDURAL HEMORRHAGE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Dhan Shrestha1, Pravash Budhathoki2, Yub Sedhai3, Pearlbiga Karki4, Pinky Jha4, Gaurab Mainali4
1Mt. Sinai Hospital, Internal Medicine, CHICAGO, United States of America, 2Bronxcare Health System, Internal Medicine, Bronx, United States of America, 3Virginia Commonwealth University, School of Medicine, Internal Medicine, Richmond, United States of America, 4Nepalese Army Institute of Health Sciences, Kathmandu, Nepal, Medical Student, Kathmandu, Nepal

Background and Aims:: Chronic Subdural Hematoma is a neurological condition characterized as a hematoma of subdural with a time period greater than 3 weeks that primarily affects elderly. Apart from surgical intervention, pharmacologic and conservative therapies are used. Glucocorticoid especially dexamethasone either alone or in combination with surgery are used in the management of Chronic Subdural Hematoma.

Methods:: PubMed, PubMed Central, Scopus, and Embase were search for relevant articles till December, 2020. Relevant data, including study characteristics, quality, and endpoints were extracted and analysis was done by RevMan 5.4. Handling of data and combining results of the studies were done using OR and random or fixed effect model based on heterogeneities.

Results:: The odds for recurrence of subdural hemorrhage was lowered by 61% in the steroid group (OR, 0.39; 95% CI, 0.19 to 0.79) comparing to control group. There was no significant difference in mortality during study period (OR, 0.66; 95% CI, 0.20 to 2.18), modified Rankins Score (mRS 0-3) (OR, 0.87; 95% CI, 0.31 to 2.40), and mRS 4-6 (OR, 1.15; 95% CI, 0.42 to 3.18) between two groups using the random effect model. However, pooling data from three studies showed 2.7 times higher odds of occurring adverse effects in steroid groups using the fixed effect model (OR, 2.70; 95% CI, 1.71 to 4.28).

Footnotes:

Conclusions:: Treatment with steroid was associated with lesser recurrence of subdural hematoma. However, there was no benefit of steroid treatment in chronic subdural hematoma compared to non-steroid treatment in terms of mortality, treatment success and increased risk of adverse events.
BLOOD PRESSURE TARGET IN NEUROSURGICAL PATIENTS: HOW HIGH AND HOW LOW SHOULD WE GO?

Stanlies D’Souza
University of Massachusetts Medical School, Neuroanesthesiology, Baystate Medical Center, Springfield, United States of America

**Background and Aims::** The cerebral autoregulation is considered to be dynamic rather than static as it was originally thought. The revised lower limit of cerebral autoregulation, narrower range of autoregulation in neurosurgical patients and data from randomized controlled trials and large retrospective analysis required the revision of blood pressure (BP) targets in neurosurgical patients.

**Methods::** The review of the neuroscience literature from 2010-2020 using PUBMED, EMBASE and the Brain Trauma Foundation (BTF) 2016 guidelines.

**Results::**

<table>

**Neurosurgical condition** | **Source/ evidence for BP target**
--- | ---
TBI | BTF 2016 guidelines based on large retrospective data analysis
sICH | INTERACT 2 and ATTACH 2 trials
aSAH | INTERACT 2 and ATTACH 2 trials
DCI | NCT 01613235 (RCT)
AIS prior to EVT | The Society of Anesthesia and Neurocritical care (SNACC) consensus statement of 2014 and World Stroke organization 2018 guidelines
AIS after EVT | Retrospective data analysis of GOLIATH, ANSTROKE and SIESTA trials
DBS | Data from case series

**Conclusions::** The lower limit of cerebral autoregulation is considered to be 70 mm Hg
MAP and autoregulation is dynamic and narrower in acute neurosurgical conditions. Sympathetic surge is the primary reason for hypertension and therefore adherence to BP targets is essential.
SUSTAINED AXONAL DEGENERATION IN PROLONGED DISORDERS OF CONSCIOUSNESS

Sergio Bagnato, Maria D'Ippolito, Cristina Boccagni, Antonio De Tanti, Lucia Francesca Lucca, Antonio Nardone, Pamela Salucci, Teresa Fiorilla, Valeria Pingue, Serena Gennaro, Maria Ursino, Valentina Colombo, Teresa Barone, Francesca Rubino, Maria Andriolo

Background and Aims:: Sustained axonal degeneration may play a critical role in prolonged disorder of consciousness (DOCs) pathophysiology according to brain injury severity and etiology. We evaluated levels of neurofilament light chain (NFL), an axonal injury marker, in patients with unresponsive wakefulness syndrome (UWS) and in the

Methods:: This prospective multicenter blinded study involved 70 patients with prolonged DOC (12 females, mean age 39.2 ± 14.8 years) and 70 sex- and age-matched healthy controls. Serum NFL levels were evaluated by enzyme-linked immunosorbent assay at 1–3 and 6 months post-injury and compared with those of controls. NFL levels were compared by DOC severity (UWS vs. MCS) and etiology (TBI vs. HIBI). Correlations of NFL levels at study inclusion with Glasgow Outcome Scale–Extended (GOSE) scores 6 months post-injury were examined.

Results:: Patients’ serum NFL levels were significantly higher than those of controls at 1–3 and 6 months post-injury (medians, 1729 and 426 vs. 90 pg/ml; both P < 0.0001). NFL levels were higher in patients with UWS than in those in MCS at 1–3 months post-injury (medians, 2080 and 1325 pg/ml; P = 0.008) and in patients with HIBI than in those with TBI at 6 months post-injury (medians, 818 and 337 pg/ml; P = 0.037). NFL levels on study inclusion did not correlate with GOSE scores.

Conclusions:: The pronounced serum NFL elevation in patients with prolonged DOC suggests that severe brain injuries can trigger neurodegeneration with axonal damage lasting at least 6 months post-injury. This sustained axonal degeneration is affected differently over time by brain injury severity and etiology.
Background and Aims:: The aim of the scientific research is to evaluate the quality of the patient’s life (QL) in the long-term period after traumatic brain injury (TBI).
Methods:: QL was evaluated at 184 patients with long-term TBI (mild (46), moderate (61), severe (77)) according to the SF-36 scale. The average age was 42.19±0.75 years old. There were 88.9% of men. The TBI catamnesis was 6.91±0.50 years old. Anxiety and depression levels were evaluated according to HADS.
Results:: According to the SF-36 scale all life quality characteristics had significantly lower indicators (p<0.05) than control ones. The lowest rates were indicated in the components of “physical role functioning”, “emotional role functioning” and “social role functioning”. Anxiety and depression had significant correlation with all characteristics of QL. In the male group the level of depression and anxiety was inversely correlated with all SF-36 components, in the female group this was distinguished only with the indicator of “mental health” and “vitality”. It has also been stated the negative dynamics of the components “vital activity”, “general health” and “mental health” with increasing of the TBI catamnesis. The negative effect of anxiety and depression at the patients with mild TBI was predominantly on the physical component of SF-36, with moderate severity of TBI – on physical and mental component of SF-36, with severe TBI – mainly on the mental component.
Conclusions:: In the long-term period of TBI the patients rated the QL significantly below the control indicators. The dependence of individual sections on gender, catamnesis and injury severity has been determined.
ONSD/ETD AS A PROGNOSTIC RATIO OF INTRACRANIAL HYPERTENSION IN TRAUMATIC BRAIN INJURY PATIENTS IN THE EMERGENCY DEPARTMENT.

Akram Ibadi
Najdi hospital(Secours PopulaireLibanais Hospital, Emergency, nabatieh, Lebanon

Background and Aims: Our objective is to determine the ultrasonographic measurement ratio (ONSD/ETD) can accurately predict the computed tomography findings as a marker for evaluation and prognostication of intracranial pressure in traumatic brain injury.

Methods: We conducted a prospective, blinded observational study of seventy adult patients at the Department of Emergency Medicine between (2017-2018) having moderate to severe TBI and GCS <8. Using a 7.5 MHZ ultrasonographic probe on the closed eyelids, the eyeball transverse diameter(ETD) and optic nerve sheath diameter(ONSD) were performed bilaterally at the ED and after 48 hours of admission, following a 20% Mannitol infusion. ONSD/ETD ratio was calculated. Cranial CT findings (according to Marshall Classification) suggestive of elevated intracranial pressure were used to evaluate optic nerve sheath diameter accuracy.

Results: Seventy patients were enrolled. USG-ONSD was greater than 5.7 mm and decreased after mannitol infusion from 6.3(6.1–6.7) to 5.2mm(5.5–6.3)(p=0.0007). ONSD/ETD has dropped from 0.25 till 0.21(0.18–0.18). Median and Mean ETD was 22.85 mm and 22.91 ± 0.93 mm. Enlarged right/left CT-ONSDs were 6.5 ± 1.5/6.4 ± 1.3 mm at 3 mm and 6.6 ± 0.8/6.6 ± 0.6 mm at 8-10 mm from the globe (cut-off value > 5.5 mm). ONSD/ETD ratio was 0.29 ± 0.05 compared with 0.19+/-.02 in healthy adults(P<0.01). The sensitivity of ultrasonography for detection of traumatic intracranial injury found by CT was 85% (95% CI 60% to 97%) and specificity was 75% (95% CI 59% to 86%).

Conclusions: ONSD/ETD has potential as a sensitive screening test for elevated intracranial pressure in traumatic brain injury.
PROGNOSTIC SIGNIFICANCE OF HYPERNATREMIA IN ALTERED SENSORIUM

Uma Ravishankar¹, Sathyamurthy P², Philo Hazeena¹, Shankar Venkatasubramanian¹, Sundar Shanmugam¹, Radhakrishna Pedapati¹
¹Sri Ramachandra Institute of Higher Education and Research, Neurology, Chennai, India, ²Sri Ramachandra Institute of Higher Education and Research, General Medicine, Chennai, India

Background and Aims:: Early prediction of prognosis of patients in coma depends on numerous factors and remains a challenge to the physician. We sought to assess if prediction of mortality during hospital stay was improved by including clinical or biochemical parameters that could be easily obtained on arrival in the Emergency Department.

Methods:: 467 adult patients presenting to the emergency with altered sensorium were analyzed with respect to outcome at the end of hospital stay and were divided into three groups - Patients with high GCS (9-14) Patients with low GCS (3-8) Intubated patients.

Results:: Out of the total 467 patients studied, 100 died and 367 survived. The mean serum sodium in deceased patients was 136.31 mmol/L and in survivors was 132.24 mmol/L (p=0.001). The mean sodium was 131.19 mmol/L in the high GCS group, 134.95 mmol/L in the low GCS group and 137.68 mmol/L in the intubated group (p=0.000). 44.4% of patients with hypernatremia died (p=0.006). Mortality dropped to 16% with sodium <125 mmol/L. Patients with higher sodium levels had a higher mortality. In the high GCS group, mortality for high, normal and low sodium levels were 30.8%, 16.2%, 16.5% respectively. In the low GCS group, mortality for high, normal and low sodium levels were 37.5%, 24.4%, 21.8% respectively. In the intubated group, mortality for high, normal and low sodium levels were 83.3%, 37.5%, 50% respectively. In all three groups mortality was higher when serum sodium levels were high.

Conclusions:: Serum sodium levels on admission can be an independent predictor of prognosis in these patients.
Background and Aims:: Porencephaly is a cystic lesion of the brain due to an encephaloclastic insult lined by white matter, which communicates with the ventricles and/or the subarachnoid space.

Methods:: Mrs. N is a 65-year-old woman with the complaints of self-talk, hearing of unknown voices and suspecting of family members. Half a century ago, during the Liberation War of Bangladesh, one of the shells accidentally exploded in their backyard. Unfortunately, a few pieces of shrapnel penetrated her arm, leg and right side of the head. Last 50 years, she has led an almost normal life except movement difficulties and weaknesses of the upper and lower limbs. Patient sufferings have intensified gradually. She has been experiencing headaches, dizziness and vomiting. Recently, she started to forget everything. Two months back, she drank some insecticide mistakenly. She also suffered from insomnia. She talks continuously and complains about hearing unknown voices. She also started to suspect family members. She also got convulsions two or three times in the last 50 years but she didn’t take any medication for it. Her X-ray skull showed a metallic foreign body (shrapnel) lodged within her skull. Furthermore, a CT scan of the brain was advised, and there was an artifact (shrapnel) at right frontal area, extensive encephalomalacia in right cerebral hemisphere that formed porencephaly communicating with lateral ventricle. She was advised Risperidone 2mg daily and her psychosis was controlled.

Results:: Porencephaly followed by TBI is an extremely rare condition.

Conclusions:: Psychotic presentation of porencephaly is also rare. Very few case studies available in scientific Journals.
Characteristics and Assessment of Potential Concussive Events in the UEFA Champions League

Darek Sokol-Randell¹, Mario Rotundo¹, Mathew Aranha¹, Claire Denley¹, Antoin Stanton¹, Mickel Attia¹, Abdulhakim Jilani¹, Conor Deasy¹, Michael Cusimano²
¹University College Cork, Medicine, Cork, Ireland, ²University of Toronto, Neurosurgery, Toronto, Canada

Background and Aims:: Athletes involved in elite sports such as Association Football (AF) are at a high risk of sustaining Sport-Related Concussion (SRC). The current study investigates the characteristics of potential concussions in AF, as well as the quality of subsequent assessment with respect to the International Football Association Board (IFAB) and International Conference on Concussion in Sport (ICCS) recommendations.

Methods:: Trained reviewers identified potential concussive events (PCEs) throughout 121 matches of the 2019/2020 Men’s UEFA Champions League (CL) tournament, using a standardized observation protocol. Each PCE was analyzed for visible signs of concussion and circumstantial factors, as well as assessment incidence, duration, and return-to-play decision.

Results:: In 121 matches of the 2019/2020 UEFA CL, we identified 218 PCE incidents (1.80 per match, 54.59 per 1000 match hours). Strikes to the frontal region were most likely to produce one or more signs of concussion (34.5%, n=10), followed by the temporal region (30.4%, n=14). Of the 218 PCEs, 54 (24.8%) were assessed by medical personnel, often on the sideline (83.3%, n=45). However, 73.3% (n=33) of sideline assessments were under 1 minute in length. Fifty (22.9%) players sustaining a PCE displayed one or more signs of concussion. Of these, 23 (46.0%) were assessed by medical personnel. One (2.0%) was permanently removed from play.

Conclusions:: Players suffering a PCE are occasionally assessed, often on the sideline. However, assessments rarely last longer than a minute. Players are seldom removed from play, even when visible signs of concussion are present. Improved adherence to IFAB and ICCS concussion guidelines is needed.
BACKGROUND AND AIMS:: Sports-related concussion (SRC) incidence and management within the English Premier League (EPL) is poorly described. This study's objective is to determine the contextual factors surrounding SRC and the quality of subsequent assessment with reference to the International Football Association Board (IFAB) recommendations.

METHODS:: Trained reviewers identified potential concussive events (PCEs) throughout 60 matches of the 2019/2020 Men's EPL season, using a standardized protocol. Each PCE was analyzed for visible signs of concussion and circumstantial factors, as well as assessment incidence, duration, and return-to-play decision.

RESULTS:: Through 60 matches, 67 PCE incidents were identified (1.03 per match, 33.83 per 1000 match hours). The mandibular region was found to be the most frequently affected region of the head (34.3%, n=23), with ball to head (17.9%, n=12) being the most common mechanisms of injury. Furthermore, ball to head contacts were significantly associated with one of more signs of concussion ($\chi^2=8.79$, $p<0.01$). Of the 67 PCEs, 30 (44.7%) were assessed on the sideline. However, 86.7% (n=26) of sideline assessments were under 1 minute duration. Thirty (44.8%) players sustaining a PCE displayed one or more signs of concussion. Of these, 20 (29.9%) were assessed by medical personnel. Only one (3.3%) player was permanently removed from play.

CONCLUSIONS:: Unfortunately, players suffering PCE are occasionally assessed on the sideline. However, assessments are typically less than a minute in duration and rarely result in permanent removal from play despite the presence of visible signs of concussion. As such, PCE identification and management during matches remains insufficient with respect to international recommendations.
PROGNOSTIC FACTORS RELATED TO THE RISK OF COVID-19 INFECTION IN MS PATIENTS

Federico Montini¹, Agostino Nozzolillo¹, Lucia Moiola¹, Maria Rocca¹,²,³,⁴, Vittorio Martinelli¹, Massimo Filippi¹
¹IRCCS San Raffaele Scientific Institute, Neurology Unit, Milano, Italy, ²IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Division Of Neuroscience, Milan, Italy, ³Vita-Salute San Raffaele University, Na, Milan, Italy, ⁴Ospedale san Raffaele, Neurology, Milano, Italy

Background and Aims:: It is still debated whether Multiple Sclerosis (MS) patients are at high-risk of COVID-19 because of their life style, disease- or treatments-associated immune alterations. We compared features of MS patients with COVID-19 infection (MS-COVID) to those of residency-, age-, sex- and treatment-matched MS controls (MS-NCOVID). Moreover, the severity of COVID-19 infection was assessed in MS-COVID patients and their cohabitants.

Methods:: So far, we have enrolled 25 MS-COVID and 104 MS-NCOVID patients. Neurological examination, premorbid laboratory tests, anthropometric variables (height, weight and BMI), life-style habits (smoke, alcohol intake, diet), working-activity and living conditions (number of cohabitants, school-aged children) were assessed. COVID-19 severity was evaluated in terms of fever (magnitude, duration), radiological pneumonia and typical symptoms.

Results:: Clinical and anthropometric features, life-style habits and living conditions were similar between MS-COVID and MS-NCOVID patients. However, they differed in terms of working activity, with lower rate of unemployment (7.1% vs 23.4%) and higher rate of team-working (61.5% vs 26.5%) in the MS-COVID group (p<0.01). Furthermore, MS-COVID patients had lower premorbid vitamin D levels (31 vs 40 ng/ml p=0.048) and higher neutrophils count (3803 vs 3182 cells/ul, p=0.046). Disease course was similar between MS-COVID patients and their cohabitants with fever, ageusia and anosmia being the most common symptoms. Fever and radiologic signs of pneumonia were also comparable.

Conclusions:: Working-activity, lower vitamin D levels and higher neutrophil count seem to be associated with the risk of COVID-19 infection in MS patients. The burden of COVID-19 disease was comparable between MS patients and their cohabitants.
Background and Aims:: The frequency of Huntington's disease (HD) may vary considerably, with higher estimates in non Asian populations. Here we present two studies performed in Sardinia, a large mediterranean island that's considered a genetic isolated: a study of HD incidence over a ten-years period, 2009 to 2018, in overall Island, and a prevalence study in the southern part of it.

Methods::

Methods. Our research was conducted in the 5 administrative areas of Sardinia island (fig1). Case-patients were ascertained through multiple sources in Sardinia and Italy.

Results:: Results. During the incidence period 53 individuals were diagnosed with clinically manifested HD. The average annual incidence rate 2009 - 2018 was 2.92 x 10^6 persons - year (95% CI, 2.2 to 3.9). The highest incidence rate was observed in South Sardinia (6.3; 95% CI, 4.2 – 9.5). This rate was significantly higher (p<0.01) than the rates from Cagliari, Oristano, and Sassari provinces but did not significantly differ (p = 0.38) from the Nuoro rate. The resulting prevalence rate was 5.98 x 10^5 in the
overall study area, however with marked variations between South Sardinia and Cagliari (9.6 x 10^5 vs. 3.0 x 10^5, p=0.02). In the study areas, we found similar CAG repeat length in normal alleles.

**Conclusions:** The overall epidemiology of HD in Sardinia is close to the correspondent estimates in Mediterranean countries. Our findings highlight also the possibility of local microgeographic variations in the epidemiology of HD that might reflect several factors, including a possible founder effect in the rural areas of South Sardinia and Nuoro.
BURDEN OF NEUROLOGICAL DISORDERS IN EUROPE: AN ANALYSIS BASED ON THE GLOBAL BURDEN OF DISEASE 2017

Matilde Leonardi\textsuperscript{1}, Alberto Raggi\textsuperscript{1}, Davide Sattin\textsuperscript{1}, Silvia Schiavolin\textsuperscript{2}
\textsuperscript{1}Fondazione IRCCS Istituto Neurologico Carlo Besta, Neurology, Public Health, Disability, Milan, Italy, \textsuperscript{2}Neurological Institute C. Besta IRCCS Foundation, Neurology, Public Health And Disability Unit, Milan, Italy

\textbf{Background and Aims::} Neurological disorders, together with other Non-Communicable Diseases (NCDs) such as mental health, musculoskeletal, cardiovascular disorders and tumors, account for 65.5\% of the burden associated to NCDs at the global level.

\textbf{Methods::} We relied on estimates referred to Prevalence, Deaths, Years of Life Lost (YLLs), Years Lived with a Disability (YLDs) and Disability-Adjusted Life Years (DALYs) taken from the 2017 wave of the Global Burden of Disease (GBD) study, and referred to 31 European countries.

\textbf{Results::} Neurological disorders prevalence was 256.0 million, i.e. 59.2\% of all NCDs, and they caused 1.1 million deaths (23.5\% of all NCDs). Neurological disorders accounted for 12.5 million YLLs (18.2\% of all NCDs), 9.6 million YLDs (16\% of all NCDs) and 22.2 million DALYs (17.2\% of all NCDs). Headache disorders and stroke were the most prevalent and disabling conditions, whereas stroke and dementias were those associated to higher mortality and YLLs. In terms of DALYs, stroke, dementias and headache disorders were the most burdensome conditions, as they accounted respectively for 5.7\%, 4.2\% and 3.7\% of DALYs attributable to NCDs in Europe.

\textbf{Conclusions::} Neurological disorders are the most prevent conditions in Europe and rank second for DALYs after tumors. The burden of neurological diseases has increased in absolute terms since 2010, mostly in reason of the dramatic explosion of the DALYs associated to headaches, stroke, Parkinson’s disease and dementias (increase rates between +145\% and +500\%). In consideration of ageing trends, public health strategies are needed to identify the best caring practices.
POST HERPETIC NEURALGIA - A STUDY OF DEMOGRAPHICS IN COSMOPOLITAN TERTIARY CENTRE IN PENANG, MALAYSIA

Shin Loong Soong¹, Gaik Bee Eow², Faiz Suhaimi², Selvakumar Thankamony², Choo Aun Neoh³
¹RCSI & UCD Malaysia Campus (RUMC), Department Of Medicine, Pulau Pinang, Malaysia, ²Pulau Pinang Hospital, Department Of Neurology, Pulau Pinang, Malaysia, ³Pingtung Christian Hospital, Research & Teaching Department, Pingtung, Taiwan

Background and Aims:: Post Herpetic Neuralgia (PHN) is a complication of VZV reactivation which remained latent in ganglion of cranial nerves, dorsal root and autonomic nerves. It is characterized by persistent pain, leading to significant psychosocial impact. The study intends to investigate the demographics of patients and sites of PHN in Penang Hospital.

Methods:: The study involves a retrospective analysis of patient diagnosed with PHN from the year 2007 to 2020.

Results:: 88 patients were identified to have PHN, consisting of 42 (48%) male and 46 (52%) females, with a female preponderance. Most cases (49%) occurred among individuals from 61 to 70 years old. The left sided PHN is slightly more common than the right accounting for 45 (51%) and 43 (49%) cases respectively. The pain commonly involves the thoracic dermatomes 43 (48%) cases followed by trigeminal nerve distribution involving 26 (29%) individuals, 19 (22%) patients have underlying hypertension, 13 (15%) have diabetes mellitus and 10 (11%) have underlying malignancy.
Conclusions: Our study has suggested that PHN commonly affects individuals from the age 61 to 70 years old and the thoracic dermatomes. In our study, approximately 26% of patients were diagnosed with immunocompromising diseases such as diabetes and malignancy, which prompted speculation on neuroimmunology etiology of PHN. In conclusion, the treatment strategy and cure for PHN remained limited. Most patients with PHN and trigeminal neuralgia remain medication dependent. Thus, the effort in addressing the burden of PHN should be focused on acute herpes zoster preventions as well as the holistic approach involving multidisciplinary teams with east west integration.
INCIDENCE AND DISTRIBUTION OF PRIMITIVE CNS TUMORS IN SOUTHERN SARDINIA, 2016-2019

Vincenzo Pierri¹, Sabino Dagostino¹, Francesca Bruder², Carlo Conti³, Tommaso Ercoli¹, Gianluca Floris⁴, Cristina Manieli⁵, Marta Melis⁶, Maurizio Melis⁷, Antonella Muroni⁶, Giuseppe Piga¹, Antonella Tuveri⁴, Mariangela Vacca⁴, Rosario Vasta⁵, Giovanni Defazio⁶
¹University of Cagliari, Department Of Medical Sciences And Public Health, Institute Of Neurology, Monserrato, Italy, ²Hospital Businco, Department Of Medical Oncology, Cagliari, Italy, ³Department of Neurosurgery, Hospital "g.brotzu", Cagliari, Italy, ⁴Azienda Ospedaliero Universitaria di Cagliari, Institute Of Neurology, Monserrato, Italy, ⁵Hospital "G.Brotzu", Service Of Pathological Anatomy, Cagliari, Italy, ⁶University of Cagliari and AOU Cagliari, Department Of Medical Sciences And Public Health, Neurology Unit, Monserrato, Italy, ⁷Hospital "G. Brotzu", Department Of Neurology And Stroke Unit, Cagliari, Italy, ⁸Turin University, Als Centre, "rita Levi Montalcini" Department Of Neuroscience, Turin, Italy

Background and Aims:: CNS tumors (CNST) carry a substantial source of morbidity and mortality in the world, but epidemiological data are poor. This study evaluated the incidence of primitive CNST in the adult population of Southern Sardinia over a four-year span and identified incidence clusters over the area under study.

Methods:: Adult patients with CNST were identified by examining the computerized database of the Departments of Neurology, Neurosurgery, Pathology and Oncology of the five hospitals localized in the study area (Cagliari Metropolitan Area and South Sardinia (SU) province). We excluded secondary tumors of the CNS, meningiomas and tumors of cranial and paraspinal nerves. Cluster analysis was performed by age- and sex- adjusted Kulldorf's spatial scan statistic (KSSS).

Results:: Histological diagnosis was available in 199/234 patients (85%). Crude incidence of CNST was 7.4/100000 persons-year and the age-adjusted standardized rate (AASR) was 6.2/100000 persons-year. Glioblastomas showed a crude incidence rate of 5.7/100000 persons-year and an AASR of 4.7/100000 persons-year. The Cagliari and SU provinces showed comparable CNST (7.1 versus 7.8/100000 person-years; p = 0.5) and glioblastomas rates (6.0 versus 4.9/100000 person-years; p=0.2). The KSSS did not reveal any incidence cluster related to the CNST overall. Considering only glioblastomas, were detected a low-incidence cluster and a non-significant high-incidence cluster.

Conclusions:: Our CNST incidence rates were similar with previous studies while our glioblastomas incidence rates tended to be higher than other European data. The population of the aforementioned clusters needs to be evaluated in further investigations, inquiring for risk or protective factors.
THE EVALUATION OF THE PAIN, STRESS AND PHYSICAL ACTIVITY ACCORDING TO THE ERGONOMIC CONDITIONS IN THE WORKPLACE OF THE ACADEMIC STAFF

Gokcen Akyurek, Betul Ustun
Hacettepe University Faculty of Health Sciences, Occupational Therapy, Ankara, Turkey

Background and Aims:: This study was conducted to examine the pain, stress and physical activity according to the ergonomic conditions in their workplace of academic staff.

Methods:: Eighty-five academic staff working at Suleyman Demirel University participated in the study. The International Physical Activity Questionnaire – Short Form (IPAQ- SF) was used to determine the physical activity levels of the participants, Nordic Musculoskeletal Questionnaire (NMQ) to determine their pain, and the Perceived Stress Scale (PSS) to determine their stress levels. A Rapid Office Strain Assessment (ROSA) was conducted to determine the ergonomic condition of the workplace.

Results:: According to the analysis, statistically significant differences were found between academic personnel with and without the ergonomic environments in their workplace in terms of total scores of the IPAQ-SF (p = 0.018). In addition, it was observed that there is not a significant difference between these groups in terms of PSS score (p > 0.05). The percentage of neck pain was higher than back pain in academic personnel.

Conclusions:: According to the result, the ergonomic conditions of the workplace affected individuals’ physical activity level but not stress level. In addition, academic staff in University could be considered as a risk group of job-related neck pain.
WHAT IS AMYOTROPHIC LATERAL SCLEROSIS PREVALENCE?

Francesca Palumbo¹, Rosario Vasta¹, Cristina Moglia¹,², Umberto Manera¹, Antonio Canosa¹,², Maurizio Grassano¹, Paolo Cugnasco¹, Fabiola De Marchi³, Letizia Mazzini³, Andrea Calvo¹,², Adriano Chio²,⁴

¹Turin University, Als Centre, "rita Levi Montalcini" Department Of Neuroscience, Turin, Italy, ²AOU Città della Salute e della Scienza, Neurology 1, Torino, Italy, ³Department of Translational Medicine, University of Piemonte Orientale, and Azienda Ospedaliero-Universitaria "Maggiore della Carità", Als Center, Neurology Unit, Novara, Italy, ⁴Turin University, Als Centre, "rita Levi Montalcini" Department Of Neuroscience, TURIN, Italy

Background and Aims:: ALS prevalence ratio is usually calculated excluding prevalent cases. This may lead to a methodological bias, given the high variability of ALS patients survival, mostly according to phenotype. We aimed at assessing ALS prevalence and to evaluate how the historical depth of data may influence the prevalence ratio estimate.

Methods:: Data from the PARALS Register were used. Crude prevalence ratio was estimated on December 31, 2015 for the period 2015-2013 and then repeated extending the time interval by three years each time. For each time interval, prevalence ratio was calculated globally and stratified by sex, age at diagnosis, and phenotype. Prevalence was also calculated considering patients who underwent tracheotomy during the same period.

Results:: Prevalence ratios increased proportionally to the length of the time period considered, ranging from 6 (95% CI 5.3 - 6.7) for a 3-year period to 12.1 (95% CI 11.1 - 13.1) per 100.000 for 21-year period. Respiratory phenotype did not contribute to the increase of prevalence ratio as time periods lengthened (from 0, 95% CI 0 - 0.2, to 0.1, 95%CI 0 - 0.3). Conversely, predominant UMN showed the highest increase (from 0.5, 95% CI 0.3 – 0.8, to 2.1, 95% CI 1.7 – 2.6, +320%).

Conclusions:: the depth of data collection influences the prevalence ratio estimate. A 12-year period should be sufficient to get a reliable evaluation of ALS prevalence including long-survival patients. This results may be useful in assessing predictive values of prognostic markers but also in planning health resources, given the significant social and assistential burden of the disease.
RECOMPRESSION OF SPINAL CORD DECOMPRESSION SICKNESS

Jinyoung Ahn¹, Heetae Kim²
¹Seoul Medical Center, Neurology, Seoul, Korea, Republic of, ²Hanyang University Hospital, Neurology, Seoul, Korea, Republic of

Background and Aims:: Symptoms of spinal cord decompression sickness(DCS) occur almost immediately when out of water. It is recommended that recompression treatment should be performed soon in order to avoid further tissue injury. Unfortunately, there may be a significant time delay from surfacing to recompression. The aims of the study were to evaluate the effect of delayed hyperbaric treatment, initiated more than 30hr after surfacing for DCS and to evaluate the different treatment protocols.

Methods:: 68 injured divers presenting symptoms of spinal cord DCS were retrospectively included from Seoul Medical Center. Diving information, time interval between symptom onset and hyperbaric treatment were studied. The initial severity of spinal cord DCS was rated with the Boussuges severity score and muscle power examination and the presence of sequelae was evaluated at 2 weeks. Initial recompression treatment at 2.8 - 4 ATA (atmospheres absolute) with 100% oxygen breathing or deeper recompression.

Results:: There were no significant differences between each group in age, diving experience, depth of dive. bottom time of dive, Boussuges's score. With respect to treatment results, at the delayed treatment divers, good recovery was achieved in 47.1% of the divers. When treatment started early, good recovery was achieved in 58.8% of the divers. Hyperbaric treatment using US Navy Table6a protocol trended toward a better clinical outcome, statistically significant (p=0.04) compared to US Navy Table6.

Conclusions:: The prognosis is good when the recompression therapy is delayed in patients with spinal decompression sickness. Hyperbaric oxygen treatment is better in US Navy Table6a than Table6 in patients with spinal decompression sickness.
TOBACCO USE AND HEALTH: PERCEPTION AND PRACTICE AMONG TEENAGER STUDENTS OF TELANGANA STATE INDIA.

Nalin Chaudhary¹, Venkata Randi²
¹T N C MEDICAL FOUNDATION, Neurology, HANAMKONDA, India, ²Seven Hills Hospital, Neurology, visakhapatanam, India

Background and Aims:: Background & aims: Tobacco related diseases (cancer, heart & brain stroke) cause 20 millions death per year. Out of these 2/3rd death occur in China and India. There is urgent need to identify the target population and implement effective policies for prevention of tobacco use. Aim of study was to identify the prevalence and level of knowledge among high school students of tobacco use and the factors influencing their act for early intervention.

Methods:: A cross-sectional survey was done on 1000 high school students in the age group of 14 to 16 years from rural area of Warangal, and Jangaon, districts of Telangana state, India from June 2019 to December 2019. This survey was done by epidemiologist of TNC medical foundation (A Registered Non-Governmental organization).

Results:: 600 boys and 400 girls were interviewed through a prepared questionnaire. Among study group, 20% accepted smoking habit (95% boys and 5% girls). Various reasons were cited for smoking and tobacco chewing e.g. fun and enjoyment (20%), imitation of the action hero of the popular movies (25%), to alleviate the boredom etc. 80% knew the content and toxic effect of tobacco on health. 64% students wish to stop smoking. 75% students want ban on tobacco products (cigarettes, ghutka ) use in public places by the government.

Conclusions:: Conclusion: Majority of the students had the knowledge of tobacco toxicity. Student counseling, health education and awareness programs by trained professionals at school stage should be planned by the government to reduce tobacco related death in developing countries.
THE PREVALENCE OF LOWER URINARY TRACT SYMPTOMS IN PATIENTS WITH MULTIPLE SCLEROSIS IN RIYADH, SAUDI ARABIA

Awad Al Harbi
PNU, Medicine, Riyadh, Saudi Arabia

Background and Aims:: Exploring the prevalence of lower urinary tract symptoms (LUTS) in multiple sclerosis (MS) patients may lead to optimizing therapeutic interventions that could improve their quality of life (QoL). The main objective of this study was to assess the prevalence of LUTS in patients with MS in Riyadh, Saudi Arabia.

Methods:: This cross-sectional study targeted Saudi nationals aged 18-50 who were previously diagnosed with MS and presented with urinary tract dysfunction symptoms. It was conducted from November 2020 to January 2021 through the distribution of a self-administered electronic questionnaire.

Results:: Data were collected from 158 patients with MS. Most participants (44.3%) were between 30 and 39 years old, and 64.6% were female. The severity of LUTS is significantly associated with the QoL of patients, where an increase in severity of LUTS would worsen their QoL (p < 0.001). More than half of the sample (52.5%) indicated that they had taken treatment for these symptoms, 40.7% of whom reported using medicinal treatment. The duration of illness, age, or gender was found to have no significant effect on LUTS severity.

Conclusions:: We found that LUTS and urinary incontinence prevalence among patients with MS do not significantly correlate with different genders and age groups. LUTS seem to have a significant negative impact on the QoL of patients with MS.
Background and Aims:: Neglected tropical diseases (NTDs) are a set of 20 diseases classified by WHO that affect populations with low access to health services. In 2012, Brazil took part in the “London Declaration on NTDs”, an international partnership to combat 10 NTDs by 2020. All NTDs in Brazil may have neurological manifestations, so it is essential to know about the epidemiology and clinical implications.

Methods:: An observational, retrospective and epidemiological study based on available data of the Department of the Unified Health System obtained through the application Health Information. We evaluated the absolute means of incidence in two groups (2007-2013 and 2014-2020), it was organized and analyzed based on statistical methods. The neurological manifestations of NTDs were searched in literature.

Results:: These NTDs appeared in the London Declaration: leprosy, trachoma, schistosomiasis, soil-transmitted helminthiasis, Chagas disease, visceral leishmaniasis, and onchocerciasis. Trachoma and onchocerciasis are not mandatory notification diseases, and epidemiological data is scarce in Brazil. Leprosy, schistosomiasis (data until 2017) and helminthiasis had decreased incidences. Chagas disease (data up to 2019) incidence increased by 95.25% in national data - and there is no report in Paraná. Visceral leishmaniasis increased (data up to 2019) in Paraná by 138.81%, and its incidence decreased by 1.82%. The neurological manifestations may be stroke, neurological injury, meningoencephalitis, myelopathy, neuropathy, and death due to neurological damage.

Conclusions:: Although incidences of NTDs have fallen, Brazil has not met the deal agreed in 2012, furthermore, it has reduced investments to combat these diseases. The neurological manifestations of NTDs have significant implications for morbidity and mortality.
Background and Aims:: Patients with Parkinson’s disease have higher rates of hospital admissions and longer length of stay than patients without the disease. This study aims to evaluate the epidemiology of hospitalizations for Parkinson’s disease in Brazil during 2019 and 2020.

Methods:: Cross-sectional, descriptive and retrospective study, which evaluated the epidemiology of hospital admissions for Parkinson’s disease in the Brazilian National Health System in the years 2019 and 2020. Hospital admissions were evaluated by sex, race, and age group using the national database (DATASUS – Department of Informatics of the Unified Health System).

Results:: During this time period, there was a total of 1623 hospitalizations for Parkinson’s disease in the Brazilian National Health System, with 947 (58.4%) hospital admissions in 2019 and 676 (41.6%) in 2020. Also, 972 (59.9%) patients were male and 651 (40.1%) were female. Regarding race (n=1299); 777 (59.8%) patients considered themselves white, 442 (34%) brown, 54 (4.2%) black and 26 (2%) others. Regarding age groups; 278 (17.1%) were >80 years old, 847 (52.2%) were 60-79, 453 (27.9%) were 40-59 and 45 (2.8%) were <40.

Conclusions:: The majority of patients hospitalized for Parkinson’s disease were male, white, and 60-79 years old. There was a decrease in hospital admissions for Parkinson’s disease from 2019 to 2020, which may be related to the hospital’s oversaturation by COVID-19. In addition to that, the disease is still little analyzed epidemiologically in the country and needs more attention.
HOSPITAL ADMISSIONS FOR BACTERIAL MENINGITIS DURING 2019-2020 IN BRAZIL

Valquiria Garcez, Tulio Correa
Universidade Federal de Pelotas, Faculty Of Medicine, Pelotas, Brazil

Background and Aims:: Bacterial meningitis is a prevalent concern in low and middle-income countries, accounting for a high number of deaths and hospitalizations. This study aims to evaluate the epidemiology of hospitalizations for bacterial meningitis in Brazil during 2019 and 2020.

Methods:: Cross-sectional, descriptive and retrospective study, which evaluated the epidemiology of hospital admissions for bacterial meningitis in the Brazilian National Health System in the years 2019 and 2020. Hospital admissions were evaluated by sex, race and age group using the national database (DATASUS – Department of Informatics of the Unified Health System).

Results:: There was a total of 6921 hospitalizations for bacterial meningitis, being 4091 (59.1%) from 2019 and 2830 (40.9%) from 2020. In addition, 3922 (56.6%) patients were male and 2999 (43.4%) were female. Regarding race, 2421 (35%) considered themselves white, 2710 (39%) brown, 275 (4%) black, 130 (2%) yellow, 31 (0.5%) indigenous and 1354 (19.5%) did not have skin color informed. Regarding age groups; 1156 (16.7%) were <1 year old, 796 (11.5%) were 1-4, 560 (8.1%) were 5-9, 439 (6.3%) were 10-19, 818 (11.8%) were 20-29, 730 (10.5%) were 30-39, 641 (9.3%) were 40-49, 625 (9%) were 50-59, 436 (6.3%) were 60-69, 209 (3%) were 70-79, 85 (1.3%) were >80.

Conclusions:: The majority of patients hospitalized for bacterial meningitis disease were male, brown and <1 year old. There was a decrease in hospital admissions for bacterial meningitis from 2019 to 2020, which may be related to the increased social isolation due to COVID-19.
A NOVEL WDR45 MUTATION IN A 6-YEAR-OLD BOY WITH AUTISM, LENNOX-GASTAUT SYNDROME, AND ADHD

William Baek1, Hua Wang2
1Parkside Medical Group, Neurology, Upland, United States of America, 2Loma Linda University School of Medicine, Department Of Pediatrics, Division Of Genetics, Loma Linda, United States of America

Background and Aims:: Beta-propeller protein-associated neurodegeneration, i.e., neurodegeneration with brain iron accumulation type 5, is due to mutations in the WDR45 gene. We report a case where a novel pathogenic mutation was discovered.

Methods:: Case Report

Results:: A 6-year-old boy presented with autism, developmental delay, seizures, and aggression. Details of his birth history were unknown. He had been on levetiracetam since 3. His parents first witnessed near-daily drop attacks. Valproic acid was added to toleviracetam, which resolved his drop attacks but head banging increased, hence discontinued. He was 117cm (7th percentile) and weighed 23.5kg (39th percentile). Head circumference was 50cm (17th percentile). He was not dysmorphic, but very hyperactive and disruptive. EEG was indicative of Lennox-Gastaut syndrome. MRI showed neurodegeneration with iron accumulation. Amphetamine-dextroamphetamine and Methylphenidate for ADHD did not help. Levetiracetam was increased and valproic acid was restarted, which had resolved his seizures. Risperdone was started for aggression. Genetic testing revealed a novel pathogenic variant (c.577C>T, p.Gln193) in WDR45. Allele fraction was 46%, suggesting mosaicism. At 8 his verbal communication improved, and he was seizure-free.

Conclusions:: A novel pathogenic variant (c.577C>T, p.Gln193) was found in the WDR45 gene as a mosaic with an allele fraction of 46%. The clinical features of our case were unique; he clearly did not have cerebral palsy nor was he bedridden. To date, at age 8, he still does not exhibit any signs of parkinsonism or dystonia. Whether this was due his mosaicism or the specific novel mutation remains unclear. Postzygotic mosaicism might explain why his phenotype was not as severe.
Background and Aims:: Single nucleotide polymorphism (SNP) HTR1A C1019G (rs6295) is located in promoter area and binds the NUDR / Deaf1 transcription factors with different affinities, which result in the level change of gene transcription. Minor allele G is associated with mental disorders, the development of depression, post-traumatic mental disorders, and resistance to anti-psychotic drugs. The aim of our study was to investigate the contribution of the SNP to development of neurological disorders in patients with neuro ICU.

Methods:: Study cohort included 134 neuro ICU patients with trauma, anoxic brain injury and brain tumors. HTR1A rs6295 polymorphism was studied by using an HTR1A specific oligonucleotide tetraprimer set. The content of oxidized DNA was determined using immunoassay.

Results::
Nihss (scale of neurological disorders) values on days 1 and 5 were significantly lower in patients with CC genotype compared to G carriers (16 vs. 18, $P=0.025$ and 15 vs. 18, $P=0.024$, respectively, $N=134$). Unexpectedly, we found association HTR1A rs6295 genotypes with concentration of oxidized DNA fragments (but not all cell-free DNA) in the plasma of patients. In patients carrying the G risk allele, the amount of oxidized DNA in plasma was lower (191 vs. 645, $P=0.03$ $N=63$). Thus, the low oxidized DNA value in plasma appears a significant unfavorable marker for neuro ICU patients.

**Conclusions:** G allele HTR1A rs6295 is associated with increase of neurological disorders in the group of neuro ICU patients with tumors, trauma, and anoxic brain injuries.
CLINICAL AND GENETIC FEATURES OF A LARGE COHORT OF ITALIAN SPG4 PATIENTS FROM THE D.A.I.S.Y. COLLABORATIVE NETWORK.

Background and Aims:: Hereditary spastic paraplegias (HSPs) are rare, inherited neurological disorders, characterised by degeneration of the corticospinal tracts and dorsal columns. SPG4, caused by heterozygous mutations of the SPAST gene, represents the most common form. Herein, we present findings from the largest described cohort of Italian SPG4 patients, aiming to define the clinical spectrum of SPG4 in Italy, and find any significant genotype-phenotype correlations.

Methods:: We retrospectively collected clinical and molecular data from 723 patients (419 males, 58%) from 316 families. Family history for SPG4, age at onset (AAO), disease severity by SPATAX disability and SPRS scales were gathered from medical records. Numerical and categorical variables were analyzed by Mann-Whitney and Chi-squared test, respectively.

Results:: Overall, penetrance of SPG4 was 0.98. Mean AOO was 32.46±17.41 years, with a bimodal distribution (Fig.
Males showed more frequently spastic gait (96.9% vs 90.2%) with a higher SPRS score (19.56 vs 16.18), and were more frequently assuming myorelaxant drugs (70.1% vs 59.3%). Overall, 186 different SPAST mutations were recorded (Fig. 2).
Compared to truncating mutations, patients with missense mutations had more frequently intellectual deficiency. On the other hand, patients with truncating mutations showed more frequently spasticity at rest, lower limbs proximal weakness, urinary disturbances, polyneuropathy, cerebral atrophy, and cognitive decline (Fig. 3).

**Figure 2.** Frequency of the different *SPAST* mutations found in our cohort (n=186).
Conclusions:: We documented a more severe motor involvement in males, and a more diffuse disorder in patients carrying truncating mutations. This wide multicenter study allowed to define phenotypic and genotypic spectrum of SPG4 in Italy, creating a network addressing SPG4 patients to hopefully forthcoming clinical trials.

**Figure 2.** Comparison of clinical and diagnostic findings between truncating and missense mutations' carriers (only significant ones shown, p<0.05).
MULTIPLE SCLEROSIS ASSOCIATED HLA VARIANTS AFFECT THE IMMUNOLOGICAL T LYMPHOCYTES REPERTOIRE

Melissa Sorosina¹, Silvia Santoro¹, Laura Ferrè¹,², Elisabetta Mascia¹, Ferdinando Clarelli¹, Antonino Giordano¹,², Cannizzaro Miryam¹,², Massimo Filippi¹,³,⁴, Federica Esposito¹,²
¹IRCCS San Raffaele Scientific Institute, Laboratory Of Neurological Complex Disorders, Division Of Neurosciences, Milan, Italy, ²IRCCS San Raffaele Scientific Institut, Neurology, Neurorehabilitation And Neurophysiology Unit, Milan, Italy, ³Vita-Salute San Raffaele University, Na, Milan, Italy, ⁴IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Divisione Of Neuroscience, Milano, Italy

Background and Aims:: Multiple sclerosis (MS) is a neurodegenerative and autoimmune disorder in which genetic predisposition plays an important role, with the major histocompatibility complex (MHC) region accounting for 32 independent associations. We aim to investigate the impact of MHC MS-risk alleles on T-lymphocytes repertoire in MS patients.

Methods:: 183 untreated relapsing-remitting MS subjects have been studied. Class I and II HLA alleles were inferred from whole-genome genotyping data using SNP2HLA and Beagle_v3.3 tools. T-cell receptor (TCR) CDR3 sequences were obtained from whole blood DNA according to the ImmunoSEQ hsTCRB kit (Adaptive Biotechnologies®). A weighted HLA-risk score (wHRS) was calculated. The inverse of the Simpson’s Index (INV.S) was calculated as representative of immune repertoire diversity. Statistical analyses were performed within R environment and plink v.1.9.

Results:: The final set was composed by 144 individuals and 30 MS-risk MHC loci. Four loci showed association with INV.S: HLA DRB1*15:01 (P=0.014), rs11751659 (P=0.02), rs9271366 (P=0.003), SNP_DRB1_32660116_A (P=0.036). A mild association was found between INV.S and wHRS (P=0.049), with individuals with a higher wHRS showing a lower diversity. Moreover, individuals carrying the risk alleles showed a different percentage of clonotypes occupying the 10% of the repertoire with a set of clonotypes enriched only in MS-risk HLA carriers that were identified.

Conclusions:: MS-risk MHC loci appear to influence TCR repertoire in MS patients, with the risk alleles reducing the diversity and inducing an expansion of specific clonotypes. Analyses are ongoing to better define the amplified clonotypes and their role.
EXTRA-REPEAT INSERTIONAL MUTATION IN THE PRNP GENE WITH CEREBRAL AMYLOID ANGIOPATHY: A CASE REPORT

Federica Cencini¹, Giuseppe Di Fede², Marcella Catania², Chiara Manfredi¹, Chiara Rosci¹, Lucia Tancredi¹, Elisabetta Groppo¹, Laura Campiglio¹, Amedeo De Grado¹, Francesca Bartesaghi¹, Alberto Priori¹, Emma Scelzo¹
¹III Clinical Neurology Unit, Department Of Health Sciences, University Of Milan, Polo Universitario Ospedale San Paolo, Asst Santi Paolo E Carlo, Milan, Italy, ²Unit of Neurology 5 and Neuropathology, Fondazione Ircs Istituto Neurologico Carlo Besta, Milan, Italy

Background and Aims:: Cerebral amyloid angiopathy (CAA), a major cause of spontaneous intracerebral haemorrhage and cognitive decline, has been documented in some forms of prion diseases (PrDs). Octapeptide Repeat Insertions (OPRIs) in the prion protein gene (PRNP) are mutations associated with genetic prion diseases (gPrDs). This is the first report of a patient with rapidly progressive dementia, carrying one OPRI in the PRNP gene and neuroimaging features consistent with CAA.

Methods:: We evaluated an 80-year-old man with no family history of neurodegenerative disease for cognitive impairment. Brain MRI, EEG-EMG polygraphy and analysis of Amyloid Precursor Protein gene (APP), Presenilins (PSEN1 and PSEN2) and PRNP gene were performed. 14–3–3, Tau proteins and Aβ42 were assessed in the cerebrospinal fluid (CSF).

Results:: The patient had cognitive dysfunction, abulia, postural limb myoclonus and unsteady wide-based gait. About 9 months after onset, he was bed-bound, almost mute and akinetic. Brain MRI showed sequelae of intraparenchymal haemorrhage, microbleeds and cortical siderosis, consistent with CAA. Genetic tests revealed the presence of one OPRI (24 bp insertion) in the coding region of PRNP. CSF had high Tau and p-Tau, decreased Aβ42 and absent 14.3.3 protein. EEG-EMG polygraphy showed diffuse slowing, bilateral frontal theta activity and generalized spikes-waves related to upper limb myoclonus induced by intermittent photic stimulation.

Conclusions:: To our knowledge, this is the first report of a patient with rapidly progressive dementia with detection of one OPRI in the PRNP gene and CAA. Although one OPRI is of questionable pathogenicity, our observations raise the question whether these two findings are causally linked.
AN ATYPICAL CASE OF SPASTIC PARAPLEGIA TYPE 11 MIMICKING A GM2 GANGLIOSIDOSES

Diego Lopergolo¹,², Gianna Berti¹,², Francesca Mari³,⁴, Enrico Bertini⁵, Carla Battisti¹,², Alessandra Renieri³,⁴, Alessandra Rufa¹,², Alessandro Malandrini¹,²
¹University of Siena, Department Of Medicine, Surgery And Neurosciences, Siena, Italy, ²Azienda Ospedaliero-Universitaria Senese, Uoc Neurologia E Malattie Neurometaboliche, Siena, Italy, ³University of Siena, Medical Genetics, Siena, Italy, ⁴Azienda Ospedaliero-Universitaria Senese, Genetica Medica, Siena, Italy, ⁵Bambino Gesù Children Hospital IRCCS, Neuromuscular And Neurodegenerative Diseases Unit, Rome, Italy

Background and Aims:: Spastic paraplegia type 11 (SPG11) is the most frequent autosomal recessive HSP. SPG11 patients' fibroblasts and mouse models revealed endolysosomal system dysfunction; endolysosomal lipid accumulation, especially gangliosides, was observed in post-mortem brains. We report an atypical patient with clinical onset and biopsy findings mimicking a GM2 gangliosidoses.

Methods:: A clinical, biochemical and metabolic characterisation was performed from the childhood, in the late 1980's, to the adulthood. Electron microscopy analysis was performed on rectal mucosa and skin biopsy specimens. A NGS panel including 154 genes associated to neuronal ceroid lipofuscinosis and HSP was performed.

Results:: The patient presented with worsening walking difficulty and psychomotor slowdown since childhood. In the late childhood, to exclude a neurometabolic storage disease, skin and rectal biopsy was performed: enteric neurons showed lipofuscin-like intracellular inclusions thus suggesting a possible GM2 gangliosidoses. However, the GM2A gene sequencing and the lysosomal enzymatic assay did not allow to confirm such hypothesis. In adulthood we detected flaccid paraplegia, distal hypotrophy, reduced deep tendon reflexes and horizontal gaze nystagmus. Further analysis revealed axonal motor neuropathy, carpus callosum atrophy and colon atony. Surprisingly, the NGS panel detected two already reported SPG11 mutations in a compound heterozygous state.

Conclusions:: We describe the atypical clinical and pathological features of a genetically ascertained SPG11 patient. For the first time we detected pathological hallmarks in enteric neuron from a rectal mucosa biopsy. The report thus illustrates the possible overlap between SPG11 and GM2-Gangliosidosis, especially in the first disease phases, and helps to improve our knowledge about SPG11 physiopathology neurodegeneration.
DCTN1 VARIANTS’ ROLE IN NEURODEGENERATIVE DISEASES: A REGIONAL TWO-CENTERS EXPERIENCE.

Nicola Mometto¹, Marco Spallazzi², Anna Bartoletti-Stella³, Simone Baiardi³, Rocco Liguori⁴, Piero Parchi⁵, Paolo Caffarra², Sabina Capellari⁶
¹AUSL Piacenza, Gugliemo da Saliceto Hospital, Department Of Neurology, Piacenza, Italy, ²Azienda Ospedaliero-Universitaria di Parma, Department Of Medicine And Surgery, Parma, Italy, ³IRCCS Istituto delle Scienze Neurologiche di Bologna, Ospedale Bellaria, Bologna, Italy, ⁴IRCCS Istituto delle Scienze Neurologiche di Bologna, Neurology Unit, Bellaria Hospital, Bologna, Italy, ⁵University of Bologna, Department Of Experimental Diagnostic And Specialty Medicine, Bologna, Italy, ⁶IRCCS Istituto delle Scienze Neurologiche di Bologna, Department Of Biomedical And Neuromotor Sciences, Bologna, Italy

Background and Aims:: The DCTN1 (dynactin 1) gene encodes for the major subunit of the dynactin protein complex which plays a crucial role in axon maintenance and organelles and vesicle transport regulation. Variants in this gene have been associated with various neurodegenerative disorders, most notably Perry syndrome, but also other types of parkinsonism, FTD, ALS and inherited neuropathies. In this work, we screened for DCTN1 variants a population of 607 patients referred to two centers of the Emilia Romagna region (Italy) affected by various type of neurodegenerative disorders, to define prevalence and clinical features associated with these variants.

Methods:: 607 patients affected by different neurodegenerative disorders for which a genetic origin was suspected (because of familiarity, early age of onset or peculiar phenotype) underwent genetic testing via a custom Next Generation Sequencing panel including the DCTN1 gene.

Results:: We identified 13 rare variants of the DCTN1 gene that were predicted to be pathogenic or likely pathogenic by at least one of the three different in-silico tools used for deleteriousness prediction (9 of them by 2/3 of the tools). The predominant clinical presentation was cognitive impairment (77%), particularly bvFTD, often associated with parkinsonism (31%). Two patients (15%) presented only with atypical parkinsonism, and one (8%) with isolated progressive lower motor neuron disease.

Conclusions:: Variants in DCTN1 gene are a rare but unneglectable cause of neurodegenerative disorders, with protean manifestations, and this gene should be included in the extensive search for genetic variants in different phenotypes.
Background and Aims:: The Global Parkinson’s Genetics Program (GP2) is an international collaborative effort aiming at improving knowledge on genetics in Parkinson’s disease (PD). The “Monogenic Hub” plans to perform whole-genome sequencing (WGS) for a total of 5-10,000 PD patients over a period of 5 years, to discover novel monogenic PD causes and better characterize genetic modifiers influencing disease manifestation and progression. We aim to develop an easy-to-use online platform for case/family submission to support the efforts of GP2.

Methods:: Researchers with expertise in PD genetics collaborated with web designers and developed a registration site to submit information regarding institutional ethical clearance for international data and sample sharing, as well as an electronic case report form to submit pseudonymized data of patients/families in whom a monogenic cause of PD is suspected. To maximize participation, especially from underrepresented populations, clinical and available genetic pre-screening datasets are designated as “Minimal”, “Core” and “Extended”. All submitted cases will undergo comprehensive genotyping with the Illumina Global Diversity Array.

Results:: The Monogenic Hub website, including the Monogenic Portal (https://monogenic.gp2.org), was launched on February 8th, 2021. Feedback received from users is continually used to further refine the accessibility/user-experience of the platform. A video tutorial was also created to help the submitters during their first registration to the Monogenic Portal.

Conclusions:: We established an online platform for case/family submission within the “Monogenic Hub” of GP2. The collection of rich patient/family data will facilitate prioritization of samples for WGS, enable deeper analysis of genetic, clinical-demographic and environmental factors influencing disease expression.
THE GLOBAL PARKINSON’S GENETICS PROGRAM (GP2): THE MONOGENIC HUB 500-GENOMES PILOT PROJECT

Lara Lange¹, Katja Lohmann¹, Enza Maria Valente², Shen-Yang Lim³, Ai Huey Tan³, Eva-Juliane Vollstedt⁷, Micol Avenali⁴, Harutyun Madoev¹, Peter Heutink⁵, Kishore Kumar⁶, Niccolò Mencacci⁷, Christine Klein¹
¹University of Luebeck, Institute Of Neurogenetics, Luebeck, Germany, ²Department of Molecular Medicine, University of Pavia, Neurogenetics Research Centre, Irccs Mondino Foundation, pavia, Italy, ³University of Malaya, Division Of Neurology, Department Of Medicine And The Mah Pooi Soo & Tan Chin Nam Centre For Parkinson’s & Related Disorders, Faculty Of Medicine, Kuala Lumpur, Malaysia, ⁴Department of Brain and Behavioural Sciences, University of Pavia, Neurorehabilitation Unit, Irccs Mondino Fondation, PAVIA, Italy, ⁵German Center for Neurodegenerative Diseases, Dzne, Tuebingen, Germany, ⁶University of Sydney, Garvan Institute, Molecular Medicine Laboratory, Concord Hospital, Sydney, Australia, ⁷Northwestern University, Feinberg School Of Medicine, Department Of Neurology, Chicago, IL, United States of America

Background and Aims:: The Global Parkinson’s Genetics Program (GP2) is an international collaborative program that focuses on improving our understanding of the role of genetics in Parkinson’s disease (PD) and on making this knowledge globally available and actionable. The “Monogenic Hub” aims to perform both short and long-read whole-genome sequencing (WGS) for a total of 10,000 PD patients starting with a 500-genomes pilot project, with the goal of identifying novel monogenic causes of PD.

Methods:: Clinical and pre-existing genetic data on patients from around the globe were obtained through online questionnaires and are further collected through the Monogenic Portal, an easy-to-use online application. All submitted cases were evaluated and prioritized for pilot WGS based on the following criteria: number of affected family members and sample availability, pedigree structure, consanguinity history, early age at onset (AAO) and availability of genetic prescreening. A particular focus was placed on currently underrepresented populations in genetic studies.

Results:: 16 research teams from 10 different countries submitted 757 PD patients to the Monogenic Hub. We selected 512 cases for our 500-genomes pilot; 75% of them were familial cases and the remaining were singletons with an AAO ≤ 40 years. The majority had negative genetic pre-screening and ~20% are from underrepresented populations.

Conclusions:: Within the Monogenic Hub of GP2, we established a screening process and an online platform for case/family submission allowing us to perform WGS for the first 500 PD patients from 279 families with an as yet unknown but suspected monogenic cause of their PD.
Background and Aims:: Leukodystrophies are genetic neurological disorders characterized by involvement of the white matter of the CNS that may occur at all age. The ovarioleukodystrophies comprise a group of rare leukodystrophies associated with primary or premature ovarian failure.

Methods:: A case report to determine the clinical and radiological characteristics of ovarioleukodystrophy.

Results:: A 44-year-old woman presented with progressive difficulties in walking during the last 3 years. Her medical background showed spaniomenorrhea and infertility and she had no familial medical history. Neurological examination showed depression, dementia and bilateral pyramidal weakness. On biology, she had ovarian failure with low estrogen levels and high LH and FSH levels with undetectable ovaries on pelvic ultrasonography. Brain magnetic resonance imaging (MRI) revealed diffuse and symmetric white matter abnormalities with lesions having cerebrospinal fluid-like signals. The diagnosis of ovarioleukodystrophy was made on the basis of Van Der Knaap criteria.

Conclusions:: Ovarioleukodystrophy is an association of adult-onset vanishing white matter disease and premature ovarian insufficiency (POI). It is a rare autosomal recessive leukoencephalopathy caused by mutations in any of five genes encoding the eukaryotic initiation factor 2B (EIF2B1–5). The mean age of clinical onset in female patients is 36.8 years. The symptoms may combine progressive subcortical cognitive decline with behavioural disorders and motor signs. Ovarian failure occurred in all patients and usually preceded the neurological symptoms. Neuroimaging shows bilateral confluent leukoencephalopathy and periventricular cystic degeneration. For patients presenting with POI with neurological signs the MRI and screening of the EIF2B mutations is indicated.
PYRAMIDAL PATHWAY CHANGES AT CONVENTIONAL BRAIN 3T-MRI IN PATIENTS WITH HEREDITARY SPASTIC PARAPLEGIA

Giovanni Rizzo1, Stella Battaglia1, Anna Federica Marliani1, Luca Albini Riccioli1, Veria Vacchiano2, Silvia De Pasqua1, Patrizia Avoni1,2, Ilaria Bartolomei1, Fabrizio Salvi1, Rocco Liguori3,4
1IRCCS Istituto delle Scienze Neurologiche di Bologna, Ospedale Bellaria, Bologna, Italy, 2IRCCS Istituto delle Scienze Neurologiche di Bologna, Uoc Clinica Neurologica, Bologna, Italy, 3University of Bologna, Dipartimento Di Scienze Biomediche E Neuromotorie, Bologna, Italy, 4IRCCS Istituto delle Scienze Neurologiche di Bologna, Neurology Unit, Bellaria Hospital, Bologna, Italy

Background and Aims:: Conventional MRI can identify abnormalities associated with upper motor neuron (UMN) involvement. Motor cortex (MC) and cortico-spinal tract (CST) imaging abnormalities are reported in patients with amyotrophic lateral sclerosis (ALS), but their prevalence in other disease with UMN involvement is poorly studied. Our aim was to evaluate the occurrence of such changes in patients with hereditary spastic paraplegia (HSP).

Methods:: We retrospectively evaluated 3T-MRI from 44 HSP (27 men, mean age 49.3 ± 14.6), 55 ALS patients (35 men, 56.3 ± 7.6) and 52 controls (34 men, 53.4 ± 5.1). Features of interest were CCS T2/FLAIR hyperintensity, MC SWI hypointensity and selective MC atrophy. Differences among groups were tested using χ2 or ANOVA based on data (p < 0.05). We adjusted the analysis for age using logistic regression.

Results:: HSP patients had more frequently CCS FLAIR hyperintensity than controls but less than ALS patients (40.5%, 30% and 67.3% respectively; p<0.001). The prevalence of MC SWI hypointensity (HSP 69.2%, ALS 73.5%, controls 18.8%; p<0.001) and atrophy (HSP 73.8%, ALS 64.2%, controls 42.3%; p<0.01) was similar in HSP and ALS patients, both higher than in controls. The results did not changed adjusting for age.

Conclusions:: The prevalence of MC and CCS MRI abnormalities in HSP patients is higher than controls. However, it was similar to ALS patients, except for CCS FLAIR hyperintensity, less frequent in HSP, possible reflecting pathophysiological differences. The finding of such MRI features support a pyramidal involvement but is not able to discriminate between HSP and ALS.
VOLOTSKY INDEX IN PATIENTS WITH ISCHEMIC STROKE ACCORDING TO THE DERMATOGLYPHIC STUDY

Aida Seitaliyeva¹, Kamila Srailova², Bekmurat Raimkulov², Ziyada Tanat³
¹Asfendiyarov Kazakh National Medical University, Pharmacology, Almaty, Kazakhstan, ²Asfendiyarov Kazakh National Medical University, Nervous Diseases With A Course Of Neurosurgery, Almaty, Kazakhstan, ³Astana Medical University, Neurology, Nur-Sultan, Kazakhstan

Background and Aims:: Aim is to determine and compare the Volotsky index and index range in patients with ischemic stroke and in healthy individuals using dermatoglyphic study.

Methods:: Fingerprints were taken from 52 patients with ischemic stroke and from 64 healthy individuals using the method of T.Gladkova. Dermatoglyphic analysis of the prints was carried out on the Papilone DC machine. Finger patterns-loops, arcs, curls, an the delta index are calculated. The Volotsky delta index is calculated using the formula: DL10 = (L+2W)/(A+L+W)*10, according to finger patterns A-L-W (arc-loop-curl).

Results:: In the group of patients, the index was 10.7%, and the index range was 8-18%, and in the group of healthy men, the index was 11.2%, the range was 6-16%; In women from the group of patients, the index was 14.5%, the range 9-20%; in women from the group of healthy individuals, the index was 10.6%, the range 6-16%; When determining the overall index in the group of patients, the index in male and female patients was 12.7%, and the range 8-20%. The overall index in the group of healthy individuals was 10.8%, and the range was 0-19%.

Conclusions:: In men from both groups Volotsky index and the range are similar. The index and the range are lower in healthy women than in women with ischemic stroke. Average value (in both men and women) of the index and the range are higher in the group of patients with ischemic stroke.
ADULT ONSET CEREBELLAR ATAXIA DUE TO NOVEL MUTATIONS IN BRAT1

Grazia Maria Igea Falcone¹, Alessandra Tessa², Filippo Maria Santorelli², Graziana Tavilla¹, Antonio Toscano¹, Olimpia Musumeci¹
¹University of Messina, Unit Of Neurology And Neuromuscular Disorders, Department Of Clinical And Experimental Medicine, Messina, Italy, ²IRCCS Fondazione Stella Maris, Molecular Medicine, Pisa, Italy

Background and Aims:: BRAT 1 (BRCA1-associated ATM activator 1) variants were first reported in 2012 in newborns with lethal neonatal rigidity and multifocal seizure syndrome (RMFS). They have also been associated with early onset neurodevelopmental disorder with cerebellar atrophy and with or without seizures (NEDCAS). More recently a milder phenotype characterized by nonprogressive cerebellar ataxia (NPCA) has been reported. We describe the case of a 66 year old woman with sporadic cerebellar ataxia, spasticity and mental retardation in whom we detected two novel mutations in BRAT1.

Methods:: NGS screening using targeted gene panels using a NextSeq Illumina platform was performed. The pathogenicity was investigated using Polyphen, SIFT and CADD score. The mutations were confirmed by Sanger sequencing.

Results:: The patient had started to complain gait disturbances with frequent falls since she was 55. She had also experienced rigidity, mild dysphagia and excessive sleepiness. Neurological examination showed ataxic gait, spasticity at four limbs, vertical gaze palsy, dysmetria and dysdiadochokinesia. Dysmorphic features as short stature, micrognathia and low set ears were also present. Extensive metabolic investigations were normal. EEG was normal. Brain MRI showed frontoparietal atrophy and cerebellar atrophy. Cognitive tests revealed mild cognitive impairment. Mutations in most common SCA loci were ruled out. Genetic analysis on NGS panels for genes associated with ataxia identified two novel compound heterozygous mutations in BRAT 1, c.605T>G (p.V202G) and c.333_346del (p.A112fs*74).

Conclusions:: Our case further expands the clinical spectrum of BRAT1 pathogenic variants suggesting to include BRAT1 gene in NGS panels screening for adult patients with cerebellar ataxias or spastic paraplegias.
CIDP ASSOCIATED WITH A NEW CONGENITAL MYASTHENIC SYNDROME: A CASE REPORT

Paolo Emilio Alboini¹, Lucia Florio², Maurizio Leone²
¹Fondazione IRCCS Casa Sollievo della Sofferenza, Neurology Unit, San Giovanni Rotondo (fg), Italy, ²Fondazione IRCCS Casa Sollievo della Sofferenza, Neurology Unit, San Giovanni Rotondo (FG), Italy

Background and Aims:: Congenital myasthenic syndromes (CMS) are a broad group of genetic-related neuromuscular transmission disorders. CIDP is an immune-mediated inflammatory disorder of peripheral nervous system. Both of these diseases are characterized by weakness, progressive in CIDP and often fluctuating in CMS. We report a case of CIDP associated with a new CMS subgroup

Methods:: A 27-year-old female patient was referred to our Institution with a diagnosis of CIDP. She was treated with intravenous immunoglobulins (IVIg) with marked benefits. When she was 33, during pregnancy, she complained ptosis, diplopia and marked weakness in both extensor digitorum muscles. Neurophysiological studies showed stable signs of CIDP, but these new symptoms did not respond to IVIg. So the patient underwent to repetitive nerve stimulation studies and single fibre EMG, which showed a neuromuscular transmission disorder. A repeated search for AChR and MuSK antibodies was always negative. No mediastinal alterations after CT scan were observed. Patient was diagnosed with seronegative myasthenia gravis. Pyridostigmine was not tolerated. Prednisone, azathioprine and mycophenolate treatments were ineffective and discontinued.

Results:: Due to the early onset of this neuromuscular transmission disorder a CMS was hypothesized and a genetic study was performed, showing a heterozygosis P506S in CHRNG gene, encoding gamma subunit in foetal AChR. This alteration had never been described so far and it is considered to be responsible for a slow-channel CMS.

Conclusions:: Foetal AChR is generally absent in adult neuromuscular junction: we hypothesized that the co-occurrence of CIDP may have triggered its expression, causing myasthenic signs development.
CHARCOT MARIE TOOTH DISEASE 2A, KIF1B PHENOTYPE; A CASE REPORT

Adrian Infante Valenzuela, Beatriz Eugenia Chávez Luévanos, Fernanda Flores Alfaro, Rómulo Ramírez Gutiérrez
Hospital Universitario de Monterrey, UANL, Servicio De Neurología, Monterrey, Mexico

Background and Aims:: Background. Charcot Matie Tooth Disease (CMTD) has diverse inheritance patterns, affecting peripheric nerves through alterations in genes responsible for protein codification in Ranvier nodes. CMTD classification considers peripherical nerve velocity, inheritance pattern, among other factors; however, after the acknowledgment of multiple genes involved, a genetic classification should be considered. We present a case with an alteration in KIF1β.

Methods:: Case. 30-year-old female presenting axonal and demyelinating polyneuropathy (symmetric, sensory, and motor), multiple joint contractures, abnormalities in limb morphology, chronic skin erosions, vomiting crisis, and nausea. Alongside this, she presented cortical irritative activity, bilateral optic nerve atrophy, neurogenic bladder, and corpus callosum dysgenesis. She began with dermatological alterations at 6 years old. Variant in KIF1β was corroborated after a comprehensive diagnostic approach, suggesting CMT2A1.

Results:: Discussion. Alteration in MFN2 and KIF1β genes are classified in the same CMTD subgroup. Our patient presents phenotypic alterations not reported in other subgroups of CMTD. Case series of MFN2 disease coincide in the presence of axonal damage and optic atrophy. Although these were present in our case, KIF1β precipitates damage in other systems that constitute a phenotype not shared by subjects with MFN2 alterations.

Conclusions:: Conclusion. KIF1β alterations lead to a particular type of CMTD. This case shows the pathological presentation generated by its mutation and gives rise to considering the KIF1β CMTD subtype as an independent entity, suggesting the need for reclassification. We recommend the use of exome sequencing for mutations difficult to identify using previously available tools.
GENETIC MARKERS OF CATAMENIAL EPILEPSY IN WOMEN.

Dilnoza Yusupova, Gulnora Rakhimbaeva
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

**Background and Aims::** To study the role of the sodium channel gene (SCN1A) in the development of catamenial epilepsy.

**Methods::** Molecular genetic studies with determination of the frequency of alleles of the SCN1A gene were performed in 100 women examined by us. Of these, 60 patients with catamenial epilepsy, 20 with symptomatic epilepsy. The control group consisted of 20 healthy women of the same age. The alleles of the SCN1A gene of the polymorphic locus D2S2330 and D2S124 were studied.

**Results::** The frequency of occurrence of the alleles D2S2330*9, D2S2330*12 and D2S2330*11 was greater and reached from 10 to 15%, respectively. And we found the D2S2330*10 allele in only one patient with symptomatic epilepsy. In the control group, the alleles D2S2330*10 and D2S2330*12 were more common, which makes it possible to consider their presence as a criterion of reduced risk for catamenial epilepsy. The most common in the main group of patients were the D2S124*4 loci (28.3%) and D2S124*5 (21.6%), while the D2S124*5 locus in the control group was found in 10% of cases in the control group. Patients with DNA loci D2S214*2 (25%) and D2S214*3 (45%) were more common, while in the group of patients with catamenial epilepsy they were less common, locus D2S214*2-15% and locus D2S214*3-21.6%.

**Conclusions::** The relationship between the development of catamenial epilepsy and the SCN1A gene polymorphism at the D2S2330 and D2S214 loci was revealed, which does not exclude canalopathy in the pathogenesis of this type of epilepsy. This, in turn, plays an important role in the development of methods for predicting and differentiating therapy for catamenial epilepsy.
SEX-SPECIFIC DIFFERENCES IN TRANSCRIPTOMIC PROFILES AND CELLULAR CHARACTERISTICS OF OLIGODENDROCYTE PRECURSOR CELLS

Ken Yasuda¹, Takakuni Maki¹, Ryusei Nishigori¹, Yusuke Kinoshita², Yuichi Ono², Ryosuke Takahashi¹
¹Kyoto University Graduate School of Medicine, Department Of Neurology, Kyoto, Japan, ²KAN Research Institute, Inc, Department Of Integrated Cell Biology, Kobe, Japan

Background and Aims:: Oligodendrocyte precursor cells (OPCs) regulate the neuronal system in various ways and play crucial roles in brain homeostasis. Although recent studies have shown regional diversity and heterogeneity of OPCs, sex-related differences in OPCs are largely unknown. The purpose of present study was to investigate sex-specific differences in transcriptomic profiles and cellular characteristics of OPCs.

Methods:: For in vitro experiments, we prepared primary OPC culture obtained from neonatal rats. Sex identification was performed by PCR using sex-determining region Y gene. First, we evaluated the capacity of proliferation, migration, and differentiation in OPCs. Second, we examined the ischemic tolerance in OPCs after oxygen glucose deprivation. Third, we assessed the effects of OPC-derived factors on the integrity of blood brain barrier (BBB). For in vivo experiments, we conducted BrdU incorporation assay to assess the proliferation and differentiation of OPCs in adult mice. Finally, we performed RNA-seq analysis to investigate the sexual dimorphism in transcriptome profiles of cultured OPCs.

Results:: Female OPCs have a higher capacity for proliferation and migration. In addition, female OPCs are more resistant to ischemic stress, and can enhance the BBB integrity. Meanwhile, male OPCs have a higher capacity for differentiation and myelination. RNA-seq analysis revealed substantial transcriptomic differences in OPCs.

Conclusions:: The present study demonstrates sex-related differences in the cellular characteristics and transcriptional profiles of OPCs. Our findings may help to better understand the pathomechanisms of neurological and psychiatric diseases with sexual dimorphism.
EXPANDING THE DISEASE SPECTRUM OF RECESSIVE ECEL1 MUTATIONS BEYOND DISTAL ARTHROGYPOSIS PHENOTYPE

Akshata Huddar¹, Kiran Polavarapu¹,², Veeramani Preethish Kumar¹, Gopikrishnan Unnikrishnan¹, Seena Vengalil¹, Saraswati Nashi¹, Mainak Bardhan¹, Atchayaram Nalini¹
¹National Institute of Mental Health And Neurosciences (NIMHANS), Neurology, Bengaluru, India, ²Children's Hospital of Eastern Ontario Research Institute; Division of Neurology, Department of Medicine, The Ottawa Hospital; Brain and Mind Research Institute, University of Ottawa, Ottawa, Neurology, ottawa, Canada

Background and Aims:: Distal arthrogryposis type 5D (DA5D) is a rare autosomal recessive disorder with wide phenotypic spectrum. DA5D is caused by mutations in ECEL1.

Methods:: We describe two families (3 patients) with novel ECEL1 gene mutations detected by Next generation sequencing (NGS).

Results:: Patient 1: 12-year-old boy, born to consanguineous parents. He presented with birth asphyxia, motor developmental delay, severe contractures of fingers with webbing, pes planus, kyphoscoliosis, high arched palate, micrognatia, undeveloped testes, hypoplastic speech with nasal twang, asymptomatic ptosis, absent adductor digit minimi, bifacial and distal LL weakness. Muscle MRI revealed asymmetric fatty infiltration in gluteus maximus, rectus femoris, hamstrings and gastrocnemius. Patients 2,3: 17-year-old monozygotic twins born to consanguineous parents and presented with motor development delay, white hairlock, small low set ears, elbow and wrist contractures, hypotonia, thinning and weakness of all limbs (distal>proximal), pes cavus, areflexia with high steppage gait. One had perinatal insult, recurrent seizures, mental subnormality, nystagmus and primary optic atrophy. Electrophysiology revealed motor axonal neuropathy. MRI revealed extensive fatty infiltration of gluteus maximus, quadriceps, hamstrings, anterior and posterior compartment of leg. NGS revealed rare homozygous missense variants c.602T>C (p.Met201Thr) and c.83C>T (p.Ala28Val) in exon 2 of ECEL1 gene (Refseq: NM_004826.4). The variants were heterozygous in unaffected parents. In-silico predictions were damaging for both variants. While c.602T>C (p.Met201Thr) lies in the crucial Peptidase M13 domain with zero gnomAD frequency, c.83C>T (p.Ala28Val) is in proximal cytoplasmic domain with a minor allele frequency (MAF) of 0.006% in gnomAD.

Conclusions:: Our three cases expands the clinical and imaging spectrum of the ECEL1 mutations and associated DA5D.
A CASE OF 16 P11.2 DELETION WITH DELAYED DIAGNOSIS

Debashis Nath, Salwa Eltawil
Queen Elizabeth hospital, Kings Lynn, Neurology, King’s Lynn, United Kingdom

Background and Aims:: Chromosomal aberrations most commonly present with developmental delay and congenital malformation in childhood. Deletion 16 p11.2 is a rare chromosomal abnormality that leads to language dyspraxia, behavioural problems with autistic spectrum disorders and poor social skills, with less affection of global intellect. Epilepsy occurs in 20% of cases. Mild symptoms can lead to diagnostic delay

Methods:: Patient was reviewed in the adult neurology clinic. Case records and investigation results are summarised

Results:: A 32 years old lady presented to the neurology department with episodes of black outs that started during her first pregnancy. She had background of speech dyspraxia as a child, resolved by secondary school. She required support at school due to emotional and behavioural difficulties, attributed to social problems. The first episode was a collapse at work. Further episodes are brief periods of going blank, with no motor features or post ictal manifestations. EEG and MRI were normal. Lamotrigine led to reduced frequency of the episodes. 16 p11.2 deletion was detected as part of the workout for a son with developmental delay

Conclusions:: Developmental delay and behavioural changes can be caused by social, environmental or biological causes, such as genetic or metabolic disorders or perinatal insults. All patients, including mild and improving patients, should be worked out for potential underlying cause. Early diagnosis is important to provide appropriate support for patient and their families. Further studies are needed to define most cost-effective screening tests in milder cases.
Background and Aims:: Numerous studies have established that factors of the VEGFs (Vascular Endothelial Growth Factors) which are key regulators of angiogenesis, have a vasoactive effect and control the degree of vascularization of the vascular pathology.

Methods:: Objective studies were 188 patients with ischemic stroke. Of these, 105 with ischemic stroke associated metabolic syndrome with 3 or more components of MS (1 subgroup), 83 patients - with ischemic stroke on the background of relatively good somatic status, the presence of 1, 2 or the absence of components of the MS, (2 subgroup). The control group included 91 practical healthy people. Genomic typing was performed by methods based on the polymerase chain reaction.

Results:: Our study of the frequency of distribution of the alleles of the rs2010963 polymorphism of the VEGFA gene in groups of patients with stroke and control showed that the mutant allele “C” in the main group was statistically more frequent than in the control (the main group of patients was 27.1%; control - 13.7%; χ² = 10.18; p = 0.001; OR = 0.43; 95% CI (0.25-0.73)). The data obtained suggest the existence of an association between the carriage of the allele “C” of the rs2010963 polymorphism of the VEGF gene and the development of the stroke. The frequency of the allele “C” was significantly higher as in the subgroup of patients with stroke with no metabolic syndrome (subgroup B), (subgroup B - 28.13%; control - 13.74%; χ² = 8.56; p = 0.003 ; OR = 0.41; 95% CI 0.22–0.75), and patients with stroke with MS (subgroup A - 26.04%; control - 13.74%; χ² = 6.45; p = 0.01; OR = 0.45; 95% CI (0.24-0.84).

Conclusions:: In general, the data obtained indicate that the heterozygous genotype of the rs2010963 polymorphism of the VEGF gene makes a definite contribution to the development of the stroke, but is not associated with the metabolic syndrome.
CANNABINOIDS EFFICACY IN VANISHING WHITE MATTER DISEASE: A CASE REPORT.

Giulia Galli1, Eleonora Virgilio2,3, Paola Naldi3, Riccardo Fornaro4, Domizia Vecchio3,5,6, Roberto Cantello1
1Department of Translational Medicine, University of Piemonte Orientale, and Azienda Ospedaliero-
Universitaria "Maggiore della Carità", Neurology Unit, Novara, Italy, 2Neurology Unit, S. Andrea Hospital,
University of Piemonte Orientale, Department Of Translational Medicine, Vercelli, Italy, 3Ms Center ,
University of Piemonte Orientale, Translational Medicine, Novara, Italy, 4AOU Maggiore della Carità,
Neurosurgery Unit, Novara, Italy, 5Interdisciplinary Research Center of Autoimmune Diseases (IRCAD),
University of Piemonte Orientale, Department Of Health Sciences, Novara, Italy, 6University of Piemonte
Orientale, Translational Medicine, Neurology Department, Novara, Italy

Background and Aims:: An oromucosal spray formulation (Sativex®) containing delta-9-
tetrahydrocannabinol and cannabidiol (THC-CBD) is indicated to treat unresponsive severe spasticity in
Multiple Sclerosis. A lot of clinical trials are underway demonstrating a potential role as supplemental
therapy in various neurological conditions, in particular addressing pain and spasticity in adults and
children.

Methods:: We present a 30-year-old man who was diagnosed with Vanishing White Matter Disease
(VWMD) at the age of 9. VWMD is a rare autosomal recessive syndrome characterized by progressive
white matter deterioration, due to mutations in either one of the five subunits of eukaryotic translation
initiation factor eIF2B. The classic phenotype includes ataxia, spasticity, cognitive decline and seizures
from early childhood. As young adult, our patient showed severe spastic tetraparesis with spasms and
neck muscle stiffness with right laterocollis.

Results:: Clonazepam, baclofen and botulinum injections were tried with poor results. THC-CBD spray,
at the dose of 8 sprays per day, improved muscular pain, spasms and night sleep, reduced modestly
spasticity and caused only mild drowsiness. To maximize the spasticity treatment, a baclofen intrathecal
infusion pump was positioned, but Sativex® was continued after surgery for its positive effect on patient’s
quality of life.

Conclusions:: To our knowledge, this is the first time that THC-CBD has been used in an adult patient
with VWMD. The treatment was well-tolerated and muscular spasm and night sleep improved as well as
the quality of life, despite the effect on spasticity was limited.
HEREDITARY LEUKODYSTROPHY WITH SPHEROIDS (HLDS) AND NASU-HAKOLA DISEASE (NHD): REPORTS OF SEVEN ITALIAN CASES TO HIGHLIGHT KEY DIAGNOSTIC FEATURES

Chiara Benzoni¹, Marco Moscatelli², Daniela Di Bella³, Stefania Magri³, Costanza Lamperti³, Elena Mauro¹, Franco Taroni³, Davide Pareyson¹, Alessandra Biffi⁴, Ettore Salsano¹
¹Fondazione IRCCS Istituto Neuroligico Carlo Besta, Unit Of Rare Neurodegenerative And Neurometabolic Diseases, Department Of Clinical Neurosciences, Milan, Italy, ²Fondazione IRCCS Istituto Neuroligico Carlo Besta, Unit Of Neuroradiology, Departement Of Diagnostics And Technology, Milan, Italy, ³Fondazione IRCCS Istituto Neuroligico Carlo Besta, Unit Of Medical Genetics And Neurogenetics, Departement Of Diagnostics And Technology, Milan, Italy, ⁴Pediatric Hematology, Oncology and Stem Cell Transplant Center, University of Padua, Department Of Women And Child's Health, Padua, Italy

Background and Aims:: HLDS, an autosomal-dominant CSF1R-related leukoencephalopathy, and NHD, an autosomal-recessive TREM2- or TYROBP-related leukoencephalopathy, are ultra-rare adult-onset inherited microgliopathies. Based on their pathophysiology, hematopoietic stem cell transplantation (HSCT) might be a realistic therapy if performed at early stage. Aim of our work was to highlight diagnostic hints to promote prompt identification of affected subjects by reporting our experience.

Methods:: We reviewed data of four (1 male, 3 females) subjects with HLDS and three (two index cases) males with NHD assessed in the last 5 years in our Institute.

Results:: The diseases presented at a mean age of 43 (HLDS) and 31 (NHD) years with progressive cognitive-behavioral decline, often complicated by motor symptoms during the disease evolution. All the patients with the same diagnosis exhibit comparable neuro-images. Retrospectively, family history was positive in all HLDS cases and a possible founder effect was hypothesized for NHD based on identical genotype and geographical origin. Notably, all the patients were diagnosed late in the disease course.

Conclusions:: HLDS and NHD should be always considered in patients with progressive cognitive-behavioral decline and leukoencephalopathy. Specifically, predominantly anterior and asymmetric T2/FLAIR white matter (WM) hyperintensities with corpus callosum involvement are suggestive of HLDS, while diffuse atrophy with mild T2/FLAIR WM hyperintensity and basal ganglia micro-calcifications are suggestive of NHD. Provided the potential HSCT therapeutic efficacy, a diagnostic delay should be avoided, and a hub-and-spoke network among neurological and HSCT centers should be implemented for early diagnosis, familial counseling, HSCT eligibility assessment and structured follow-up.
A NOVEL DNM2 MUTATION IN A CASE WITH A PURE SENSORY AXONAL POLYNEUROPATHY

Vito Campana¹, Mariano Oliva¹, Lorenzo Cipriano¹, Simona Bonavita¹, Stefano Gambardella², Cinzia Coppola¹
¹University of Campania "Luigi Vanvitelli", Department Of Advanced Medical And Surgical Sciences, Naples, Italy, ²IRCCS Istituto Neurologico Mediterraneo Neuromed, Dipartimento Di Genetica Molecolare, Pozzilli, Italy

Background and Aims: Dynamin 2, encoded by DNM2 gene, belongs to a family of pleiotropic GTPases. DNM2 gene mutations have been associated with several neuromuscular disorders, such as intermediate and axonal forms of Charcot-Marie-Tooth (CMT) disease. In this report, we describe clinical, instrumental and genetic aspects of a 59-year-old male patient carrying a novel DNM2 mutation and exhibiting a distinct phenotype of pure sensory axonal polyneuropathy.

Methods: We describe a case of a 59-year-old male with familial history positive for gait disorders. He presented an insidious onset of numbness and burning pain in the lower limbs. In addition, he had been suffering from obstinate constipation with intestinal obstruction. Neurological examination showed a “stomping” gait, reduced patellar reflexes, lower limbs global hypoesthesia with stocking distribution. Nerve conduction study revealed an axonal damage. Considering the overall clinical picture and the positive familial history, we performed a comprehensive molecular analysis of the genes responsible for hereditary neuropathies.

Results: The molecular analysis of the genes responsible for hereditary neuropathies, by means of Next Generation Sequencing approach, showed a novel p.Hys128Arg-DNM2 heterozygous mutation.

Conclusions: We described clinical, instrumental and genetic aspects in a patient affected by pure sensory axonal polyneuropathy and carrying the novel p.Hys128Arg-DNM2 heterozygous mutation, which further expands the spectrum of DNM2 mutations and related phenotypes. Another interesting feature we observed is subtle constipation, possible expression of gastro-intestinal autonomic dysfunction.
BETHLEM MYOPATHY TYPE 1 CAUSED BY A NEW MUTATION IN COL6A1GENE IN AN ALBANIAN PATIENT

Anila Babameto1,2, Aida Bushati3, Aferdita Tako3, Jera Kruja4,5
1Faculty of Medicine, UMT, Genetics, Tirana, Albania, 2UHC Mother Teresa, Genetics, Tirana, Albania, 3UHC Mother Teresa, Pediatrics, Tirana, Albania, 4Faculty of Medicine, UMT, Neurology, Tirana, Albania, 5UHC Mother Teresa, Neurology, Tirana, Albania

Background and Aims:: Bethlem myopathy represents the milder form of the spectrum of Collagen VI myopathies which are characterized by a clinical continuum with Ullrich congenital muscular dystrophy and Bethlem myopathy at each end of the spectrum, and less well-defined intermediate phenotypes between them. Bethlem myopathy is mainly an autosomal dominant disorder and the causing mutations occur in the COL6A1, COL6A2 and COL6A3 genes.

Methods:: We describe a case of a 12 year old male patient, the first Albanian case of Bethlem myopathy type 1. His symptoms begun in early childhood, with mild muscle weakness leading to delayed motor milestones. Symptoms progressed slowly, revealed mild proximal muscle weakness, lumbar hyperlordosis, protuberant abdomen, Achilles tendon retractions and a slightly myopathic gait. Gowers' sign was positive and laboratory testing revealed elevated creatine kinase value. Electromyography identified myopathic features with normal nerve conduction studies and muscle biopsy showed a myopathic pattern. Respiratory and cardiac function did not revealed significant changes.

Results:: Whole exome sequencing performed on the DNA of the patient and his parents identified a heterozygous likely pathogenic variant c.956A > G (Lys319Arg) in COL6A1 gene of the patient that explained the clinical phenotype. This mutation occurred de novo, since it was absent in the clinically unaffected parents.

Conclusions:: To our best knowledge, this is the first case report of Bethlem myopathy type 1 caused by a mutation in COL6A1gene in Albania. The molecular analysis provide the basis for the early diagnosis and proper management of these patients and expands genetic heterogeneity of the disease.
CASE REPORT: ROLE OF SCN9A THE SODIUM CHANNEL IN GENETIC EPILEPSY

Julieta Franco¹, Juan Alvarado², Valentina Suarez², Valentina Franco², Oskar Gaviria², Luis Celis Regalado²
¹Universidad de La Sabana, Cundinamarca, ., Colombia, ²Universidad de La Sabana, Cundinamarca, Chia, Colombia

Background and Aims:: Childhood seizures are a frequent cause of pediatric emergency service admission. Genetic epilepsy is commonly related to multiple gene alterations. We report a case of childhood epilepsy associated with alteration in the sodium channel SCN9A gene sequence.

Methods:: Literature review was performed on the PUBMED, ScienceDirect and SCOPUS electronical database using the keywords: SCN9A gene mutation, CLDN16 mutation. All types of study design were taken into account, prioritizing those written in English or Spanish language and those using our keywords.

Results:: Mutations in the SCN9A gene were connected firmly with fever associated seizures or epilepsy with febrile seizures +, and that autosomal dominant patronus was the most common inherited pattern. However, Mutations, in γ-aminobutyric acid A receptor , commonly called GABA, and in sodium channels genes, which is the case of GABRG2, have been noticed to be related with febrile seizures and genetic epilepsy with febrile seizures +. In the case of the young female patient, there was a probably pathogenic variant, in the CLDN16 gene sequence, related to hypomagnesemia, additionally a pathogenic haplotype in the SCN9A gene sequence, in association with small fiber neuropathy. Both with an autosomal recessive inheritance pattern. The Clinic was mainly characterized by generalized tonic-clonic seizures, absences-type episodes and were exacerbated with emotions of anxiety and euphoria, obsession with certain activities such as ordering clothespins by color and playing all the time a single game.

Conclusions:: Child seizures represent a diverse set of medical conditions. The clinical course of the disease, response to treatment is significantly different.
NEURO-ENCEPHALIC FEATURES OF TUBEROUS SCLEROSIS COMPLEX

Hatim Belfquih
Avicenne hospital Marrakech, Neurosurgery, Marrakech, Morocco

Background and Aims:: Tuberous sclerosis is a phacomatosis resulting from an autosomal dominant inheritance. It is characterized by the presence of multiple hamartomas in various organs, especially the brain, the skin, the kidneys and the heart. The aims of this study is to focus on neuro-encephalic features of tuberous sclerosis complex.

Methods:: The authors report personal cases series and review the literature highlighting epidemiology, clinical features and imaging of neuro-encephalic tuberous sclerosis.

Results:: The diagnosis of tuberous sclerosis is based on imaging and clinical examination, where magnetic resonance imaging constitutes the key investigation showing characteristic brain lesions.

Conclusions:: Neuro-encephalic manifestations may be particularly severe, and may even be life threatening. the advances in the field of genetics offer the possibility of a new avenue of research in the management of tuberous sclerosis based, on the one hand, on the inactivation of mTOR, and, on the other hand, on the factors acting on the TSC1 – TSC2 interaction.
EXPRESSION PROFILING OF CIRCULATING MIRNA IN THE NEUROFIBROMATOSIS TYPE 1 AND RELATED CANCERS IN A LARGE NF1 ITALIAN COHORT

Filomena Napolitano¹, Milena Dell'Aquila², Simone Sampaolo², Mariarosa Anna Beatrice Melone²
¹Second Neurology, AOU Luigi Vanvitelli, Department Of Advanced Medical And Surgical Sciences, Naples, Italy, ²Second Neurology, AOU Luigi Vanvitelli, Department Of Advanced Medical And Surgicalsciences, Naples, Italy

Background and Aims:: MiRNAs are short noncoding RNAs involved in regulating gene expression at post-transcriptional level. Several studies have suggested their role as biomarkers for various diseases. Its roles in mediating tumorigenesis remain largely unexplored in many disorders, including Neurofibromatosis type 1 (NF1, OMIM#162200), the most frequent autosomal dominant tumour predisposition syndrome, caused by loss-of-function mutations in the NF1 gene. The study aims to identify circulating miRNA profiling in the NF1 and NF1-related cancers and deregulated miRNA gene-target pathways associated to different NF1 phenotypes.

Methods:: The study includes familial/sporadic NF1 patients, enrolled at Division of Neurology of AOU Luigi Vanvitelli and diagnosed based on the NIH Consensus Conference criteria of 1988. According to clinical characteristics, different subgroups have been classified: NF1 without systemic complications (Group 1), NF1 with systemic complications (Group 2), NF1-MPNST (Group 3), NF1 with neurological malignancies (Group 4), NF1 associated to other organ tumours (Group 5). For each clinical groups and controls 15 serum samples were pooled and RNA was extracted and analyzed through NGS. Deregulated miRNAs were studied to identify their specific target genes and related molecular pathways.

Results:: Differential miRNA signatures were identified in each NF1 clinical groups. Deregulated miRNAs identified in this study are involved in the tumorigenesis, cell cycle, cell proliferation, DNA damage, necrosis, apoptosis and angiogenesis processes.

Conclusions:: NF1 is characterized by a highly inter- and intrafamilial clinical variability. The identification of circulating miRNA profile is essential for an early NF1 diagnosis and to distinguish between different disease phenotypes.
NEUROFIBROMATOSIS TYPE 1: MOLECULAR SPECTRUM OF THE NF1 MUTATIONS IN A LARGE COHORT OF ADULT ITALIAN PATIENTS

¹Second Neurology, AOU Luigi Vanvitelli, Department Of Advanced Medical And Surgical Sciences, Naples, Italy, ²Guglielmo da Saliceto Hospital, Neurology Unit, Piacenza, Italy

Background and Aims:: Neurofibromatosis type I (NF1, OMIM #162200) is one of the most common genetic tumor predisposition syndrome, caused by loss of function mutations in the NF1 gene. To date, no clear genotype-phenotype correlation has been discerned in NF1. We aimed to investigate the molecular spectrum of NF1 gene and evaluated the genotype-phenotype correlations in a large cohort of adult Italian NF1 patients.

Methods:: Our series includes 85 familial/sporadic NF1 patients, enrolled at Division of Neurology, Neurofibromatosis and Rare Diseases Center of AOU Luigi Vanvitelli. The clinical data were collected at the time of mutation analysis and re-verified for accuracy at the time of this study. Blood samples were collected for molecular NF1 genetic testing and informed consent was obtained in all patients. A combination of targeted next-generation sequencing and multiplex ligation-dependent probe amplification was performed for molecular analysis.

Results:: We identified 69 different NF1 mutations, including missense, nonsense, start loss, frameshift and splicing mutations, distributed along the entire gene. Multi-exons duplications/deletions and deletion of the entire NF1 gene were also identified. In our cohort, nonsense and splicing affected mutations were mainly detected in NF1 patients showed skeletal complications, while frameshift mutations could be associated to learning impairment in NF1 female patients.

Conclusions:: This study led to the identification of novel NF1 mutations and offered an important contribution to the genotype-phenotype studies in the NF1 pathogenesis.
FAHR’S SYNDROME ASSOCIATED WITH HEREDITARY ANGIOEDEMA: A CASE REPORT

Hajar Qorchi¹, Najib Kissani²
¹University Hospital Mohamed VI Marrakesh, Neurology Department, Marrakesh, Morocco, ²Mohammed VI University Medical Center, Marakesh, Neurology, Marrakesh, Morocco

Background and Aims:: Fahr’s syndrome is defined by the presence of bilateral and symmetrical intracerebral calcifications, nonarteriosclerotic, localised to the basal ganglia. Hereditary angioedema associated with Fahr’s syndrome is unheard of.

Methods:: we report a case report of hereditary angioedema associated with a Fahr’s syndrome.

Results:: the observation of a 28-year-old patient from a consanguineous marriage, followed since the age of 7 for epilepsy under sodium valporoate, with discovery of a hereditary angioedema associated with a Fahr’s syndrome. Clinically, the patient presents with mental retardation, behavioral disturbances, soft and painless white facial edema with eyelid occlusion suggestive of angioedema. Laboratory assessment: hypocalcemia (33 mg / L), hyperphosphatemia (99 mg), hypoparathormonemia (10 IU), and hypovitaminosis-D (10 g / L). The inhibitory C1 level is less than 30% of the normal value, the serum C4 is less than 0.10, and the C3 is normal. Brain scan: bilateral and symmetrical calcifications of the two caudate, lenticular nuclei, the two thalami, and the dentate nuclei. Patient was put on replacement therapy (calcium 2 g / d + Un alfa 0.5ug × 2 / d + magnesium 300mg / d), exacyl 1500mg / d, in combination with neuropsychiatric treatment.

Conclusions:: The discovery of hereditary angioedema during Farh syndrome constitutes an exceptional association, and should lead to a study of the inhibitory C1 complement with assay of these C3 and C4 fractions.
LIPOTOXICITY ALTERS THE CHAPERONES AND SYNAPTIC FIDELITY VIA EPIGENETIC MODULATIONS IN MAMMALIAN DERIVED HIPPOCAMPAL CELLS

Valencia Fernandes, Dharmendra Khatri, Shashi Singh
National Institute of Pharmaceutical Education and Research (NIPER) - Hyderabad, Department Of Pharmacology And Toxicology, Hyderabad, Telangana, India

Background and Aims:: Epigenetics are the inaudible signatures of several pathological processes in the brain. This study understands the influence of DNA methylation, a major epigenetic modification, in the lipotoxic hippocampal neurons and its notable effect on the cellular chaperones and synaptic proteins.

Methods:: The neurolipotoxicity was induced in HT22 hippocampal cells using LPS and sodium palmitate, a saturated fatty acid; and the DNA methyltransferase (DNMT) levels were measured to study the DNA methylation, a major epigenetic marker. The levels of cellular chaperones and synaptic proteins were examined using DNMT inhibitor, 5-aza-2′-deoxycytidine (5-aza-dC)-treated cells. Methylation analysis were also done to understand the hypo- or hyper-methylation of these proteins. Apart from it, the DNMT enzymes were docked with the synaptic proteins, to understand the protein-protein interactions a bit in detail, using the PIPER algorithm in the Schrodinger (bioinformatic tool) suite.

Results:: Altered DNA methylation were confirmed in the LPS and palmitate induce lipotoxic cells. Pretreatment with AzadC, ameliorated the protein and gene expression of cellular chaperones and synaptic proteins, concluding a link between the proteins and methylation. The insilico results showed a stable and preferred binding of these proteins within the active domain of the DNMT enzyme. Methylation analysis in the promoter region of these proteins further justified the epigenetic involvement in the lipotoxic hippocampal cells.

Conclusions:: Lipotoxic damage to the hippocampal cells, were rescued by demethylation treatment, and also accorded in improving the memory-associated proteins, suggesting a substantial contribution to the underlying pathophysiology of several metabolic syndromes linked with the cognitive abilities.
MODERATE PHENOTYPE OF A CONGENITAL MYASTHENIC SYNDROME TYPE 19 IN AN ALGERIAN PATIENT.

Mohamed Islam Kediha¹, Meriem Tazir¹, Damien Sternberg², Bruno Eymard³, Lamia Ali Pacha¹
¹Medical school of Algiers, Neurology, ALGIERS, Algeria, ²centre de génétique, Biochimie Métabolique, Paris, France, ³Pitié Salpetriere hospital, Neurology, Paris, France

Background and Aims:: Congenital myasthenic syndromes (CMS) represent phenotypically and genotypically very heterogeneous conditions. No less than 32 genes have been identified to date. CMS caused by mutations in the COL13A1 gene are very rare and have a phenotype described as severe. We present the first case of CMS described in Algeria and the Maghreb with a mutation of this gene.

Methods:: Our patient underwent a complete neurological examination with myasthenic score, electromyographic examination and DNA sampling for a genetic study.

Results:: Our patient presenting a rather moderate phenotype with bilateral ptosis, fluctuating during the day and evolving from birth. Neonatal hypotonia is not noted, nor any delay in motor acquisitions. During the investigation of this patient, and despite the very probable congenital origin, we ruled out other diagnoses which could induce pathology of the neuromuscular junction (NMJ). The genetic study confirmed our diagnostic suspicion by highlighting a new mutation in the COL13A1 gene.

Conclusions:: This is the first mutation of this gene found in the Maghreb and which demonstrates that its phenotype can be moderate, contrary to what is reported in most of the cases reported to date.
ASSOCIATION OF DEPRESSION WITH POLYMORPHIC MARKER VAL158MET OF COMT GENE IN AN OPEN POPULATION 25-44 YEARS: EPIDEMIOLOGICAL STUDY

Valery Gafarov¹, Elena Gromova¹, Dmitriy Panov¹, Igor Gagulin¹, Vladimir Maximov², Almira Gafarova²
¹Institute of Internal and Preventive Medicine – branch of Institute of Cytology and Genetics RAS, Collaborative Laboratory Of Cardiovascular Diseases Epidemiology, Novosibirsk, Russian Federation, ²Institute of Internal and Preventive Medicine – branch of Institute of Cytology and Genetics RAS, Genetics Study, Novosibirsk, Russian Federation

Background and Aims:: We aimed to study the association of polymorphic marker Val158Met COMT gene regulating the concentration of extracellular dopamine with depression in an open population of 25-44 years.

Methods:: A representative sample of the population in Novosibirsk of 25-44 years of age was examined in 2013-2016 (n=975, 43.8% males, mean age 34.5±0.4 years) in frame of budgetary theme # AAAA-A17-117112850280-2. Levels of depression assessed by means of the "MONICA-psychosocial" scale. A cohort of 441 persons (50.8% males) underwent genotyping for Val158Met (rs4680) polymorphism of the COMT gene.

Results:: In the open population of 25-44 years of age the prevalence of major depression (MD) was 13.2%, the average level was 24.4%. Persons with G/G genotype of the COMT gene were more likely to have MD. It was found in 61.8% compared to those with the A/A genotype (38.2%) (χ²=6.097 df=2, p=0.047); also the carriers of G allele (55.3%) had MD more often than carriers of A allele (44.7%) (5.408 df=1; p=0.02). Among male carriers of the A/A genotype of the COMT gene, MD was less common (15.8%) than among carriers of the G/A genotype (84.2%) (χ²=4.603 df=1; p=0.032). Female carriers of G/G genotype had MD more often (65.5%) than carriers of A/A genotype (34.5) (χ²=4.769 df=1; p=0.029). G allele (58.2%) was more common among women with MD than A allele (41.8%) (6.658 df=2; p=0.01).

Conclusions:: Based on the received data we can assume that the G/G polymorphic marker of the COMT gene may be associated with high levels of depression.
THE ROLE OF THE NEUROLOGIST IN THE DIAGNOSTIC ROUTE OF HSP AND CEREBELLAR ATAXIAS IN THE NEXT GENERATION SEQUENCING ERA: A SINGLE CENTER EXPERIENCE

Vittorio Riso¹, Salvatore Rossi², Tommaso Nicoletti³, Alessandra Tessa⁴, Lorena Travaglini⁵, Ginevra Zanni⁶, Chiara Aiello⁶, Alessia Perna³, Melissa Barghigiani⁴, Maria Grazia Pomponi⁵, Filippo Maria Santorelli⁴, Gabriella Silvestri³
¹Ospedale Belcolle - Viterbo, Neurology, Viterbo, Italy, ²Catholic University of the Sacred Heart, Institute Of Neurology, Rome, Italy, ³Catholic University of the Sacred Heart, Neuroscience, Rome, Italy, ⁴IRCCS Fondazione Stella Maris, Molecular Medicine, Pisa, Italy, ⁵Unit of Neuromuscular and Neurodegenerative Disorders, Laboratory of Molecular Medicine, Bambino Gesù Children's Hospital, IRCCS, Department Of Neurosciences, Rome, Italy, ⁶Catholic University of the Sacred Heart, Genetics, Rome, Italy

Background and Aims: The molecular characterization of Hereditary Spastic Paraplegias (HSP) and inherited cerebellar ataxias (CA) is challenged by their clinical and molecular heterogeneity. The recent application of NGS technologies is increasing the diagnostic rate, which can be also influenced by patients’ selection.

Methods: To assess how a clinical diagnosis of CA/HSP received in a third-level reference center might impact on the molecular diagnostic yield, we retrospectively evaluated the molecular diagnostic rate reached in 192 unrelated families (90 HSP and 102 CA) i) before NGS ii) by the use of NGS gene panels.

Results: Overall, 46.3% families received a genetic diagnosis by first-tier individual gene screening: 43.3% HSP and 50% SCA. The diagnostic rate was 56.7% in AD-HSP, 55.5% in AR-HSP, and 21.2% in sporadic HSP. On the other hand, 75% AD-, 52% AR- and 33% sporadic CA were diagnosed. 32 patients (24 CA and 8 HSP) were assessed by NGS gene panels, and 34.4% were diagnosed, including 29.2% CA and 50% HSP patients. 11 novel gene variants classified as (likely) pathogenic were identified.

Conclusions: Compared with literature data, our results support the critical role of experienced clinicians in the diagnostic assessment and the clinical research of CA and HSP even in the next generation “era”.
Background and Aims:: Hereditary Spastic Paraplegias (HSPs) are characterized by progressive spasticity and weakness of lower limbs and comprise of ‘pure’ and ‘complicated’ phenotypes. HSPs are genetically diverse and data from India are limited. We aimed to comprehensively analyze the genetic basis in a large cohort of HSP from India and correlate with the phenotype.

Methods:: Patients with HSP phenotype from a single neurology unit were evaluated for their clinical features, electrophysiological and radiological abnormalities. Genetic analyses were carried out by clinical exome sequencing (n=52) and targeted sequencing (n=5).

Results:: The cohort comprised 40 men and 17 women. The age ranged from 3.5 to 49 years. There were 25 children (age<=18 years). All patients presented with insidious onset, progressive difficulty in walking and bilateral pyramidal signs. Based on the clinical features, 15 (26.3%) patients were classified as ‘pure’ and the remaining 42 (73.7%) as ‘complicated’ forms of HSP. Brain MRI showed thin corpus callosum (n=10), periventricular hyperintensities (n=20), cerebral atrophy (n=3), cerebellar atrophy (n=3) and diffuse atrophy (n=4). Sixty-seven variants representing 40 genes were identified including 47 novel variants. Forty-eight patients (84.2%) had variants in genes previously implicated in HSP and other spastic paraplegia syndromes (SPG genes=24, non-SPG genes=24), among these 13 had variations in more than one gene.

Conclusions:: The current study led to the identification of the spectrum of genetic variations in a large cohort of comprehensively evaluated patients with HSP phenotype from India. Our cohort was characterized by a wide age range, male predominance, and increased representation of sporadic and ‘complicated’ HSPs.
GENOMIC ANALYSIS IDENTIFY A NEW EIF2B3 GENE VARIANT DETECTED IN AN UNCERTAIN CASE OF CADASIL DISEASE

Background and Aims:: Vanishing white matter disease (VWM) is an autosomal recessive leukodystrophy caused by mutations genes encoding the translational initiation factor 2B: EIF2B1-EIFB5. It is a heterogeneous neurological disorder with prominent cerebellar ataxia and spasticity in childhood-onset form and behavioural changes, dementia and seizures in adult-onset form (15% of cases). We present the case of a 60 years old patient, MTHFR homozygous, presenting white matter lesions and a subcortical vascular encephalopathy being diagnosed. To investigate a possible genetic cause, suspecting CADASIL, genetic and genomic analysis were performed.

Methods:: Sanger sequencing and Next Generation Sequencing (NGS) analysis were performed on the patient. NOTCH3 sequencing was performed using primer pairs for all 22 exons, for NGS analysis we used a genes panel including 753 genes involved in neurological diseases.

Results:: NGS detected a novel heterozygous non-synonymous variant in exon 5 of EIF2B3 gene (c. C554G; p. S185C), whose mutations have been strongly related to leukoencephalopathy and VWM disease. Furthermore, all in silico analysis conducted on this variant predicts its deleterious impact that could affect protein function.

Conclusions:: S185C variant in EIF2B3 gene was discovered in an atypical condition of adult onset Leukodistrophy, a disease that usually occurs in childhood. It is uncertain if S185C could be responsible for the clinical history of our patient or if the peculiarity of his symptoms could be related to the potential contribution of this new detected variant on the phenotypical spectrum observed in the disease.
AN INTERESTING CASE OF DIZZINESS: BOW HUNTER’S SYNDROME DUE TO KIMMERLE ANOMALY DIAGNOSED WITH PROVOCATIVE DSA

Ahamed Subir Humyun Kabir, Fazal Ghafoor, Krishnadas Nc, Mohammed Rafique
MES MEDICAL COLLEGE, Neurology, MALAPPURAM, India

Background and Aims:: BACKGROUND: Rotational occlusion of the vertebral artery known as Bow hunter’s syndrome (BHS) is a very rare cause for transient vertebrobasilar insufficiency symptoms. Complete or incomplete ossification of the posterior atlantooccipital membrane is called a Kimmerle anomaly which causes symptom in only 5.5% of patients with this anomaly. Early diagnosis with high index of clinical suspicion and provocative digital substraction angiography aids in prompt surgical repair, relieving the patient from the disabling symptoms and avoiding unnecessary ineffective symptomatic therapies. Objective: To report a rare case of 51-year-old driver who presented with transient giddiness who was on vestibular sedatives for long, having symptoms only on reversing his car in rightward head rotation diagnosed with provocative digital subtraction angiography (DSA).

Methods:: An interesting clinical history and unique advanced imaging findings with illustrative images are reported.

Results::
Provocative DSA revealed dynamic stenosis of left vertebral artery at C1 vertebral level. CT angiogram revealed ponticulus posticus or kimmerle anomaly occurring due to calcification of the posterior atlanto-occipital (PAO) membrane and treatments with surgical correction was advised. A high index of clinical suspicion helps in prompt diagnosis of BHS in patients with transient vertebrobasilar insufficiency.

**Conclusions:** This case highlights the importance of provocative DSA in making the definitive diagnosis of the rare Bow hunter's syndrome and also reports its causal association with calcified PAO membrane or Kimmerle anomaly which if managed early can improve symptoms significantly.
Background and Aims:: White matter hyperintensities on magnetic resonance imaging (MRI) are a frequent finding. Anaplastic astrocytoma as a cause of persistent, symmetrical white matter hyperintensities is unusual.

Methods:: A 22-year-old male presented with an episodic, non-specific headache for one month duration, which was followed by brief episodes of altered awareness and a progressive decrease in consciousness. The physical examination showed a reduced conscious state without any focal neurological signs. Non-contrast CT brain showed cerebral oedema and dilated temporal horns of the lateral ventricles. MRI-brain showed extensive, symmetrical T2 and FLAIR hyperintensities involving the corpus callosum, pericallosal region, periventricular white matter, deep white matter and bilateral cerebellar hemispheres surrounding the dentate nuclei, without diffusion restriction or contrast enhancement. In addition, the body of the lateral ventricles were compressed leading to dilatation of the temporal horns. The CSF full report was normal and the CSF cultures and cytology was negative. External ventricular drainage was placed after consultation with the neurosurgeons. He was treated with IV 3% sodium chloride for a few days and IV dexamethasone, IV ceftriaxone and IV aciclovir for 14 days. There was no significant clinical or radiological improvement. A ventricular wall biopsy was performed. This showed an anaplastic astrocytoma (WHO Grade 111). The patient was subsequently referred for specialized oncological management, but succumbed to his illness following the initiation of chemotherapy.

Results::
GFAP immunostain

**Conclusions:** This case highlights the unusual presentation of a primary CNS tumour with symmetrical, persistent white matter hyperintensities.
Background and Aims:: Neuromyelitis optica (NMO) is characterized by acute transverse myelitis and bilateral or rapidly sequential optic neuritis. The diagnosis is based on clinical, imaging and laboratory data. We describe a case where transorbital sonography (TOS) shows a promising role in performing diagnosis and monitoring clinical course, when combined with strict clinical follow up.

Methods:: A 23-year-old woman complained of acute visual loss in left eye associated with pain and loss of color vision; ophthalmic examination revealed a papillitis. Visual evoked potential showed unilateral prolongation of P100 latency. TOS revealed increased optic nerve sheath diameter (ONSD). She was treated with intravenous prednisolone with rapid recovery. Four months later, she experienced an identical episode of visual loss in the left eye.

Results:: Extensive laboratory work-up, including viral, toxic, metabolic and vasculitis screening and cerebrospinal fluid analysis, was unremarkable. IgG Aquaporin-4 (AQP) serum antibody test was positive. MRI revealed a longitudinal syringomyelia cavity extending T7-T10, without brain abnormalities. According to the international diagnostic criteria, a diagnosis of NMO was made. At TOS, initially, an enlargement of ONSD on the left side was found, that subsequently decreased up to normalization; at subsequent control at 120 days, when the patient experienced a relapse of optic neuritis, both unilateral ONSD enlargement and optic disc elevation were observed, that later normalized after that immunomodulatory therapy was started.

Conclusions:: Seriated TOS monitoring was a useful predictor of clinical course of recurrent papillitis in neuromyelitis optica. Further studies are needed to demonstrate accuracy of TOS respect to visual evoked potentials and retinal imaging.
FUNCTIONAL CONNECTIVITY AS AN EARLY MARKER FOR DEEP BRAIN STIMULATION IN PARKINSON’S DISEASE

Background and Aims:: To identify functional neuroimaging patterns anticipating the clinical indication for DBS in PD.

Methods:: PD patients underwent clinical and cognitive evaluations and resting-state fMRI (RS-fMRI) at baseline and every year for a maximum of four years. Patients were divided into two groups: 19 patients eligible for DBS (PD-DBS) over the follow-up and 41 patients who did not meet the criteria to undergo DBS (PD-noDBS). Sixty age- and sex-matched healthy controls performed baseline evaluations. Graph analysis and connectomics assessed global and local topological network properties and regional functional connectivity at baseline and at each time point.

Results:: Network analysis showed a higher mean nodal strength, local efficiency and clustering coefficient of the occipital areas in PD-DBS relative to both controls and PD-noDBS at baseline. The occipital hyperconnectivity pattern was confirmed also by regional functional connectivity analysis. On the contrary, a significantly decreased functional connectivity between basal ganglia and sensorimotor/frontal networks was found in PD-DBS compared to PD-noDBS patients at baseline. In the longitudinal analysis, PD-DBS patients showed a progressive decreased topological brain organization and functional connectivity, mainly in the posterior brain networks, and a progressively increased connectivity of basal ganglia network compared to PD-noDBS patients. Baseline occipital hyperconnectivity in PD-DBS patients was related to tremor severity at baseline and over time.

Conclusions:: RS-fMRI may support the clinical indication to DBS and could also be useful in predicting which patients would be eligible to undergo DBS in the earlier stages of PD. Funding: Ministry of Education, Science, and Technological Development, Republic of Serbia (#175090)
Background and Aims:: Brain structures other than basal ganglia are likely to be involved in the pathophysiological process of Parkinson’s disease (PD). The role of cerebellum in PD has been explored during motor tasks involving the hand, while few studies investigated its activity during gait-simulating tasks and dual-task situations. This study aimed at assessing structural and task-based functional cerebellar alterations in PD patients with postural instability and gait disorders (PD-PIGD).

Methods:: Twenty-one PD-PIGD patients and 23 age and sex-matched healthy controls underwent clinical, structural and functional MRI, including a motor-task (foot anti-phase movements) and a dual-task (foot anti-phase movements while counting backwards by threes). Regional grey matter cerebellar volumes were assessed automatically using an atlas propagation and label fusion strategy based on the freely available human cerebellum template and probabilistic atlas (SUIT). FMRI images were co-registered with structural images and cerebellar fMRI analysis was performed.

Results:: PD-PIGD patients showed reduced volumes in several cerebellar motor and non-motor areas relative to controls. During both fMRI motor-task and dual-task, patients showed greater activation of cognitive cerebellar areas (crus 1-2) relative to healthy subjects and a reduced activity of motor areas (lobules I-IV and VIIIb).

Conclusions:: The increased activity of non-motor cerebellar areas might be a consequence of grey matter atrophy or an attempt to compensate the functional failure of cerebellar motor areas. Structural and functional MRI metrics focusing on cerebellum are useful to characterize brain correlates of motor and dual-task abilities in PD-PIGD patients.
BIANCA-MS: A NOVEL ARTIFICIAL INTELLIGENCE TOOL FOR MULTIPLE SCLEROSIS AUTOMATED LESIONS SEGMENTATION

Giordano Gentile¹, Mark Jenkinson², Ludovica Griffanti², Ludovico Lucchetti¹, Matteo Leoncini¹, Myra Inderyas¹, Rosa Cortese¹, Nicola De Stefano², Marco Battaglini¹
¹University of Siena, Department Of Medicine, Surgery And Neuroscience, Siena, Italy, ²Wellcome Centre for Integrative Neuroimaging (WIN), FMRIB, University of Oxford, Nuffield Department Of Clinical Neurosciences, Oxford, United Kingdom

Background and Aims:: Automated white matter lesions segmentation in multiple sclerosis (MS) is still an open field and no standardized approach has been widely employed yet. We aim to validate BIANCA-MS, a novel tool for MS lesions segmentation on brain MRI, based on the original version of BIANCA (https://fsl.fmrib.ox.ac.uk/fsl/fslwiki) and which implemented: i) a harmonized setting tested under different conditions, avoiding the need to further tune algorithm parameters to each dataset; ii) a post-processing cleaning step to refine lesion segmentation.

Methods:: 470 scans at 1.5 and 3T from three different datasets were analysed. For each scan, manually outlined masks were provided. We first tested algorithm behaviour across different scanning conditions. Further, on datasets where FLAIR images (2-3D) were provided, we compared BIANCA-MS to lesion prediction algorithm (LPA), lesion growth algorithm (LGA) and nicMSlesions. Performances were evaluated in comparison to manual segmentation using spatial similarity index (SI) and the number of false positive/negative clusters (nFPC/nFNC).

Results:: BIANCA-MS provided consistent results across datasets for SI, irrespective of the scanning protocol. The third datasets showed higher nFPC and nFNC (table 1, p<0.01). BIANCA-MS showed higher SI (table 2, p< 0.01) and higher sensitivity (lower nFNC, p<0.01) than LPA, LGA and nicMSlesions. However, BIANCA-MS showed less specificity (higher nFPC, p<0.01) than LGA and nicMSlesions.

Conclusions:: The comparable performances achieved across datasets proved BIANCA-MS robustness.
and flexibility. Further, our pipeline avoided the long optimization procedure needed to tune algorithm parameters. Finally, compared to other tools, our approach showed higher degree of similarity to manual segmentation.
ATROPHY QUANTIFICATION IN MULTIPLE SCLEROSIS: APPLICATION TO THE MULTICENTER INNI DATASET

Loredana Storelli¹, Elisabetta Pagani¹, Patrizia Pantano², Nikolaos Petsas², Gioacchino Tedeschi³, Antonio Gallo³, Nicola De Stefano⁴, Marco Battaglini⁴, Paola Zaratin⁵, Maria Rocca¹, Massimo Filippi¹,³,³
¹IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Milan, Italy, ²Sapienza University of Rome, Department Of Human Neurosciences, Rome, Italy, ³University of Campania "Luigi Vanvitelli", Dept. Of Neurology, Naples, Italy, ⁴University of Siena, Department Of Medicine, Surgery And Neuroscience, Siena, Italy, ⁵Italian Multiple Sclerosis Foundation, Fism, Genoa, Italy, ⁶IRCCS San Raffaele Scientific Institute, Neurology Unit, Milano, Italy, ⁷Vita-Salute San Raffaele University, Na, Milan, Italy, ⁸IRCCS San Raffaele Scientific Institute, Neurology Unit, Neurorehabilitation Unit And Neurophysiology Service, Milan, Italy

Background and Aims:: Aim of this study was to compare a set of methods for gray matter (GM) and whole-brain atrophy measurements on the Italian Neuroimaging Network Initiative (INNI) dataset, where MRI and clinical data from multiple sclerosis (MS) patients and healthy controls (HC) are collected by Italian Research Centers with recognized expertise.

Methods:: SIENAX, SPM v12 and Jim8 (Xinapse-Systems) software were selected. 3D MPRAGE from 457 MS and 271 HC were collected from INNI repository. For cross-sectional GM and whole-brain atrophy measures, we evaluated the agreement and correlation among the results of the pipelines. Moreover, the capability of the software in discriminating between HC and MS was assessed. A bias due to the different acquisition Center and the sample size requirement were also evaluated.

Results:: We found significant agreement (p<0.05) among the software: the highest between the results of SPM and Jim8 (0.91, p<0.05) and the lowest between SIENAX and Jim8 (0.6, p<0.05), for both GM and whole-brain. Comparing distributions, SIENAX for GM and Jim8 for brain volumes better separated HC from MS (p<0.05). None of the pipeline showed a bias in respect to a particular Center.

Conclusions:: We found acceptable agreement among the software. The free-licence (SIENAX), the speed and the facility of integration in the clinical routine (Jim8, SIENAX) are noteworthy for the selection of the atrophy pipeline. To move those atrophy tools from the research setting to the clinical practice, normative data from at least 150 HC should be available. Funding. This study was partially supported by Fondazione Italiana Sclerosi Multipla (Grant n.FISM2019/S/3).
Background and Aims:: We assessed white matter (WM) atrophy in multiple sclerosis (MS) both cross-sectionally and longitudinally with advanced DWI-techniques and explored whether these measures would better explain clinical and cognitive outcomes in comparison with conventionally used metrics.

Methods:: Baseline and one-year clinical evaluation, 3DT1-weighted and DWI sequences were obtained from 86 MS patients and 55 healthy controls (HC). Maps of fractional anisotropy and mean diffusivity were derived from DWI; intra-cellular volume (v_{IC}) maps were computed from neurite orientation dispersion and density imaging model. A fixel-based morphometry analysis was applied to estimate voxel-wise fiber-bundle cross-section (FC) atrophy in MS compared to HC.

Results:: Only FC measure showed a significant atrophy in relapsing-remitting (RR) MS compared to HC and in progressive patients compared to RRMS, mainly located in the cortico-spinal tract, splenium of the corpus callosum, optic-radiation and cingulum (p-value<0.05), both at baseline and after one year. Globally at baseline, FC and v_{IC} were significantly associated with the Expanded Disability Status Scale (r=-0.3) and the Symbol Digit Memory Test (r=0.39) respectively, being the selected predictors of clinical (R-sq=0.33, p=0.007) and cognitive scores (R-sq=0.29, p=0.0014) in a linear regression model.

Conclusions:: By identifying tract-specific differences, voxel-based analyses confirmed the ability of FC measure to detect WM atrophy with greater anatomical specificity compared to other measures and better capability to distinguish MS clinical phenotypes and their longitudinal WM degeneration. FC and v_{IC} were the best predictors of clinical disability and cognitive scores at baseline. Funding: This study was partially supported by Fondazione Italiana Sclerosi Multipla (Grant 2018/R/16).
CORTICAL REMODELING ACROSS THE LIFESPAN IN HEALTHY BRAIN REVEALS STRUCTURAL NETWORK VULNERABILITY TO NEURODEGENERATION

Background and Aims:: Aging is the main risk factor for most of the neurodegenerative diseases. The aim of this study was to investigate cortical thinning changes across lifespan in healthy brain revealing structural network vulnerability to neurodegeneration.

Methods:: The cohort included 128 healthy individuals aged 20-85 years, who underwent an MRI scan. T1-weighted images were used to estimate vertex-wise cortical thickness maps, then grouped into 83 regions. For each region, cortical thickness trajectory with advancing age was estimated, including sex as covariate. Regions were ranked based on their relative thickness at the end of the observed lifetime, assessing regional changes over time. Mean regional thickness was correlated with relative change over time.

Results:: The highest cortical thinning was observed in the temporal lobe (parahippocampal, entorhinal, superior and middle temporal, and fusiform), frontal lobe (lateral orbitofrontal, superior and inferior frontal, including pars triangularis and opercularis, and rostral anterior cingulate), parietal lobe (the isthmus of cingulate, precuneus, supramarginal and inferior parietal) and in the insular cortex. Interestingly, occipital regions (cuneus, lateral occipital, lingual, pericalcarine), and motor and premotor areas (precentral, postcentral and paracentral regions) showed the least cortical thickness change compared to the whole brain across lifespan. Finally, positive correlation was found between mean regional thickness and its relative change over time.

Conclusions:: This study highlights structural vulnerability of brain regions to aging and provides information concerning trajectories of normal brain aging, identifying those areas that might be more vulnerable to the attack of neurodegeneration. Funding: European Research Council (StG-2016_714388_NeuroTRACK).
NEUROIMAGING IMPROVES THE PREDICTION OF POST-STROKE MAJOR NEUROCOGNITIVE DISORDER

Eva Aamodt¹, Till Schellhorn¹, Edwin Stage², Apoorva Sanjay², Paige Logan², Diana Svaldi², Liana Apostolova², Ingvild Saltvedt³, Mona Beyer¹
¹Oslo University Hospital, Division Of Radiology And Nuclear Medicine, Oslo, Norway, ²Indiana University School of Medicine, Department Of Neurology, Indianapolis, United States of America, ³Norwegian University of Science and Technology, Department Of Neuromedicine And Movement Science, Trondheim, Norway

Background and Aims:: Neurocognitive disorder (NCD) appears in 10% of survivors of a first-ever stroke and in 30% after a recurrent one. We aimed to classify clinical and imaging factors related to major NCD 3 months after stroke, so as to find the optimal composition of factors for prediction of rapid development of the disease.

Methods:: 227 stroke survivors (age = 71.7 (11.3), NIHSS = 3.8 (4.8), females = 43.6%) were included from the ‘Norwegian COgnitive Impairment After STroke’ study. Clinical- and MRI data at baseline, and neuropsychological data at baseline and 3 months was used. The imaging factors included cortical thicknesses (automatically measured using Freesurfer), white matter hyperintensity volumes (semi-automatically measured using FSL Bianca), and stroke lesion volumes (semi-automatically measured using ITK-snap). Support Vector Machine classification was used in order to investigate the prognostic value of the factors. Model performance was measured using Area Under Receiving Operating Characteristics (ROC) and -Curve (AUC).

Results:: The model containing clinical factors only was driven by 12 of 14 variables and achieved an AUC of .790. The model containing both clinical and imaging factors was driven by 19 of 26 factors and achieved an AUC of .876.

Conclusions:: The model containing both the clinical and the imaging factors was able to predict rapid onset of major NCD with a higher accuracy than did the model with only clinical factors, demonstrating the importance of including imaging findings in rapid onset post-stroke NCD prediction.
POSTERIOR REVERSIBLE ENCEPHALOPATHY SYNDROME (PRES) AS A COMPLICATION OF PURULENT MENINGITIS: CASE REPORT AND REVIEW OF THE LITERATURE.

Silvia Gallo¹, Roberto Cantello¹, Edoardo Pronello², Gianluca Avino¹, Isabella Campini¹, Thomas Fleetwood¹
¹University of Eastern Piedmont, Neurology Unit, Department Of Translational Medicine, Novara, Italy, ²University of Piemonte Orientale - University and City of Health and Science Hospital, Turin, Neurology Unit, Department Of Translational Medicine - Division Of Neuro-oncology, Novara, Italy

Background and Aims:: Posterior reversible encephalopathy syndrome (PRES) is a clinico-radiological syndrome characterized by subcortical parieto-occipital vasogenic edema. Pathophysiology is not fully understood but endothelial injury and disregulation of vascular autoregulation seem to play a key role. We describe the case of a patient diagnosed with meningitis complicated by PRES and intracranial hemorrhage.

Methods:: A 71-year-old woman presented to the emergency department with impaired level of consciousness, headache, photophobia and hypertension (185/85 mmHg). Brain CT and CTA were normal. Shortly after admission fever appeared and alertness worsened further. Clinical examination revealed nuchal rigidity and a positive Kerning’s sign. Cerebrospinal fluid (CSF) analysis revealed pleocytosis and elevated protein leading to a diagnosis of bacterial meningitis. Despite thorough investigation no pathogen was identified. Empirical broad-spectrum antibiotic treatment was started. Brain MRI showed a necrotic-hemorrhagic lesion in left posterior parietal-occipital lobe with bilateral posterior white matter edema, consistent with PRES. After one week, repeated MRI and CSF analysis showed a significant reduction of white matter edema and pleocytosis. The patient fully recovered except for right homonymous hemianopia.

Results:: Severe infection is a known cause of endothelial damage which can lead to failure of cerebral vessel autoregulation and PRES. The exact occurrence of this correlation may be underestimated. PRES has a generally favorable prognosis but patients may develop severe complications among which intracranial hemorrhage.

Conclusions:: PRES is a neurologic syndrome characterized by typical imaging findings and associated with a wide variety of comorbidities, including severe infections. Early recognition of underlying conditions and appropriate treatment are fundamental to revert parenchymal involvement.
CONVERGING LONGITUDINAL PATTERNS OF ATROPHY IN CLINICAL VARIANTS OF FRONTOTEMPORAL LOBAR DEGENERATION

Background and Aims:: We aimed to assess longitudinal patterns of atrophy shown by magnetic resonance imaging (MRI) in the cortical and subcortical GM of patients affected by different clinical variants of the FTLD spectrum.

Methods:: Fifty-nine patients, including 26 with behavioral variant of frontotemporal dementia (bvFTD), 10 non-fluent/agrammatic variant of primary progressive aphasia (nfvPPA), 12 semantic PPA (svPPA), and 11 motor neuron disease (MND), underwent MRI on a 3T scanner at 6-month intervals for one year. Thirty-three healthy controls underwent the same protocol. 3D T1-weighted MRI sequences were analyzed using voxel-based morphometry to assess the longitudinal evolution of GM atrophy in patients, compared with HC.

Results:: At baseline, severe diffuse atrophy of frontotemporal cortical regions and basal ganglia was found in bvFTD, nfvPPA and svPPA groups, whereas MND did not show significant GM atrophy. At 6-month follow-up, bvFTD and PPA showed progression of atrophy in the insular (bvFTD, nfvPPA and svPPA) and anterior cingulate cortices (bvFTD and nfvPPA), bilaterally, as well as in the left caudate nucleus and middle temporal cortex (svPPA). At 12-month follow-up, similar patterns of atrophy progression were found, with the additional involvement of the superior frontal cortical gyri in nfvPPA, and right hippocampus in svPPA. No significant progression of atrophy was found in MND.

Conclusions:: Atrophy of insular and anterior cingulate cortical regions closely reflects the progression of neurodegeneration across the behavioral and linguistic presentations of FTLD, in contrast with a substantial sparing of GM in MND. Funding: European Research Council (StG-2016_714388_NeuroTRACK).
IMPROVED ASSESSMENT OF LONGITUDINAL SPINAL CORD ATROPHY IN MULTIPLE SCLEROSIS USING A REGISTRATION-BASED APPROACH: RELEVANCE FOR CLINICAL STUDIES

1IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Division Of Neuroscience, Milan, Italy, 2Vita-Salute San Raffaele University, Na, Milan, Italy, 3IRCCS San Raffaele Scientific Institute, Neurology Unit, Milan, Italy, 4Xinapse Systems, N/a, West Bergholt, United Kingdom, 5Neurocenter of Southern Switzerland, Civic Hospital, Multiple Sclerosis Center, Department Of Neurology, Lugano, Switzerland, 6University of Campania “Luigi Vanvitelli”, Department Of Advanced Medical And Surgical Sciences, And 3t MRI Center, Naples, Italy, 7IRCCS San Raffaele Scientific Institute, Neurophysiology Service, Milan, Italy, 8IRCCS San Raffaele Scientific Institute, Neurorehabilitation Unit, Milan, Italy

Background and Aims:: Reliable measurements of cervical cord atrophy progression may be useful for monitoring neurodegeneration in multiple sclerosis (MS). Here, we compared a new, registration-based (Reg) method with two existing methods (active surface [AS] and PropSeg) to measure cord atrophy changes over time in MS patients.

Methods:: Cervical cord 3D T1-weighted scans were collected at baseline and after 1.13 years median follow-up (range=0.7-3.2 years) from one cohort acquired at 1.5T (8 healthy controls [HC]/28 MS patients), and one cohort acquired at 3.0T at three European sites (25 HC/67 MS patients). The Reg method included an accurate registration of baseline and follow-up straightened cord images, followed by optimized cord segmentation using the AS method. Cross-sectional areas (CSA) from Reg, AS and PropSeg were used for sample size calculations. Intra- and inter-observer agreement of Reg and AS was also assessed.

Results:: Percentage CSA changes (PCSAC) and related standard deviations (SDs) were lower with Reg than with the other methods. For example, PCSAC in relapsing-remitting MS patients at 3.0T was -0.82% (SD=1.67) with Reg, -0.98% (SD=2.32) with AS and -1.24 (SD=3.93) with PropSeg. This was reflected in a lower sample size, being n=232 with Reg, n=354 with AS and n=885 with PropSeg in this population to detect a 50% treatment effect. Intra- and inter-observer agreement ranged from 0.72 to 0.91 with AS, while they were >0.99 with Reg method.

Conclusions:: Lower sample size and improved reproducibility support the use of the Registration method to measure cervical cord atrophy progression in future MS clinical studies.
MACRO- AND MICRO-STRUCTURAL CEREBELLAR AND CORTICAL CHARACTERISTICS OF COGNITIVE EMPATHY TOWARDS FICTIONAL CHARACTERS IN HEALTHY INDIVIDUALS

Eleonora Picerni¹, Daniela Laricchiuta¹, Fabrizio Piras², Daniela Vecchio², Laura Petrosini¹, Debora Cutuli¹, Gianfranco Spalletta²
¹Santa Lucia Foundation, Laboratory Of Experimental And Behavioural Neurophysiology, Rome, Italy, ²Santa Lucia Foundation, Department Of Clinical And Behavioral Neurology, Rome, Italy

Background and Aims:: Few investigations have analyzed the neuroanatomical substrates of empathic capacities in healthy subjects, and most of them have neglected the potential involvement of cerebellar areas. The main aim of the present study was to investigate the associations between bilateral cerebellar structural measures and levels of cognitive and affective trait empathy.

Methods:: We estimated macro- and micro-structural morphometric variations of cerebellar and cerebral Gray Matter structures in a sample of 70 healthy subjects of both sexes, tested by Interpersonal Reactivity Index (IRI) to ascertain whether the potential empathy-related peculiarities in cerebellar areas were accompanied by structural differences in other cerebral regions. At a macro-structural level, volumetric differences were analyzed by Voxel-Based Morphometry and Region of Interest-based approaches, and at a micro-structural level, we analyzed Diffusion Tensor Imaging (DTI) data, focusing on Mean Diffusivity (MD) and Fractional Anisotropy.

Results:: Fantasy IRI-subscale (which examines participants’ abilities to imaginatively transpose themselves into feelings and actions of fictitious characters) was found to be positively associated with volumes in right cerebellar Crus2 and pars triangularis of inferior frontal gyrus (figure1). DTI analyses revealed cerebellar Crus2 MD values negatively associated with Fantasy IRI subscale scores (figure2).
Conclusions:: Cerebellar engagement in Fantasy IRI subscale highlights its involvement in socio-cognitive processes and supports the view of a "social cerebellum", and specifically of an "empathic cerebellum". Then, morphological variations of cerebellar Crus2 and pars triangularis allow to extend the traditional cortico-centric view of cognitive empathy to the cerebellum and indicate that in empathizing with fictional characters the cerebellar and frontal areas are co-recruited.
VOLUMETRIC ANALYSIS OF HIPPOCAMPAL VOLUME: CORRELATION WITH BDNF - VAL66MET POLYMORPHISM AND COGNITIVE IMPAIRMENT IN SOUTH INDIAN PD PATIENTS

Tazeem Fathima Syed, Santosh Kumar, Tasneem Sd, Abhishek Arora, Rajesh Alugolu, Rukmini Kandadai, Vijay Kutala, Rupam Borgohain
Nizam's Institute of Medical Sciences, Department Of Neurology, Hyderabad, India

Background and Aims:: Brain-derived neurotrophic factor (BDNF) is a neurotrophin that plays role in neurogenesis and synaptic plasticity of the hippocampus. To calculate the hippocampal volume, association with BDNF (Val66Met) polymorphism, and correlation with cognitive impairment.

Methods:: 90 PD patients were recruited and scanned for 3Tesla MRI. T2 images used to calculate the volume manually using the Syngovia workstation.

Results:: The average of right and left hippocampal volumes was 3.67±0.49 Cm$^3$ where, the right hippocampal volume (3.76 ± 0.48 Cm$^3$, p=0.02) was significantly higher than the left (3.58 ± 0.55 Cm$^3$). Hippocampal volume was compared among males and females where right hippocampal volume (3.83±0.46 Cm$^3$, p=0.05) of males was significantly high compared to females (3.56±0.55 Cm$^3$). The low hippocampal volume group found to have a significantly high UPDRS III ON score (16.78±5.25; p=0.0009) and significantly high cognitive impairment (25.91±3.08; p=0.01). Wild genotype G/G of BDNF Val66Met frequency was higher i.e., 56.7% followed by heterozygous G/A 31.1% and mutant A/A genotypes 12.2%. Mutant A/A genotype found to have (6.50±1.58 years; p=0.03) significantly lower disease duration and lower right (3.45±0.56 Cm$^3$, p=0.03), left (3.35±0.58 Cm$^3$, p=0.05) hippocampal volumes. The average hippocampal volume was positively correlated with the MoCA score (r=0.2193, p=0.03) indicating that reduction in volume reduces the MoCA score.

Conclusions:: Our study suggests the significant association of hippocampal volume with BDNF Val66Met polymorphism and cognitive impairment in south Indian PD patients.
ABNORMAL CORTICAL AND SUBCORTICAL STRUCTURE IN JUVENILE MYOCLONIC EPILEPSY DEMONSTRATED WITH ADVANCED MRI ANALYSIS

Enrico Fratto¹, Alessia Giugno¹, Ilaria Sammarra¹, Francesco Fortunato¹, Pio Zoleo¹, Vincenzina Rubino², Maria Eugenia Caligiuri³, Michele Trimboli¹, Angelo Labate¹, Antonio Gambardella¹
¹Magna Graecia University, Institute Of Neurology, Department Of Medical And Surgical Sciences, Catanzaro, Italy, ²Magna Graecia University, Institute Of Neurology, Department Of Medical And Surgical Sciences, CATANZARO, Italy, ³Magna Graecia University, Neuroscience Research Center, Department Of Medical And Surgical Sciences, Catanzaro, Italy

Background and Aims:: Juvenile myoclonic epilepsy (JME) is the most frequent genetic generalized epilepsy syndrome. It typically occurs during adolescence with predominant myoclonic seizures, variably intermixed with generalized tonic-clonic and absences. Neurophysiological, neuropsychological and imaging studies in JME have shown focal abnormalities in the medial and dorsolateral prefrontal lobe. Our study’s aim was to explore for additional evidence of focal cortical abnormalities in JME using advanced neuroimaging techniques.

Methods:: We enrolled 16 consecutive patients (9 women, mean age: 30.2±10.4 years) with JME, and 16 age and sex-matched controls. All subjects underwent 3T MR study using standard protocol, including T1-3D Turbo Field Echo images with 1 mm thickness, to measure surface and thickness of several cortical Regions of Interest (ROIs) and volumes of several subcortical ROIs. Subcortical GM structures volumes were extracted and vertex-wise shape analysis was performed using standard Freesurfer analysis. 158 quantitative parameters were analysed.

Results:: Thirteen/158 variables presented significative differences between the two groups. In patients with JME, we observed bilateral volumetric reduction of thalami, putamina, nuclei caudati, nuclei accumbentes and bilateral increase in pallidal volume. Moreover, we found decreased right pars opercularis surface and left medial orbitrofrontal cortex thickness, along with increased left frontal pole surface.

Conclusions:: Our study found significative thalamic volumetric alterations in JME; dysregulation of fronto-thalamic network is considered a causative mechanism underlying seizures in this syndrome, due to the lack of inhibitory thalamic output towards cortical structures. We also found significative volumetric differences in basal ganglia, whose modulatory role on cortical excitability has recently been advocated.
WHITE MATTER LESION CHARACTERISTICS ON MRI CAN DIFFERENTIATE MULTIPLE SCLEROSIS FROM PATENT FORAMEN OVALE

Gianmarco Severa, Rosa Cortese, Antonio Covelli, Marco Battaglini, Jian Zhang, Ludovico Lucchetti, Giordano Gentile, Maria Laura Stromillo, Monica Ulivelli, Nicola De Stefano
University of Siena, Department Of Medicine, Surgery And Neuroscience, Siena, Italy

Background and Aims:: It is important to identify brain MRI features to help differentiating white matter lesions (WMLs) associated with demyelination and vascular mimics. We aimed here to find differences in MRI characteristics of WMLs occurring in multiple sclerosis (MS) and in patients with patent foramen ovale (PFO).

Methods:: 13 patients with MS (10 F, mean age: 47 years) and 13 with PFO with WMLs (10 F, mean age: 47) underwent 3T brain MRI, including FLAIR, 3D-T1, and SWI sequences. Each WML was first identified on FLAIR and classified considering topography, size (punctate, >3mm, or >10mm), shape (rounded or oval); subsequently, the presence of a correspondent hypointensity on T1 and the central vein sign (CVS) on SWI were assessed. Linear regression was used to compare lesion characteristics between diseases, stepwise logistic regression models to assess the association between lesion characteristics and disease type.

Results:: In MS, a total of 298 WMLs were detected, while in PFO 210 WMLs. The number of lesions located in the infratentorial and periventricular regions was higher in MS than PFO. They measured >10mm, had oval shape, were largely hypointense and showed the CVS. Instead, WMLs form PFO were mostly located in the deep white matter, were punctate and with a rounded shape in PFO. The combination of infratentorial location, oval shape, hypointensity and CVS best discriminated MS from PFO (accuracy 78%, specificity 87%, sensitivity 72%, p=0.02).

Conclusions:: The combination of different WML characteristics can facilitate an accurate differentiation between MS and PFO.
Background and Aims:: Posterior reversible encephalopathy syndrome (PRES) is an heterogeneous syndrome with the neurologic symptoms of hypertensive encephalopathy. In the majority of cases has typical MRI radiological landmark corresponding to edema that is classically parieto-occipital. Rare are the form with spinal cord involvement (PRES-SCI).

Methods:: A 27 year-old bengalis man arrived at the emergency department of our hospital because two weeks previous presents lumbar pain, lower limb weakness and paresthesia, mild urinary retention. These were followed by mild headache and visual loss. Neurological examination disclosed severe visual reduction and diffuse increase of tendon reflex. The past medical history was unremarkable. At the time of examination, his blood pressure was 240/130mmHg. The optic fundus examination disclosed signs of bilateral hypertensive retinopathy grade 3°. Serum electrolytes were normal except for severe hypokaliemia and mild hyponatriemia while kidney function tests were normal. MRI of the brain and spine revealed a hyperintense signal of medulla and spinal cord on T2 and FLAIR images The lesions were also hyperintense on diffusion-weighted imaging. As there was no clinical or lab evidence to support the diagnosis of encephalomyelitis or acute disseminating encephalomyelitis. Blood pressure was normalized, and the patient became asymptomatic few days. An MRI at 2 weeks revealed that the spinal cord changes were completely reversed.

Results:: A PRES-SCI was considered as the most plausible diagnostic possibility.

Conclusions:: PRES is a disorder of cerebral blood autoregulation and endothelial function causing vasogenic edema, occurring by an uncertain mechanism. Similar arterial regulatory mechanisms appear to occur in the spinal cord unusual finding.
Background and Aims:: Reporting age-related changes in neuroimaging findings is challenging. There is no clinical thresholds for normalized brain volumes. Assessing individual cases non-adjusted in size is even more difficult. We aimed to provide neuroradiologists a concise model of aging of the Central Nervous System (CNS) to simplify an assessment of structural features related to age.

Methods:: With CAT-12 and LST-2.0 we segmented 231 brain MRI scans of healthy participants (4–83 yo). To examine age-related changes of the CNS composition we built the ordinary least squares regression trendlines. To study the velocity of atrophic changes in brain compartments, we divided the study cohort into age groups: Adolescents < 20, Young adults (YA) ∈ [20, 40), Midlife adults (MA) ∈ [40, 60) and Older adults (OA) ≥ 60 yo. For brain structural estimates we built trendlines using non-linear Locally Weighted Scatterplot Smoothing and tested data for statistically significant differences between slopes. The volumes of cerebrospinal fluid (CSF), white (WM) and gray matter (GM) were expressed as fractions of intracranial volume. Intraventricular CSF (iCSF) was counted in proportion to cerebral CSF.

Results:: CSF% raised significantly (p<0.05) quicker in YO and OA compared to the general population. In OA there was a significant increase in iCSF%. Cortical and total GM% decreased across the life with a significantly faster pace in adolescents and OA. The dynamics for WM% were opposite with a significantly different slope for adolescents.

Conclusions:: Building a model of age-related brain atrophy will help distinguish the normal brain aging from the accelerated one.
Dynamic Cognitive Reserve in the Adult Lifespan

Sonia Ambrogi, Fabrizio Piras, Daniela Vecchio, Valentina Ciullo, Federica Piras
Santa Lucia Foundation IRCCS, Neuropsychiatry Laboratory, Department Of Clinical And Behavioral Neurology, Rome, Italy

Background and Aims:: The relationship between brain and cognition is dynamic and may change across the lifespan. Age-related changes in brain structure/function are tied to changes in cognitive efficiency in normal aging, although the factors contributing to inter-subject differences have been scarcely investigated. One of the heuristics explaining such variance in cognitive aging is reserve (Stern et al., 2020), a construct suggesting that dynamic cognitive and underlying structural/functional brain processes cope with age-related brain changes in determining cognitive functioning. Here we investigated, in a large (N=197) cross-sectional sample of healthy adults across the lifespan (18-77 years), the impact of age on dynamic cognitive reserve (dCR), i.e. measured cognitive abilities after confounding factors (gender, socio-economic status, brain volume and vascular lesion burden) have been removed.

Methods:: Neurocognitive/neuroimaging data were analyzed in univariate ANOVAs including age and gender, confounding factors, and their interactions, as to investigate the mediating effect of static cognitive and brain reserve on cognitive efficiency. Multivariate regression models also explored the differential impact of included variables on cognitive abilities.

Results:: We found a general effect of age on dCR, and specific interactions with other factors as for example, efficiency in set-switching was better predicted in females, by a model including age, static cognitive reserve and vascular lesion burden as predictors.

Conclusions:: Understanding the dynamics of age-related cognitive changes can lead to optimized detection and intervention methods of addressing cognitive decline. Moreover, the way has been paved for further investigating the role of brain micro/macrostructure in cognitive aging and decline processes.
A CASE OF ENCEPHALOPATHY WITH REVERSIBLE SPLENIAL LESION OF THE CORPUS CALLOSUM

Houssèm Slimène¹, Khadija Sonda Moalla², Salma Sakka², Olfa Hdiji², Sawsan Daoud², Nadia Bouattour², Mariem Damak², Nouha Farhat², Chokri Mhiri³
¹Habib Bourguiba Hospital, Sfax, Tunisia, Neurology, Sousse, Tunisia, ²Universal Hospital Habib Bourguiba, Neurology, SFAX, Tunisia, ³Habib Bourguiba University Hospital, Neurology, Sfax, Tunisia

Background and Aims:: The concept of mild encephalopathy with reversible splenial lesion (MERS) was identified for the first time as a rare clinic-radiological syndrome by Tada et al in 2004. It is classified in MERS type I and MERS type II, depending on the involvement of the splenium of the corpus callosum (SCC) alone or also other white matter areas. The exact pathophysiology is unknown; however, infectious-related MERS remains the most common cause of reversible splenial lesions in childhood.

Methods:: A previously healthy 22-year-old women was admitted to our hospital due to a 2-days history of headaches and confusion associated with fever. Neurological examination revealed neck stiffness without localizing signs. Chemistry panel showed an elevated blood white cell counts. Brain MRI showed isolated abnormal signals in the SCC without contrast enhancing. The examination of cerebrospinal fluid revealed lymphocytic meningitis without common bacterial or viral agents. After combined antiviral and antibiotic treatments, the symptoms resolved within 7 days and the follow-up MRI, taken 28 days after the initial examination, demonstrated resolution of the lesion.

Results:: MERS is characterized by a transient mild encephalopathy and MRI findings of a reversible lesion in the SCC. The syndrome mainly affects children and young adults. Fever, confusion and headaches are the most common clinical manifestation like in our case. The major cause is infection by virus or bacteria.

Conclusions:: Psychiatrist and neurologist should be aware about the presence of confusion, isolated lesion in the SCC and lymphocytic meningitis suggesting the diagnosis of MERS.
T1-HYPERINTENSITY IN THE PULVINAR UNRELATED TO FABRY DISEASE OR OTHER CAUSES OF BASAL GANGLIA MINERALIZATION: A CASE REPORT

Laura D’Acunto1, Luca Panebianco2, Bruna Nucera3, Fabrizio Rinaldi3, Paolo Manganotti1,4, Christoph Scheurer2, Francesco Brigo3
1University of Trieste, Neurology Unit, Department Of Medical, Surgical And Health Sciences, Cattinara University Hospital, Asugi, Trieste, Italy, 2Hospital of Merano (SABES-ASDAA), Department Of Radiological Functions, Merano, Italy, 3Hospital of Merano (SABES-ASDAA), Department Of Neurology, Merano, Italy, 4Cattinara University Hospital, ASUGI, University of Trieste, Trieste, Italy, Neurology Unit, Department Of Medical, Surgical And Health Sciences, Trieste, Italy

Background and Aims:: Hyperintensity in both pulvinar nuclei in T1-weighted MRI sequence, known as “Pulvinar sign” (PS), is usually considered a pathognomonic sign of Fabry disease (FD). We describe a patient with PS unrelated to FD or other causes of basal ganglia mineralization.

Methods:: Case report. A 41-year-old man presented with left arm weakness and neck pain after an abrupt movement during gardening. The neurological examination was unremarkable. His medical history was significant for Klinefelter Syndrome, bradyarrhythmia, prior deep venous thrombosis of lower limbs, hypertension, and dyslipidemia. A 1.5 T brain magnetic resonance imaging (MRI) showed T1-hyperintensity in the posterior thalamus bilaterally, more pronounced in the pulvinar, with symmetrical and bilateral areas of T2* signal void in the globus pallidus (fig.1); it showed also multiple small areas of gliosis in the white matter. MRI findings and the history of bradyarrhythmia in this patient raised suspicion of possible FD. Specific hematological and genetic enzymatic activity tests were thus required.
Results: Calcium and parathyroid hormone, glucose, serum iron, ferritin, transferrin, and ammonia levels were within normal ranges, screening for vasculitis and autoimmune disorders was unremarkable, and human immunodeficiency virus was excluded on serology testing. There was a slight reduction of leukocyte a-galactosidase A with normal plasma lyso-Gb3 concentration. FD and other causes of basal ganglia mineralization were excluded.

Conclusions: The “pulvinar sign” can be unrelated to FD or other disorders leading to basal ganglia mineralization. This sign is not pathognomonic of specific conditions and should be interpreted in the context of the whole clinical picture.
CHANGES IN DEFAULT MODE NETWORK CONNECTIVITY IN PATIENTS WITH POSTMASTECTOMY SYNDROME

Ivan Ternovykh¹, Tatiana Bukkieva², Anastasia Kasumova¹, Maria Pospelova¹, Alexandr Efimtsev², Olga Fionik³, Tatiana Alekseeva¹, Gennadiy Trufanov², Konstantin Samochernykh⁴, Natalia Ivanova⁴, Varvara Krasnikova⁵, Elena Gorbunova², Anna Levchuk²
¹Almazov National Medical Research Centre, Neurology And Psychiatry, Saint-Petersburg, Russian Federation, ²Almazov National Medical Research Centre, Radiation Diagnostics And Medical Imaging, Saint-Petersburg, Russian Federation, ³Almazov National Medical Research Centre, Cardiovascular Surgery, Saint-Petersburg, Russian Federation, ⁴Almazov National Medical Research Centre, Polenov Neurosurgical Institute, Saint-Petersburg, Russian Federation, ⁵Almazov National Medical Research Centre, Rehabilitation Medicine, Saint-Petersburg, Russian Federation

Background and Aims:: In the modern concept of postmastectomy syndrome (PMES), more attention is paid to the neuropsychiatric component, which observed in more than 90% of patients. Resting state functional magnetic resonance imaging (rs-fMRI) is a promising technique for detecting initial changes of the functional connectivity of brain neural networks in these patients. The aim of the study was to assess changes in the functional connectivity of the default mode network in patients with PMES using resting state functional MRI (rs-fMRI).

Methods:: 25 women in the late postoperative period (>6 months) after radical mastectomy for breast cancer and 25 healthy women (control group) were underwent a clinical examination with an assessment of complaints, anamnesis and questionnaires for depression, anxiety, pain syndrome, quality of life and standard and rs-fMRI on 3.0T MR-scanner.

Results:: In patients with PMES, a functional reorganization of neural networks with the involvement of DMN with a predominance of processes of separation of intra- and interhemispheric connections was revealed (p<0.001). There was a decrease in functional connections between the medial prefrontal cortex (the key structure of the DMN) and a number of important centers of the brain (hippocampus, cerebellum, medial thalamic nuclei, subcallosal cortex, middle temporal gyrus cortex), which are responsible for the regulation of cognitive processes, emotions, memory.

Conclusions:: The data obtained indicate a functional reorganization of the resting state neural networks of the brain in PMES patients in comparison with healthy volunteers and require further study.
EXTENSIVE TRACTOPATHY WITH ANTERIOR CORD INVOLVEMENT AND “INVERTED V SIGN” IN B12 DEFICIENCY DUE TO PERNICIOUS ANEMIA

Chulika Makawita, Sudath Ravindra, Kasun Udenika, Ishani Rajapakshe, Bimsara Senanayake
National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

Background and Aims:: Background
Subacute combined degeneration of the cord (SACD) due to vitamin B12 deficiency typically causes demyelination of the dorsal and lateral spinal cord sparing the anterior portion. We present a Sri Lankan lady who developed severe SACD due to B12 deficiency with pernicious anemia. Her radiology demonstrated involvement of all tracts of the spinal cord including the anterior with the inverted V sign.

Methods:: A 49 years old non vegetarian woman presented with marked upper and lower limb weakness and numbness for 2 years. She was pale and pigmented. She had flaccid paraparesis of the lower limbs. Distal motor weakness was noted in the upper limbs. All sensory modalities of the lower limbs were impaired.

Results::

Blood picture revealed severe macrocytic anemia with hyper-segmented neutrophils. Bone marrow examination demonstrated a megaloblastic marrow with giant metamyelocytes and erythroid hyperplasia. Serum vitamin B12 was low 67 (140 -650mol/l). MRI spine demonstrated significant high signal intensities in anterior, lateral and dorsal columns with white matter changes in brain. Dorsal column hyperintensity specifically showed the inverted V sign. Both intrinsic factor and parietal cell antibodies were positive. Severe SACD due to pernicious anemia was diagnosed. Treatment with vitamin B12 partially alleviated her symptoms.

Conclusions::
Tractopathy in vitamin B12 deficiency is rare. Involvement of the anterior column has been previously reported only in a single case study. Inverted V sign "rabbit ear sign" is a classic finding in SACD. Severe vitamin B12 deficiency if not detected early and treated could result in severe neurological sequel.

Figure 2
T2 Weighted MRI spine axial views (A,B) and sagittal view (C) showing hyperintensities in anterior, posterior and lateral columns suggestive of tractopathies. Hyper intense signals in dorsal column showing inverted "V" sign (D) seen in subacute combine degenerative of the cord. T2 Weighted MRI brain axial view (E) showing bilateral periventricular white matter hyperintensities in B12 deficiency.
LOCUS COERULEUS ASSESSMENT BY MRI: A COMPARISON OF THREE DIFFERENT APPROACHES

Background and Aims:: This study aims to evaluate inter-individual differences in Locus Coeruleus (LC) MRI-contrast and volume through three different post-processing approaches.

Methods:: LC-MRI was acquired in 45 subjects (27M; 60-80 yrs) using a 2D Fast-Spin-Echo (FSE) T1-weighted sequence (TE/TR 14/600ms; flip-angle90°; voxel size 0.39x0.39x2.2mm; NEX5). Three different post-processing approaches for the LC analysis have been evaluated: a Semi-Automatic (SA), a Deep-Learning (DL) and a Template-Based (TB) one. Three different LC metrics were calculated using the SA, DL and TB methods: the normalized maximum intensity (LCmax), the mean intensity (LCmean) and the volume (LCvol) of the LC.

Results:: SA and DL methods analyzed the LC signal in the T1-w native space while the TB method offered the advantage of a high-resolution template (0.5 mm isotropic) and of loco-regional analysis. Pair-wise correlation between the three different post-processing approaches showed high degree of association in terms of LCmax and LCmean ("average r"=0.70) and moderate degree of association for LCvol ("average r"=0.44). The latter could be partly due to the different resolution of native and template spaces.

Conclusions:: Our results indicate a moderate-to-high degree of agreement between global LC analyses in native or template space, with the latter approach being seemingly more suitable for the LC loco-regional analysis.

This work is supported by the Italian Ministry of Health -Ministero della Salute, Ricerca Finalizzata #PE-2013-02359574 (P.I.: FSG).
Background and Aims:: Vanishing brain space occupying lesion is defined as reduction or disappearance of a brain lesion spontaneously or after steroid treatment to ≤ 70% of its size before establishing its definitive diagnosis. Resolution of lesion leads to diagnostic and management challenge. Here we describe a case with a vanishing brain SOL which was radiologically suggestive of CNS lymphoma with inconclusive brain biopsy findings.

Methods:: 75-year-old woman presented with subacute onset right sided upper and lower limb weakness for two weeks. Examination detected, lower motor weakness on the affected side with normal sensory. Reflexes were diminished globally. Basic investigations were normal. NCS showed peripheral nerve demyelination. CSF analysis revealed lymphocytosis at 26 with elevated protein (64mg/dl). MRI brain detected homogeneous mass lesion in the posterior body of the corpus callosum which extended into parietal lobes on either side. This was hypo-intense on T1 and hyperintense on T2 & FLAIR images. Splenium of the corpus callosum was swollen. MRS showed Choline peak with reduced NAA levels. MRI was suggestive of a CNS lymphoma; however, CNS demyelination could not be ruled out in the presence of peripheral nerve demyelination. Therefore, she was given IV methyl prednisolone.

Results:: Brain biopsy findings after steroids were inconclusive. MRI at 4 weeks after steroids and subsequent imaging showed complete resolution of the lesion correlating with clinical improvement.

Conclusions:: Vanishing brain space occupying lesion is a rare radiological diagnosis which poses diagnostic and management challenge. Our patient highlights the importance of early histo-pathological diagnosis in CNS-SOL before steroid therapy.
Background and Aims:: Joubert syndrome (JS) is a rare autosomal recessive central nervous system malformation characterized by hypotonia, ataxia, abnormal psychomotor development and mental retardation, variable ophthalmologic features such as oculomotor apraxia and neonatal breathing abnormalities. Many patients die in infancy or childhood, but some survive into adulthood with variable cognitive and motor impairments. Radiographically it is characterized by “molar tooth sign” in MRI, includes cerebellar vermis hypoplasia or dysplasia, thick and horizontally oriented superior cerebellar peduncles, and abnormally deep interpeduncular fossa. A 34 year-old female presented in our institution with parental complaints of generalized chorea with difficulty in ambulation and speech. She had no problems in respiration or breathing. Neurological examination showed atrophic changes in both arms and feet, ptosis of the left eye, truncal ataxia, severe dysarthria, and global hyperreflexia. She was noted lack of appropriate awareness to surroundings and notably stuttering and severely dysarthric. Showing abnormal gait, major difficulty in walking that of the appearance of a staggering-like gait disorder.

Methods:: case report

Results:: Cranial MRI was done showing thickened and elongated superior cerebellar peduncle giving midbrain a molar tooth appearance; cerebellar vermis appeared mildly deformed. The diagnosis of Joubert syndrome was made based on patient’s history, physical examination, and pathognomonic neuroimaging features. No genetic testing done due to its unavailability in our institution.

Conclusions:: Joubert Syndrome is a rare autosomal recessive disease which affects approximately 1/80,000 to 1/100,000 people worldwide. This reported case is presented with hypotonia, abnormalities in gait and balance, developmental delay, and pathognomonic “molar tooth sign” in her MRI.
ACERULOPLASMINEMIA: A NOVEL SPLICING MUTATION PRESERVING THE GLOBUS PALLIDUS FROM IRON ACCUMULATION

Maria Salsone¹, Gennarina Arabia², Grazia Annesi³, Monica Gagliardi⁴, Rita Nisticò⁵, Fabiana Novellino⁶, Luigi Ferini-Strambi⁷, Andrea Quattrone², Aldo Quattrone⁸
¹National Research Council, Neuroscience, Milan, Italy, ²Magna Graecia University, Institute Of Neurology, Department Of Medical Sciences, Catanzaro, Italy, ³National Research Council, Institute For Biomedical Research And Innovation, Cosenza, Italy, ⁴National Research Council, Institute Of Molecular Bioimaging And Physiology, Catanzaro, Italy, ⁵National Research Council, Neuroimaging Research Unit, Institute Of Molecular Bioimaging And Physiology, Catanzaro, Italy, ⁶National Research Council, Neuroimaging Research Unit, Catanzaro, Italy, ⁷Università Vita-Salute San Raffaele, Division Of Neuroscience, Sleep Disorders Center, Milan, Italy, ⁸University Magna Graecia, Neuroscience Research Centre, Catanzaro, Italy

Background and Aims:: Hereditary aceruloplasminemia (HA) is a rare inherited disease caused by homozygous mutation of ceruloplasmin (CP) gene, characterized by brain iron overload. Hypointensity of MRI signal in thalami and basal ganglia, especially globus pallidus (GP) is considered a neuroimaging hallmark of this disease. Here, we report the case of two Italian cousins carrying a novel splicing homozygous mutation in intron 6 (IVS6+1 G>A) of CP gene

Methods:: Methods Genomic DNA was extracted from peripheral blood by standard methods. A written informed consent was obtained from each subjects involved in the study. The primers flanked all 19 exons and intron–exon boundaries of CP (NM_000096) were designed using the web site Primer 3 (http://bioinfo.ut.ee/primer3-0.4.0/). The purified PCR products were analyzed on 3500 Genetyc Analyzer (Life Technologies, Carlibad, CA, USA). The new identified mutation was checked in a control population of 200 ethnically matched controls. The MRI protocol included whole-brain, T1-weighted images DTI and conventional T2-weighted and FLAIR images.

Results::
Interestingly, the proband was symptomatic for neurological and visceral symptoms whereas his cousin was asymptomatic. MRI features in both patients were characterized by marked iron accumulation in the thalami and basal ganglia nuclei, while GP was spared. MRI performed in the proband at 2 and 4-years of follow-up, confirmed progressive neurodegeneration of thalami and basal ganglia without involvement of GP.

Conclusions: Our findings expand the phenotypic spectrum of this disease demonstrating that in HA-carriers of splicing homozygous mutation in intron 6, GP can remain spared by iron accumulation over time.
ACUTE CARBON MONOXIDE POISONING: MAGNETIC RESONANCE IMAGING FEATURES

Senda Mnif¹, Mariem Messelmani¹,²,³ Raja Ben Sassi⁴, Hedi Gharsallah⁴, Jamel Zaouali¹,³,⁴, Ridha Mrissa¹,⁵
¹military hospital, Neurology, tunis, Tunisia, ²Military Hospital of Tunis, Neurology, Monfleury, Tunisia, ³Military Hospital of Instruction of Tunis, Department Of Neurology, sousse, Tunisia, ⁴military hospital, Department Of Hyperbaric Oxygen Therapy, tunis, Tunisia, ⁵military hospital, Department Of Hyperbaric Oxygen Therapy, sfax, Tunisia

Background and Aims:: INTRODUCTION: Carbon monoxide (CO) intoxication is still one of the most frequent conditions causing brain damage as a result of hypoxia. Several neuropsychiatric features and cerebral magnetic resonance imaging (MRI) lesions were found in these patients. The aim of our study was to describe clinical and radiological features of CO intoxication.

Methods:: METHODOLOGY: A retrospective study of 4 years was performed, including patients who presented an acute CO intoxication. Clinical and cerebral MRI findings were collected and analysed.

Results:: RESULTS: Twenty-six patients were included (16 men and 10 women). The average age was 40 years old (11-82 years old). All patients presented mental status change with different severity. Repeated clinical examination revealed cortical visual impairment in four patients. Twelve patients had memory loss and five had extrapyramidal syndrome. Cerebral MRI had shown restricted diffusion of the bilateral globi pallidi in twelve patients (46%). Cerebral cortex, and fronto-parieto-occipital white matter were involved in five patients (19%). Four patients had bilateral lesions of hippocampi (15%). Two patients had an occlusion of the cerebral posterior artery and extracranial internal carotid with ischemic stroke lesions respectively. One patient had a lesion in the splenium of the corpus callosum. Nine patients had normal cerebral MRI (34%).

Conclusions:: CONCLUSION: Several clinical features may be caused by acute CO poisoning. Bilateral globi pallidi, cerebral cortical and cerebral white matter with restricted diffusion may be a characteristic MRI features in patients with CO intoxication.
LINKING STRUCTURAL AND FUNCTIONAL BRAIN ALTERATIONS IN PATIENTS WITH RELAPSING-REMITTING MULTIPLE SCLEROSIS

Antonio Giorgio¹, Jian Zhang¹, Claudia Vinciguerra¹, Maria Laura Stromillo¹, Marzia Mortilla², Riccardo Tappa Brocci¹, Marco Battaglini¹, Rosa Cortese¹, Emilio Portaccio³, Maria Pia Amato³, Nicola De Stefano¹ ¹University of Siena, Dept. Of Medicine, Surgery And Neuroscience, Siena, Italy, ²Anna Meyer Children’s University Hospital, Department Of Radiology, Florence, Italy, ³University of Florence, Department Of Neurofarba, Florence, Italy

Background and Aims: Imaging studies have consistently but separately shown structural and functional brain alterations in patients with multiple sclerosis (MS), although an integrated understanding of them is currently lacking. We aim to provide a unified representation of the complex structural-functional scenario in the brain of patients with MS.

Methods: We included 100 patients with relapsing-remitting MS (median expanded disability status scale [EDSS]=1.5, cognitive impairment [CI] in 30%) and 43 normal controls. We applied an innovative data-driven “fusion” approach able to simultaneously modeling relationships and contributions across MRI modalities.

Results: Out of 20 linked structural-functional patterns across study population, only one (GM density: 41%; fractional anisotropy along WM tracts:42%; intra-network functional connectivity (FC) across brain: 17%) showed significant group difference, with a cross-modalities loading coefficient lower in MS than NC (-0.29±1.05 vs 0.69±0.34, corrected-p <0.004). This was already present at very early disease stage and particularly low in the MS subgroups with larger white matter (WM) lesion volume (>3.5 cm³), higher EDSS (>1.5), presence of CI and longer disease duration (>5 years). Overall, with worsening disease severity, relative contribution to the significant linked covarying pattern was decreasing for structural integrity and increasing for FC. Specific linked covarying patterns, mostly driven by altered intra-network FC, significantly explained EDSS and CI, especially attention and processing speed (adjusted R² = 0.62, p < 0.001).

Conclusions: These findings suggest the presence in the brain of MS patients with mild disability of multidimensional and clinically relevant “architectures” linking GM atrophy, WM tract damage and network functional reorganization.
ALTERED INTERPLAY AMONG LARGE-SCALE BRAIN FUNCTIONAL NETWORKS UNDERPINS MULTI-DOMAIN ANOSOGNOSIA IN EARLY-AD

Jose Manuel Valera Bermejo¹, Matteo De Marco¹, Annalena Venneri²
¹University of Sheffield, Department Of Neuroscience, Sheffield, United Kingdom, ²Brunel University London, Department Of Life Sciences, Uxbridge, United Kingdom

Background and Aims:: Decline in self-awareness (anosognosia) is a prevalent early symptom of Alzheimer’s disease (AD). The integrity of the functional hubs of the default mode network (DMN) has been heavily implicated in retained self-awareness abilities in AD patients. Moreover, an early breakdown of this network has been found to be a hallmark feature in the clinical profile of AD. However, the interplay among other large-scale brain networks in support of cognitive awareness in early-AD remains poorly understood.

Methods:: Resting-state functional MRI scans were acquired and pre-processed from fifty-three early-stage AD individuals. An independent component analysis isolated four intrinsic connectivity large-scale brain functional networks, namely left and right central executive fronto-parietal networks (FPN), salience network, anterior and posterior DMN. In addition, hypothesis-driven seed-based connectivity analyses were performed. Multiple regression models were carried out between scores of memory, non-memory (executive) and total anosognosia and large-scale network and seed-based connectivity maps.

Results:: All anosognosia domains displayed consistent lower fronto-temporal connectivity. However, higher connectivity was found between memory anosognosia and parieto-temporal regions. Non-memory anosognosia displayed stronger connectivity between the DMN-cerebellum and the contralateral prefrontal cortices. Finally, total anosognosia yielded increased connectivity between the right FPN and the anterior cingulate.

Conclusions:: Multi-domain anosognosia in early AD is characterised by selective fronto-temporal disconnection. Selectively increased fronto-parietal-subcortical connectivity seems to provide cognitive resources to cope with unawareness, explaining the heterogeneity of the symptom. Therefore, these findings support the hypothesis that alterations in functional connectivity of frontal regions involved in executive related mechanisms represent the neural correlate of domain-specific anosognosia in early AD.
DIFFERENT EYES, SAME BRAIN: A COMPARISON OF BRAIN VOLUMES BETWEEN CHINESE AND CAUCASIANS

Jian Zhang¹, Marco Battaglini¹, Ludovico Lucchetti¹, Giordano Gentile², Rosa Cortese¹, Nicola De Stefano¹
¹University of Siena, Department Of Medicine, Surgery And Neuroscience, Siena, Italy, ²University of Siena, Department Of Medicine, Surgery And Neuroscience, Siena, Italy

Background and Aims:: Differences in brain volume (BV) between Chinese and Caucasian populations remain largely unexplored. This might be due, at least in part, to the lack of robust normalization and harmonization of multi-site lifespan MRI data with varying acquisition protocols. We aim to assess here differences in site- and scanning harmonized MRI-derived brain volumes in a large lifespan population of Chinese and Caucasian healthy subjects (HS).

Methods:: A multi-center 3T Siemens MRI dataset of 1829 Chinese HS (aged 15-80 years old, 55.9% women) and 3234 Caucasian HS (aged 15-88 years old, 52.4% women) was collected from 2 research groups worldwide and from 19 open-source datasets. Normalized (for head size) volumes of the whole brain (NBV), grey matter (NGMV), white matter (NWMV), lobes and thalamus were assessed using SIENAX2.0. Lifespan trajectories of site and scanning variances harmonized volumes were derived with multivariate regression, including age (with quadratic and cubic terms), gender, ethnicity and interactions as predictors.

Results:: Chinese and Caucasian did not differ in any structure except for higher temporal lobe volume in Chinese (β=0.784, 95% confidence interval [CI]: 0.319-1.248, p<0.001). In all subjects, with increasing age, both NBV ($R^2=0.54$, p<0.001) and thalamus ($R^2=0.30$, p<0.001) decrease linearly, while NGMV ($R^2=0.66$, p<0.001) and NWMV ($R^2=0.12$, p<0.001) decrease quadratically.
Conclusions: Age-related volume trajectories of Chinese and Caucasian brains are very similar. The difference in temporal lobe volume between the two populations needs further analysis to ascertain whether or not they may reflect ethnicity-related influence on brain structures.
MICRO-STRUCTURAL ALTERATION OF SUBSTANTIA NIGRA IN PARKINSON'S DISEASE; A 7 TESLA MRI STUDY

Atsushi Shima1,2,3, Koji Furukawa3, Daisuke Kambe3, Akira Nishida3, Haruhi Sakamaki3,Kenji Yoshimura3, Ikko Wada3, Yuta Terada3, Yusuke Sakato3, Hodaka Yamakado3, Yosuke Taruno3, Etsuro Nakaniishi3, Masanori Sawamura3, Dinh Ha Duy Thuy1, Koji Fujimoto1, Yasutaka Fushimi4, Tomohisa Okada1, Yuji Nakamoto4, Ryosuke Takahashi3, Nobukatsu Sawamoto2,3

1Kyoto University Graduate School of Medicine, Human Brain Research Center, Kyoto, Japan, 2Kyoto University Graduate School of Medicine, Department Of Human Health Sciences, Kyoto, Japan, 3Kyoto University Graduate School of Medicine, Department Of Neurology, Kyoto, Japan, 4Kyoto University Graduate School of Medicine, Department Of Diagnostic Imaging And Nuclear Medicine, Kyoto, Japan

Background and Aims:: Dopamine-containing neurons in Parkinson's disease (PD) degenerate in different parts of substantia nigra (SN) to different degrees. The maximal neuron loss occurs in nigrosome-1, which is considered as a diagnostic biomarker in PD with iron-sensitive MRI techniques. However, clinical correlates of iron accumulation in nigrosome-1 remain unknown. Here, we measured quantitative susceptibility mapping (QSM) of nigrosome-1 using a 7 Tesla MRI and computed correlation with motor symptoms and with striatal dopamine terminal degeneration using 123I-ioflupane SPECT, to identify the clinical parameter that reflects nigrosome-1 degeneration.

Methods:: 57 PD patients and age-, sex-matched 56 healthy control subjects (HC) were recruited. Three-dimensional QSM and T1 weighted images were acquired using a 7 tesla MRI scanner. 54 PD patients also underwent 123I-ioflupane SPECT. QSM images were registered to standard space and permutation analysis was performed to elucidate the alteration within the SN in PD compared to HC.

Results:: PD patients showed higher QSM values within the dorsolateral part of SN compared to HC, which correspond to nigrosome-1. MDS-UPDRS part 3 score showed a positive correlation with the QSM value of nigrosome-1 (p < 0.05). Furthermore, the striatal uptake ratio of 123I-ioflupane SPECT showed a significant negative correlation with the QSM value of nigrosome-1 (p < 0.005).

Conclusions:: The present findings suggest that alteration of nigrosome-1 detected by QSM corresponds to the motor disabilities and the severity of terminal degeneration of dopaminergic neurons in the striatum of PD.
ACCURACY OF BEDSIDE SONOGRAPHIC MEASUREMENT OF OPTIC NERVE SHEATH DIAMETER FOR INTRACRANIAL HYPERTENSION DIAGNOSIS IN THE EMERGENCY DEPARTMENT

Chiara Busti¹, Federico Germini², Giuseppe Calabró³, Francesco Corea⁴, Giuseppe Batori⁵, Francesco Marchetti⁶, Matteo Marcosignori⁷

¹USL Umbria 2, Ospedale San Giovanni Battista, Pronto Soccorso, Foligno, Italy, ²McMaster University, ³Department Of Health Research Methods, Evidence, And Impact, Hamilton, Canada, ⁴USL Umbria 2, Ospedale San Giovanni Battista, Foligno, Italy, ⁵USL UMBRIA 2, Neurology, Italy, Italy, ⁶Università degli Studi di Perugia, Scuola Di Specializzazione In Medicina Interna, perugia, Italy, ⁷Azienda Ospedaliera Santa Maria della Misericordia, Radiologia1, Perugia, Italy, ⁸Ospedali Riuniti Torrette di Ancona, Pronto Soccorso, Ancona, Italy

Background and Aims:: Ultrasound measurement of optic nerve sheath diameter (US ONSD) has been proposed as a method to estimate elevated intracranial pressure (ICP) even if the optimal ONSD threshold is nowadays unclear. The aim of this study is to assess the accuracy of ONSD, as compared to head computed tomography (CT), in detecting elevated ICP on both Traumatic and Non-Traumatic Brain Injury (TBI).

Methods:: This is an ongoing, prospective, cross-sectional, multicenter study. Patients presenting to emergency department (ED) for an Acute Brain Injury underwent to ultrasound ONSD measurement and urgent CT scan. Sensitivity and specificity of US ONSD is calculated using CT as reference standard considering 5.5 mm OSND threshold.

Results:: To date 64 patients were enrolled. CT was ABNORMAL in 14.1% of cases and ONSD was positive in all of these, achieving a sensitivity of 100% and a negative predictive value of 100%. Instead CT was negative in 85.9% of cases while ONSD measurement was positive in 78.2% of these, achieving a specificity of 29% and a positive predictive value of 17%.

Table 1: Sn = sensitivity, Sp = specificity, PPV = positive predictive value, NPV = negative predictive value, LR = likelihood ratio.

<table>
<thead>
<tr>
<th>Cut-off</th>
<th>Sn (95% CI)</th>
<th>Sp (95% CI)</th>
<th>VPP (95% CI)</th>
<th>VPN (95% CI)</th>
<th>LR +</th>
<th>LR -</th>
</tr>
</thead>
<tbody>
<tr>
<td>≥ 5.5</td>
<td>100% (100; 100)</td>
<td>22% (12; 32)</td>
<td>17% (8; 27)</td>
<td>100% (100; 100)</td>
<td>1.3</td>
<td>0</td>
</tr>
</tbody>
</table>

Conclusions:: Our data suggest good sensitivity and a good negative predictive value of ONSD. In limited-resources contexts a negative US ONSD could allow emergency physicians to rule out elevated ICP in low risk patients, deferring CT. Furthermore in out-of-hospital setting a negative US ONSD could help clinicians to exclude an immediate neurosurgical need for Traumatic Brain Injury patients avoiding unnecessary centralization in Hub hospitals.
ROLE OF NEUROSPECIFIC PROTEINS IN THE PATHOGENESIS OF PARKINSONISM SYNDROME DEVELOPMENT IN CHRONIC BRAIN ISCHEMIA

Gulchiroykhon Vafoeva¹, Yakuthon Madjidova², Durdona Usmanova², Saida Saidkhodjaeva³
¹Tashkent Pediatric Medical Institute, Neurology, Child Neurology And Medical Genetics, - , Uzbekistan, ²Tashkent Pediatric Medical Institute, Neurology, Tashkent, Uzbekistan, ³Tashkent pediatric medical institute, Neurology, Tashkent, Uzbekistan

Background and Aims:: Background: Autoimmune reactions are important pathogenic part for parkinsonism syndrome in chronic brain ischemia (CBI). Aims: To reveal significance of the measurement of levels of autoantibodies to neurospecific protein S100 and myelin basic protein (MBP) in blood serum of patients with parkinsonism syndrome in CBI.

Methods:: Material and methods of research: In 52 (72.2%) patients with CBI associated with parkinsonism syndrome we analyzed autoantibodies to neurospecific protein S100 and MBP. Biochemical findings were compared with data of control group, consisted of 20 (27.8%) practically healthy donors.

Results:: Results and discussion: The investigations showed that the levels of autoantibodies to S100 were 119.85±3.38 IU (P<0.05), and to MBP 124.42±3.00 IU (P<0.001) that is higher than control values, accounted 68.22±3.53 IU and 55.69±4.74 IU, respectively.

Conclusions:: Conclusion: Biochemical investigations revealed increase in the level of autoantibodies to protein S100 and MBP in patients with parkinsonism syndrome in CBI. This is evidence of the role of neurospecific proteins in the pathogenesis of development of vascular parkinsonism. The study of protein S100 is useful both for monitoring and determination of the prognosis for disease development. These biochemical indicators may be used with diagnostic and prognostic purpose in chronic disorders of cerebral circulation, as well as optimization of therapeutic tactics for such patients.
PROGRESSION TO MIXED CEREBRAL MICROBLEEDS IN PATIENTS WITH COGNITIVE IMPAIRMENT WITH MULTIPLE STRICTLY LOBAR MICROBLEEDS

Yuichiro Ii1, Hidehiro Ishikawa1, Akihiro Shindo1, Kana Matsuda2, Maki Umino3, Masayuki Maeda4, Hidekazu Tomimoto1
1Mie University, Neurology, Tsu, Japan, 2Mie University, Rehabilitation, Tsu, Japan, 3Mie University, Radiology, Tsu, Japan, 4Mie University, Neuroradiology, Tsu, Japan

Background and Aims:: Cerebral microbleed (CMB) is one of the neuroimaging markers of cerebral small vessel disease (SVD). Multiple strictly lobar CMBs are thought to be caused by cerebral amyloid angiopathy (CAA). Mixed CMBs are thought to be due to hypertensive arteriopathy (HA), but it has also been pointed out that CAA may coexist. Here we examined changes in CMBs distribution over time in patients with cognitive impairment with multiple strictly lobar microbleeds.

Methods:: We retrospectively evaluated MRI findings in 19 patients (mean age 80.9 years) with cognitive impairment with multiple strictly lobar microbleeds, which had been taken multiple MRIs scans at intervals of 1-5 years. The CAA-SVD score, which reflects the severity of CAA, was calculated according to a previously reported scoring system (Charidimou A, JAMA Neurol 2016).

Results:: Thirteen of 19 patients (68.4%) had an increased number of CMBs, and 10 of them (76.9%) had hypertension. The median CAA-SVD score at the first MRI scan was 3.0 in patients with increased CMBs. In 4 of 13 patients (30.8%) with increased CMBs, new CMB appeared in the deep region resulting in mixed CMBs. Cortical superficial siderosis newly emerged in one of these four patients.

Conclusions:: In the four patients which progressed to mixed CMB imaging findings, coexistence of HA and CAA, or alternatively, progression of CAA itself was suspected. Even in patients with CAA in the background pathology, imaging findings of mixed CMBs may be presented depending on the timing of MRI scan.
CONFIRMATION OF THE NEUROIMAGING SIGNIFICANCE OF ASYMPTOMATIC TRANSIENT ISCHEMIC ATTACK (TIA) IN THE COURSE AND PROGNOSIS OF ISCHEMIC STROKE

Alimardon Ismatov, Gulnora Rakhimbaeva, Kamola Mirzaeva, Dilshod Tolibov
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: To study the role of asymptomatic areas on MRI in the course of future strokes and their prognosis in patients with multiple anamnesis of TIA.

Methods:: MRI and MSCT-angiography were performed in 64 patients aged 50-70 years (average age-59.78±0.77) who had 3 or more TIAs in their anamnesis. Group 1 included 31 (48.4%) patients with only arterial hypertension and cerebral atherosclerosis, and group 2 included 33 (51.6%) patients with arterial hypertension, cerebral atherosclerosis, diabetes and coronary heart disease.

Results:: In group 1: bilateral lacunar ischemia were detected in 9 (29.1%) patients, in 8 (25.8%) and 14 (45.1%) were in the unilateral carotid and vertebrobasilar pool, respectively. In group 2, the lacunar ischemia were detected in 20 (60.6%) patients, in 8 (24.2%) in the carotid pool, and in 6 (18.2%) in the vertebrobasilar pool. In all groups of patients, stenosis and vascular deformity on MSCT-angiography did not correlate with the localization of cerebral changes on MRI. Among observed patients, 38.7% (in group 1) and 63.6% (in group 2) had cerebrovascular accident with severe neurological deficit within 2 years, which directly correlated with the speed of recovery and the size of asymptomatic ischemic areas.

Conclusions:: MRI and Multispiral CT-angiography should be performed regardless of the presence of changes in neurological status and any cerebrovascular problems. The identified changes later play an important role in the regression and prognosis of the disease, the solution of rehabilitation problems, when there is a significant stroke clinic with a large neurological deficit.
CEREBRAL SMALL VESSEL DISEASE IS DETECTABLE ON 3.0 TESLA MAGNETIC RESONANCE IMAGING: ESTABLISHED 3.0 TESLA MAGNETIC RESONANCE IMAGING FIRST TIME IN MONGOLIA

Odgerel Ochirkhuu, Tungalag Enkhbat, Dulamragchaa Purev
Second State Central Hospital, Neurology, Ulaanbaatar, Mongolia

Background and Aims:: Cerebral small vessel disease (CSVD) is a common neurological disease in older people. For patients diagnosed with small vessel disease by CT brain, for the first time in Mongolia, MRI brain (3.0 TESLA) was performed. The purpose of the study was to collect data from 58 patients aged 50-85 years old.

Methods:: In this descriptive study, we identified 56 elderly, aged between 50-85 years patients Small vessel disease was assessed on baseline computer tomography rating for leukoaraiosis and lacunes from our clinical data file from January 2021 to March 2021 at the Second general hospital of Mongolia. We assessed clinical features, sex, age, risk factors, and radiologic findings of these patients.

Results:: There were 56 patients with available brain MRI with 35 men and 23 women; mean age, 60.91±6.57 years. Features of the main clinical syndromes and MRI signs in patients with CSVD. The MRI measuring were including brain inflammation (2/3,4%) small subcortical infarcts (12 / 20.6 % ) lacunes microbleeds (7 cases/ 12%) enlarged perivascular spaces (6 cases/ 10,3% ), brain atrophy (12 cases/20,6% ) White Matter Hyperintensities (11cases/18,9% ) and Lacunar Infarct ( 8 cases/13,7% ).

Conclusions:: The study has the potential to further unravel the causes and consequences of changes in white matter integrity in elderly with CSVD by using new imaging techniques, MRI segmentation method capable of identifying multiple types of imaging features of CSVD and brain atrophy, we showed that WMH and lacunar had the greatest independent predictive value for vascular risk factors outcome in older individuals.
HYDRANENCEPHALY: A CASE REPORT OF A 32-YEAR-OLD WOMAN WITH PRESERVED WALKING ABILITY

Andrea Di Pietro¹, Giuseppina Miele¹, Lorenzo Cipriano¹, Lorenzo Ugga², Mario Fratta¹, Simona Bonavita¹
¹Università della Campania L. Vanvitelli, Second Division Of Neurology, Napoli, Italy, ²AOU Federico II, Scienze Biomediche Avanzate, Naples, Italy

Background and Aims:: Hydranencephaly is a rare post-neurulation disorder characterized by the extensive hemispheric destruction with preservation of diencephalic and posterior cranial fossa structures. Brain matter is mostly replaced with a membranous sac filled with cerebrospinal fluid.

Methods:: A 32-year-old woman came to our attention for general assessment. She had a previous diagnosis of microencephaly of unknown origin. She was born at term. Her mother referred a severe psychomotor delay: she walked at 36 months after intensive fisiokinesitherapy and has never developed sphincter control and any form of speech. At neurological evaluation, she was able to walk with assistance, showing spastic gait. She was regularly fed by her mother. She opened her eyes spontaneously and turned her face in response to sounds. No meaningful actions were observed. She emitted only incomprehensible vocalization.

Results:: Comparative Genomic Hybridization did not reveal any chromosomal abnormalities. Electroencephalogram showed low amplitude and slowed activity. Brain MRI documented a severe telencephalic hypoplasia and cortical malformation with relative sparing of diencephalon and posterior fossa structures, consistent with the diagnosis of hydranencephaly. She died three months later, at the age of 32 years and 8 months, because of Sars-Cov19 pneumonia.

Conclusions:: Life expectancy in patients with hydranencephaly is very reduced. Most patients do not survive beyond the neonatal stage, nevertheless, some have been rarely diagnosed into adulthood. In these surviving cases, preserved brainstem regions maintain vital functions. Here we reported the case of one of the most long-lived patients affected by hydrancephalia with a surprising walking ability.
SPINAL EXTRADURAL ARACHNOID CYST: AN UNCOMMON CAUSE OF THORACIC SPINE COMPRESSION

Hatim Belfquih
Avicenne hospital Marrakech, Neurosurgery, Marrakech, Morocco

Background and Aims: Spinal extradural arachnoid cysts are unusual causes of symptomatic spinal cord compression. They represent expanding diverticula of the subarachnoid space herniating through a dural defect into the extradural space. The pathogenesis of this entity is still unclear.

Methods: We describe the clinical, neuroradiological and surgical aspects of two young patients in whom symptoms attributable to thoracic spine compression were caused by Spinal extradural arachnoid cysts.

Results: The first child presented with progressive spastic paraparesis accompanied by urinary incontinence, superficial and deep sensory disturbance below the umbilical level. The second patient presented with unstable gait as a result of weakness and diminished sensation in the lower extremities. Magnetic resonance imaging (MRI) showed a thoracic posterior extradural arachnoid cyst in both patients. The cyst was completely removed by posterior approach. Histological examination confirmed the diagnosis of arachnoid cyst. Neurological symptoms progressively resolved after surgical decompression.

Conclusions: Although quite rare, the diagnosis of arachnoid cyst should be included in the differential diagnosis of intraspinal extradural cystic lesions, causing spinal cord compression. Surgery is the treatment of choice, providing good clinical outcome.
HYPERTROPHIC PACHYMENINGITIS: A SINGLE ENTITY FOR A VARIETY OF NEURORADIOLOGICAL FINDINGS

Sara Iolanda Piras1, Maria Tappatà2, Elena Pasini2, Patrizia Riguzzi2, Roberto Michelucci2, Lilia Volpi2
1Dipartimento di Neurologia, IRCCS Istituto Delle Scienze Neurologiche Di Bologna, Bologna, Italy, 2IRCCS Istituto delle Scienze Neurologiche di Bologna, Department Of Neurology, Bologna, Italy

Background and Aims:: Hypertrophic pachymeningitis (HPM) is an infrequent disorder characterized by thickening of the dura mater with underlying processes of inflammation and fibrosis. The most frequent clinical manifestation is chronic headache, but it can also present several other neurological deficits.

Methods:: We present a case of HPM which presented as a deficit of the XII cranial nerve.

Results:: A 51-year-old man, previously diagnosed with catarrhal otitis media, came to our attention for the appearance in February 2019 of cervical/nuchal headaches, dysphagia, dysarthria and right deviation of the tongue: a contrast-enhanced brain MRI demonstrated a left infratentorial pachymeningitis, extended towards the foramen and the canal of the XII cranial nerve, and revealed a thrombosis of transverse and sigmoid sinuses. In July 2019 he underwent a subtotal petrosectomy, but the symptoms persisted and the postoperative contrast-enhanced brain MRI attested a worsening of the pachymeningitis with supratentorial involvement. He started a long-term treatment with oral steroids, achieving amelioration of the clinical manifestations; in October 2019 another MRI confirmed the clinical findings, showing a reduction of the supratentorial and infratentorial pachymeningeal thickening. While the microbiological screening was negative, positivity for serum IgG4 subclass was found. Upon suspicion of IgG4-related HPM a biopsy was performed (results in progress).

Conclusions:: We assessed how HPM can be accompanied by several and sometimes unusual neuroradiological findings, which can overlap in a single patient. Moreover, etiological assessing can be difficult: in our patient we hypotesized first an infectious disease, then a post-operative hypotension and finally a primary autoimmune etiology.
CORPUS CALLOSUM AGENESIS: ROLE OF FETAL MRI: A CASE REPORT AND REVIEW OF THE LITERATURE.

Radhouane Achour, Radhouane Achour, Dhekra Trabelsi, Rim Ben Hmid
Maternity and Néonatology center of Tunis, Emergency Department, Tunis-TUNISIA, Tunisia

Background and Aims:: INTRODUCTION: Corpus callosum agenesis is an important condition in man that can reveal numerous genetic syndromes. CASE REPORT: We report a case of diagnosis of isolated fetal corpus callosum agenesis (CCA). MRI improve prognosis evaluation, In our case MRI was confirmed isolated fetal corpus callosum agenesis. CONCLUSION: MRI appears to be an essential and reliable complement to fetal ultrasound in the event of suspected complete or partial agenesis of the corpus callosum and to search for associated malformations.

Methods:: Case report and review of literature

Results:: Prenatal MRI is a valuable complementary technique for either diagnosis of corpus callosum agenesis and depiction of associated neurologic abnormalities. In light of results and data reported in the literature, MRI appears to be an essential and reliable complement to fetal ultrasound in the event of suspected complete or partial agenesis of the corpus callosum and to search for associated malformations. Antenatal counselling in the event of diagnosis of agenesis of the corpus callosum is difficult because the individual prognosis remains poor.

Conclusions:: Prenatal MRI is a valuable complementary technique for either diagnosis of corpus callosum agenesis and depiction of associated neurologic abnormalities. In light of results and data reported in the literature, MRI appears to be an essential and reliable complement to fetal ultrasound in the event of suspected complete or partial agenesis of the corpus callosum and to search for associated malformations. Antenatal counselling in the event of diagnosis of agenesis of the corpus callosum is difficult because the individual prognosis remains poor.
DELPHI IN THE DETECTION OF NEUROLOGICAL CONDITIONS AND WHITE MATTER PATHOLOGIES

Iftach Dolev
QuantalX Neuroscience Ltd., Clinical, Beer Yaakov, Israel

**Background and Aims::** Evaluation of brain white matter fibers connectivity damage in stroke and traumatic brain injury (TBI) subjects by direct electrophysiological imaging (DELPHI) which analyzes TMS (transcranial magnetic stimulation) evoked potentials.

**Methods::** Study included 123 participants out of which: 53 subjects with white matter related pathologies of (39 stroke, 14 TBI) and 70 healthy age-related controls. All subjects underwent DELPHI brain network evaluations of TMS-EEG evoked potentials, and DTI scans for quantification of white matter microstructure fractional anisotropy.

**Results::** DELPHI output measures show a significant difference between healthy and stroke\|TBI groups, a multidimensional approach was able to classify healthy from unhealthy with a balanced accuracy of 0.81±0.02 and AUC of 0.88±0.01. Moreover, a multivariant regression model of DELPHI output measures achieved prediction of white matter microstructure changes measured by fractional anisotropy (FA) with highest correlations observed for fibers proximal to stimulation area such as frontal corpus callosum (r=0.7±0.02), anterior internal capsule (r=0.7±0.02) and fronto-occipital fasciculus (r=0.65±0.03).

**Conclusions::** These results indicate that features of TMS evoked response are correlated to white matter microstructure changes observed in pathological conditions such as stroke and TBI, and that a multi-dimensional approach combining these features in supervised learning methods serve as a strong indicator for abnormalities and changes in white matter integrity.
Background and Aims:: CT brain imaging is customary in clinical practice after Transient Ischemic Attack (TIA). However, NICE (2020) guidelines recommend MRI brain with diffusion weighted and blood-sensitive sequences; to be completed on the same day as the assessment. The aim of this audit was to assess the diagnostic radiology investigations performed on patients presenting with TIA to a university teaching hospital.

Methods:: We conducted a retrospective audit of all patients coded as TIA on the Hospital Inpatient-Enquiry (HIPE) system between July 2019 to July 2020. Data on brain imaging was accessed using the National Integrated Medical Imaging System (NIMIS) system. Hospital attendance records were accessed via the Emergency Department patient database. Data was analysed using Microsoft Excel.

Results:: One hundred and six patients had brain imaging performed (n=50 CT brain only; n=56 MRI only; n=49 CT and MRI). Of these patients, only eight had an MRI brain completed within twenty-four hours where Forty-eight patients had an MRI scans outside of twenty-four hours. Forty-nine patients had both a CT and MRI brain imaging performed. The median time to MRI brain was 2 days and 6 hours and the median time to CT brain was 2 hours and 45 minutes.

Conclusions:: This audit confirms duplication of TIA brain imaging and CT as the primary imaging tool for TIA which is not in keeping with best practice (NICE, 2020). This has implications for resources, radiation exposure and patient's length of stay. Development of dedicated ambulatory care pathways for TIA must incorporate rapid MRI access as the primary imaging modality.
CEREBROVASCULAR AUTOREGULATION IMPAIRMENTS DURING CARDIAC SURGERY WITH CARDIOPULMONARY BYPASS ARE ASSOCIATED WITH POSTOPERATIVE COGNITIVE DETERIORATION

Vytautas Petkus¹, Birute Kumpaitiene², Milda Svagzdiene², Edmundas Sirvinskas², Rolandas Zakelis¹, Rimantas Benetis², Arminas Ragauskas¹
¹Kaunas University of Technology, Health Telematics Science Institute, Kaunas, Lithuania, ²Hospital of Lithuanian University of Health Sciences Kauno Klinikoss, Clinic Of Cardiothoracic And Vascular Surgery, Kaunas, Lithuania

Background and Aims:: Post-operative cognitive dysfunction (POCD) occurs in 33–83% of patients after cardiac surgery with cardiopulmonary bypass (CPB). Intraoperative non-invasive monitoring of cerebrovascular autoregulation (CA) of individual patient may help to prevent POCD by detecting and control of optimal mean arterial blood pressure (optABP) or optimal cerebral perfusion pressure (optCPP). Objectives of the study are to investigate the association between CA dynamics and POCD.

Methods:: The study of non-invasive ultrasonic CA monitoring included 59 patients undergoing elective coronary artery bypass graft surgery with CPB. Non-invasive ultrasonic CA monitor for identification of real-time volumetric reactivity index (VRx(t)) was used in order to identify dynamics of CA changes. Feedback from CA monitor to surgical theatre will be used at first time in order to optimize dynamic control of optCPP(t) in our new prospective study.

Results:: 22 patients experienced POCD, 37 patients (63%) showed no cognitive deterioration. The duration of the single longest CA impairment (LCAI) event was associated with occurrence of POCD. The critical duration of the single longest CA impairment event was 5.02 min (odds ratio 14.5; CI 3.9-51.8). ROC area under curve 0.81, sensitivity 76%, specificity 82% has been shown for the duration of the LCAI event. Protocol of novel study with feedback will be presented.

Conclusions:: Prospective observational clinical study showed that too long patient-specific single CA impairment is associated with POCD. Novel prospective clinical study already started in order to get evidences that dynamic control of optABP keeping intact CA can decrease a rate of POCD.
CEREBRAL VENOUS THROMBOSIS IN BEHCET'S DISEASE. ABOUT 24 CASES

Jawad Oumerzouk
Military Hospital of Marrakech. Avicenne. CHU Mohamed VI, Neurology, Marrakech, Morocco

**Background and Aims:** La thrombose veineuse cérébrale (TVC) est la manifestation la plus courante de l’angiobehçet qui peut être superficielle et / ou profonde. Le but de notre étude était d’évaluer les aspects épidémiologiques, cliniques, paracliniques, thérapeutiques et évolutifs de la CVT survenant dans la maladie de Behçet.

**Methods:** We report a retrospective study of 24 cases of CVT secondary to Behçet's disease, collected between 1999 and 2019 in the neurology department of military hospital Mohamed V (Rabat) Mohamed VI hospital (Marrakech). The diagnosis of Behçet disease was retained in all cases according to criteria established by the International Study Group for Behçet’s disease (1990). All the patients have benefit of symptomatic management, associated with antithrombotic and etiological treatment.

**Results:** La CVT représente 19,2% de toutes les manifestations neurologiques de la maladie de Behçet. Notre série est individualisée par la prédominance des localisations profondes dans 18 cas. Les manifestations cliniques étaient polymorphes, dominées par le déficit moteur pour les localisations profondes et l'hypertension intracrânienne pour les localisations superficielles. Les signes et symptômes moteurs étaient les résultats les plus courants au cours de l'évolution de la maladie, en accord avec les rapports précédents.

**Conclusions:** Grâce aux progrès de l'imagerie, en particulier de l'angiographie et de l'angio-IRM, le diagnostic de CVT est devenu incontournable. Une thérapie associant anticoagulation et prise en charge de la maladie de Behçet à base de corticostéroïdes et d'immunosuppresseurs a amélioré le pronostic de cette maladie mais avec une persistance de séquelles dominée par le déficit moteur partiel et la céphalée résiduelle.
THE CONTRIBUTION OF MRI IN BRAIN RADIONECROSIS AND POSTRADIQUE MYELOPATHY: ABOUT 15 CASES

Jawad Oumerzouk, Najib Kissani
Military Hospital of Marrakech. Avicenne. CHU Mohamed VI, Neurology, Marrakech, Morocco

Background and Aims:: The brain and focal spinal cord radionecrosis are relatively rare but severe iatrogenic complications in patients irradiated for nasopharyngeal cancer. We proceed in this work to the description of the MRI brain radionecrosis and postradique myelopathy.

Methods:: The brain and focal spinal cord radionecrosis are relatively rare but severe iatrogenic complications in patients irradiated for nasopharyngeal cancer. We proceed in this work to the description of the MRI brain radionecrosis and postradique myelopathy.

Results:: Neurological complications are to type in 2 cases of myelitis, cerebellar necrosis in 3 cases, necrosis of the brain stem in 9 cases and temporal necrosis in 4 cases. The evolution is favorable after corticosteroid therapy in 6 patients and stationary in 9 patients.

Conclusions:: Imaging has a major role in the diagnosis of neurological complications of radiotherapy. However, MRI remains nonspecific and is the dynamic study of parenchymal brain perfusion which will allow one to distinguish between radionecrosis and tumor recurrence.
Background and Aims:: To identify and validate gray matter volume network in Alzheimer's disease (AD).

Methods:: We used two datasets. Training data were obtained with a 3-Tesla magnetic resonance machine (Trillium Oval, Hitachi) at Tokushima University and comprised 9 AD patients (women, 4; dementia, 7; mild cognitive impairment, 2; age, 66.7 ± 8.8 [mean ± SD] years) with positive amyloid positron emission tomography and 8 age-matched healthy controls (HCs). Validation data were obtained with a 1.5-Tesla machine (Vision, Siemens) in The Open Access Series of Imaging Studies and comprised 12 AD patients (women, 4; dementia, 12; age, 70.0 ± 3.7 years) and 12 age-matched HCs. We applied a principal component analysis-based algorithm, Scaled Subprofile Model, to gray matter volume data produced by voxel-based morphometry.

Results:: We identified a significant pattern from the training data, for which subject expression differed for the two groups (p=0.006; permutation test). It differentiated between the groups with 100% sensitivity and 100% specificity in the training (area under the curve =0.83, p =0.02) and with 83% sensitivity and 91% specificity in the validation (area under the curve =0.85, p =0.003). This network was represented by the principal components 1, 2, and 3 and showed relative decrease in the bilateral hippocampus, inferior temporal gyrus, inferior parietal lobes.

Conclusions:: We identified a AD-related gray matter volume network that captured relevant cortical regions, and validated it using data of a different machine and ethnic group, suggesting generalizability of the findings.
ANTI-GLUTAMATERGIC PROPERTY OF N-ACETYLCYSTEINE (NAC) DOCUMENTED IN VIVO IN THE HUMAN BRAIN USING PROTON MAGNETIC RESONANCE SPECTROSCOPY

Dikoma Shungu
Weill Cornell Medicine, Radiology, New York, United States of America

Background and Aims:: N-acetylcysteine (NAC), a cysteine prodrug and glutathione (GSH) synthesis precursor, is believed to have anti-glutamatergic properties for which direct in vivo evidence is lacking. To search for such evidence, the effect of 4 weeks of NAC supplementation on glutamate (Glu) and GSH levels was assessed in this study in vivo in the human brain using $^1$H magnetic resonance spectroscopy (MRS).

Methods:: Study participants consisted of 12 patients with chronic fatigue syndrome (CFS) and 12 healthy volunteer (HV) subjects. Each participant underwent baseline MRS scans (Fig. 1), and then was treated with 1800mg NAC/day for 4 weeks. After 4 weeks, $^1$H MRS scans were repeated to determine the effect of NAC supplementation on cortical Glu and GSH levels.

Results:: See Figure 2: At baseline GSH was 17% lower in CFS than HV (p=.04). Following 4 weeks of NAC treatment, GSH rose and normalized in CFS (p=.42), but was unchanged in HV (p=.33). Glu did not differ between groups at baseline (p=.24), but decreased in both CFS (p=.02) and HV (p=.04) after 4 weeks of NAC.

Figure 1
Conclusions:: Four weeks of NAC led to elevation of GSH levels in CFS only, while decreasing Glu levels in both CFS and HC, in support of NAC as an anti-glutamatergic agent. The concerted elevation of GSH and decrease of Glu suggest (Fig. 3) that NAC modulates Glu levels by deacetylating to Cys, whose bioavailability thus increases. Cys then combines with Glu to initiate GSH synthesis. Consistent with this study, the net effect is a decrease of total Glu.

Figure 2

Conclusions:: Four weeks of NAC led to elevation of GSH levels in CFS only, while decreasing Glu levels in both CFS and HC, in support of NAC as an anti-glutamatergic agent. The concerted elevation of GSH and decrease of Glu suggest (Fig. 3) that NAC modulates Glu levels by deacetylating to Cys, whose bioavailability thus increases. Cys then combines with Glu to initiate GSH synthesis. Consistent with this study, the net effect is a decrease of total Glu.
levels.

Figure 3
Background and Aims:: Automated brain volume analysis from MRI images, is gaining an important role in computer-aided diagnosis. This study compares the volumes of brain segments that measured by two automated brain analysis software: NeuroQuant and volBrain. The aim is to investigate the quantitative and qualitative reliability of automated brain analysis.

Methods:: We compared same brain segment volume measurements, from 45 patients, that calculated with both NeuroQuant and volBrain software. The statistical two-tailed unpaired t-test method used to determine if there is a significant difference on the same segment measurements performed from each software. Additionally, least square method used, to provide any evidence of linear correlation between them. In a case of extreme difference, manual volume measurement of a segment was performed, with JIM8 software.

Results:: From the comparison of brain segments volumetric measurements made by NeuroQuant and volBrain, the differences for the Intracranial Cavity considered extremely significant ($P=0.0001$), the Whole Brain considered not significant ($P=0.4690$), Cerebellum considered not significant ($P=0.2730$), White Matter considered quite significant ($P=0.0334$), Amygdala considered extremely significant ($P=0.0001$), Hippocampus considered not significant ($P=0.2332$), Putamen considered extremely significant ($P=0.0001$), Thalamus considered extremely significant ($P=0.0001$). In most cases strong linear correlation between the two software measurements found.

Conclusions:: The unexpected significant differences found in some segments raised questions about the reliability of automated volume analysis as a quantitative tool. Strong linear correlation of the volumes presents that both software finally provide good qualitative information on brain structures, which is an important factor for computed aided diagnosis.
Background and Aims:: We report a case of a young female with recurrent stroke-like episodes who developed disabling cerebral infarction which, after extensive aetiological investigation, was found to be caused by internal carotid artery (ICA) vasospasm. This rare condition is difficult to diagnose but has treatment implications and should be considered in the differential for idiopathic carotid territory stroke in young patients.

Methods:: A single case report.

Results:: A 32 year-old woman presented following a 5 year history of recurrent episodic hemiparesis affecting either side, and recurrent unilateral carotid watershed territory infarctions affecting both hemispheres. On this occasion she had presented with fluctuating consciousness, limb jerking and left hemiparesis. CT carotid angiography demonstrated bilateral ICA stenosis (figure 1: A,B), initially reported as acute bilateral dissection. Subsequent MR angiographic imaging revealed dynamic changes in left ICA stenosis (figure 1: C,D). Repeat CT angiogram 1 month later showed patent carotids bilaterally (figure 1: E,F). A diagnosis of recurrent ICA vasospasm was made. Multiple vasodilatory treatments were trialled without success in preventing future episodes. She underwent unilateral thoracic sympathectomy of the most symptomatic side, with initial prolonged resolution of events. Subsequent recurrent events have been treated with corticosteroids.
Conclusions:: Spontaneous vasospasm of the extracranial ICA has been rarely reported as a cause of stroke. Diagnosis is reliant on early and repeated angiographic studies. The pathophysiology has been postulated to be migraineous, or related to ICA sympathetic hypersensitivity. Optimal management remains uncertain for this rare condition.
A PRIMARY STUDY OF TRPM2 ON SH-SY5Y CELL INJURY AFTER OGD/R

Xinrui Li, Fei Yu, Dongya Huang
Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China, Department Of Neurology, Shanghai, China

Background and Aims:: The role of TRPM2 in cerebral ischemia/ reperfusion (I/R) injury is gaining increasing attention in research, but the underline mechanism remains unclear. The purpose of our study was to investigate the role of TRPM2 in SH-SY5Y cell injury induced by I/R and its time points of effect.

Methods:: SH-SY5Y cells were subjected to oxygen-glucose deprivation/reperfusion (OGD/R) to mimic cerebral I/R injury in vitro. Cell morphology, viability and apoptosis were detected by histology, Cell Counting Kit-8 assay and flow cytometry, respectively at different time points after OGD/R. Expression of TRPM2 were measured by quantitative real-time PCR and Western blotting analysis.

Results:: Our data showed that SH-SY5Y cell viability was significantly decreased at OGD 6h (P<0.05). Cell viability was the lowest at OGD6h/R3h (P<0.05). Cell apoptosis rate increased the most at OGD 6h (P<0.05). After reperfusion, cell apoptosis rate was the highest at OGD6h/R3h (P<0.05). The expression level of TRPM2 reached its peak at OGD 6h. TRPM2 was positively correlated with cell apoptosis rate (r=0.9114, P<0.05), and was negatively correlated with cell viability (r=-0.9973, P<0.05) within OGD6h. During reperfusion, TRPM2 was positively correlated with cell apoptosis rate (r=0.9947, P<0.05), and was negatively correlated with cell viability (r=-0.9361, P<0.05) within R3h. Parallelly, TRPM2 gene and protein expression were the highest at OGD 6h/ R 3h (P<0.05).
Conclusions:: TRPM2 expression was upregulated in OGD/R conditions with peak at OGD6h/R3h. TRPM2 was positively correlated with cell apoptosis within R3h. We speculate that TRPM2 may play a key role in delayed cell injury caused by OGD/R.
USE OF NON-CONTRAST ENHANCED T1-WEIGHTED THREE-DIMENSIONAL FAST-SPIN ECHO IMAGING FOR THE EVALUATION OF INTRACRANIAL VASCULAR STENT PLACEMENT

Hiroyuki Mizuno, Masanori Aihara, Koji Sato, Chikashi Negishi, Yuhei Yoshimoto
Gunma University Graduate School of Medicine, Department Of Neurosurgery, Maebashi, Gunma, Japan

Background and Aims:: Evaluation of intracranial stent placement by magnetic resonance imaging suffers the problems of signal artifacts during time-of-flight magnetic resonance angiography (TOF-MRA). Therefore, angiographic examination is required for detailed intravascular assessment of the stent placement site. Recently, three-dimensional T1-turbo spin echo (3D-TSE) has been developed for evaluation of carotid artery stent placement. We investigated the use of the 3D-TSE imaging method for the evaluation of intracranial vascular stent placement.

Methods:: The subjects consisted of nine patients who underwent intracranial vascular stent placement from April 2015 and December 2019. Postoperatively, the lumens of the placed stents were measured by TOF-MRA, digital subtraction angiography (DSA), and 3D-TSE imaging. Analysis was performed by type of stent and placement site.

Results:: The stents used were Neuroform Atlas (3 patients), LVIS (3 patients), LVIS Jr (2 patients), and Integrity (1 patient). TOF-MRA of the stent placement site showed defects in the image or poor visualization in all nine patients, whereas 3D-TSE imaging visualized the lumen at the stent indwelling site in all patients. The blood vessel diameter measured by the DSA and 3D-TSE imaging exhibited positive correlations regardless of the stent type and placement site.

Conclusions:: 3D-TSE imaging allows visualization of the lumen of the site of an intracranial vascular stent, regardless of the type of stent or the vessel. Thus, this method may be useful for evaluating the vascular lumen of a lesion.
Background and Aims:: Neurological complications of the peripheral nervous system are frequent in people living with HIV and neuromuscular pathology is associated with significant morbidity. The purpose of this study was to describe the clinical profile of people living with HIV suffering from peripheral neuropathy (PN) in Lubumbashi, Democratic Republic of Congo.

Methods:: This is a cross-sectional study at the Centre d’Excellence VIH/Sida of the University of Lubumbashi for a period of one year. A total of 101 people living with HIV were selected. Our analysis was essentially clinical. To refine the diagnosis, we used the DN4 Assessment Tool (diagnosis of neuropathic pain) and the Visual Analogue Scale (evaluation of the severity of pain).

Results:: Of a total of 3237 people living with HIV followed, 101 presented the PN, a prevalence of 3.12%. 53.3% of patients had an abolition of the deep tendon reflexes of the lower limbs and 77.89% have a ‘socks and gloves’ hypoesthesia. 80% of patients consulted for pains of lower limbs, 25% presented an amyotrophy of the lower limbs and about 3.6% have a real difficulty to walk. The totality of the patients had a score greater than or equal to 5 out of 10 at the Visual Analogue Scale. The assessment of neuropathic pain using the DN4 Assessment Tool showed that 94.5% of patients had a score greater than or equal to 4.

Conclusions:: The PN alters the quality of life of people living with HIV and decreases adhesion to antiretroviral therapy.
Efficacy and Safety of Eculizumab in Patients with Treatment-Refractory Anti-Acetylcholine Receptor Antibody-Positive Generalised Myasthenia Gravis Previously Treated with Rituximab

Francesco Patti¹, Tahseen Mozaffar², Marcus Yountz³, Fanny O'Brien⁴, Zaeem Siddiqi⁵
¹University of Catania, Department Of Medical And Surgical Sciences And Advanced Technologies "g.f. Ingrassia", Catania, Italy, ²University of California Irvine, Als And Neuromuscular Center, Irvine, United States of America, ³Alexion Pharmaceuticals, Inc, Clinical Development, Neurology, Boston, United States of America, ⁴Alexion Pharmaceuticals, Inc, Biostatistics, Boston, United States of America, ⁵University of Alberta, Department Of Medicine, Edmonton, Canada

Background and Aims:: The phase 3 REGAIN study (NCT01997229) and its open-label extension (OLE; NCT02301624) evaluated eculizumab’s efficacy and safety in patients with anti-acetylcholine receptor antibody-positive refractory generalised myasthenia gravis (gMG). Although not approved for MG, rituximab has been used in such patients. The aim of this secondary analysis was to assess response to eculizumab in individuals with gMG previously treated with rituximab. Eculizumab is not reimbursed for neurology indications in Italy as of April 2021.

Methods:: Baseline disease characteristics, safety and response to eculizumab were compared in patients who had previously received rituximab (prior-rituximab group) and those who were rituximab naïve. Rituximab was prohibited within 6 months before screening or during REGAIN/OLE.

Results:: Of 125 patients, 14 had previously received rituximab (placebo, n=7; eculizumab, n=7). Patients with and without rituximab exposure had comparable mean baseline MG-Activities of Daily Living (MG-ADL) total scores (10.6 vs 10.1) (Table 1). A higher proportion of patients in the prior-rituximab group had used ≥4 immunosuppressants (57.1% vs 16.2%) (Table 1). Patients who had received 18 months’ eculizumab treatment experienced similar clinical improvements, regardless of previous rituximab administration (mean [standard deviation] change in MG-ADL total score from REGAIN baseline to OLE week 52, −3.8 [3.54] in prior-rituximab group [n=6] and −5.3 [3.49] in rituximab-naïve patients [n=43]). Eculizumab safety was consistent with its known profile.
Conclusions:: Although patients in the prior-rituximab group had more refractory disease, they experienced similar long-term clinical improvement with eculizumab to rituximab-naïve patients. Updated data will be presented. This study was funded by Alexion Pharmaceuticals, Inc.

Background and Aims:: Few data are available regarding the epidemiology of Myasthenia Gravis (MG) in Italy during the most recent years. The study aims to evaluate the MG prevalence in a real-world setting and to estimate the number of patients currently living with MG in Italy.

Methods:: We conducted an observational retrospective study based on administrative databases covering around 11.4 million subjects across Italy. Patients were included between 01/2011-12/2018 (inclusion period) by hospitalization discharge diagnosis for MG, or by active exemption code for MG or by presence of ≥1 pyridostigmine prescription. Prevalence was calculated on patients alive at 01/01/2018 and stratified by gender. Data were reproportioned to the Italian Population.

Results:: From preliminary data, we identified 4,078 MG patients (mean age 61.3 years, 46.2% male), mostly by pyridostigmine prescription (72%), followed by exemption code (15%) and hospitalizations (13%). Among the latter, 65.8% was hospitalized for MG without exacerbation, 33.8% with exacerbation. MG prevalence was 28.9 patients per 100,000 subjects (27.1 cases per 100,000 males, 30.6 cases per 100,000 females) (Figure 1). Data projected to the Italian population estimated a total of 17,480 patients (7,972 males and 9,508 females) affected by MG.

Conclusions:: Preliminary results show an MG prevalence at 01/01/2018 of 28.9 patients per 100,000 subjects, slightly higher compared to previous Italian studies. However, our study is consistent with recent evidence suggesting an increase in MG prevalence. We estimate 17,480 MG patients in Italy, which is in line with current estimates of 15,000-20,000 MG patients.
LAMBERT EATON MYASTHENIC SYNDROME MASQUERADING AS MYOPATHY IN ASYMPTOMATIC LUNG MALIGNANCY

Nijanth Manohara Raj, Koh Yeow Hoay, Shahul Harmeed
National Neuroscience Institute, SGH, Singapore, Neurology, Singapore, Singapore

Background and Aims:: Introduction: Lambert-Eaton Myasthenic Syndrome (LEMS), is a rare disorder characterized by antibodies against presynaptic voltage-gated calcium channels in the neuromuscular junction. It is regarded as a paraneoplastic syndrome, as most patients have an underlying malignancy, commonly a small-cell lung cancer (SCLC).

Methods:: Case Presentation: 59-year-old Malay male, a 30 pack-year smoker with no past medical history, presented with 3-week history of progressive proximal weakness affecting ambulation, lethargy, and dry mouth with no respiratory complaints or constitutional symptoms. Examination revealed proximal weakness, global hyporeflexia, and waddling gait. Significant incremental response with high-frequency repetitive nerve stimulation (RNS) suggested a presynaptic neuromuscular junction disorder. CT Thorax revealed a 3cm right lung mass with biopsy confirming small-cell carcinoma. Anti-Voltage-gated Calcium-channel antibody was positive. He received intravenous Immunoglobulin therapy and 3,4-diaminopyridine for LEMS, chemotherapy for malignancy, and rehabilitation. During follow-up visits, he showed marked improvement.

Results:: Discussion: LEMS is a complex and rare paraneoplastic syndrome that presents with proximal muscle weakness, hyporeflexia, and autonomic disturbances. LEMS is more common in males with smoking being a known major risk factor for lung cancer. LEMS is predominantly associated with SCLC and in gastric cancer, lymphosarcoma, malignant thymoma, breast & colon cancer. Cornerstone of diagnosis is clinical suspicion with nerve conduction studies and Anti-Voltage-gated Calcium-channel antibodies which are pathognomonic for LEMS.

Conclusions:: While evaluating proximal muscle weakness, paraneoplastic syndrome LEMS as a cause should be suspected, even without respiratory or constitutional symptoms, especially in smokers. RNS to confirm LEMS and malignancy screening would enable early pathohistological-detection and treatment of underlying cancer.
Background and Aims:: Myasthenic crisis (MC) affects 15-20% of patients with myasthenia gravis (MG), requiring mechanical ventilation (MV) and intensive care unit (ICU) assistance. Patients may develop more than one crisis during life. Aim of the study was to assess whether patients with multiple MC have a worse prognosis.

Methods:: We identified 90 patients referred to Neurology Department in Modena presenting MC between January 2000 and September 2020.

Results:: Out of 90 patients, 29 cases (32%) had more than one episode of MC, ranging from 2 (20 patients) to 4 episodes (2 patients). In the group of patients with multiple MC, 18 (62%) were females and 17 (59%) had a late onset MG. Anti-AChR antibodies were detected in 24 (83%) and one exhibited anti-MUsK antibodies. There were no significant differences between patients with one or more MC in respect of gender, age at onset or anti-AChR-Ab titer at baseline, whereas patients with recurring MC were significantly more affected by multiple (>3) comorbidities (p=0.04). Fifty per cent of patients with relapsing MC needed invasive MV. Patients with multiple MC did not show higher risk for need of MV or tracheostomy due to weaning failure, whereas they exhibited significantly longer than 7 days ICU stay (p=0.01). Out of the 4 deaths for MC, 3 patients had more than one MC.

Conclusions:: MG patients with more than one MC do not exhibit higher risk of MV or tracheostomy, but they may be at risk of longer ICU stay.
AN UNUSUAL CASE OF BULBAR PALSY PLUS/ASMAN OVERLAP

Alfredo Granata, Stefano Tonini, Elena Allegri, Francesca Cioli, Elena Coco, Tiziana Tassinari
S. Corona hospital - ASL2 Liguria, Neurology, Pietra Ligure, Italy

Background and Aims:: Bulbar palsy plus (BPp) is a variant of Guillain Barré syndrome (GBS), characterized by bulbar symptoms and others cranial nerves deficits or ataxia, without limbs or neck weakness, usually associated with presence of GQ1b and G11a antibodies.

Methods:: We describe a case of BPp overlapped by a sensory-motor axonal neuropathy (ASMAN).

Results:: A 62 years old man, without relevant medical history, was admitted to Emergency Room for dysphagia, voice reduction and paraesthesia to distal extremities started 4 days earlier, after a diarrhoeic episode. Neurological examination showed absent tendon reflexes, mild ophthalmoparesis and asymmetrical palpebral ptosis. Cerebrospinal fluid (CSF) analysis and neurophysiological study (NPS) were normal, showing only absent H reflex. Repetitive nerve stimulation at low and high frequencies was normal. Intravenous immunoglobulins 0.4 gr/kg die for 5 days were started. Subsequently he developed tetra-hyposthenia and worsening of bulbar function, complete gaze palsy and bilateral ptosis, requiring mechanical ventilation and nasogastric tube. 15 days after symptoms onset, CSF analysis showed albuminocytological dissociation and NPS showed diffuse sensory-motor axonal neuropathy. Initially no serum anti ganglioside were detected, but 15 days after GT1a, Gq1b, GD2 and GD3 IgG were positive. RT-PCR and serology for SARS-COV 2 were negative. Campylobacter search was negative. About 15 days after onset he started recovery and at 50 days he was discharged from rehabilitative ward.

Conclusions:: BPp is recently recognised as a rare GBS variant, such as Miller Fisher syndrome (MFS) or pharyngeal-cervical-brachial (PCB) variant. Overlap between AMSAN and the other variants was already described. This is an interesting case of BPp/ASMAN overlap syndrome.
NXP2-POSITIVE DERMATOMYOSITIS: A CHALLENGING SUBGROUP OF INFLAMMATORY MYOPATHIES

Giulio Gadaleta¹, Chiara Brusa², Manfredi Ferraro³, Loredana Chiadò-Piat¹, Tiziana Enrica Mongini¹
¹AOU Città della Salute e della Scienza di Torino - Molinette Hospital, Neuroscience, Turin, Italy, ²Children's Hospital Regina Margherita, Child Neuropsychiatry, Turin, Italy, ³G.Giglio di Cefalù Foundation, Neurology, Cefalù, Italy

Background and Aims:: Dermatomyositis (DM) represents an idiopathic inflammatory disorder with distinctive skin and muscle involvement. NXP2 (Nuclear Matrix Protein) antibodies positivity defines an uncommon subgroup of patients, with variable clinical outcomes.

Methods:: We describe four cases of NXP2 positive DM diagnosed at Neuromuscular Centre in Torino (Italy), with a long-term follow up (up to 5 years). Age of patients ranged from 30 to 69 years; all of them had a severe clinical involvement, with proximal muscle weakness, marked persistent skin involvement and high CK levels.

Results:: A 46-year-old man with severe persistent generalized weakness and dysphagia, requiring percutaneous nutrition, showed a good response to Rituximab therapy, after multiple steroids, IVIG, Methotrexate and Azathioprine unsuccessful trials. A 69-year-old woman with extended multifocal areas of myositis ossificans with intolerance to steroid therapy reached a good control of clinical manifestations after repeated courses of Rituximab. A 30-year-old woman diagnosed with dermatomyositis and lupus panniculitis is now in remission with Azathioprine and low doses of Prednisone after several trials of higher doses of steroids, Methotrexate and Mycophenolate; lastly, a 56-year-old woman with a predominant cutaneous dermatomyositis had a sustained improvement with oral Prednisone and Azathioprine.

Conclusions:: In the NPX2 positive subgroup of DM we observed a clinical course generally more severe than in other DM cases, especially for skin and subcutaneous involvement. In three out of four patients the combination of multiple immunomodulatory agents was necessary to obtain a remission; in two of them only Rituximab therapy caused a remission.
CASE REPORT OF SOD1 ALS PRESENTING WITH PROMINENT HEARING IMPAIEMENT

Piyush Anshu, Dnyaneshwar Jadhav, Shruti Agrawal, Vruj Durge, Neeraj Jain, Sangeeta Ravat
Seth GSMC and KEM hospital Mumbai, Neurology, Mumbai, India

Background and Aims:: Amyotrophic lateral sclerosis is the neurodegenerative disease involving both upper and lower motor neurons. Familial amyotrophic lateral sclerosis (fALS) accounts for almost 10% of all cases of ALS. It is a gradually progressive disease with duration of more than 10 years and occurrence of atypical features such as pain, paraesthesia or urgency micturition. In case of ALS presenting with deafness, riboflavinopathies and madras motor neuron disease must be suspected from Indian subcontinent. Evaluating for ALS genes is important as SOD1 mutation can present with predominant deafness.

Methods:: A 44 year old female born out of nonconsanguineous marriage with 2 years history of decreased hearing and 1 year history of progressive bulbar complaints in form of episodes of choking and nasal regurgitation with spastic dysarthria. She had asymmetric weakness affecting upper limbs distal followed by proximal. On examination there was thinning noticed predominantly affecting thenar muscles, forearm extensors and triceps and biceps. Profuse fasciculations, spasticity with brisk reflexes and upgoing plantar was noticed involving all four limbs. Spastic dysarthria with tongue atrophy with prominent fasciculations were seen.

Results:: Electrophysiological studies were suggestive of active and chronic denervation affecting cervical, thoracic and bulbar segments. Pure tone audiometry showed bilateral sensorineural hearing loss. Paraneoplastic and other secondary causes were ruled out. Exome panel revealed missense mutation in exon 3 of SOD1 gene which was reported to be pathogenic.

Conclusions:: This case highlights that SOD 1 mutation ALS should be considered in differential diagnosis of patients presenting with progressive hearing loss with bulbar onset ALS.
LGMD LIKE PRESENTATION OF MARINESCO SJOGREN SYNDROME: ATYPICAL PRESENTATION OF RARE DISEASE

Dnyaneshwar Jadhav, Piyush Anshu, Shruti Agrawal, Sangeeta Ravat, Neeraj Jain
Seth GSMC and KEM hospital Mumbai, Neurology, Mumbai, India

Background and Aims:: Marinesco-sjogren syndrome is a rare, autosomal recessive disorder. Mutation in SIL-1 gene account for majority of cases. It commonly presents with cerebellar ataxia, congenital cataracts, myopathy and mental retardation. Skeletal abnormalities including short stature, dysarthria, nystagmus and hypergonadotropic hypogonadism are also occasionally observed. Myopathic presentation without ataxia is rare. We are reporting this rare LGMD like presentation of genetically proven marinesco sjogren syndrome as it is probably the first case report after thorough review of literature.

Methods:: A 26-year-old female born out of non-consanguineous marriage, presented with purely motor symmetrical predominantly limb-girdle weakness started at the age of 11-12 years without any history of ataxia. She was operated for bilateral cataracts at 3 years of age and had primary amenorrhea. Birth and developmental history revealed delayed cry and mild delayed motor milestones. Family history revealed history cataract surgery at age of 6 year with limb-girdle weakness in 2nd elder sister. General examination showed microcephaly. Neurological examination showed hypotonia, proximal more than distal weakness in all the four limbs with preserved deep tendon jerks. Cerebellar signs were absent.

Results:: On evaluation, Serum creatine kinase was elevated, electrophysiology showed myopathic units, and IQ was 69 %. FSH, LH were elevated and MRI brain showed mild cerebellar atrophy. Genetic studies showed homozygous mutation in SIL-1 gene at exome 3 which was consistent with marinesco-sjogren syndrome.

Conclusions:: This case highlights that Marinesco-sjogren syndrome should be considered in differential diagnosis of patients presenting with LGMD phenotype, cataracts and hypergonadotropic hypogonadism even without ataxia.
REST OR 30 MIN WALK AS EXERCISE INTERVENTION (RESTOREX) IN MYASTHENIA GRAVIS: A RANDOMIZED CONTROLLED TRIAL

Usha Misra¹, Jayantee Kalita², Varun Singh³, Aditya Kapoor⁴, Abhilasha Tripathi², Prabhaker Mishra⁵
¹Vivekananda Polyclinic and Institute of Medical Sciences, Neurology, LUCKNOW, India, ²SANJAY GANDHI POST GRADUATE INSTITUTE OF MEDICAL SCIENCES, Neurology, LUCKNOW, India, ³Institute of Medical Science, Banaras Hindu University, Neurology, Varanasi, India, ⁴SANJAY GANDHI POST GRADUATE INSTITUTE OF MEDICAL SCIENCES, Cardiology, LUCKNOW, India, ⁵SANJAY GANDHI POST GRADUATE INSTITUTE OF MEDICAL SCIENCES, Biostatistics, LUCKNOW, India

Background and Aims:: There is lack of evidence about the usefulness of exercise or rest in myasthenia Gravois (MG). The study is aimed to evaluate the efficacy and safety of exercise or rest in MG.

Methods:: In a single center open labeled randomized controlled trial, the patients with mild to moderate MG were randomized to 30 minute walk or rest in addition to the standard treatment. The primary endpoint was 50% improvement in the MG Quality of Life (MG-QOL15), and secondary endpoints were change in the Myasthenic Muscle Score (MMS), MG Activities of Daily Living (MGADL), grip strength, dose of acetylcholine esterase inhibitor and prednisone, 6 minute walk test (6MWT), decrement in trapezius on low rate repetitive nerve stimulation test and adverse events. The outcomes were defined at three months, by more than 50% improvement in these outcome parameters.

Results:: Forty patients with MG were randomized to exercise or rest arm. The two arms were matched for demographic and clinical parameters. The patients in the exercise arm had significantly better QOL evidenced by MG-QOL15 (P=0.02). The secondary end points, distance covered in 6MWT (P=0.007) was also better in the exercise arm without any adverse event.

Conclusions:: Regular exercise for 30 min in mild and moderate MG improves quality of life and walking distance compared to rest, and is safe.
PATISIRAN IN HATTR AMYLOIDOSIS: 6 MONTHS LATENCY BEFORE EFFICACY

Luca Gentile¹, Massimo Russo¹, Marco Luigetti², Ilenia Arimatea¹, Mario Sabatelli², Antonio Toscano¹, Giuseppe Vita¹, Anna Mazzeo¹
¹AOU Policlinico G.Martino, Clinical And Experimental Medicine, Messina, Italy, ²Fondazione Policlinico A. Gemelli IRCCS, Neurology, Roma, Italy

Background and Aims:: Hereditary amyloidosis associated with mutations in the transthyretin gene (hATTR) is a progressive devastating disease, with fatal outcome occurring within ten years after onset. In recent years, TTR gene silencing therapy appeared as a promising therapeutic strategy, showing evidence that disease progression can be slowed and perhaps reversed.

Methods:: We report here 18 subjects affected by hATTR amyloidosis treated with patisiran, a small interfering RNA acting as TTR silencer, and evaluated with PND score, NIS and NIS-LL scale, and Norfolk QOL-DN questionnaire at baseline and then every 6 months.

Results:: A global clinical stabilization was observed for the majority of the patients, with mild-moderate improvements in some cases, even in advanced disease stage (PND score >2).

Conclusions:: Analysis of NIS, NIS-LL and Norfolk QOL-DN results and PND score variation suggest the possible presence of a 6-month latency period prior to benefit of treatment becomes evident.
GENOTYPE-PHENOTYPE CORRELATION IN FSHD-LIKE PATIENTS WITH UNCOMMON FEATURES

Lucia Ruggiero1, Maria Francesca Di Feo2, Francesco Sera3, Cinzia Battio2, Valentina Salsi2, Giulia Ricci4, Rossella Tupler2
1 University of Naples Federico II, Department Of Neuroscience And Reproductive And Odontostomatological Sciences, Napoli, Italy, 2 University of Modena and Reggio Emilia, Department Of Biomedical, Metabolic And Neural Sciences, Modena, Italy, 3 University of Florence, Department Of Statistics, Computer Science And Applications "g. Parenti", Firenze, Italy, 4 University of Pisa, Department Of Clinical And Experimental Medicine, Pisa, Italy

Background and Aims:: Since the first descriptions of the FSHD phenotype, an interesting range of uncommon features have been described. This clinical variability is captured by the Comprehensive Clinical Evaluation Form (CCEF). We investigate the genotype-phenotype correlation in FSHD-like patients (D1 patients on the basis of CCEF) and the distribution of clinical categories in D1 families.

Methods:: The study was performed on the subjects accrued through the Italian National Registry for FSHD (INRF), from January 2016 to October 2019. The cohort selected includes all subjects, carrying or not a D4Z4 allele of reduced size, assessed with clinical category D1.

Results:: We identified 198 D1 subjects (101 females), 176 were probands and 22 relatives. Mean age at onset was 39.8; mean FSHD score was 6.2 (SD 2.8) in probands and 5.3 (SD 2.7) in relatives (p value = 0.2128) and no significant differences were detected between males and women in FSHD score. No particular size of DRA prevails among subjects assessed with category D1. No significant clustering of any uncommon feature was found. 61.3% of the relatives of D1 patients were asymptomatic (category C).

Conclusions:: D1 subjects are myopathic subjects with the co-presence of genetic and environmental factors and the D4Z4 reduced allele may be one of the various factors contributing at the clinical picture. The probability for relatives of D1 probands to develop a myopathic phenotype is low. This observation is highly relevant for clinical management because additional parameters to be used in clinical practice for diagnosis ad interpretation of the clinical phenotype.
THE LIGHT AT THE END OF THE TUNNEL: MNGIE BETWEEN LIVER TRANSPLANTATION AND BONE MARROW TRANSPLANT.

Hamad Aldraye
KFSHRC, Neurosciences, Riyadh, Saudi Arabia

Background and Aims:: Mitochondrial neurogastrointestinal encephalomyopathy (MNGIE) an autosomal recessive disease caused by loss-of-function mutations in the nuclear gene coding for the cytosolic enzyme thymidine phosphorylase. New Research that has been published in the past few years are recommending more and more that HSCT and liver transplantation is a therapy of choice if the patient is found early and has no complications to eliminate MNGIE's manifestations and provide our patients with a quality of their lives. Here we review the literature and efforts done to further prove the efficacy and safety of transplantation (whether bone marrow or liver) for MNGIE condition.

Methods:: A systemic review through the databases of Pubmed and Google Scholar (articles selected for the review/articles found on pubmed: 19); Bone marrow Transplantation 13/19 AND Liver Transplantation 6/19.

Results:: Review of cases that had the opportunity to receive either a bone marrow or liver transplant prior to 2010 were unfortunately presenting late and in poor medical condition or were not in the most optimal transplant conditions that are available with today's quality of care and transplantation services and breakthroughs. Newer published cases prove that improvement of the transplantation process and care shows promising results. However, it is too early to judge with the short follow up dates.

Conclusions:: The limited number of published cases and the expert opinions regarding the bone marrow and liver transplantation as a potential management for MNGIE proves to be a frontier worth looking into and advancing the limits of management provided to our patients.
A CASE OF LATE ONSET SEVERE NEUROLOGICAL IMMUNE-RELATED TOXICITY DUE TO
NIVOLUMAB TREATMENT IN A PATIENT WITH METASTATIC MELANOMA

Ginevra Tecilla¹, Sabrina Rossi², Arianna Braccia³, Francesca Carta⁴, Domenico Fiorillo³, Valeria Tognoli⁵
¹Clinical Neurology, University Of Ferrara, Ferrara, Italy, ²Hospital of Ferrara, Neurology, Ferrara, Italy, ³University of Ferrara, Sant'Anna Hospital, Clinical Neurology, Ferrara, Italy, ⁴Azienda ospedaliera universitaria Sant'Anna (Ferrara), Neurologia, Ferrara (FE), Italy, ⁵Ferrara Hospital, Neurology, Ferrara, Italy

Background and Aims:: Even though rare, neurological immune-related toxicity due to immune checkpoint inhibitors (ICIs) therapy (e.g. Nivolumab) is described¹. We report an uncommon case of late-onset Nivolumab-related neurological toxicity.

Methods:: A 65-year-old woman was diagnosed with metastatic melanoma and treated with Nivolumab with full remission. After three years of treatment, she reported subacute distal lower limbs paresthesia and hypopallesthesia, followed by progressive paraparesis, dysautonomic failure (severe hypotension, bradycardia episodes), monolateral facial nerve’s peripheral palsy, visual impairment and fluctuating diplopia. Her clinical history was relevant for previous HCV-hepatitis.

Results:: The following investigations were performed. (1)EMG/ENG/SFEMG/RNS/SSR: severe demyelinating multifocal sensory-motor and dysautonomic polyneuropathy with cranial involvement; increased jitters, pathological blocks; (2)VEP: abnormalities bilaterally; (3)Brain/spinal cord MRI: no relevant outcomes; (4)CSF: albumin-cytologic dissociation and rare lymphocytes; (5)Anti-AChR antibodies: absent. (6)Biochemical investigations (anti-onconeural antigens and anti-ganglionic AchR antibodies, diabetes, autoimmune screening, infectious diseases) were unremarkable. (7)Instrumental tests excluded oncological relapse or myositis. Corticosteroid oral treatment generated no benefits. Plasmapheresis led to an initial clinical stabilization, followed by a relapse. An overall neurophysiological and clinical improvement was obtained with IGIV.

Conclusions:: Immune-related adverse events due to ICIs, including neuromuscular disorders (MG, myositis, GBS, CIDP), usually occur after 3-6 months of therapy¹. Our case presented an unusual late onset. This case is characterized by multifocal demyelinating polyneuropathy with associated dysautonomic component (rarely described before²) and concomitant signs of neuromuscular junction disorder. Neuromuscular disorders should be considered when deciding for starting ICIs administration. A prompt diagnosis is essential to set up an effective immunomodulant therapy. ¹Möhn-et-al-Journal-of-Clinical-Medicine-(2019),8,1777;https://doi:10.3390/jcm8111777 ²Gao-et-al-Journal-for-Immuno-Therapy-of-Cancer-(2019),7,262;https://doi.org/10.1186/s40425-019-0748-0
COGNITIVE FUNCTION ASSESSMENT IN PATIENTS WITH MYOTONIC DYSTROPHY TYPE 2

Stojan Peric, Ilija Gunjic, Biljana Salak-Djokic, Neda Delic, Ivo Bozovic, Ivana Basta, Vidosava Rakocevic-Stojanovic
University Clinical Center of Serbia, Neurology Clinic, Belgrade, Serbia

Background and Aims:: Myotonic dystrophy type 2 (DM2) is an autosomal dominant, slowly progressive, multisystemic, late-onset disease. Previous research showed impaired cognitive function in DM2. The aim of our study was to assess cognitive functions and the presence of dementia in a large cohort of DM2 patients using an extensive battery of neuropsychological tests.

Methods:: The study included 76 patients with genetically confirmed DM2. Raven Standard Progressive Matrices (RSPM) were used to assess general intellectual level. MMSE and Addenbrooke’s tests were used as a cognitive screening. Patients underwent neuropsychological testing in following domains: memory, language, attention, executive and visuospatial functions.

Results:: Only 6% of DM2 patients achieved a below-average score on RSPM. The presence of cognitive decline was found in 6% of patients according to MMSE and 26% of patients according to ACE-R. Regarding individual neuropsychological domains, the worst results were observed in the visuospatial and language areas with around 50% of patients being one standard deviation below the norm, followed by executive dysfunction. Twenty (26%) patients had impairment of at least 2SD below the norm on at least 2 tests from 2 different domains. Even more, fifteen (20%) patients and their relatives reported a significant impact of cognition on daily activities. Age at testing and at disease onset, education, and muscle weakness correlated with cognitive findings.

Conclusions:: DM2 patients frequently had visuospatial, language, and executive function impairments, while the general intellectual level was preserved. One-fifth of patients had signs of dementia.
A NERVE METASTASIS IN THE BRACHIAL PLEXUS

Wolfgang Grisold¹, Stefan Meng², Ellen Gelpi³, Paata Pruidze²
¹Ludwig Boltzmann Institute for Experimental und Clinical Traumatology, Vienna, Austria, ²Center for Anatomy and Cell Biology, Vienna, Austria, ³Medical University of Vienna, Division Of Neuropathology And Neurochemistry, Department Of Neurology, Vienna, Austria

Background and Aims:: Cancer rarely metastasizes into peripheral nerves. Increasingly imaging and in particular ultrasound allow a precise diagnosis.

Methods:: A tumorous growth was found in the brachial plexus of the body of a patient with a known breast cancer. Body donation to the anatomic institute is the basis of ongoing anatomical studies. Persons can be identified by name, and age, but clinical data are not available. This is why a classical „case report“ is not available. The brachial plexus was examined anatomically by HR nerve ultrasound. Neuropathological examination of the tissue, including immunohistochemistry was performed at the Institute of neurology, of the university of Vienna.

Results:: The exact site of nerve enlargement could be documented by ultrasound, Histology confirmed a local nerve metastasis in the proximal parts of the median nerve, arising from the brachial plexus. Neuropathology showed epi- and perineurial cancer infiltration, compatible with breast cancer (cytokeratin and GATA-3 positive) . Tumorous enlargement of cranial and peripheral nerves in malignancy are caused lymphoma, leukemia, cancer and other malignancies. Peripheral nerve involvement in malignancies ranges from compression to focal invasion, to different types of parenchymatose involvement, which can be diffuse, intra- or extrafascicularly, in the vessel, around the vessel or as a solid metastatic growth. Epineurial and paraepineurial spread can appear. The frequency of nerve metastasis often are underestimated.

Conclusions:: This is a rare observation. Despite the absence of clinical data the identification with HD ultrasound, anatomical preparation and histological evaluation allows a comparison of the evaluation of structures by different methods.
CARPAL TUNNEL SYNDROME: FACTORS INTERFERING WITH THE SURGICAL RESPONSE AND THE SATISFACTION DEGREE OF THE OPERATED PATIENT

Ingrid Goes¹, Alice Duart¹, Dayanne Oliveira², Paulo Correia¹, Lisiane Ferreira³
¹Universidade de Brasília, Faculty Of Medicine, Brasília, Brazil, ²Instituto Hospital de Base do Distrito Federal, Department Of Neurophysiology, Brasília, Brazil, ³Universidade de Brasília, Associate Professor Of The Faculty Of Medicine, Brasília, Brazil

Background and Aims:: The Carpal Tunnel Syndrome (CTS) is the most common compressive mononeuropathy of the upper limbs. Nervous compression may cause functional and motor injuries. The surgical intervention is a highly effective therapeutic option. The aim of this study was to evaluate factors that interfere in the surgical response and the degree of postoperative satisfaction.

Methods:: This research was approved by the Ethics Research Committee (48320815.1.0000.5553). We evaluated 74 patients who underwent surgery for CTS. Factors such as sex, age, body mass index, occupation, comorbidities, lifestyle, and surgical response were studied. If the symptoms persist, the patient’s satisfaction degree was assessed, categorized as dissatisfied and unresponsive to treatment.

Results:: Sixty-eight were women. Mean age of the patients was 48 years. Twenty-three patients were obese. Thirty-one were homemakers or manual workers. Of the 67 patients evaluated, 48 (71.64%) were dissatisfied and categorized as not responding to surgical treatment. Linear regression analysis identified that alcoholism, at the time of surgery, was a significant factor, leading to 3.5 times more complications than in the non-alcoholic group (p = 0.05). In the smoking group, the complication rate was 1.2 times lower (p = 0.1). Other variables studied did not interfere with the surgical response.

Conclusions:: Most patients were categorized as dissatisfied and unresponsive to surgical treatment. The alcoholism was the only factor identified as relevant to the increase in complications. Paradoxically, smoking was configured as a protective factor, which may reflect a bias in the sample selection.
DERMATOMYOSITIS WITH SUPERIMPOSED COVID-19 MYOSITIS

Neeraj Balaini¹, Megha Varshney², Abeer Goe³, Vivek Lal³, Ritu Shree³
¹PGIMER, Chandigarh, Neurology, Chandigarh, India, ²PGIMER, Neurology, Chandigarh, India, ³Postgraduate Institute of Medical Education and Research, Chandigarh, Neurology, Chandigarh, India

Background and Aims:: Background and aims: Covid-19 pandemic has the potential to modify the presentation of neuromuscular disorders. We describe one such patient who had COVID-19 infection along with dermatomyositis. He had typical rash and muscle weakness but also had rhabdomyolysis at presentation and muscle biopsy showed necrotic muscle fibres. He was treated with intravenous steroids and rituximab and showed gradual recovery.

Methods:: We present a case of 16 year old male who presented to us with bodyaches, myalgia, proximal muscle weakness, rash over face and limbs along with fever for 1 month duration. We examined him clinically, investigated accordingly and performed muscle biopsy.

Results:: On clinical examination he had typical rash of dermatomyositis with heliotrope eruption and gottron papules along with proximal muscle weakness, neck and truncal weakness with preserved deep tendon reflexes. CK-NAC was elevated and urine myoglobin was present. EMG was suggestive of myopathic illness and anti Mi-2 beta was positive. Muscle biopsy showed multiple necrotic fibres without increase in inflammatory infiltrate. Intravenous steroids followed by oral steroids along with rituximab was given and he recovered gradually.

Conclusions:: COVID-19 can alter clinical presentation, histopathological findings and prognosis of neuromuscular diseases. We must be cautious in interpretation during ongoing COVID-19 pandemic.
THE INCIDENCE OF MYASTHENIA GRAVIS IN THE REPUBLIC OF MOLDOVA BEFORE AND DURING THE COVID-19 PANDEMIC

Ana-Maria Bubuioc¹, Paolo Emilio Alboini², Maurizio Leone², Vitalie Lisnic¹
¹Nicolae Testemitanu State University of Medicine and Pharmacy, Department Of Neurology, Chisinau, Moldova, ²IRCCS Casa Sollievo della Sofferenza Hospital, Neurology Unit, San Giovanni Rotondo, Italy

Background and Aims:: The aim of this study is to provide an estimated incidence of Myasthenia Gravis (MG) and to describe the pattern of the disease in the Republic of Moldova before and during the COVID-19 pandemic.

Methods:: Multiple sources of cases were explored prospectively and retrospectively during a nationwide study of MG in the Republic of Moldova. The date the SARS-CoV-2 infection (11 March 2020) was declared a pandemic was used as a reference and the clinical features of the new (incident) cases ascertained one year before and one year after that date were compared.

Results:: During the period 11 March 2020 - 11 March 2021, 28 new cases of MG were ascertained yielding a crude incidence rate of 10.6 per million person-years (95% CI 6.7-14.5), 13.1 in women (95% CI 7.1-19.1) and 7.8 in men (95% CI 3-12.6) (F:M ratio of 1.6:1). The mean age of onset was 49.8 years (43.2 in women and 62.7 in men). Only 5 thymectomies were performed. During 11 March 2019 - 10 March 2020, 35 new cases of MG were identified yielding a crude incidence rate of 13.0 per million person-years (95% CI 8.7-17.3), 14.9 in women (95% CI 8.6-21.2) and 10.9 in men (95% CI 5.2-16.6), (F:M ratio of 1.3:1). The mean age of onset was 48.3 years (47.1 in women and 57.2 in men). 17 thymectomies were performed.

Conclusions:: During the COVID-19 pandemic, the incidence of MG was slightly lower than the previous year. This could be due to the fact that patient management and hospital care have been markedly impacted.
REPETITIVE NERVE STIMULATION TEST IN PATIENTS WITH MYASTHENIA GRAVIS

Selenge Enkhtuya, Davaadulam Khutagbaatar, Munkhbayar Rentsenbat
Reflex Neurological Clinic, Neurology, Ulaanbaatar, Mongolia

**Background and Aims:** Myasthenia gravis (MG) is a rare and an autoimmune disease mainly caused by antibodies against the acetylcholine receptor on the postsynaptic membrane at the neuromuscular junction. Localized or generalized muscle weakness is the predominant symptoms. Repetitive nerve stimulation (RNS) confirms diminished neuromuscular transmission. We aimed to study the RNS test in myasthenic patients in Mongolia.

**Methods:** We retrospectively reviewed collected data obtained from myasthenic patients who have undergone examination at our clinic between January, 2016 and February, 2021. RNS test results were also recorded based on electrodiagnostic reports at the time of initial visit to our clinic. We made RNS test in muscles of facialis, accessorius, medianus, and peroneus nerves. A decrement in compound muscle action potential amplitude of ≥10% was considered abnormal. Statistical analysis was performed by using the SPSS, version 21.

**Results:** We surveyed 50 patients with MG; 31 (62.0%) were females and 19 (38.0%) were males. Overall mean age was 35.45±17.74 years (range 2-72). The abnormal response of the amplitude of the compound muscle action potentials was 94.0% in nasalis muscles, 88.0% in trapezius muscles, 58.0% in abductor pollicis brevis muscles and 56.0% in extensor digitorium brevis muscles. RNS test abnormality of abductor pollicis brevis (p=0.003) and extensor digitorium brevis (p=0.003) muscles were significantly associated with generalized MG.

**Conclusions:** RNS test is important role to identify MG in a majority of patients.
AN UNUSUAL PHENOTYPE OF RECESSIVE CONGENITAL MYOPATHY: EXPANDING THE SPECTRUM OF ORAI-1 ASSOCIATED DISORDERS.

Dipti Baskar1, Saraswati Nashi2, Kiran Polavarapu2, Yasha T C3, Rashmi S3, Seena Vengali2, Veeramani Preethish Kumar2, Akshata Huddar2, Gopikrishnan Unnikrishnan2, Gautham Arunachal2, Leena Shingavi2, Mainak Bardhan2, Atchayaram Nalini2

1National Institute of Mental Health and Neurosciences (NIMHANS), Neurology, Bangalore, India, 2NIMHANS, Department Of Neurology, Bangalore, India, 3NIMHANS, Neuropathology, Bangalore, India

Background and Aims:: The primary storehouse of the intracellular calcium ions, which play a crucial role in the excitation-contraction of skeletal muscles, is the sarcoplasmic reticulum. Calcium flux is mediated by the store-operated Ca2+ entry (SOCE) pathway interacting with stromal interacting molecule 1 (STIM-1), an SR calcium sensor, and ORAI-1, a plasma membrane calcium release-activated channel (CRAC). Loss of function mutation of ORAI-1 causes severe combined immunodeficiency (SCID), non-progressive muscle hypotonia, and anhidrotic ectodermal dysplasia. Autosomal dominant gain of function mutation causes syndromic and non-syndromic tubular aggregate myopathy. Here we report a unique case of homozygous ORAI-1 mutation presenting clinically as congenital myopathy and histologically as Congenital fibre type disproportion (CFTD).

Methods:: An 18 years old female presented with two and a half years history of progressive pain in both thighs followed by weakness of proximal lower limbs. She has squint in both eyes along with difficulty in running since childhood. The patient was thin built along with long facies. There was hypotonia of lower limbs along with muscle power of 4 in upper limbs and 3 in lower limbs. She had a waddling gait.

Results::

a and b - shows Muscle MRI T2 sequences shows fatty infiltration with atrophy of Glutei (blue arrow) and Quadriceps (Green arrow).
Investigations showed normal creatine kinase levels. Muscle MRI showed fatty infiltration of Glutei and quadriceps (Figure 1). Muscle biopsy was suggestive of CFTD (Figure 2). Clinical exome sequencing revealed homozygous mutations in exon one of ORAI-1 gene in chromosome 12 with two variants - pathogenic variant c.208G>T and variant of uncertain significance c.262C>G.

**Conclusions:** Unique features include slowly progressive myopathy, ophthalmoparesis, absence of immunodeficiency, ORAI-1 mutation with histological CFTD morphology, which has not been reported previously.
OCULO-PHARYNGEAL MUSCULAR DYSTROPHY: PHENOTYPIC AND GENOTYPIC STUDIES IN ABRUZZO

Marianna Gabriella Rispoli¹,², Laura Ferri¹,², Paola Ajdinaj¹,², Marco Onofri¹, Antonio Di Muzio²
¹University G. D'Annunzio of Chieti-Pescara, Department Of Neuroscience, Imaging And Clinical Sciences, Chieti, Italy, ²Centre for Neuromuscular Diseases, “ss Annunziata” Hospital, Chieti, Italy

Background and Aims:: Oculo-pharyngeal muscular dystrophy (OPMD) is a late-onset, inherited muscle disorder, characterized by progressive ptosis, dysphagia and variable proximal limb weakness. The highest prevalence is reported in French Canadians (1:1000)(1) and Bukhara Jews (1:600)(2). Few Italian cases have also been reported(3,4). OPMD is caused by short (GCN)¹¹-¹⁷ expansions in the polyadenylate-binding protein nuclear 1 gene (PABPN1)(5).

Methods:: We summarized the neurophysiological and genetic findings of 15 OPMD patients born in Abruzzo, belonging to 9 unrelated families.

Results:: In our cohort, age at onset was between 42 and 74 years (mean 57). The M/F ratio was 1.14:1. Family history was positive in 13 patients. As expected, ptosis was the most common initial complaint. There was a 6.3-year mean delay before the onset of a second symptom, which was dysphagia in 86.7% of cases. External ophthalmoplegia was present in 73.3% of patients. Two siblings presented cognitive impairment. Genetically, we identified three genotypes, including two GCN¹¹ homozygous patients. Mean age at first evaluation was 68.6 and mean age at genetic screening was 71.5. Creatine kinase levels were mildly elevated in 6 patients. Electromyography, performed in 6 patients, showed myopathic features in three cases. Five patients had ptosis surgery and one patient reported cricopharyngeal myotomy.

Conclusions:: According to our results, OPMD has an estimated minimal prevalence of 1.14 per 100.000 persons in Abruzzo (Figure). A disease cluster can be hypothesized in Caramanico, where OPMD prevalence is about 0.37%. Despite rapid diagnosis through PABPN1 gene screening, OPMD is yet under-recognized and confirmed after several years from symptoms.
onset.
VALIDATION OF THE ITALIAN VERSION OF THE MYASTHENIA GRAVIS IMPAIRMENT INDEX (MGII)

Francesca Pasqualin¹, Carolina Barnett², Silvia Guidoni¹, Elisa Albertini¹, Mario Ermani³, Domenico Bonifati¹
¹Ca’ Foncello Hospital, Neurocardiovascular, Treviso, Italy, ²University Health Network, Toronto, Canada, Medicine, Division Of Neurology, Toronto, Canada, ³Università degli Studi di Padova, Neuroscience, Padova, Italy

Background and Aims:: Myasthenia Gravis Impairment Index (MGII) is a recent promising measure developed for MG patients evaluation. It includes a clinical severity evaluation and a patient reported questionnaire. It has been developed in English and has demonstrated feasibility, reliability, and construct validity. Recently its Dutch translation has been validated. The aim of this study is to validate the Italian version of MGII.

Methods:: A multi-step forwards process was used to translate MGII to Italian. We assessed correlations with the following scores: Istituto Nazionale Carlo Besta score for Myasthenia Gravis (INCB-MG), the MG Activities of Daily Living (MG-ADL), the Myasthenia Gravis Composite (MGC), the quality of life 15 for Myasthenia Gravis (QOL15-MG) and the Myasthenia Gravis disability (MG-DIS). We also assessed differences in MGII scores by disease severity with ANOVA Kruskal Wallis test.

Results:: 141 patients were enrolled. The mean MGII total score was 13.3 ± 11.9 (range 0-49), with mean ocular subscore of 3.7 ± 4.7 and mean MGII generalized subscore of 9.6 ± 9.0. As expected, the MGII had a good correlation with the other severity scores. The MGII had lower floor effect (3.5%) than the other measures. 25 patients were assessed in follow-up: as expected, the MGII change scores had moderate correlations with change in other MG severity measures, and lower correlations with quality of life measures.

Conclusions:: The MGII score was cross-culturally validated in a Italian cohort of MG patients. We confirmed its lower floor effect and the correlations with other MG measures including INCB-MG that was not evaluated in previous studies.
ASYMMETRICAL SCAPULAR WINGING, BILATERAL FACIAL MUSCLE INVOLVEMENT AND DISTAL MYOPATHY WITH NORMAL CPK; UNUSUAL FEATURES IN ANTI JO-I POSITIVE POLYMYOSITIS

Sudath Ravindra, Chulika Makawita, Kasun Udenika, Bimsara Senanayake
National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

Background and Aims: Introduction Polymyositis is an idiopathic inflammatory myopathy which present with typical symmetrical proximal muscle weakness with the evidence of muscle inflammation. The acute inflammation of muscle results in high levels of CPK and has a relapsing remitting course with a good response to anti-inflammatory treatment. We present here a patient presented with a chronic myopathy with relapsing remitting fashion, with asymmetrical scapula winging, and bilateral facial weakness, with predominant distal muscle weakness which was supported by EMG.

Methods: Case report 65 year old woman has presented with 6 year history of progressive muscle weakness. Her initial symptoms were associated with involvement of lower limb proximal muscles and then she noticed difficulty in walking mainly due to slapping of her feet on the ground. There were episodes of worsening of weakness which was responsive to IV methyl prednisolone. She never experienced muscle pains, muscle cramps or positive or negative sensory symptoms.

Results: On examination, She had bilateral foot drop with limb girdle weakness. Additionally, She asymmetrical scapula winging( R>L ) and bilateral facial muscle weakness. Her CPK was found to be mildly elevated.(300).EMG was in favour of myopathy( distal>Proximal ) and her nerve conduction was normal. Muscle biopsy was suggestive of inflammation. Specific antibody testing with Jo-1 results was found to be positive. Figure : A-bilateral facial muscle wasting. B-Asymmetrical scapular winging (R>L).
Conclusions:: Long standing idiopathic inflammatory myopathy can be a diagnostic challenge when presented with atypical features. High degree of suspicion is need as these are treatable conditions with good response to immunosuppressive therapy.
A CASE OF RECURRENT THYMOMA WITH DOUBLE PARANEOPlastic SYNDromes: ARE ANTIBODIES BETTER THAN CLINICAL JUDGEMENT IN PREDICTING THYMOMA RELAPSE?

Mayur Thakkar, Karan Desai, Dnyaneshwar Jadhav, Rahil Ansari, Akash Chheda, Sangeeta Ravat, Neeraj Jain
Seth GSMC and KEM hospital Mumbai, Neurology, Mumbai, India

Background and Aims:: The co-existence of paraneoplastic CASPR2-antibody mediated Morvan Syndrome(MoS) and myasthenia gravis(MG) with thymoma is extremely rare. We report the case of an elderly male with an autoimmune thymoma-associated MG, whose myasthenic symptoms relapsed after eight years of thymectomy with the co-occurrence of MoS.

Methods:: A 46-year-old farmer with past-history of anti-Acetylcholine Receptor Antibody(AchR-Ab) positive MG (thymoma excision eight years back), came with a two-year progressive history of cramps, occasional involuntary rippling movements over both his thighs, burning paresthesias in distal lower limbs and hyperhidrosis along-with recurrence of Myasthenic symptoms. His detailed workup was done considering provisional diagnosis of peripheral nerve hyperexcitability syndrome and MG with recurrence of thymoma.

Results:: On examination he had myokymia, acral hyperalgesia, fatigable ptosis, and limb-girdle weakness. His slow RNS showed decremental response and EMG showed neuromyotonic discharges with normal motor units. His anti-AchR-Ab, anti-CASPR-2 and anti-Titin antibodies were positive. Fusion FDG-PET and contrast-enhanced CT-Thorax revealed multiple pleural based lesions.A subsequent biopsy of the lesions revealed WHO histology grade-B1 and Masaoka Stage-4 thymomas.He is in complete pharmacological remission for MG and MoS symptoms after eight cycles of cisplatin and paclitaxel-based chemotherapy, gabapentin, and carbamazepine.

Conclusions:: We highlight the rarity of the co-occurrence of MoS, MG and Thymoma. Our clinical suspicion unravelled the relapse of Myasthenia and MoS in our case while evaluating for the cramps and rippling. It is the first description of anti-Titin antibodies in Thymoma-associated MoS to the best of our knowledge, but its significance will need more research.
ACHR MYASTHENIA GRAVIS (MG) ATYPICAL PRESENTATION IN HUMAN IMMUNODEFICIENCY VIRUS (HIV) POSITIVE PATIENT

Alessandro Di Santo¹, Fabio Pilato¹, Fioravante Capone¹, Liana Africa², Vincenzo Di Lazzaro¹
¹Campus Bio-Medico University of Rome, Neurology, Neurophysiology And Neurobiology Unit, Department Of Medicine, Roma, Italy, ²“San Biagio” Hospital, Neurology Department, Domodossola, Italy

Background and Aims:: MG is an autoimmune disease characterized by muscle weakness and fatigability and it is associated with autoantibodies direct to specific muscular proteins like acetylcholine receptor (AchR). The co-occurrence of HIV infection and immune-mediated disorders is known but HIV-MG association is rare.

Methods:: A 30-year-old man without previous medical history, suddenly developed weakness and paresthesias of right limbs, dizziness, postural instability, and intermittent diplopia. Routine blood chemistry, brain MRI, MEPs and SEPs were normal. NCS and electromyography exams showed normal results. CSF analysis revealed 8 cells and mild proteins increase. High serum HIV viral load and CD4+ count 331/mmc were found. HIV specific treatment was started. During hospitalization diplopia and muscular weakness became prominent; moreover, bilateral palpebral ptosis and hypophonia arise. All these symptoms worsened during prolonged exercise. 3-Hz repetitive stimulation to bilateral deltoid and nasalis muscles showed a significant decremental response. Serum antibody against AChR was present (0.52 nmol/l) and CT chest showed thymic hyperplasia. The patient started oral pyridostigmine treatment (120 mg daily) resulting in resolution of hypophonia, muscular weakness but there was incomplete improvement of ptosis and diplopia.

Results:: Few case reports of MG-HIV co-occurrence are reported, but several evidences suggest that causative correlation is probable. Furthermore, previous studies highlight that HIV infection could play a role in the manifestation and natural history of MG.

Conclusions:: MG should always be concerned in diagnostic process of diplopia, even if atypical symptoms are prominent. Despite MG-HIV co-infection is rare, HIV screening test for novel MG diagnosis could be considered.
BARTTER SYNDROME PRESENTING AS PERIODIC LIMB PARALYSIS

Ishani Rajapakshe, Bimsara Senanayake
National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

Background and Aims:: Bartter syndrome is a rare autosomal recessive disorder with a defect in the thick ascending limb of the loop of Henle. The estimated prevalence is one in a million. We report a case of Batter syndrome presenting with periodic paralysis.

Methods:: A 15-year-old boy presented with recurrent episodes of sudden onset paralysis of lower and upper limbs mostly nocturnally and after exertion. Each episode lasts 6-10 hours with spontaneous recovery. This continued to happen for the past 8 years. Treatment with Acetazolamide considering hypokalemic periodic paralysis failed. Initially he had 3-4 episodes/year and then 2-3 episodes/month leading to limitation of daily activities and school performance. During episodes, all limbs were flaccid and areflexic. Rest of the exam including blood pressure was normal between episodes. Investigations revealed hypokalemia, metabolic alkalosis and hypercalciuria. A diagnosis of Batter syndrome was made. Spironolactone and oral KCL was started with significant clinical improvement.

Results:: In 1962, Bartter et al. described a clinical syndrome characterized by hypokalemic alkalosis, hyperreninemia, hyperaldosteronism, hypomagnesemia, hypercalciuria and normal blood pressure. It occurs mostly in childhood or adolescence. Cause is yet unknown. Fatigue, proximal muscle weakness and tetany are clinical features. Treatment is with potassium and magnesium repletion, propranolol, spironolactone and prostaglandin inhibitors. Recurrent hypokalemia and chronic renal failure are complications.

Conclusions:: Hypokalemic periodic paralysis should be thoroughly evaluated to unmask any underlying etiology as therapeutic options vary. A proper evaluation would unravel this rare cause of periodic paralysis, which if appropriately treated has an excellent prognosis and in turn will prevent renal failure.
AN AMBISPECTIVE COHORT STUDY OF INFLAMMATORY MYOPATHIES TO UNDERSTAND THE CLINICAL PROFILE AND TEMPORAL TRENDS IN MANAGEMENT

Yogeesh P M¹, Vishnu V Y², Mv Padma Srivastava², Rohit Bhatia³, Mamta Singh², Roopa Rajan², Awadh Pandit², Rajesh Singh²
¹All Indian Institute of Medical Sciences, Neurology, Delhi, India, ²All India Institute of Medical Sciences, Neurology, Delhi, India, ³AIIMS, New Delhi, Neurology, Delhi, India

Background and Aims:: BACKGROUND •Inflammatory myopathies are rare disorders involving multiple systems mainly involving muscles. Their rarity and variable phenotype, there are no standardized protocols for management AIM- To document the clinical profile, treatment response, and regimes used in patients with idiopathic inflammatory myopathies

Methods:: 1.Type of study: A single-center-ambispective cohort observational study 2.Study population: •Patients admitted with a diagnosis of inflammatory myopathy in the department of neurology between 2014 and July 2019 were assessed retrospectively and between November 2019 to March 2021 with a diagnosis of inflammatory myopathy in the department of Neurology were assessed prospectively. •Study protocol- Baseline demographic profile, patient's clinical features, type of inflammatory myopathy, investigations reports including biopsy reports, treatment received, treatment pattern, number of relapses, drugs used, duration of drugs, and the outcomes were assessed. Prospectively patients were assessed for clinical profile, laboratory features, myositis antibody profile, electromyographic findings, treatment received, response to treatment, relapses and chest imaging and PET CT was analyzed

Results:: We analyzed a total of 75 patients of which 62 were retrospective and 14 were prospective cases of which 54 (82%) were dermatomyositis 16 (21%) were polymyositis and 5 (7%) patients were inclusion body myositis. Of these 34 (45.3) were males and 41 (55.6) were females. 19 (25%) of these had relapsed during follow-up. 7 patients refractory to treatment received rituximab and 5 patients received cyclophosphamide.

Conclusions:: Management of IIM varies throughout the world. Our study throws light upon various evidence-based treatment strategies used in the management of IIM which helps in further designing natural history and management studies in the future.
CARDIAC MRI FINDINGS IN DUCHENNE AND BECKER MUSCULAR DYSTROPHY

Atchayaram Nalini¹, S G Manu¹, Ashita Barthur², Seena Vengalil¹, Saraswati Nashi¹
¹National Institute of Mental Health and Neurosciences, Department Of Neurology, Bangalore, India, ²Sri Jayadeva Institute of Cardiovascular Sciences and Research, Cardiovascular And Thoracic Imaging, Bangalore, India

Background and Aims:: We sought to determine the prevalence of cardiac involvement in Duchenne and Becker Muscular Dystrophy(DMD/BMD) using MRI and its association with clinical and laboratory parameters.

Methods:: A prospective, observational study was conducted on 24 patients(19 DMD and 5 BMD), genetically confirmed to have DMD/BMD and underwent cardiac MRI on 1.5T Philips Ingenia MRI system.

Results:: In our Dystrophinopathy cohort, mean age=13.46 ± 4.84 years [DMD=11.84 ± 3.2; BMD=19.6 ± 5.37], mean duration=8.08 ± 3.88 years. All had proximal muscle weakness, 70.83% were ambulant and 29.17%-wheel chair bound. 80.95% had variable deletion of exons in DMD gene (82.35% confined to regions between exons 45 to 54), 19.05% had non-sense mutations. Cardiac MRI revealed late gadolinium enhancement(LGE) confined to the left ventricle(LV) consistent with fibrosis in 54.17% of cases[DMD=52.63%; BMD=60%]. In patients with LGE, 53.85%(7 of 13) had reduced LV Ejection Fraction and one patient showed LV dilation. Patients with myocardial fibrosis had longer disease duration(mean duration 9.77 ± 4.38 v/s 6.09 ± 1.87 years, P value=0.017). LGE was not associated with age, genotype, severity of muscle weakness or creatine kinase levels. LGE most often involved the inferolateral mid myocardium and extended to involve other areas with more severe disease.

Conclusions:: There is a high prevalence of subclinical cardiac involvement in DMD/BMD patients which can be detected using Cardiac MRI, that helps in initiating early cardioprotective therapy in this subgroup. Although, our study population is small, there was a small but significant relationship between the development of subclinical myocardial fibrosis and duration of disease.
Background and Aims: Thymolipomas are rare, benign thymic lesions (2%-9% of thymic tumors) and has scarce local and systemic manifestations. Myasthenia gravis (MG)'s association with thymolipomas is uncommon, with just 34 cases reported in the literature until August 2020.

Methods: We report 3 new cases of this uncommon association through a retrospective study at a single institution which were resected between 1992 and 2020.

Results: Three patients initially presented with MG (2 patients were men, and one was a woman) with a median age of 43 years. One patient had positive antiacetylcholine receptor antibodies. All patients underwent a resection of the thymus, even though imaging techniques did not reveal a tumor in 2 cases and showed a thymus nodule in one patient and the histologic study revealed thymolipoma in all three cases. The phenotype was severe in two patients: one patient died after thymectomy due to respiratory distress and the other one has suffered several myasthenic crisis requiring intubation and relapses post thymectomy in spite of well conducted oral medication based on mestinon and corticosteroids. The third one was well controlled after thymectomy.

Conclusions: The possibility of thymolipoma as an anterior mediastinal mass should be kept in mind when dealing with an older age group of myasthenia gravis patients. However, further comparative studies are needed for a more reliable conclusion of the postoperative myasthenia gravis response after resection.
HEREDITARY TRANSTHYRETIN AMYLOIDOSIS WITH POLYNEUROPATHY IN THE NEUROLOGIC CLINIC: RESULTS FROM 12 MONTHS OF GENETIC SCREENING IN THE WESTERN SICILY

Vincenzo Di Stefano, Andrea Gagliardo, Antonino Lupica, Salvatore Iacono, Angelo Torrente, Francesca Gentile, Filippo Brighina
University of Palermo, Department Of Biomedicine, Neuroscience And Advanced Diagnostics, Palermo, Italy

Background and Aims:: Background and aims. Hereditary transthyretin amyloidosis with polyneuropathy (ATTR-PN) is caused by mutations in the TTR gene, leading to misfolded monomers which aggregate generating amyloid fibrils. The clinical phenotype in non-endemic areas is characterized by a late onset with a multisystemic disease affecting the sensorimotor, autonomic functions along with other organs. Hence, the diagnosis may be quite difficult with a relevant misdiagnosis and high costs for the community. We aim to study “red flags” for ATTR-PN to improve recognition and early diagnosis.

Methods:: Methods. A genetic screening was proposed in patients presenting with a sensory-motor idiopathic polyneuropathy and one or more of the following: family history of polyneuropathy or cardiopathy; bilateral carpal tunnel syndrome, cardiac insufficiency, renal amyloidosis, lumbar tract stenosis, autonomic dysfunction, gastrointestinal idiopathic disease, amyloid deposits on biopsy, vitreous opacities, diagnosis of CIDP-not-responsive to standard treatments. Non-parametric analysis has been carried out to underline differences among screened-positive versus negative patients.

Results:: Results. 136 patients underwent genetic testing for suspected for TTR-PN. 25 patients resulted positive (18%). Not significant differences appeared between patients screening positive vs negative depending on age and gender. Patients with a positive genetic test presented a higher frequency of family history of polyneuropathy and cardiopathy, or ATTR (p<0.001) and a reduced frequency of autoimmunity (p=0.013), CIDP (p=0.008).
Conclusions: Conclusions. A systematic screening for ATTR-PN might lead to an increased recognition of the disease even, leading to an earlier diagnosis, identification of asymptomatic carriers, who will be promptly treated after a strict follow-up at the clinical onset.
Background and Aims:: Acute motor axonal neuropathy (AMAN) is a pure motor axonal subtype of Guillain-Barré syndrome presenting with rapidly progressive ascending symmetrical neuromuscular paralysis. Its immunopathogenesis is attributed to autoantibodies that bind to GM1 or GD1a gangliosides often following Campylobacter jejuni infection. We present an unusual case of AMAN where the patient was initially diagnosed with cerebro-vascular event due to acute right-sided hemiparesis and paraesthesia.

Methods:: A 60-year old with a history of hypertension presented with acute right-sided upper and lower limb numbness which in few hours progressed to hemiparesis. Urgent imaging of the brain and cervical spine was performed with no pathological findings. Over the next 24-hours there was rapid progression of the weakness to the contralateral side and respiratory difficulties leading to ventilatory support. This raised suspicion of Guillain-Barré syndrome and a lumbar puncture was performed. The protein level was normal thus not supporting acute inflammatory demyelinating disease. Electrophysiological studies revealed evidence of severe motor demyelinating polyneuropathy with axonal loss and conduction block. The sensory response showed reduced amplitude but normal conduction velocity. Serum samples revealed raised concentrations of IgG antibodies against GM1 and GD1a. These findings led to the diagnosis of AMAN.

Results:: The patient was started on intravenous immunoglobulin treatment. She has received four cycles but with slow recovery. She is now off the ventilator with spontaneous breathing but still unable to mobilise.

Conclusions:: The diagnosis was challenging due to the unusual clinical presentation where the patient had also sensory symptoms and the motor deficit was asymmetric and descending in nature.
AN ATYPICAL CASE OF DERMATOMYOSITIS ASSOCIATED WITH CLEAR CELL RENAL CELL CARCINOMA

Biswa Mohan Mishra, Ayush Agarwal, Divya Radhakrishnan, Awadh Pandit, Achal Kumar Srivastava

1AIIMS, New Delhi, Neurology, Delhi, India, 2AIIMS, Neurology, NEW DELHI, India, 3All India Institute of Medical Sciences New Delhi, Neurology, New Delhi, India

Background and Aims:: Up to 30% of idiopathic inflammatory myopathies cases are associated with an underlying malignancy. Renal tumours have only rarely been described in patients with DM and, to the best of our knowledge, this is the second report of clear cell renal cell cancer (RCC) presenting with dermatomyositis.

Methods:: We describe a 43-year male, without any previous comorbidities, who presented with acute onset and progressive quadriparesis of two weeks duration. After initial routine hemogram and biochemical evaluation, appropriate imaging followed tissue biopsy clinched the diagnosis.

Results:: On initial evaluation patient had power MRC grade 2/5 in bilateral proximal upper limbs and lower limbs and 4/5 in distal limbs, with a maculopapular rash on upper chest and back. At presentation, CK (creatine kinase) was 22,000 U/L (N=39-308). Muscle biopsy showed mild endomysial inflammatory infiltration comprising of T helper and suppressor cells and positive for Mi2a, Ku, Jo-1, Ro-52. Whole body PET was done which revealed uptake in the right kidney. Suspecting paraneoplastic Dermatomyositis, he was started on pulse methylprednisolone followed by oral steroids. Subsequently his power improved, and the rash disappeared completely. After 6 weeks, elective partial nephrectomy was done, and histopathology showed clear cell RCC (WHO ISUP Grade I). At 4 weeks follow up, power bilateral upper and lower limbs was 5/5, CK reduced to 237U/L and patient was on tapering of oral steroids and Mycophenolate 500mg BD.
Conclusions: Though rare, RCC can lead to dermatomyositis and instead of considering it as an incidentaloma, early tumour removal leads to better outcomes.
PATISIRAN IN PATIENTS WITH HATTR AMYLOIDOSIS POST-ORTHOPEDIC LIVER TRANSPLANT: 12-MONTH RESULTS

Anna Mazzeo¹, Francisco Munoz-Beamud², Teresa Coelho³, Julian Gillmore⁴, Davide Adams⁵, Jonas Wixner⁶, Violaine Planté-Bordeneuve⁷, Laura Llado⁸, Seth Arum⁹, Matthew T White¹⁰, Patrick Jay¹¹, Hartmut Schmidt¹²

¹University of Messina, Clinical And Experimental Medicine - Unit Of Neurology, Messina, Italy, ²Juan Ramón Jiménez Hospital, Internal Medicine Service, Huelva, Spain, ³Centro Hospitalar Universitário do Porto, Department Of Neurosciences, Porto, Portugal, ⁴National Amyloidosis Centre, University College London, Royal Free Hospital, Division Of Medicine, London, United Kingdom, ⁵Université Paris-Saclay, U1195, INSERM, Department Of Neurology, Paris, France, ⁶Umeå University, Department Of Public Health And Clinical Medicine, Umea, Sweden, ⁷CHU Henri Mondor, APHP, INSERM U955 Team 10, Université-Paris Est, Neurology Department, Créteil, France, ⁸Hospital Universitari de Bellvitge, Surgery, Barcelona, Spain, ⁹Alnylam Pharmaceuticals, Global Patient Safety & Risk Management, Cambridge, United States of America, ¹⁰Alnylam Pharmaceuticals, Data Sciences And Statistics, Cambridge, United States of America, ¹¹Alnylam Pharmaceuticals, Clinical Research, Cambridge, United States of America, ¹²University Hospital Muenster, Department Of Medicine B, Gastroenterology And Hepatology, Muenster, Germany

Background and Aims:: Hereditary transthyretin-mediated (hATTR) amyloidosis is a progressive, debilitating disease. Orthotopic liver transplant (OLT) eliminates variant transthyretin (TTR) to slow progression in early-stage hATTR amyloidosis. Patisiran reduces production of variant and wild-type TTR, as shown in patients who had not undergone OLT in the APOLLO study.

Methods:: Phase 3b open-label study (NCT03862807) to evaluate safety, efficacy, and pharmacokinetics (PK) of patisiran in patients with hATTR amyloidosis with polyneuropathy and disease progression post-OLT. Patients received patisiran 0.3 mg/kg intravenously q3w for 12 months.

Results:: Twenty-three patients enrolled; median age 58.0 years, 13 (56.5%) male, and 15 (65.2%) had V30M mutation. At baseline, 1 (4.3%) patient had polyneuropathy disability (PND) score I, 9 (39.1%) PND II, and 13 (56.5%) PND IIIA/B. Five patients (21.7%) had New York Heart Association (NYHA) classification I, 5 (21.7%) NYHA II, and none had NYHA III/IV at study baseline. At month 6, the mean (SEM) TTR level was 21.2 (3.7) mg/L, representing an 89.2% reduction from baseline. All patients experienced ≥1 adverse event (AE) and 5 patients experienced at least one serious AE; majority of AEs were mild or moderate in severity. Liver function tests were stable in the majority of patients. One patient experienced transplant rejection deemed unrelated to patisiran.

Conclusions:: To date, reduction in serum TTR levels and safety profile of patisiran in patients with hATTR amyloidosis with polyneuropathy with disease progression post-OLT has been consistent with results from APOLLO. Patisiran has the potential to address an unmet need in these patients.
Background and Aims:: Allgrove syndrome is a rare, autosomal recessively inherited syndrome characterised by achalasia, alacrima, adrenal insufficiency and progressive neurological dysfunction. Afflicted individuals usually manifest with 2-4 of these symptoms and most cases have no positive family history. Mutations in ALADIN gene located on chromosome 12q13 are responsible.

Methods:: A 46-years old gentleman, born of non-consanguineous marriage, presented with progressively increasing proximal lower and upper limb weakness for past 20 years. He had concomitant dysphagia and nasal intonation complicated by recurrent dyspepsia for past 5 years, whose evaluation lead to a diagnosis of achalasia. He developed complaints of severe dryness of eyes since 5 years and has been on lubricating eyedrops. He developed erectile dysfunction since past 3 years, whose evaluation lead to a diagnosis of concomitant azoosperma. Examination revealed a postural hypotension with wasting of small muscles of hand and tongue, with fasciculations. Power in the proximal and distal joints was MRC grade 4/5 and 5/5 respectively. Spasticity was present, reflexes were brisk and plantars were extensor.

Results:: Nerve conduction studies revealed an axonal neuropathy with electromyography suggestive of preganglionic neurogenic involvement. Autonomic function tests revealed severe sympathetic-parasympathetic involvement. MRI brain and spine were normal. Next generation clinical exome sequencing revealed a homozygous c.C43A/p.Gln15Lys missense mutation on exon 1 of the ALADIN gene on Chromosome 12.

Conclusions:: Allgrove syndrome should be suspected in patients presenting with features of CNS/PNS dysfunction with achalasia, alacrima and/or adrenal insufficiency. Although, no treatment modalities exist, earlier diagnosis can lead to proper counselling, symptomatic management and incorporation in research trials, which can hopefully provide a cure in the future.
EVALUATION OF COMORBIDITIES IN MYASTHENIA GRAVIS: THE EXPERIENCE OF AN ITALIAN CENTER

Antonino Lupica¹, Vincenzo Di Stefano¹, Salvatore Iacono², Placido Lanza¹, Filippo Brighina³
¹University of Palermo, Department Of Biomedicine, Neuroscience And Advanced Diagnostics, Palermo, Italy, ²Azienda Ospedaliera Universitaria Policlinico Paolo Giaccone, Department Of Biomedicine, Neuroscience And Advanced Diagnostic, Palermo, Italy, ³University of Palermo, Department Of Experimental Biomedicine And Clinical Neurosciences, Palermo, Italy

Background and Aims:: Myasthenia gravis (MG) is an autoimmune disorder of neuromuscular junction; management of therapy in MG can be very complex, because of the most common used drugs can worse chronic comorbidities and increase disabilities and assistance need. We evaluated the prevalence of comorbidities among a cohort of MG patients and a control group.

Methods:: Patients with diagnosis of MG where collected from the Italian centre of Palermo. Control patients were collected with a web-available questioner asking after age and sex, questions about chronic diseases. Prevalence of main chronic disorders found in MG patients was compared with control cases using chi squared test.

Results:: 125 MG Patient (65 M) were analysed and compared with 200 unaffected controls. A significative difference (P<0.05) was found comparing results for hypertension, hypercholesterolemia, diabetes, cardiovascular disorders, osteoporosis.

Conclusions:: Our findings show that a lot of comorbidities are more common than in general population in MG patients. Hence the diagnosis and therapy of MG can be very difficult because of comorbidity can mimics symptoms and can be worsened by administration of steroid and immunosuppressors agents routinely used in MG. MG type and comorbidities risk should be carefully considered for a positive outcome.
CONGENITAL MYASTHENIC SYNDROMES: PHENOTYPIC VARIABILITY AND THE DIAGNOSTIC CHALLENGE

Isadora Cavalcante¹, Melina Marques¹, Paulo Correia², Caroline Pessoa¹, Lisiane Ferreira³
¹Universidade de Brasília, Department Of Pediatrics, Brasília, Brazil, ²Universidade de Brasília, Faculty Of Medicine, Brasília, Brazil, ³Universidade de Brasília, Associate Professor Of The Faculty Of Medicine, Brasília, Brazil

Background and Aims:: Congenital myasthenic syndromes (CMS) are a rare and heterogeneous group of neuromuscular junction disorders, caused by genetic mutations. It has an estimated incidence of 9.2 cases per million in children under 18 years-old. Dok-7 deficiency (OMIM#254300) accounts for less than 10% of all CMS cases. The purpose of this report is to emphasize the importance of genetic testing to complete a complex diagnosis of CMS, whose phenotype initially suggested congenital myopathy.

Methods:: This article was written based on data of medical record of a 23 months-old, female patient, diagnosed with CMS caused by Dok-7 deficiency.

Results:: Female, 23 months-old, daughter of a consanguineous couple, had a history of weak crying, left eyelid ptosis and global hypotonia observed at birth. Developed weight and height deficit and motor delay, in addition to dysphagia for fluids and frequent hospitalizations for pneumonia. On physical examination, she presented scaphocephaly, asymmetric bipalpebral ptosis, ogival palate, retrognathia, ears rotated posteriorly, ramp shoulders, kyphoscoliosis, global hypotonia, predominantly axial, involving mainly the neck musculature, hyperreflexia and exhaustible clonus in the feet. Electroneuromyography, using a low frequency repetitive stimulation technique, showed an electrodecrement of up to 50%, showing postsynaptic junction disorder. The genetic panel revealed a mutation in the heterozygous DOK7 and CHRNA1 gene, with pathogenic significance, confirming CMS.

Conclusions:: CMS may mimic many classic manifestations of myasthenia, but they can also present wide phenotypic variability, as in this case. Due to its rarity the diagnosis of CMS is a challenge, but the suspicion must be raised when we encounter early onset hypotonia.
Background and Aims:: Myasthenia gravis (MG) is an autoimmune disease characterized by muscle weakness. It is associated with antibodies to neuromuscular junction proteins such as AChR and MuSK. In mothers with AChR-MG transplacental passage of antibodies to foetus may cause neonatal MG. We report a case in which the same patient suffered from MG twice in her life.

Methods:: A 18-year-old female patient was referred to our Institution for ptosis, diplopia and mild generalized muscle weakness. After a single fiber EMG and a positive AChR antibody assay, MG was diagnosed and patient underwent to thymectomy with histological findings of hyperplasia. Pyridostigmine treatment led to minimal manifestations according to Myasthenia gravis foundation of America classification. At a later time we knew that patient’s mother was also affected by AChR-MG from the age of 27 and our patient suffered from neonatal MG (difficulty with latching on, breastfeeding and crying) in postpartum period: a course of liquid pyridostigmine was beneficial and after a month neonatal MG signs were definitely absent.

Results:: As maternal IgGs disappear after 6 months, a delayed action of mother’s AChR autoantibodies can be excluded. Actually in this case, the same autoimmune disease developed after many years.

Conclusions:: To our knowledge this is the first case of two different manifestation of MG in the same patient and it may be helpful to understand how environment and genetic play a crucial role in autoimmune disease.
Background and Aims:: Background and aims. Hereditary transthyretin amyloidosis with polyneuropathy (ATTR-PN) is caused by mutations in the TTR gene, leading to misfolded monomers which aggregate generating amyloid fibrils. The clinical phenotype is heterogeneous, characterized by a multisystemic disease affecting the sensorimotor, autonomic functions along with other organs.

Methods:: Methods. All patients were assessed with a standardized questionnaire on well-recognized symptoms of ATTR-PN, neurophysiological evaluation (ENG/EMG) and bioimpedance analysis. The data are presented as means and standard deviations. Pearson’s correlation has been carried out when appropriate. A linear regression model has been created to identify associated variables to pathology severity.

Results:: Results. 16 patients with ATTR-PN (62.8±8.9 years; 165.0±12.5 cm; 74.9±14.9 kg) of which 7 women have been recruited. The data indicate that at increased pathology severity as indicated by FAP, increased presence of bilateral carpal tunnel syndrome and increased overall symptoms of neuropathy (Table 1). A concomitant decrease of the CMAP amplitude of the median nerve was also observed (Table 2). FAP degree alone may explain 45% of the decrease of the median nerve amplitude. Also, when severity of disease is associated to bioimpedance analysis (BIA) we observe increased presence of weight loss with increased severity, which is associated to a reduction only in lean muscle mass. Increased FAP is also strongly associated to a reduction of the phase angle.

**Conclusions:** Conclusions. The progression of bilateral carpal tunnel syndrome, polyneuropathy, lumbar stenosis and weight loss is related to the FAP grade in ATTR-PN. Also, we propose BIA as an important tool for disease progression in ATTR-PN.
MISDIAGNOSIS OF CHRONIC INFLAMMATORY DEMYELINATING POLYRADICULONEUROPATHY (CIDP): A TWO YEARS FOLLOW-UP STUDY.

Antonia Pignolo¹, Vincenzo Di Stefano², Andrea Gagliardo², Antonino Lupica², Salvatore Iacono³, Gabriele Neto³, Filippo Brighina⁴
¹Università di Palermo, Department Of Biomedicine, Neuroscience And Advanced Diagnostics (bind), Palermo, Italy, ²University of Palermo, Department Of Biomedicine, Neuroscience And Advanced Diagnostics, Palermo, Italy, ³Azienda Ospedaliera Universitaria Policlinico Paolo Giaccone, Department Of Biomedicine, Neuroscience And Advanced Diagnostic, Palermo, Italy, ⁴University of Palermo, Department Of Experimental Biomedicine And Clinical Neurosciences, Palermo, Italy

Background and Aims:: Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) is an immune-mediated disorder involving peripheral nerves, characterized by sensory alteration and weakness with gradual progression over years leading to disability. Diagnosis is obtained through clinical history, neurological examination, serum and liquoral biomarkers and neurophysiology. Neurophysiological criteria proposed by European Federation of Neurological Societies and Peripheral Nerve Society (EFNS/PNS) are used for the diagnosis allowing high sensitivity and specificity. However, several conditions can mimic CIDP.

Methods:: In this study we observed 53 patients with diagnosis of CIDP according to EFNS/PNS criteria, followed in an ambulatory setting for two years. After two years of follow-up a revision of EFNS/PNS criteria was performed again through a neurological evaluation, serum and neurophysiologic assessment.

Results::

53 patients have been enrolled, satisfying EFNS/PNS criteria at study start. Clinically 34 (64%) patients with typical CIDP, 13 (24%) with not defined CIDP and 19 (12%) with atypical CIDP, including 2 (4%) with distal acquired demyelinating symmetric neuropathy (DADS), 1 (2%) with purely motor, 3 (6%) with Lewis-Sumner syndrome (LSS). However, after two-years of follow-up in 18 patients EFNS/PNS criteria were any more satisfied leading to a different diagnosis: 7 (13%) diabetes mellitus, 5 (9%) monoclonal gammopathy of undetermined significance (MGUS), 1 (2%) hereditary amyloidosis ATTR, 1 (2%) anti-myelin-associated glycoprotein (anti-MAG) and 4 (8%) deficit of vitamin B12.

Conclusions:: Our study showed that other diagnosis can mimic CIDP at clinical onset; a careful revision of criteria is needed during the follow-up to achieve the correct diagnosis and choose the better treatment option for patients with neuropathies.
OUTCOME MEASURES CHARACTERIZATION IN AN ITALIAN COHORT FOR CMT PATIENTS STRATIFICATION

Elena Merico, Alessandra Govoni, Divina Valeria Viola, Lucia Chico, Rosanna Calabrese, Erika Schirinzi, Gabriele Siciliano
University of Pisa, Neurological Clinics, Department Of Clinical And Experimental Medicine, Pisa, Italy

Background and Aims:: Charcot-Marie-Tooth (CMT) disease is the most common inherited neuromuscular disorder, with variable age of onset (from infancy to adulthood) and a broad phenotypic spectrum. Several motor function and disability scales in CMT patients are available. The aim of this study is to better characterize CMT in its forms, also providing a clinical follow-up tool.

Methods:: We selected a cohort of 40 patients with confirmed diagnosis of CMT. For each patient we collected natural history, genetic characterization and electrophysiological data. All patients underwent clinical evaluation including following assessments: Muscle strength evaluated by Medical Research Council score, CMT Neuropathy Score (CMTNS) second version and CMT Functional Outcome Measure (CMT-FOM) scale.

Results:: We have recruited 40 CMT patients, 23 women and 17 males, aged between 23 and 65 years at the time of evaluation. In our cohort the most frequent form was CMT1A (29 patients) followed by hereditary Neuropathy With Liability to Pressure Palsies (HNPP) (N=7), CMT2A (4 patients) and CMT2N (1 patient). For each patient we collected and analyzed clinical data correlating them to the disease genotype, highlighting different degrees of disability and motor impairment in each group.

Conclusions:: The use of the two scales allows a more specific characterization of the different form of CMT, defining any specifics or limits, useful not only in clinical practice but also as outcome measures reference for potential future clinical trials.
QUADRIPARESIS SECONDARY TO CEREBRAL VENOUS SINUS THROMBOSIS: RARE CAUSE OF ACUTE FLACCID WEAKNESS

Ritu Shree¹, Abeer Goeł², Manoj Goyal¹
¹Postgraduate Institute of Medical Education and Research, Chandigarh, Neurology, Chandigarh, India, ²PGIMER, Neurology, Chandigarh, India

Background and Aims: Cerebral venous sinus thrombosis (CVST) presents with headache, seizures, focal deficits, altered consciousness and papilledema. False localising sign in the form of sixth cranial nerve palsy is commonly seen. Other cranial nerve palsies reported in CVST are oculomotor, facial, trigeminal and trochlear nerve palsies. Polyradiculopathy if seen, is in the form of reduced deep tendon reflexes (DTR), however dense quadriparesis with trunk and neck involvement and areflexia is rarely seen.

Methods: 16 year-old obese male had flaccid quadriparesis with severe neck and trunk weakness over 10 days followed by headache and blurring of vision. Examination revealed signs of raised intracranial pressure in the form of bilateral grade 4 papilledema, finger counting on right side and no light perception on left side along with bilateral 3rd, 6th, 7th and 5th cranial nerves palsies, power of grade 2/5 with hypotonia and areflexia.

Results: Gadolinium enhanced magnetic resonance imaging (Gd-MRI) revealed thrombosis of right transverse and sigmoid sinuses. Gd-MRI spine was unremarkable. CSF pressure by lumbar puncture was 34 mmHg. He started improving immediately after CSF drainage and acetazolamide. On 2 months follow-up, his mRS was 1. Weakness was likely due to polyradiculopathy secondary to transmitted raised intracranial pressure which was reversible once pressure was reduced.

Conclusions: Acute flaccid weakness due to polyradiculopathy secondary to CVST is another false localising sign along with multiple cranial palsies and denotes completely reversible dysfunction of spinal nerve roots.
WHAT IS THE CLINICAL SIGNIFICANCE OF THE FACIAL-SPARING PHENOTYPE IN FACIOSCAPULOHUMERAL MUSCULAR DYSTROPHY? A NATION-WIDE CROSS-SECTIONAL STUDY

Giulia Ricci¹, Maria Francesca Di Feo², Francesco Sera³, Cinzia Bettio², Valentina Salsi², Lucia Ruggiero⁴, Rossella Tupler², Italian Clinical Network For Fshd²
¹University of Pisa, Department Of Clinical And Experimental Medicine, Pisa, Italy, ²University of Modena and Reggio Emilia, Department Of Biomedical, Metabolic And Neural Sciences, Modena, Italy, ³University of Florence, Department Of Statistics, Computer Science And Applications "g. Parenti", Florence, Italy, ⁴University of Naples Federico II, Department Of Neuroscience And Reproductive And Odontostomatological Sciences, Napoli, Italy

Background and Aims:: Does the FSHD facial-sparing phenotype have peculiar features, regarding degree of severity, risk of disease in relatives and the size of D4Z4 repeat array?
Methods:: A multicenter cross-sectional study included 460 subjects (125 with facial-sparing phenotype and 328 subjects with the complete FSHD phenotype) from the Italian National Registry for FSHD. The phenotypic classification was obtained by applying the Comprehensive Clinical Evaluation Form (CCEF) and the degree of muscle impairment was measured as FSHD score (0-15).
Results:: We found that subjects with facial-sparing phenotype (B1 clinical category) have a significantly milder phenotype in comparison with subjects presenting classic FSHD phenotype (P value <0.001). Out of 33 families having a proband with facial-sparing phenotype in 54.5%, the proband was the only participant expressing a myopathic phenotype. Interestingly, of the 125 clinically assessed B1 subjects, 36% did not carry a D4Z4 allele with 10 or fewer repeat units.
Conclusions:: This study found that the facial-sparing phenotype defines a distinct nosological entity with different disease course and lower penetrance. It is recommended that clinicians use the CCEF for clinical classification and study the extended family to provide the most adequate clinical management and genetic counseling. The same phenotype was found in participants carrying D4Z4 alleles of normal size in contrast to the indication that a positive molecular test is the only determining aspect for FSHD diagnosis.
IMMUNOGLOBULINE THERAPY IN CHRONIC INFLAMMATORY DEMYELINATING POLYNEUROPATHY: INTRAVENOUS VERSUS SUBCUTANEOUS ADMINISTRATION.

Divina Valeria Viola¹, Alessandra Govoni², Erika Schirinzi¹, Elena Merico¹, Gabriele Siciliano³, Rosanna Calabrese¹, Lucia Chico¹, Andrea Bacci¹
¹University of Pisa, Neurological Clinics, Department Of Clinical And Experimental Medicine, Pisa, Italy, ²Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico di Milano, Neuroscience Section, Department Of Pathophysiology And Transplantation (dept), Milan, Italy, ³University of Pisa, Neurology Unit, Pisa, Italy

Background and Aims:: Chronic inflammatory demyelinating polyneuropathy (CIDP) is an acquired sensory-motor neuropathy with autoimmune pathogenesis. First line treatments include corticosteroids, plasmapheresis, and immunoglobulin therapy. The classic form of immunoglobulin administration is intravenous, however subcutaneous immunoglobulin (SCIG) therapy became a valid alternative option especially for maintenance therapy. Cross-sectional study to compare long-term response to intravenous immunoglobulin (IVIG) and SCIG.

Methods:: We selected a cohort of patients suffering from CIDP for which we collected data about age and onset symptoms, neurophysiology, comorbidities, clinical course and response to therapy. Patients underwent regular neurological evaluations every 3 months, including Medical Research Council Sum-Score (MRC-SS), Inflammatory Neuropathy Cause and Treatment scale (INCAT), Inflammatory Neuropathy-Rasch-Built Overall Disability Scale (I-RODS), patient treatment preference and treatment satisfaction questionnaire.

Results:: We’ve evaluated 150 patients (65% male) in a range of age of 22-88 years and with an average of 10 years illness duration. 51 patients require regular administration of IG, which 36 are treated with IGIV infusions every 30 or 60 days, while 15 patients have switched to SCIG treatment with a frequency administration of 1, 2 or 3 times a week. Both forms of administration are equally safe and tolerated and allow to stabilize the disease progression. We notice that compliance with the use of SCIG is also greatly affected by the practicality or difficulty in home management nevertheless it is globally preferred.

Conclusions:: Both routes of administration are effective maintenance therapies. Our data confirm those reported in literature and expand the knowledge about the response to immunomodulatory therapy in CIDP.
IMMUNE-MEDIATED RIPPLING MUSCLES WITH MYASTHENIA GRAVIS, THYMOMA, AND OTHER IMMUNE-MEDIATED DISORDERS: A REVIEW OF THE LAST 25 YEARS

Carl Ansevin
Ohio Neurologic Institute, Neuromuscular, Boardman, United States of America

Background and Aims:: In 1996, we described the first case of rippling muscles with myasthenia gravis. This patient also had a thymoma. Since then, numerous cases of rippling muscles with myasthenia gravis have been reported. Some have had thymomas, but other immune-mediated disorders have also been reported. This review will attempt to categorize these patients and their associated disorders.

Methods:: The literature will be reviewed and the published data from the patients described to date summarized. This will include immune-mediated rippling muscles with and without myasthenia gravis.

Results:: The most common immune disorder associated with rippling muscles is myasthenia gravis with over 20 cases reported to date. Thymoma also has been reported in about 20% of the cases. Rippling muscles with myasthenia gravis have also been reported after viral infections, yersinia enterocolitica, bronchial asthma, alopecia areata, and thymitis. There have also been isolated cases reported with autoimmune hemolytic anemia, lymphoma, pernicious anemia, sarcoidosis, breast and prostate cancer, and after taking statins. There have been rare cases of immune-mediated rippling muscles without evidence of myasthenia gravis or positive acetylcholine receptor antibodies.

Conclusions:: Patients who present with rippling muscles and no family history of this should be assumed to have myasthenia gravis plus or minus a thymoma until proven otherwise. Other immune-mediated disorders should also be reported, especially if their onset is temporally related to the rippling muscles.
D4Z4-PATHIES: EVIDENCE FROM THE ITALIAN NATIONAL REGISTRY FOR FSHD

Cinzia Bettio¹, Cecilia Ruini¹, Giulia Ricci², Lucia Ruggiero³, Valentina Salsi¹, Floriana Napoli¹, Francesco Sera³, Rossella Tupler¹, Italian Clinical Network For Fshd¹
¹University of Modena and Reggio Emilia, Department Of Biomedical, Metabolic And Neural Sciences, Modena, Italy, ²University of Pisa, Department Of Clinical And Experimental Medicine, Pisa, Italy, ³University of Naples Federico II, Department Of Neuroscience And Reproductive And Odontostomatological Sciences, Napoli, Italy, ⁴University of Florence, Department Of Statistics, Computer Science And Applications "g. Parenti", Firenze, Italy

Background and Aims:: The Italian Clinical Network for FSHD (ICNF) has established the Italian National Registry for FSHD (INRF), collecting data from patients affected by Facioscapulohumeral dystrophy (FSHD) and their relatives from fourteen centers distributed across Italy.

Methods:: Starting from 2007, INRF has gathered data from molecular analysis, clinical evaluation, anamnestic information and family history from more than 4000 participants. INRF includes sociodemographic information and healthcare information such as molecular analyses, anamnestic records and clinical features based on a standardized medical-reported form called CCEF.

Results:: The analysis of the distribution of D4Z4 reduced allele revealed that 15.2% of index cases from INRF carry a very short allele with 1-3 D4Z4 allele, 70.6% carry alleles with 4-8 D4Z4 repeats, 14.1% alleles with 9-10 D4Z4 allele. We observed a more homogenous FSHD phenotype among index cases with 1-3 D4Z4 reduced allele, although a significant percentage of them (21.8%) showed atypical features. Among index cases with larger D4Z4 repeats allele, 56.4% of them displayed a classical FSHD phenotype with facial and scapular muscle weakness, whereas 13% presented incomplete phenotype with facial weakness or scapular girdle involvement. Notably, 24.3% of index cases with 4-10 D4Z4 allele showed more complex phenotypes with atypical clinical features.

Conclusions:: Our research activities highlight that among carriers of D4Z4 reduces alleles and their families it is possible to recognize distinct nosological entities with different disease courses and lower penetrance. We suggest introducing a new term, D4Z4-pathies, to better define the clinical variability of disease.
**Background and Aims:** There is a wide variability of phenotype expression in patients affected with Charcot-Marie-Tooth disease type 1A (CMT1A) but no univocal explanations are available. Single nucleotide polymorphisms (SNPs) could play a role in modulating clinical picture in several conditions but definite evidence regarding CMT1A is missing.

**Methods:** Twenty-three CMT1A patients were enrolled and SNPs rs4280262 in LITAF, rs6875902, rs3763022 and rs230403 in SH3TTC2, rs10910527, rs4649265, rs7536385 and rs1547740 in SIPA1L2, H63D and C282Y in HFE were analyzed. Each patient was clinically assessed by several validated scales in order to quantify sensory and motor involvement.

**Results:** The presence of LITAF rs4280262, SH3TTC2 rs3763022, SIPA1L2 rs10910527, rs4649265 and rs7536385 was associated with a more severe motor phenotype. SH3TTC2 rs2304034, SH3TTC2 rs6875902 and SIPA1L2 rs1547740 did not appear to affect the severity of the phenotype. HFE H63D was associated with a lower strength in foot dorsiflexion (p 0.022). We observed an inverse correlation between the number of SNPs and the meters walked at 6MWT (p 0.011) and a positive relationship between the number of SNPs and the burden of disability in the upper (p 0.012) and lower limbs (p 0.019) and sensory involvement (p 0.025).

**Conclusions:** SNPs could play a role in modulating CMT1A phenotype, in particular H63D in HFE which was not previously described. Our results showed a possible summation effect of the individual SNPs in influencing the phenotypical expression of the disease. Certainly, larger case studies are needed in order to confirm these observations.
Background and Aims:: Myasthenia gravis (MG) is an autoimmune neuromuscular junction disease. An association between thymic epithelial neoplasms and MG is well known. However, it is rarely associated with hematologic malignancies. In particular, very few cases of lymphoblastic lymphoma (LL) involving the thymus and MG have been reported.

Methods:: A case report of a patient with MG and a malignant LL involving the thymus.

Results:: A 45-year-old woman was admitted with a 1 month history of bilateral, asymmetric and fluctuating ptosis. The diagnosis of MG was made on the basis of the clinical data, a positive neostigmine test, elevation of acetylcholine receptor antibodies and EMG with repetitive nerve stimulation tests revealing neuromuscular junctional dysfunction. Chest CT demonstrated a solid mass at the anterior mediastinum that was considered to be a thymoma. Total thymectomy was subsequently performed. The anatomapathological study concluded to T-cell lymphoblastic lymphoma.

Conclusions:: An association between lymphoid malignancies and MG have been reported in the literature. However, coexistence of LL involving thymus and MG are rare. Myasthenic symptoms either preceded, succeeded or were present at the time of diagnosis of lymphoblastic lymphoma which is the case of our patient. Although the causal relationship between lymphoblastic lymphoma and the autoimmune response cannot be demonstrated, it is tempting to speculate that the T-cell defect induced by lymphoma and subsequent chemotherapy might have contributed to the development of autoimmunity.
NEURALGIC AMYOTROPHY AFTER SHINGLES VACCINATION

Bashar Katirji, Carl Ansevin
University Hospitals Cleveland Medical Center, Neuromuscular Center & Emg Laboratory, Cleveland, United States of America

Background and Aims:: Neuralgic amyotrophy (aka Parsonage-Turner Syndrome) is often idiopathic but, in about half of the cases, may follow strenuous exercise, pregnancy, surgery, bacterial or viral infections, or vaccinations.

Methods:: Review clinical, laboratory, imaging, and electrophysiological data of a patient who developed neurologic amyotrophy after receiving a vaccination for shingles.

Results:: A 56-year-old woman developed severe pain in the right shoulder and arm 2 weeks after receiving herpes zoster vaccine in the right arm. Within several weeks of the pain, she noted severe weakness of shoulder elevation. The pain improved over the next 2-3 months. Her neurological examination, 2 months after onset of symptoms, was pertinent for severe weakness of the right shoulder abduction, shoulder external rotation and elbow flexion (MRC 4-/5). Elbow extension and hand/wrist strength were normal. There was no sensory loss. The right biceps reflex was absent while the left biceps, and both triceps reflexes were +2. MRI of the cervical spine showed a mild C4-5 disc bulging with no foraminal stenosis at C4-5 or C5-6 on the right. Both motor and sensory nerve conduction studies were normal including median and lateral antebrachial sensory responses. Needle examination showed prominent active denervation with reinnervation in the right supraspinatus, infraspinatus, deltoid and biceps muscles. The brachioradialis, pronator teres, rhomboid and cervical paraspinal muscles were normal.

Conclusions:: This patient developed classical manifestations of neuralgic amyotrophy soon after herpes zoster vaccination in the ipsilateral arm. She had acute pain followed by weakness/denervation in the right suprascapular, axillary and musculocutaneous nerves.
USE OF DRUGS FOR ATTRV AMYLOIDOSIS IN THE REAL WORLD: HOW THERAPY IS CHANGING SURVIVAL IN A NON-ENDEMIC AREA

Massimo Russo\textsuperscript{1}, Luca Gentile\textsuperscript{2}, Gianluca Di Bella\textsuperscript{1}, Fabio Minutoli\textsuperscript{3}, Antonio Toscano\textsuperscript{1}, Filippo Brighina\textsuperscript{4}, Giuseppe Vita\textsuperscript{1}, Anna Mazzeo\textsuperscript{1}

\textsuperscript{1}University of Messina, Department Of Clinical And Experimental Medicine, Messina, Italy, \textsuperscript{2}University of Messina, Department Of Clinical And Experimental Medicine, MESSINA, Italy, \textsuperscript{3}University of Messina, Department Of Biomedical And Dental Sciences And Morphofunctional Imaging, Messina, Italy, \textsuperscript{4}University of Palermo, Department Of Experimental Biomedicine And Clinical Neurosciences, Palermo, Italy

Background and Aims:: Background: Over the past decade, 3 new drugs have been approved for the treatment of familial TTR amyloid polyneuropathy; aim of this work is to analyze if current therapies have prolonged survival in patients affected by ATTRv amyloidosis.  
Methods:: The study was conducted retrospectively, analyzing the medical records of 105 patients with genetic diagnosis of familial amyloidotic polyneuropathy followed at the 2 referral centers for the disease in Sicily (University of Messina and Palermo ). Of these, 71 patients received disease-modifying therapies, while 34 received only symptomatic treatments or no therapy  
Results:: The most used treatment in our patient cohort was tafamidis followed by liver transplant, patisiran, inotersen and diflunisal. Survival was significantly longer in treated vs untreated patients. Patients diagnosed in the early stage of the disease (PND 0-1) had a significantly longer survival than those diagnosed in the late stage (PND 2-3-4).  
Conclusions:: As predicted in previous reports, the prevalence of transthyretin amyloidosis is significantly increasing in Sicily Island thanks to a greater attention to this pathology. The disease modifying therapies, up to now in percentage mainly represented by tafamidis, have significantly improved the survival of patients. When patients are diagnosed at PND stage 1, their overall survival is longer.
RELATIONSHIP OF PHARMACOKINETICS AND PHARMACODYNAMICS TO APITEGROMAB EFFICACY IN PATIENTS WITH LATER-ONSET SPINAL MUSCULAR ATROPHY (TYPES 2 AND 3 SMA): RESULTS FROM THE TOPAZ STUDY

Thomas Crawford1, Amy Place2, Doreen Barrett3, Shaun Cote4, George Nomikos5, Guochen Song5, Sanela Bilic6, Ashish Kalra7, Mara Sadanowicz8, Janet O’Neil8, Ryan Iarrobino9, Nathalie Kertesz2, Yung Chyung5

Background and Aims:: Apitegromab is an investigational, fully human, monoclonal antibody that inhibits myostatin activation by specific binding to myostatin proforms, promyostatin and latent myostatin. We will present data, from the Phase 2 TOPAZ clinical trial (NCT03921528), on the relationships of pharmacokinetics (PK) and pharmacodynamic (PD) (marker of target engagement, latent serum myostatin levels) to apitegromab efficacy.

Methods:: The phase 2 study of apitegromab was a 52-week trial conducted in subjects with late-onset SMA (age 2-21 years). Patients received IV apitegromab every 4 weeks, either as monotherapy or as an adjunct to nusinersen. Primary endpoints were efficacy (assessment of motor function improvements via the Hammersmith scale scores) and safety.

Results:: In the TOPAZ study, 58 patients were dosed in 3 cohorts. Cohort 1 enrolled 23 ambulatory patients with SMA. Cohort 2 enrolled 15 patients with nonambulatory Type 3 SMA or Type 2 SMA. Patients in cohorts 1 and 2 received 20 mg/kg apitegromab. Cohort 3 enrolled 20 patients with Type 2 SMA and received either 2 mg/kg or 20 mg/kg in a double-blind, randomized 1:1 manner. Relationship of PK/PD measures with motor function efficacy endpoints of apitegromab will be presented.

Conclusions:: This information is helpful in understanding latent myostatin dynamics, apitegromab’s effects in SMA and to the planning of future studies. Apitegromab has the potential to be the first muscle-directed therapy to address motor function impairment affecting patients with Types 2 and 3 SMA.
NORMATIVE ELECTROPHYSIOLOGIC REFERENCE VALUES FOR THE LATERAL AND MEDIAL ANTEBRACHIAL CUTANEOUS NERVES AMONG ADULT SUDANESE POPULATION

Mohammed Salah Magzoub¹, Ahmed Gesmelseed²
¹College of Applied Medical Sciences - Jubail / Imam Abdulrahman bin Faysal University, Neuroscience, Jubail, Saudi Arabia, ²Faculty of Medicine, Physiology, Khartoum, Sudan

Background and Aims:: Nerve conduction studies (NCS) help in assessing peripheral nerve injuries by localizing focal lesions, defining severity, and distinguish axonal from demyelinating disorders. Objective: To obtain electrophysiological normative values for the lateral and medial antebrachial cutaneous nerves (LACN and MACN) among healthy adult Sudanese populations.

Methods:: This is a descriptive, analytic, cross-sectional study conducted in El Magzoub Neuroscience Center Khartoum, Sudan. It included 200 LACN and 200 MACN from eligible Sudanese volunteers using standardized techniques.

Results:: The mean ± SD values of the onset and peak latencies (ms), amplitude (µV), and conduction velocity (m/s) of LACN for the whole participants were 1.75 ± 0.31, 2.27 ± 0.31, 22.77 ±11.71 and 71.01 ±14.06 respectively. Parameters of the left LACN were 1.65 ± 0.29, 2.20 ± 0.27, 23.43 ± 13.18 and 75.59 ± 15.27. While that of the right LACN were 1.85± 0.3, 2.34 ± 0.33, 22.11 ± 10.04 and 66.43 ± 11.0 respectively. The findings of the MACN for the whole participants were 1.67 ± 0.33, 2.17 ± 0.43, 15.53 ± 9.01, and 74.69 ± 13.91, respectively. Values of the left MACN were 1.64 ±0.35, 2.14 ± 0.42, 15.47 ± 8.86 and 76.84 ± 14.2, and those of the right LACN were 1.69 ±0.31, 2.20 ±0.44, 15.22 ±9.21 and 73.43±13.47 respectively.

Conclusions:: Proper positioning of electrodes and the use of low-intensity stimulation are essential measures to obtain a satisfactory recording for these nerves. Furthermore, anthropometric measures, particularly gender, sidedness, and temperature must be taken into consideration as they influence the values of the obtained recordings.
IMPACT OF COVID-19 ON A GROUP OF PATIENTS WITH MYASTHENIA GRAVIS

Giulio Sansone¹, Elisa Albertini², Silvia Guidoni², Domenico Bonifati²
¹Università degli Studi di Padova, Neurology, Padova, Italy, ²Ca' Foncello Hospital, Neurocardiovascular, Treviso, Italy

Background and Aims:: Myasthenia gravis (MG) is an autoimmune disease affecting the neuromuscular junction. The most severe complications are bulbar exacerbations and myasthenic crises, of which respiratory infections represent an important risk factor. The aim of the present study is to evaluate the impact of COVID-19 on MG patients.

Methods:: We retrospectively reviewed clinical records of all SARS-CoV2 positive MG patients who regularly attended the myasthenic outpatient clinic at the Treviso Hospital from March 2020 to March 2021. For each patient, we collected clinical features, MG outcome and COVID-19 severity using a WHO- and SIAARTI-based classification.

Results:: Nineteen patients have been enrolled (10 females, 9 males, mean age 62 years). COVID-19 severity resulted as follows: 1 patient was asymptomatic, 10 had mild symptomatic disease/pneumonia, 6 had severe pneumonia, 1 had moderate-severe acute respiratory distress syndrome (ARDS), 1 died. MG outcome was unchanged in 15 patients, an increase/change of therapy was necessary in 2, there were 1 bulbar exacerbation and 1 myasthenic crisis treated with intravenous immunoglobulins. In 4 patients we found other known exacerbating factors, in particular: infections other than SARS-CoV2 and medications to use with caution in MG.

Conclusions:: This is a preliminary group of MG patients with COVID-19. A high prevalence of severe COVID-19 cases have been found (7/19 had severe respiratory manifestations and 1/10 died). On the other hand, MG outcome does not seem to be associated with COVID-19 severity. Larger studies are necessary to confirm these data and to evaluate associations between COVID-19 severity, MG severity and baseline therapy.
NORMAL NEUROPHYSIOLOGIC PARAMETERS OF THE TIBIAL NERVE AMONG ADULT HEALTHY SUDANESE POPULATION

Mohammed Salah Magzoub¹, Ahmed Noury²
¹College of Applied Medical Sciences - Jubail / Imam Abdulrahman bin Faysal University, Neuroscience, Jubail, Saudi Arabia, ²Orotta College of Medicine and Health Sciences, Physiology, Asmara, Eritrea

Background and Aims:: Nerve conduction studies (NCSs) are noninvasive diagnostic tools of peripheral nervous system disorders. They help in the prognosis, and monitoring of a disease process. The aim of this study is to establish the normative data of the tibial nerve among the healthy adult Sudanese population and to study the effects of age, gender, height, weight, and temperature on the obtained parameters.

Methods:: NCSs were performed in 210 tibial nerves of 105 adult healthy Sudanese subjects using standardized techniques.

Results:: It was found that the tibial nerve values were as follows; distal latency 4.063±1.0533 m/sec, proximal latency 13.238 ±1.7253 m/sec, the amplitude at ankle 8.528±3.6658 μV, the amplitude at popliteal fossa 6.343±3.2871μV, conduction velocity 48.58±5.634 m/sec, F wave 51.509±6.1013 m/sec. Duration of CMAP at ankle 6.199± 1.0254 m/sec, Area at ankle 17.569±7.7389μV/ms. Duration of at popliteal 7.075±1.3173 m/sec, and area at popliteal fossa 14.914±7.8684 μV/ms.

Conclusions:: This is the first study to establish reference values for tibial NCS in Sudan. Parameters for the tested nerve compared favorably with the existing literature with some discrepancies that were justified.
PROXIMAL WEAKNESS INVOLVEMENT IN THE FIRST ITALIAN CASE OF CHARCOT-MARIE-TOOTH
2CC HARBORING A NOVEL FRAMESHIFT VARIANT IN NEFH

Francesco Aruta¹, Daniele Severi¹, Aniello Iovino¹, Emanuele Spina¹, Melissa Barghigiani², Lucia Ruggiero¹, Rosa Iodice², Filippo Maria Santorelli², Fiore Manganelli¹, Stefano Tozza¹
¹University of Naples Federico II, Department Of Neuroscience And Reproductive And Odontostomatological Sciences, Napoli, Italy, ²IRCCS Fondazione Stella Maris, Molecular Medicine, Pisa, Italy

Background and Aims:: Charcot-Marie-Tooth (CMT) disease is a clinically and genetically heterogeneous group of inherited sensory-motor neuropathies. In 2016, Rebelo et al. identified in two family a new causal CMT2 gene: a frameshift mutation in the neurofilament heavy chain (NEFH) gene with autosomal dominant inheritance (CMT2CC). The aim of this report is to describe the first Italian case of CMT2CC related to de novo frameshift mutation in the NEFH gene.

Methods:: The index case was a 28-year-old woman; at the age of 25 years, she developed difficulties to climb stairs and muscle weakness progressively worsened. No sensory symptoms were complained. Electrophysiological findings showed a sensory-motor axonal neuropathy, predominantly affecting the lower limbs.

Results:: In the proband, we identified the de novo heterozygous frameshift mutation c.3058_3059insT (p.K1020fs*) in the NEFH gene. The majority of patients harboring a frameshift mutation in NEFH had early and prominent involvement in proximal muscles, an unusual finding for classical length-dependent neuropathies. Conversely, the clinical phenotype was more similar to a classic, length-dependent CMT in the Chinese family harboring a missense mutation in NEFH.

Conclusions:: Type and location of mutation might influence clinical characteristics and perhaps disease progression. Under this hypothesis, frameshift variants cause a prominent involvement of hip and thigh muscles, whereas point mutations might cause a more typical length-dependent neuropathy with distal muscular involvement. NEFH-related neuropathy should be regarded as a form of CMT with proximal involvement. Red flags to assist clinicians before embarking in NGS studies include prevalently proximal muscle weakness in the legs in patients with axonal sensory-motor neuropathy.
A NEW CASE OF TRIM32/ASTN2 DELETIONS CONFIRM THE ASSOCIATION OF LMGD WITH MCI

Roberta Bencivenga¹, Monica Traverso², Emanuele Giaquinto¹, Rosa Iodice¹, Fiore Manganelli¹, Chiara Fiorillo², Lucia Ruggiero¹
¹University of Naples "Federico II", Department Of Neurosciences, Reproductive, And Odontostomatological Sciences, Naples, Italy, ²Pediatric Neurology and Muscular Diseases Unit University of Genoa, "G. Gaslini" Institute, Department Of Neurosciences, Rehabilitation, Ophtalmology, Genetics, Maternal And Child Health, Genova, Italy

Background and Aims:: Defects in TRIM32 gene were reported in limb-girdle muscular dystrophy type 2H (LMGD2H). Homozygosis deletion of the entire TRIM32 gene and part of ASNT2 gene was previously described in only one patient presenting LMGD2H with a mild cognitive impairment (MCI). Interesting ASTN2 gene encodes a protein expressed in the brain and probably involved in neuronal migration. We provide an extensive phenotypic description of the second case of TRIM32/ASTN2 deletion.

Methods:: The genetic defect was detected by combined approaches of next generation sequencing (NGS) and comparative genomic hybridization (CGH) array. Muscle biopsy, electromyography (EMG), muscle and brain magnetic resonance (MRI) and neuropsychological tests supported the clinical phenotype characterization.

Results:: A 40-years-old male developed progressive weakness at limbs girdle from the age of 15. Neurological examination demonstrated weakness of scapular girdle muscles, difficulty rising from the floor, climbing stairs and walking. Serum creatine phosphokinase levels were 5 times normal. Muscle biopsy showed dystrophic changes with atrophic type I fibers. Muscle MRI proved both pelvic girdle and lower limbs involvement. Brain MRI was normal. Neuropsychological tests revealed a mild cognitive impairment. An NGS panel for LGMD did not detect pathogenetic variant but conflicting results on the TRIM32 coverage. A CGH array allowed the detection of homozygous 82 kb deletion of 9q including the whole TRIM32 gene and part of ASTN2 gene.

Conclusions:: Disruption of the ASTN2/TRIM32 should be considered in patients presenting a non-specific LMGD and a neurocognitive disease. Hence the importance of considering the roles of TRIM32 and ASTN2 in synaptic connectivity and neuronal circuits.
Background and Aims:: Pompe disease is a rare disease, known as type II glycogenesis. It is classified into two forms, the first is infantile, they manifest before the first year of life, the classic form presents with cardiomyopathy and corresponds to the most severe extreme. The second is late-onset, usually involves the extremities and the diaphragm, progressive myopathy occurs, little cardiac involvement but great involvement of the accessory respiratory muscles, which leads to relatively early respiratory failure, this being the main cause of death. the objective of this study was to describe the quality of life of a group of patients with Pompe disease.

Methods:: Descriptive cross-sectional study in 27 patients with Pompe disease. The data collection was done from March 9 to May 20, 2020 by Google Form. The Medical Outcomes Study 36-Item Short Form (SF-36) was applied.

Results:: The mean age is 40.52 years, 59% female, 51% married, 63% active in the workplace, the mean age of diagnosis was 30.3 years (SD = 15.557), 66.7% do not use a wheelchair to move around and 96.3% are on enzyme therapy.

Conclusions:: The pompe is highly disabling when it affects more in the physical dimensions, however patients can actively play their social and family role. Follow-up studies are required to demonstrate the impact of the pandemic on the application of enzyme therapy.
A CASE OF PARAMYOTONIA AND PERIODIC PARALYSIS ASSOCIATED WITH AN UNREPORTED MUTATION IN THE CACNA1S GENE

Eugenio Razzino1, Ilaria Orologio2, Mariarosa Melone1, Simone Sampaolo1
1Università della Campania, I Clinica Neurologica, Napoli, Italy, 2AOU Luigi Vanvitelli, Ii Neurologia, Naples, Italy

Background and Aims:: Mutations in the CACNA1S gene are known to be associated with malignant hyperthermia, thyrotoxic periodic paralysis, hypokalemic periodic paralysis type I, and congenital myopathy, but not myotonia.

Methods:: We studied a case of overlapping episodic weakness and stiffness by using a series of assessments including medical history, physical examination, laboratory analyses, electrophysiological evaluation, MRI and genetic analysis.

Results:: We report the case of a 21-year-old man with onset at the age of 14 years of episodic painful muscle stiffness after exercise, first in the upper limbs, after a few months spread to the legs and trunk muscles, sparing the head. Two years later he began experiencing episodes of severe weakness lasting several hours, more common in cold weather, after a hard day’s work or carbohydrate-rich meal. Neurologic examination showed hyperreflexia, paradoxical myotonia and fasciculations. CPK, thyroid hormones, electrolytes levels were normal. Autoimmune disorders were excluded. EMG revealed spontaneous activity at multiple sites but not myotonia. Brain and spine MRI lacked any pathological sign. Multigene NGS analysis demonstrated a missense variant in CACNA1S p.Arg557Cys (c.1669 C>T), not previously reported in the literature, of uncertain pathological significance. Segregation analysis found the same variant in the patient’s mother, who reported a similar clinical picture, pointed to its likely pathogenicity.

Conclusions:: This is the first report of a new likely pathogenic variant of the CACNA1S gene, with a clinical phenotype combining paradoxical myotonia and periodic paralysis. Such phenotype was previously associated with variations in the SCNA4 gene, but never in the CACNA1S gene.
THYMUS CHARACTERISTICS IN SEROPosITIVE AND SERONEgATIVE MYASTHENIA GRAVIS

Oyunaa Chimedregzen1, Sarangerel Jambal2, Munkhbayar Rentsenbat2, Byambasuren Dagvajantsan1
1Mongolian National University of Medical Science, School of Medicine, Neurology, Ulaanbaatar, Mongolia, 2Reflex Neurological Clinic, Neurology, Ulaanbaatar, Mongolia

Background and Aims:: Myasthenia gravis (MG) is an autoimmune disorder of neuromuscular junctions. The study of Yi Li et al. has shown that 70-85% of all patients with MG were seropositive and 8-15% seronegative. The high frequency of thymus hyperplasia in seropositive patients. Between 10% to 20% of patients with MG have a thymoma. To our knowledge, any study of MG in Mongolia has not been published yet. To study association between thymus characteristics and serological findings in patients with MG.

Methods:: We reviewed a total of 14 adult patients with MG who were diagnosed by serological findings in a five-years period from 2015 to 2020. If Acetylcholine receptor antibody level is greater than 0.40 n/L were assessed seropositive. Thymus characteristics were assessed for Chest CT scans. Statistical analysis was performed using SPSS software.

Results:: A total 14 patients had Serological tests and Computed tomography. 85.7% (n=12) patients were seropositive, 14.3% (n=2) patients were seronegative in a serological test. Thymoma in 3 cases (10% of total MG), all patients were seropositive MG. Thymus hyperplasia in 5 cases, of these 80% of patients were seropositive MG and 20% of patients were seronegative MG. No changes of thymus in 6 cases, of these 83.3% of patients were seropositive MG, 16.7% of patients were seronegative MG.

Conclusions:: Similar to other countries, the high frequency of seropositive MG in Mongolia. Thymoma rarely occurred in 10% patients who have MG.
ACUTE MYOPATHY AT ONSET OF SARS-COV-2 INFECTION

Anna Maria Simone, Enrico Fileccia, Manuela Costa, Giulia Monti, Massimiliano Devetak, Luca Vaghi, Silvia De Pasqua, Mario Santangelo
AUSL Modena, Ramazzini Hospital, Internal Medicine, Neurology Unit, Modena, Italy

Background and Aims:: Although various reports indicated the presence of myalgia in 44–70% and “skeletal muscle injury” (increased CK and myalgia) in 23% of hospitalized patients with SARS-CoV-2 infection, the characterization of neuromuscular involvement is still unsatisfactory, and electrophysiologic studies have rarely been performed.

Methods:: We describe a case of acute myopathy at onset of SARS-CoV-2 infection.

Results:: A 73-year-old woman, with post-infarct ischemic heart disease in her medical history, presented with progressive weakness in the lower limbs and pain, without fever. On admission, neurological examination showed proximal tetraparesis, prevalent in the lower limbs, and reflexes were diminished. CK in the serum was to >6000 U/L (normal value 10-145 U/L), hepatic enzymes were elevated (GOT 814 U/L, n.v. 1-31), urin Hb > 1 (n.v. absent). Polymerase chain reaction (PCR) testing for SARS-COV-2 was positive. Chest x-ray showed right lower patchy opacities, but oxygen saturation was 94% on room air. Motor nerve conduction studies (NCS) showed mild sensory polyneuropathy; the needle electromyography (EMG) demonstrated myopathic abnormalities with fibrillation potentials in the lower limbs, rapid recruitment on interference pattern and reduced compound muscle action potential amplitude. The therapy with high dose of steroids induced significative clinical improvement. In two weeks, CK levels almost normalized and the patient recovered the ability to walk with assistance.

Conclusions:: The severe immune activation known to occur in COVID-19 patients probably plays an important pathophysiological role for onset of rhabdomyolysis, but further studies are needed to elucidate the mechanisms, appropriate treatment, and long-term clinical outcomes of muscular manifestations associated with COVID-19 disease.

ELECTROPHYSIOLOGICAL FEATURES OF GUILLAIN BARRE SYNDROME IN MONGOLIA

Gantuya Gantumur¹, Munkhbayar Rentsenbat², Sarangerel Jambal², Byambasuren Dagvajantsan³
¹School of Medicine, Mongolian National University of Medical Sciences, Department Of Neurology, Ulaanbaatar, Mongolia, ²Reflex neurological clinic, Neurology, Ulaanbaatar, Mongolia, ³Mongolian-Japan hospital, Mongolian National University of Medical Science, Department Of Neurology, Ulaanbaatar, Mongolia

Background and Aims:: Electrophysiological subtypes are important nonclinical factors to define the prognosis of patients with GBS. Many studies revealed that axonal subtype is associated with increases risks of delayed recovery, disability and mortality. It is evident that axonal subtype is higher in Asian countries. To determine the predominant electrophysiological subtype is important for treatment options. The aim of this study is to determine electrophysiological subtypes of GBS in Mongolia.

Methods:: The data was collected retrospectively from 2016 to 2019 at the Reflex Neurological Clinic. 75 patients enrolled in the study. Motor and sensor nerves were recorded on one-side using standard techniques with surface electrodes in upper and lower extremities. All statistical analyses were performed using STATA 26. The level of statistical significance was set at p<0.05.

Results:: Of 75 patients, an average age was 45±15 (18-73) and males were 44% (n=33). For antecedent events, Upper respiratory infection was 9.3%, diarrhea 21.3%, other factors 22.7%, no factors associated were 46.7%. Nerve-conduction study was evaluated with Hadden criteria, and 42.9% was classified as demyelinating (n=24), 37.5% axonal (n=21), 1.8% inexcitable (n=1), 14.3% equivocal (n=8) and 3.6% normal (n=2). Abnormal changes of demyelinating subtype were recorded in all nerves, whereas axonal subtype changes recorded clearly in N.medianus and N.Peroneus. Demyelinating and axonal subtypes were observed equally in all age groups. But axonal subtype was highly associated with disability and mortality (p<0.05). Patients with equivocal and normal ENG features were not reassessed further.

Conclusions:: In Mongolia, demyelinating subtype was predominant however axonal subtype remained higher.
THYMECTOMY IS THERAPEUTICALLY BENEFICIAL FOR PATIENTS WITH MYASTHENIA GRAVIS IN EAST AFRICA: A CLINICO-DEMOGRAPHIC STUDY OF 85 CASES

Anthony Ochola, Jasmit Shah, Peter Mativo, Juzar Hooker, Dilraj Sokhi
Aga Khan University Medical College of East Africa, Department Of Medicine, Nairobi, Kenya

Background and Aims:: There are very few studies from sub-Saharan Africa on myasthenia gravis (MG), with some evidence from South Africa that the disease differs from global trends. This has never been quantified in East Africa. We therefore sought to describe the clinical features, treatment strategies and disease course in MG patients referred to our tertiary regional neurology centre.

Methods:: In a retrospective study covering the period 2009-2019, we captured clinical data of MG patients, and recorded clinical status using the Myasthenia Gravis Foundation of America (MGFA) classification. We sub-analysed the therapeutic effects of thymectomy.

Results:: In n=85 [male=56.5% (48/85); mean age 49.6 years], 30.6% (26/85) had ocular MG (MGFA class 1), and 69.4% (59/85) had generalised MG, of which (at onset) 72.8% (43/59) had mild/moderate (class II/III) disease. Average time to diagnosis was 3.0 months. 36.1% (30/85) had a thymus, and were significantly (p<0.05) more likely to have: anti-acetylcholine receptor antibodies (89.7% vs 57.4%); generalised MG (93.1% vs 50.9%); early immunosuppression requirements (96.6% vs 76.8%); and more relapses (79.3% vs 44.6%). 29/30 underwent thymectomy. resulting in: (i) significant (p<0.05) median dose reduction of pyridostygmine (240mg to 90mg) and prednisolone (25mg to 5mg) by last follow-up [non-thymectomy patients required significantly higher median doses (pyridostigmine 181mg, prednisolone 9mg)]; and (ii) improvement by ≥1 class of MGFA in 96.5% (28/29), with 24 becoming asymptomatic and 2 achieving complete remission requiring no medication.

Conclusions:: Our cohort’s disease characteristics follow global trends: thymectomy leads to reduction in immunosuppression with better symptom control, and should therefore be standard of care in eligible patients.
NORMATIVE DATA FOR LOWER LIMB NERVE CONDUCTION STUDIES IN MONGOLIA

Gansuvd Oidovdori¹, Enkhjargal Manjiilaa¹, Amartuvshin Batbayar¹, Oyunbileg Batkhuyag², Mendjargal Naranbat¹, Byambasuren Dagvajantsan³
¹Mongolia-Japan hospital, Mongolian national university of medical sciences, Department Of Neurology, Ulaanbaatar, Mongolia, ²Mongolian National University of Medical Sciences, Postgraduate Institute, Ulaanbaatar, Mongolia, ³Mongolian-Japan hospital, Mongolian National University of Medical Science, Department Of Neurology, Ulaanbaatar, Mongolia

Background and Aims:: Nerve conduction study is widely used to diagnose peripheral nerve diseases. Normative data is essential part of the evaluating the abnormality, therefore most individual laboratories use their own techniques and reference data. We aimed to provide normative electrophysiological data for lower limb nerves in normal healthy adults in Mongolia

Methods:: Nerve conduction studies were performed in lower limbs of 69 healthy adults using standardized techniques. The peroneal and tibial nerves met the NDTF criteria. Nihon Kohden Neuropack S1 machine was used.

Results:: A 69 healthy subjects were investigated, female 47.8% and male 52.2%, age ranged 18-71. Mean onset latencies were 3.8 ±0.6 and 4.1±0.8 ms, amplitudes were 4.2±2.1 and 12.6±4.3 mV, and conduction velocities were 50.8±5.2 and 45.3±5.5 ms for peroneal and tibial motor nerves, respectively. Also, minimal latency of F waves were 46.4±3.9 ms, 46.7±4.0 ms, side to side difference were 1.8±1.2, 1.2±1.0. As H reflex, H latency was 31.08±3.06, M latency was 4.3±0.84, and H/M ratio was 0.3±0.3. In sensory nerves, mean onset latencies were 2.7±0.8 and 2.4±0.4 ms, mean amplitudes were 7.2±3.9 and 16.6±9.1 µV, and mean nerve conduction velocities were 45.3±8.2 and 49.7±8.3 ms for superficial peroneal and sural nerves, respectively. Peroneal motor conduction velocity in females higher than males, whereas tibial sensor latency in females shorter than males. Peroneal sensor amplitude in BMI<24.9 higher in BMI>25. Latency to the peroneal and tibial increased with increasing height.

Conclusions:: Our study results are similar to those data published in the literature. Also, we should be considering demographic factors in NCV.
COMPARISON OF PREVALENCE AND RISK FACTORS FOR PERIPHERAL NEUROPATHY BETWEEN PATIENTS WITH HIV INFECTION AND PATIENTS WITH CONCURRENT HIV AND DIABETES MELLITUS

Pascal Kuka1, Jasmit Shah2, Uazman Alam3, Dilraj Sokhi2, Reena Shah2
1Aga Khan University Hospital, Internal Medicine, Nairobi, Kenya, 2Aga Khan University Medical College of East Africa, Department Of Medicine, Nairobi, Kenya, 3Aintree University Hospital, Medicine, Liverpool, United Kingdom

Background and Aims:: The ageing population living with HIV is predisposed to non-communicable comorbidities, including diabetes. Peripheral neuropathy (PN) can occur in both conditions, and it is thought co-existence of both illnesses has a synergistic impact on PN. We sought to identify the prevalence of PN in our population of patients with HIV infection compared with those with both HIV and diabetes.

Methods:: We undertook a prospective cross-sectional study at tertiary regional referral hospital. We collected demographics, duration of treatments and disease characteristics. PN symptoms was assessed by the Neuropathy Symptom Score and examined using the Neuropathy Disability Score and monofilament testing.

Results:: We recruited 68 patients in either group; 55% were males, and median age was 51 years. Overall median duration for HIV was 10 years with median CD4 count of 524 cells/mm³ and for HIV/diabetes group average 3.85 years since diabetes diagnosis with a mean HbA1c of 7.65%. 67% of patients had suppressed viral loads, and 9 patients (6.6%) had history of neurotoxic anti-retroviral therapy use. PN was detected in 11 (16%) HIV-only patients, and in 17 (25%) participants who had both HIV and diabetes (Fisher exact test and corrected chi-square=0.4). In univariate analysis, old age, high BMI and long duration of HIV were associated with OR of 1.07, 1.21 and 1.07 in the overall group, respectively.

Conclusions:: The analysis of our study revealed slightly higher but non-significant prevalence of PN in patients with both HIV and diabetes when compared to HIV alone. HIV disease control had no association with development of PN.
Background and Aims:: In the last decades, there has been a steady increase in the frequency of late-onset (≥50 years-of-age) myasthenia gravis (MG). Recently, the so-called very late-onset MG (VLOMG, onset ≥65 years) was reported as the most common disease subtype. We investigated the demographic changes over two decades and VLOMG characteristics in a single-centre cohort.

Methods:: Patients with onset between 2000 and 2020 were included. AChR and MuSK antibodies (Abs) were tested by standard RIA. We recorded clinical data and Ab status, and compared the demographics of MG patients with onset in the first (2000-2009) vs. the second decade (2010-2020).

Results:: Our study included 674 patients (333/674 females, 49%): 567 AChR-Ab positive, 54 MuSK-Ab positive and 53 double-seronegative patients. MG onset peaked between 65 and 69 years of age through the whole observation period. In the last decade, we observed a sharp increase in the proportion of VLOMG cases (p<0.0001) paralleled by a significant rise of male frequency (p<0.0001). The VLOMG subtype mostly consisted of AChR-Ab positive cases. Only 6/54 (11%) MuSK-Ab positive patients had VLOMG, 5/6 with disease onset in the last decade. Compared to late-onset MG, VLOMG was characterized by a very high AChR-Ab positivity rate (95.6% vs 84.1%,p<0.0001), and a reduced association with thymoma (12.7% vs 29.4%,p<0.0001).

Conclusions:: In the last decade, VLOMG has become the larger disease subtype. The high rate of AChR-Abs we found in VLOMG facilitates its diagnostic confirmation. Our study provides diagnostic clues that aid the recognition of MG in the elderly.
Background and Aims: Background: Myasthenia gravis (MG) is an autoimmune disorder caused by antibodies to the muscle acetylcholine receptors (AChRs) at the neuromuscular junction.

Objectives: To study the demographic, clinical features and drug prescribing pattern of patients with myasthenia gravis in Penang hospital.

Methods: This is a cross-sectional retrospective study. Data were collected from the database from neurology clinic Penang hospital from 1976 to 2012.

Results: Findings: 186 myasthenia cases were identified. 55% were females. Majority were Chinese (58%) compared to Malays (32%) and Indians (10%).

Mean age at onset was 46 years.

Ocular symptoms were the most commonly seen as initial presenting symptoms. 100 patients (54%) with Osserman grade I at onset, 33 with Osserman GIIA, 42 with Osserman GIIB, 7 with grade III at onset.

20% of patients had thymectomy.

11% of patients had history of myasthenic crisis with ICU stay requiring IVIG during the course of illness.

51 MG patients has concurrent DM, 35 patients has concurrent HPT, 12 patients asthma, 4 patients has Graves or thyrotoxicosis.

Conclusions: Conclusion: Our study showed that MG has female predominance, similar to world data.
MOLECULAR DIAGNOSIS OF DUCHENNE MUSCULAR DYSTROPHY: SYSTEMATIC REVIEW AND META-ANALYSIS.

Carlos Alva-Diaz1,2,3,4, Marco Malaga Julca5,6,7, Peggy Martinez-Esteban8,9, Paula Moran Ballon5,6,7, Fabian Chavez Ecos2,10, Niels Pacheco-Barrios2,11

1Hospital Daniel Alcides Carrion, Servicio De Neurologia, Departamento De Medicina Y Oficina De Apoyo A La Docencia E Investigacion (oadi), Lima, Peru, 2Red de Eficacia Clinica y Sanitaria, Redecs, Lima, Peru, 3Universidad Cientifica del Sur, Grupo De Investigacion Neurociencia, Efectividad, Clinica Y Salud Publica, Lima, Peru, 4Universidad Cientifica del Sur, Facultad De Ciencias De La Salud, Lima, Peru, 5Grupo Estudiantil de Investigación en Neurociencia, Lima, -, Peru, 6Universidad San Martin de Porres, Lima, Lima, Peru, 7Red de Eficacia Clinica y Sanitaria, Research, Lima, Peru, 8Sociedad de Neurología, Neurology, Lima, Peru, 9Instituto Nacional de Salud del Niño - San Borja, Neurology, Lima, Peru, 10Universidad San Luis Gonzaga de Ica, Ica, Ica, Peru, 11Universidad Peruana Cayetano Heredia, Facultad De Medicina Humana, Lima, Peru

Background and Aims:: Duchenne Muscular Dystrophy (DMD) is a disease caused by a mutation in a gene linked to the X chromosome, that produces dystrophin. Its diagnosis is based in your detecting, it is possible to use different techniques such multiple ligand-dependent probes (MLPA) and new sequencing generation (NGS) among others. We aimed to know the accuracy of this methods.

Methods:: A systematic review about the genetic diagnosis for DMD using MLPA and NGS were done. A search was performed in PubMed/Medline and Scopus, the quality was assessment with Quadas-II instrument and the certainty with GRADE system. Meta-analysis were performed to estimate accuracy indicators such sensitivity, specificity or detection rate (true positives of all confirmed patients). The univariate random-effects model was used and heterogeneity was assessed with I-squared(I2), while publication bias with funnel plot and Egger's test.

Results:: For MLPA, with 10 observational studies we estimate a sensitivity of 0.80(95%CI:0.76-0.84, I-square:86.48) and specificity was 0.93(CI 95%: 0.87-0.96, I2:47.27). For NGS, with 14 observational studies we estimate a DR of 73.17(95%CI:60.46-85.88, I-squared:95.96%). Also, with 10 observational studies (n=3958) of cases evaluated by NGS in patients with clinical suspicion and negative DMD for MLPA, the DR was 94.73 (95%IC:92.34–97.11, I-squared: 95.41%)

Conclusions:: With moderate and small certainty, in patients with DMD’ suspicion, the MLPA test has a very precise sensitivity and specificity to establish the diagnosis and the NGS test has a detection rate moderate, and in who have an MLPA result negative (18to20%), the application of NGS adds a 73% detection rate, which would reach 95% of detected cases.
LEWIS-SUMNER SYNDROME WITH LOWER-LIMB ONSET: UN UNDER-RECOGNIZED ENTITY

Alina Rizvanova, Eugeniya Melnik, Daria Grishina, Natalia Suponeva
Research Center of Neurology, Department For Peripheral Nerve Disorders, Moscow, Russian Federation

Background and Aims:: Lewis-Sumner syndrome (LSS) is an atypical form of chronic inflammatory demyelinating polyneuropathy (CIDP) with clinical phenotype of asymmetric motor and sensory disturbances with initial involvement and more prominent presentation in the arms. However, some of these patients may have lower-limb onset, making the diagnosis more challenging. The aim of our study was to estimate the prevalence of lower-limb onset patients with LSS and define their clinical features. Methods:: We collected data from 32 medical charts of patients with LSS. All the patients satisfied at least “probable” criteria EFNS/PNS, 2010. Results:: We evaluated that 15/32 (46%) of the patients presented with lower-limb onset. 4/32 (12%) had only lower-limbs involvement at the time of diagnosis. All of them had an asymmetrical deficit. The mean time of the diagnosis in patients with symptoms only in the lower limbs was 10[3;12] vs 3[1;11] years (p<0,05). Nerve conduction study (NCS) of the lower limbs was lacking demyelinating features and interpreted as primary axonal in all patients. Only additional investigation of the upper extremities led to the diagnosis. Complementary investigation with nerve ultrasound revealed changes only in the upper extremities. Conclusions:: We demonstrated the high prevalence of LSS with lower-limb onset. Noteworthy, that some of the patients may have isolated clinical distribution in the lower limbs. This should raise the suspicion of LSS and highlight the importance of complex NCS of the upper and lower extremities in all patients with asymmetric neuropathy. We also found that nerve ultrasound of the lower extremities in LSS has limited significance.
A LATIUM REGION REGISTRY ON AMYOTROPHIC LATERAL SCLEROSIS

Ilaria Bacigalupo¹, Eleonora Lacorte¹, Flavia Mayer¹, Alessandra Di Pucchio¹, Fabrizio Marzolini¹, Paola Piscopo², Alessio Crestini², Maria Puopolo², Marialaura Santarelli³, Maurizio Inghilleri³,⁴, Antonio Petrucci⁵, Mario Sabatelli⁶, Nicola Vanacore⁷, I.S.S. Latium Registry Group⁸

¹Istituto Superiore di Sanità, National Center For Disease Prevention And Health Promotion, Rome, Italy, ²National Institute of Health, Rome, Italy, Department Of Neurosciences, Rome, Italy, ³ASL Roma 1, Presidio Ospedaliero San Filippo Neri, Rome, Italy, ⁴Sapienza University of Rome, Department Of Human Neurosciences, Rome, Italy, ⁵University of Rome "La Sapienza, Dept. Human Neurosciences, Rome, Italy, ⁶San Camillo Forlanini Hospital, Neurology And Neurophysiopathology, Rome, Italy, ⁷Fondazione Policlinico A. Gemelli IRCCS, Neurology, Roma, Italy

Background and Aims:: In 2016 a pathology registry of ALS was established in Latium (LaRALS) , a central region of Italy . The aim of the study was to describe the clinical and socio-demographic characteristics of patients enrolled in LaRALS, and to analyse possible gender differences.

Methods:: The LaRALS was conducted with a network of clinical centers, throughout the adoption of an information form filled . Data from ALS participants were analyzed to determine characteristics, such as site of onset, time of symptom onset to diagnosis, diagnostic level, education level, ALSFRS-R and BMI at visit, life-style and risk factors.

Results:: Between july 2016 and march 2017 were included in the LaRALS 353 patients, 200 males and 153 females, mean age at prevalence and disease onset was 66 ±11.1 years and 61.6 ± 11.9 years, respectively. The 60.9% of patients had a spinal onset, 26.6% bulbar onset and 8.2% generalized onset. The mean diagnosis delay for bulbar onset patients was 0.9±1.3 years, for spinal onset was 1.8±2.3 years and 1.1±1.2 years for generalized onset. The multivariate logistic analysis for female vs male showed an associaton statistically significant in bulbar site onset respect to spinal, BMI at visit, and some risk factors (smoking status, history of alcohol consumption, sport activity).

Conclusions:: The clinical and sociodemographic characteristic of patients included in the LaRALS are similar to patients included in other registries. The pathology registry could establish a better characterization of clinical form at site onset and gender differences in ALS.
SMALL VOLUME PLASMAPHERESIS: A CHOICE FOR GUILLAIN-BARRE SYNDROME’S TREATMENT

Khaoula Balili¹, Nissrine Louhab², Mohamed Chraa³, Latifa Adarmouch⁴, Abdelhamid Hachimi⁵, Najib Kissani⁶
¹University hospital of Mohamed VI, Neurology, Marrakesh, Morocco, ²Neuroscience Research laboratory of Marrakech Medical School, University Hospital Mohammed VI, Neurology Department, Marrakech, Morocco, ³Centre Hospitalier Universitaire Mohammed VI,, Neurology, Marrakesh, Morocco, ⁴Université Cadi Ayyad, University Teaching Hospital Mohammed VI, Marrakesh, Morocco, Public Health And Community Medicine, Marrakesh, Morocco, ⁵University Teaching Hospital Mohammed VI, Marrakesh, Morocco, ⁶Université Cadi Ayyad, Mohammed VI University Hospital Center, Neurology, Marrakech, Morocco

Background and Aims:: Plasma exchanges and intravenous immunoglobulin have proven to be effective in accelerating motor recovery in GBS. Developing countries as Morocco are often limited by the cost of treatment and the unavailability of substitute products. We report our experience to highlight the usefulness of small volume plasmapheresis (SVP) in the treatment of GBS. A technique based on nanofiltration without the use of substitutes which are limited by donors’ availability.

Methods:: The study was conducted without a commercial relationship and with respect for the ethical conditions. The study recruited 50 patients hospitalized in the neurology department of the Mohamed VI University Hospital of Marrakech for GBS according to the Brighton criteria. Patients received 5 sessions of SPV over 10 to 14 days. The efficacy evaluated by the evolution of the Hughes and MRC sum scores one month after the treatment, the use of mechanical ventilation, the mortality rate and the length of hospital stay.

Results:: We found that the mean MRC sum score increased from 29.8 ±13.1 to 45.4 ±15.3, the mean Hughes score increased from 3.7 ± 1.0 to 2.1± 1.6, the improvement in the MRC sum score was 15.6 and 84% of patients increased one or more grades on Hughes and MRC scores after one month of progression. Mechanical ventilation was required in 17.2 % with a mortality rate of 6.2 %, and the mean length of hospital stay was 15.4 ±5.1 days.

Conclusions:: SVP is an alternative for the treatment of GBS that can be used easily with a significant clinical improvement.
SPINAL MUSCULAR ATROPHY TYPE II WITH HYBRID SMN GENE: A CASE REPORT

Antoni Khosidik, Indra Sari Kusuma Harahap, Sri Sutarni, Cempaka Thursina Srie
Setyaningrum, Indarwati Setyaningsih
Gadjah Mada University, Neurology, Yogyakarta, Indonesia

Background and Aims:: Spinal muscular atrophy (SMA) is a neuromuscular disease with homozygous deletion of SMN 1 exons 7 and 8. In 5 to 30% of all SMA patients, exon 8 was retained and forming a hybrid SMN gene.

Methods:: Case Report

Results:: We report a 19-year-old female who presented with frequently fall when walking and had difficulty standing up again, since she was 1-year-old; suggested that she has SMA Type II. The ability to walk then gradually decrease; she totally could not stand and walk at 11-year-old. The weakness of upper extremities began at 14-year-old. Her older brother has the same weakness and died at 17-year-old. Neurological examination showed that the weakness was flaccid tetraparesis dominantly proximal part of the extremities. Scoliosis were found with Cob angle 71.4 degree. CK level and spirometry was normal. EMG examination showed axonophaty in motor nerve and preservation of sensory nerve, supporting the lesion in anterior cornu of the spine. Genetic examination showed that in SMN 1, exon 7 was deleted but exon 8 still remain. Usually patient with SMA type II could only sit, but in this patient she could stand and walk as highest motor milestone achievement.

Conclusions:: SMA patient with hybrid SMN gene has milder clinical manifestation and better life expectancy.
ASSOCIATION OF ALBUMIN, SODIUM AND POTASSIUM LEVELS WITH THE OUTCOME IN PLASMA EXCHANGE TREATED GUILLAIN BARRE SYNDROME

Indra Sari Kusuma Harahap, Fauziah Jayanti, Indarwati Setyaningsih
Universitas Gadjah Mada, Department Of Neurology, Yogyakarta, Indonesia

Background and Aims:: Guillain Barre Syndrome (GBS) is an autoimmune neuromuscular disease characterized by the acute progressive weakness, with the complication of respiratory distress. It is important to look for appropriate biomarker to predict the outcome of GBS. In this study, we assess three parameters: albumin, sodium and potassium, to know whether there is an association with the outcome of GBS patients.

Methods:: This cohort retrospective study used serum samples during admission from 66 GBS patients, hospitalized in public hospital Yogyakarta, treated with plasma exchange. The study started from January 2015 through November 2020. The clinical outcome was muscle weakness (measured by Medical Research Council sum score) at discharge.

Results:: Three parameters, albumin, sodium and potassium levels were measured (mean [SD] age 29.83 [17.99] years old; 40 males [60.6%] and 26 females [39.4%]; demyelination 33 [50%] and axonal 22 [50%]). During admission, the parameters level were (mean mmol/L [SD]) albumin 4.01 [0.51], sodium 137.39 [4.08], potassium 3.9 [0.42]. All patients were treated with plasma exchange with the mean number 5.45 times (SD 1.17). The association of these parameters with MRC sum score at discharge were albumin (r= -0.064, P=0.609), sodium (r=0.118, P=0.344) and potassium (r= -0.113, P=0.368). There were no significant association between albumin, sodium and potassium levels at admission with the MRC sum score at discharge.

Conclusions:: Albumin, sodium and potassium levels may not associate with the outcome of plasma exchange – treated GBS. It is important to study another parameters as biomarker to predict the outcome of GBS patient.
EATON LAMBERT SYNDROME (LEMS) IS A DIAGNOSTIC CHALLENGE AND STIMULATED SINGLE FIBER ELECTROMYOGRAPHY (SSFEMG) IS OFFERING A GREAT ROLE IN ITS EARLY DIAGNOSIS.

Ayat Allah Farouk
kasrAlainy hospital cairo university, Clinical Neurophysiology, cairo, Egypt

Background and Aims:: LEMS is a presynaptic neuromuscular disorder, its early recognition is particularly important because of its strong association with small cell lung cancer (SCLC) and up to 50% are misdiagnosed. LEMS is often suspected according to symptoms. Electrodiagnostic approach includes Routine motor nerve conduction stimulation typically elicits a small amplitude compound muscle action potential (CMAP), with its increase >100% increment after After isometric contraction for 10 seconds, or high rate repetitive supramaximal stimulation, but what if it increases but not reaching 100%?

Methods:: SSFEMG is a neurophysiological test to study the neuromuscular junction & allows stimulation rate control. That shows the typical rate-dependent reduction of the neuromuscular jitter and blocking in LEMS compared to MG that show more prolongation of jitter and even more blocking. This is a case study for a 50 year-old woman presenting with proximal and axial weakness, lately developed bilateral ptosis, and symptoms compatible with an autonomic dysfunction, electrophysiologically she showed nonsignificant increments but showed typical rate-dependent reduction of the neuromuscular jitter and blocking reduction.

Results:: The patient was diagnosed to have lung cancer and Diagnosis was confirmed by serological demonstration of circulating VGCC antibodies after diagnosis by typical rate dependent SFEMG findings.

Conclusions:: Early recognition of LEMS is particularly important because of its strong association with cancer, it may serve as a marker for early disease, and thus allow more effective treatment of malignancy and rate dependent SSFEMG offered a useful tool for the early diagnosis.
MICRO-RNA-206 LEVEL IS INCREASED IN FAST EVOLVING TRANSPORTINOPATHY (LGMD-D2), CALPAINOPATHY (LGMD R-1) AND SARCOCGLYCANOPATHY (LGMD R3-R5)

Corrado Angelini¹, Valentina Pegoraro²
¹Azienda Ospedaliera di Padova, Neurosciences, Padova, Italy, ²IRCCS S.Camillo, Biomedicine, Venezia, Italy

Background and Aims:: Limb-girdle muscular dystrophies (LGMD) are clinically and genetically heterogeneous conditions presenting with a wide clinical spectrum leading to progressive proximal weakness caused by loss of muscle fibers. LGMD are presenting with various phenotypes, high CK, leading to muscle degenerative features at muscle MRI. MiR-206 is a member of myomiRs, a group of miRNAs with important functions in skeletal muscle. The aim is to determine the value of miR-206 in detecting muscle disease evolution in LGMD. We described clinical features, disease history, and progression of eleven patients affected by LGMD subdivided into Transportinopathy, Sarcoglycanopathies, and Calpainopathy subtypes.

Methods:: In 11 Calpainopathy trasportinopathy and sarcoglycanopathy cases clinically diagnosed we performed a clinical examination and scored them to evaluate disease progression. In undiagnosed cases, the patients’ mutations were identified and in all, we studied the circulating miR-206 in serum by qRT-PCR, muscle MRI was done with 1.5 Tesla Philips apparatus.

Results:: The evolution/progression of disease was associated with the expression levels of miR-206, which was significant elevated in severe evolving LGMD patients in comparison with a control group. In particular, we observed an overexpression of miR-206 of 50-80 folds in two patients: one child affected by early-onset transportinopathy, one juvenile calpainopathy patient with a severe and fast course of the disease. The muscle substitution and changes were documented by muscle MRI.

Conclusions:: Evolutive changes were documented by muscle MRI. This study provides the first evidence that miR-206 was associated with severe phenotypic expression and it could be used as a prognostic indicator of LGMD disease progression.
EARLY ONSET CALSEQUESTRIN DEFECT: A NEW PHENOTYPE WITH LIMB ASYMMETRY.

Corrado Angelini
Azienda Ospedaliera di Padova, Neurosciences, Padova, Italy

Background and Aims:: Calsequestrin (CASQ) represents the main Ca2+ buffer in the sarcoplasmic reticulum. The CASQ1 and CASQ2 isoforms are preferentially expressed in skeletal and cardiac/smooth muscle, CASQ1 is largely predominant in fast-twitch (type II) fibers. CASQ1 buffers Ca2+ and prevents it from precipitating, maintaining large-capacity gradient release large amounts of Ca2+ on stimulus. The first human myopathy associated with CASQ1 mutations was only recently reported: a founder mutation (c.731A>G, p.Asp244Gly) was first described in patients presenting a non-debilitating vacuolar myopathy, we report an early-onset case with the same mutation, but early-onset new phenotype.

Methods:: The index case had high CK, at 9 years, at 11 years she complained of myalgia, fatiguability, limb asymmetry, winging scapulae. The elevated CK was present in her mother, that like the grandmother had a clubfoot at birth and sister that complained of myalgia. A biopsy was done and showed few vacuoles and some atrophic, degenerating regenerating fibers and analyzed by NGS, which showed in chromosome 1 the CASQ1 mutation in exon 6:cA731G:pAsp244Gly.

Results:: The patient suffered from limb asymmetry, was operated on by shortening of the right femur and elongation of the contralateral limb, but still had elevated CK and easy fatiguability. The muscle biopsy showed some atrophic fibers and vacuoles, but a definite diagnosis came from NGS, which revealed the pathogenic mutation.

Conclusions:: We interpret the asymmetric limb myopathy as a result of somatic mosaicism, resulting in different biodistribution of its effects, likely this entity is underdiagnosed, although high CK and vacuolated fibers at biopsy might suggest the diagnosis.
GUILLEIN-BARRE SYNDROME AFTER CORONARY ARTERY BYPASS GRAFT SURGERY: A CASE REPORT AND LITERATURE REVIEW

Sajid Hameed Shaikh
Aga Khan University, Stadium Road, Karachi., Neurophysiology Department, Consulting Clinic-1, Karachi, Pakistan

Background and Aims:: Guillain-Barre syndrome (GBS) is an acute polyradiculoneuropathy, often preceded by an infection. Rarely, it is preceded by a surgical procedure. Most of the postsurgical GBS cases are reported with neurosurgical, gastrointestinal, orthopedic, and cardiac procedures. GBS is rarely reported after coronary artery bypass grafting (CABG). To date, only 12 cases have been reported in the literature. Our case is 13th in number and the first case from Pakistan.

Methods:: We report a case of a 54-year-old man who presented with acute flaccid quadriparesis and areflexia after a CABG procedure.

Results:: He was subsequently diagnosed with an acute inflammatory demyelinating polyneuropathy (AIDP) variant of GBS and underwent five sessions of plasmapheresis. His weakness improved and could ambulate unassisted on follow-up visits.

Conclusions:: GBS is a potentially treatable condition if timely diagnosed and managed. It should be considered in every patient presenting with an acute-onset weakness after surgery.
A VERY RARE CASE OF PURE SENSORY GUILLAIN BARRE SYNDROME WITH AXONAL FEATURES

Raid Kofahi¹, Belal Aldabbour¹, Ma’En Aljezewi², Majdi Al Qawasmeh¹, Khalid El-Salem¹
¹Jordan University of Science and Technology Faculty of Medicine, Neuroscience, Irbid, Jordan, ²Al Al-Bayt University, Department Of Community And Mental Health, Faculty Of Nursing, Mafraq, Jordan

Background and Aims:: Pure sensory Guillain-Barré syndrome “GBS” is controversial. Case reports of the condition are scarce, and most were due to acute demyelination of peripheral sensory nerves. Cases secondary to axonal damage is rarer and overlap with sensory neuronopathy.

Methods:: We report a rare case of pure sensory GBS following primary Varicella Zoster infection (VZV).

Results:: A 31-year-old lady with recent primary VZV infection presented with acute sensory symptoms and signs of her trunk and limbs, without weakness. Examination showed severe impairment of all sensory modalities in limbs and trunk, pseudo-athetoid movements, sensory ataxia, positive Romberg’s sign, and areflexia. She could not stand or walk. CSF analysis showed albuminocytological dissociation. MRI of the spine with contrast showed multiple root enhancement. Nerve conduction studies “NCS” demonstrated absent sensory action potentials, with normal motor nerves responses. Initial electromyography was normal. After differential diagnoses were appropriately excluded, most importantly sensory neuronopathy, the patient was diagnosed with pure sensory axonal GBS and treated with IVIG for five days. She improved gradually. Her sixth month GBS disability score was two. Follow-up NCS was unchanged, but repeated EMGs revealed denervation potentials in multiple levels, suggesting a subclinical axonal motor involvement and excluding sensory neuronopathy.

Conclusions:: This case illustrates the difficulties in diagnosing pure sensory GBS and the significance of early treatment. It also demonstrates the value of follow-up EMGs in excluding sensory neuronopathy as an important differential diagnosis. Finally, clinical improvement is not necessarily reflected in sensory NCS findings.
ELECTRIC LESION MONONEUROPATHY

María Dolores Calabria Gallego
Complejo Asistencial Universitario de Salamanca, Neurology, Salamanca, Spain

Background and Aims:: Electricity can provoke a great variety of lesions in the human body. In the neurologic field, both the peripheral nervous system, as the central nervous system can be involved. High voltage discharges are the most dangerous.

Methods:: We expose a case report

Results:: A 34-years-old woman consulted us two months after suffering an electric accident with a machine connected to high tension current (she worked as a radiodiagnosis operator). She referred that in a first moment, she suffered a little burn injury with a painful sensation in her entire arm. Since that moment, she experiences dysesthesia, allodynia and weakness in the right median nerve territory. In the neurologic examination, we detected weakness in the muscles innervated by the right median nerve. The rest of the examination was normal. In the electroneurography, we detected a nerve conduction blockade in the right median nerve. We requested a magnetic resonance image (MRI) of this limb, in order to discriminate soft tissue inflammation, that was normal.

Conclusions:: The nervous system has a very low electric resistance, so it is very vulnerable to be damaged in electric accidents, sometimes in an irreversible way. These kinds of lesions can be due to alteration of the electric conductivity because of coagulative necrosis of the nerve, or because of myelin sheath damage. Another possible cause is the compression of the vasa nervorum because of edema and compartment syndrome. This last possibility was discarded in our patient with a MRI.
Background and Aims:: To determine the frequencies of electrophysiological variants of Guillain-Barre’ Syndrome and the outcome of each in Sudanese adult patients diagnosed with GBS in the period from March 2020– September 2020

Methods:: a prospective study of a 62 patients with GBS. The study was conducted in the period from March – September2020, in a 4 neurology centers in Khartoum. All patients were adults sudanese, Seen and diagnosed with GBS by a consultant neurologist All have done nerve study. That have been reported by expert electro-physiologists. All patients were seen and examined by the researcher at the disease nadir and followed at day-30 from disease onset by phone to determine the grade of HFGS.

Results:: Males are and females are equally represented, the majority of patients (70%) are between 18 years and 50 years. The onset of the weakness was less than or equal 3 days in (33.9%) of patients, from 4 to 7 days in (41.9%) , from 8 to 14 days in (11.3%) and above 14 days in (12.9%). Based on the electrophysiology, (37.09%) were classified as (AMAN), (29.03%) as (AIDP) and (29.03%) as (AMSAN). 30 patients (48.4%) fully recovered, 25 patients (40.3%) recovered with motor deficit, and 7 patients (11.3%) died.

Conclusions:: Axonal type of GBS found to be in nearly 2/3 patients. Age of the patients, onset of the disease and dysautonemia did not show statistically significant effect on outcome at day-30. The outcome of axonal types at day-30 was poorer than that of demyelinating form
DAYTIME SLEEPINESS IN MYOTONIC DYSTROPHY TYPE 1 IN TUNISIAN POPULATION

Emna Kacem¹, Salma Sakka¹, Syrine Laaroussi¹, Nadia Ben Ali², Nouha Farhat¹, Olfa Hdiji¹, Hanene Hajkacem¹, Sawsan Daoud¹, Khadija Sonda Moalla³, Mariem Damak⁴, Chokri Mhiri⁵
¹Universal Hospital Habib Bourguiba, Neurology, Sfax, Tunisia, ²Charles Nicolle Hospital, Neurology, Tunis, Tunisia, ³Universal Hospital Habib Bourguiba, Neurology, Sfax, Tunisia, sfax, Tunisia, ⁴habib bourguiba hospital, Neurology, sfax, Tunisia, ⁵CHU habib bourguiba Sfax, Neurology, sfax, Tunisia

Background and Aims::

Excessive daytime sleepiness (EDS) is the most frequent non-muscular disorder in DM1, being present in about 70-80% of patients. It may be one of the earliest symptoms of DM1. Several patients present EDS many years before DM1 is diagnosed.

Methods:: The study was conducted in the department of neurology Hbib Bourguiba sfax between June 2009 and December 2019. Daytime sleepiness was assessed with the Daytime Sleepiness Scale (DSS) which was developed specifically to measure the degree of daytime sleepiness in patients with DM1. It is a score that varies from 0 to 15. It is considered indicative when it is ≥ 7. All patients had clinical and psychiatric evaluation and cerebral MRI.

Results::

We included twenty individuals (9 females, 11 males) with DM1 genetically confirmed (mean age 40 y, range 28-49 y). Half of our patients had EDS. The mean age of onset of the disease was 27 year-old. We did not find significant relationships between the DSS score, age of onset of the disease, motor disability, cerebral MRI lesions, or cytosine-thymine-guanine (CTG) repeats (p=0.5). We found a significant relationship between the DSS score and depression (p= 0.04).

Conclusions:: DM1 patients with EDS present higher levels of depressive symptoms than those without EDS. Some authors consider it to be a Central nervous system disease although the non correlation between MRI lesions and EDS in our patients. The EDS, always misdiagnosed, seems to affect the quality of life of patients with DM1.
Background and Aims:: Myotonic dystrophy type 1 (DM1) is the most frequently inherited neuromuscular disease. Although relatively frequent, very limited data exists about psychiatric phenotypes in the adulthood form. The aim of this study was to investigate the psychiatric phenotype in individuals with DM1.

Methods:: The study was conducted in the department of neurology Habib Bourguiba sfax between June 2009 and December 2019. Depression and anxiety have been searched thanks to the Arabized Hospital Anxiety and Depression Scale (HADS). This scale includes 14 items rated from 0 to 3. Seven questions are related to anxiety (total A) and seven others to the depressive dimension (total D), allowing two scores to be obtained. The diagnosis of DM1 was genetically confirmed in all patients.

Results:: We included twenty DM1 patients (mean age 40 y, range 28-49y). Seventy five percent of patients had a score less than 7. Twenty five percent of patients had doubtful anxiety and twenty five of patients had a suspicious depressive syndrome. Neither depression nor anxiety correlated with the sex, age of onset of the disease, endocrine disorders or with CTG repeat numbers. Depression was correlated with motor disability and daytime sleepiness.

Conclusions:: Anxiety disorders have been little studied compared to mood and personality disorders in DM1. Although its non correlation with depression, these troubles may be strongly related and conduce to difficulty in social integration. Depression was related to motor disability, occasioning reciprocal worsening and hindering the progressive course of the disease. These disorders should be considered since they can be improved through psychotherapy and social skills training.
Background and Aims:: Neurophysiological patterns in patients with foodborne botulism are rarely described after the acute phase. We report data from a large Italian outbreak of botulism, with patients evaluated at different timepoints after poisoning.

Methods:: Eighteen male patients (mean age 47 ± 8.4 years) underwent 22 clinical and neurophysiological evaluations (4 patients were re-evaluated). The resting compound muscle action potential (CMAP) amplitude, postexercise CMAP amplitude, CMAP change after high-frequency (50 Hz) repetitive nerve stimulation (HFRNS), and motor unit action potentials (MUAPs) were assessed in the acute (4–8 days after poisoning; 5 patients), early post-acute (32–39 days after poisoning; 5 patients), and late post-acute (66–80 days after poisoning; 12 patients) phases.

Results:: In the acute, early post-acute, and late post-acute phases, respectively, reduced CMAP amplitudes were found in 100%, 20%, and 17% of patients; abnormal postexercise CMAP facilitation was observed in 100%, 40%, and 0% of patients; and pathological incremental responses to HFRNS were found in 80%, 50%, and 8% of patients. Baseline CMAP amplitudes, postexercise CMAP facilitation, and CMAP increases in response to HFRNS differed significantly between the acute and post-acute phases. Small MUAPs were found in 100% of patients in the acute and early post-acute phases and in 50% of patients in the late post-acute phase.

Conclusions:: The neurophysiological findings of foodborne botulism vary considerably according to the evaluation timepoint. In the post-acute phase, different neurophysiological techniques must be applied to support a diagnosis of botulism.
QUALITY OF LIFE IN PATIENTS WITH CARPAL TUNNEL SYNDROME

Jyoti Gautam\textsuperscript{1}, Madhu Nagappa\textsuperscript{1}, Partha Haldar\textsuperscript{2}, Meeka Khanna\textsuperscript{3}, Doniparthi Seshagiri\textsuperscript{1}, Sumanth Shivaram\textsuperscript{1}, Lakshminarayanapuram Viswanathan\textsuperscript{1}, Sanjib Sinha\textsuperscript{1} 
\textsuperscript{1}National Institute of Mental Health and Neurosciences (NIMHANS), Department Of Neurology, BENGALURU, India, \textsuperscript{2}All India Institute of Medical Sciences, Centre For Community Medicine, NEW DELHI, India, \textsuperscript{3}National Institute of Mental Health and Neurosciences (NIMHANS), Department Of Neurological Rehabilitation, BENGALURU, India

Background and Aims:: Though carpal tunnel syndrome (CTS) is a focal neuropathy, it causes significant distress while carrying out simple day-to-day activities, hinders professional work, and contributes to absenteeism. However, limited studies have systematically evaluated the quality of life (QoL) in CTS. We aimed to study QoL in patients with CTS and correlate with clinical severity.

Methods:: In this prospective cross-sectional study, 44 patients attending the out-patient department of a single neurology unit, diagnosed to have CTS by the American Association of Electrodiagnostic Medicine criteria, were assessed using the 36-Item Short Form Health Survey questionnaire (SF-36). Age and gender-matched healthy subjects were recruited as controls.

Results:: There were 36 women, mean(±SD) age was 43.0±8.6 years, and mean(±SD) symptom-duration was 23.13±25.3 months. Mean(±SD) SF-36 scores in domains of Physical functioning, Role limitations due to physical health, Role limitations due to emotional problems, Energy/fatigue, Emotional well-being, Social functioning, Pain, and General health were 73.97±13.6, 43.24±38.0, 90.12±22.0, 74.59±12.4, 87.13±8.2, 65.39±19.9, 64.14±23.9, and 56.22±15.6 respectively. In all these specified domains, except for emotional well-being, the scores were lower in patients than controls (p<0.05). Total SF-36 score was significantly worse in patients than controls (p=0.0001). SF-36 scores correlated with pain rating by visual analogue scale (p=0.003), and with clinical severity, as assessed by the functional severity scale and symptom severity scale components of the Boston CTS questionnaire (p<0.0001).

Conclusions:: Poor QoL correlates with clinical severity of CTS which may adversely affect work efficiency. It is important that the treatment of CTS also address improvement in these domains.
DOUBLE-BLINDED, RANDOMIZED, PLACEBO-CONTROLLED PHASE 2 STUDY OF FCRN ANTAGONIST BATOCILMAB IN CHINESE GENERALIZED MYASTHENIA GRAVIS

Chongbo Zhao¹, Chong Yan¹, Huan Yang², Haifeng Li³, Ruisheng Duan⁴, Zhangyu Zou⁵, Hongyu Zhou⁶, Hua Zhang⁷, Michael Lee⁸, Emily Chen⁹, Xiaoxiang Chen⁸
¹Huashan Hospital, Fudan University, Neurology, Shanghai, China, ²Xiangya Hospital, Central South University, Neurology, Changsha, China, ³Xuanwu Hospital, Capital Medical University, Neurology, Beijing, China, ⁴Shandong Province Qianfoshan Hospital, Shandong University, Neurology, Jinan, China, ⁵Union Hospital, Fujian Medical University, Neurology, Fuzhou, China, ⁶West China Hospital, Sichuan University, Neurology, Chengdu, China, ⁷Beijing Hospital, Neurology, Beijing, China, ⁸Harbour BioMed, Medicine, Shanghai, China

Background and Aims:: To evaluate the clinical efficacy and safety of batocilmab as a novel anti-FcRn therapy for generalized myasthenia gravis (gMG) in Chinese population.

Methods:: 30 gMG subjects (AChR Ab+) were randomly assigned (1:1:1) to received 6 doses of batocilmab 340 mg, 680 mg, or placebo once weekly combined with their standard-of-care therapy. Primary endpoint was Myasthenia Gravis Activities of Daily Living (MG-ADL) score changes from baseline on Day 43. Secondary endpoints included assessment on Quantitative Myasthenia Gravis (QMG), Myasthenia Gravis Composite (MGC), Myasthenia Gravis Quality of Life (MG-QoL), pharmacokinetics, pharmacodynamics and safety events.

Results:: Batocilmab treatment groups demonstrated significant MG-ADL score improvement on Day 43, by -4.7±0.6 (340 mg) and -4.4±1.0 (680 mg), respectively, compared with -2.2±0.9 (placebo); All 4 efficacy scales consistently demonstrated clinical improvements with robust IgG reduction (-57% and -74% for 340 mg and 680 mg, respectively). Batocilmab treatment groups showed: higher proportion (57.1% vs 33.3%) of early responder (2 points improvement in MG-ADL achieved in 2 weeks after 1st dose); and more subjects (33.0% vs 11%) of minimal symptom expression (MG-ADL 0 or 1 point). Batocilmab was well-tolerated, with treatment-emergent adverse events (TEAEs) balanced across 3 groups, no serious adverse events or AEs leading to discontinuation.

Conclusions:: Batocilmab demonstrated favorable efficacy/safety profiles, with fast, substantial, and persistent clinical improvements in Chinese gMG.
SLEEP QUALITY AND ITS CORRELATION WITH CLINICAL SEVERITY IN CARPAL TUNNEL SYNDROME

Jyoti Gautam1, Madhu Nagappa2, Partha Halder3, Meeka Khanna4, Doniparthi Seshagiri1, Sumanth Shivaram1, Lakshminarayananapuram Viswanathan1, Sanjib Sinha1
1National Institute of Mental Health and Neurosciences (NIMHANS), Department Of Neurology, BENGALURU, India, 2National Institute of Mental Health and Neurosciences (NIMHANS), Neurology, Bangalore, India, 3All India Institute of Medical Sciences, Centre For Community Medicine, NEW DELHI, India, 4National Institute of Mental Health and Neurosciences (NIMHANS), Department Of Neurological Rehabilitation, BENGALURU, India

Background and Aims:: Nocturnal pain and paresthesias are hallmark of carpal tunnel syndrome (CTS) and they commonly disturb sleep. However, there is limited literature on the nature of sleep disturbances in CTS, even though this is the commonest neuropathy. We aimed to systematically analyze sleep quality in CTS and correlate with the clinical severity.

Methods:: Prospective cross-sectional evaluation of patients diagnosed to have CTS by the American Association of Electrodiagnostic Medicine criteria from a single neurology unit was carried out using Pittsburgh Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS) and Insomnia Severity Index (ISI). Clinical severity was assessed using visual analogue scale (VAS) for pain and Boston CTS questionnaire [functional severity scale (FSS) and symptom severity scale (SSS)]. Age and gender-matched healthy subjects were recruited as controls.

Results:: There were 44 patients (M: F 1:4.5, mean(±SD) age: 43.0±8.6 years, mean symptom-duration: 23.13±25.3 months). Mean(±SD) PSQI and ESS were 6.32±2.6 and 4.55±3.7 respectively. Thirty-three (75%) patients were classified as poor sleepers (PSQI≥5). Patients had worse mean PSQI and ESS than controls (p<0.05). Mean ISI was higher in patients than controls (p<0.0001). Significant correlations were noted between PSQI and VAS (r=0.434), PSQI and FSS (r=0.431), PSQI and SSS (r=0.507), ESS and FSS (r=0.358), ESS and SSS (r=0.416), ISI and VAS (r=0.411), ISI and FSS (r=0.429), ISI and SSS (r=0.56).

Conclusions:: Patients with CTS had poor subjective sleep quality with reduced overall sleep duration, increased sleep latency, frequent awakenings, and increased daytime sleepiness. Sleep quality was worse in those with higher grades of clinical severity.
MG-LEMS OVERLAP SYNDROME ASSOCIATED WITH MUSK ANTIBODY

Madhu Nagappa¹, Sumanth Shivaram², Sanjib Sinha², Arun Taly¹
¹National Institute of Mental Health and Neurosciences (NIMHANS), Neurology, Bangalore, India, ²National Institute of Mental Health and Neurosciences (NIMHANS), Department Of Neurology, BENGALURU, India

Background and Aims:: Myasthenia Gravis (MG) and Lambert-Eaton Myasthenic syndrome (LEMS) are immune-mediated disorders of the neuromuscular junction. Clinical, electrophysiological and immunological overlap of these two conditions have been uncommonly reported. We report the unusual association of LEMS with muscle-specific kinase (MuSK) antibody associated MG.

Methods:: A 44-year-old lady who presented with exertional muscle pain and difficulty in standing from sitting position and lifting heavy weights of six years duration was evaluated with nerve conduction study (NCS), repetitive nerve stimulation (RNS) and enzyme linked immunosorbent assay (ELISA) for acetylcholine receptor (AChR) and MuSK antibodies.

Results:: Clinical features included normal blood pressure without orthostatic fall, bilateral ptosis, normally reacting pupils, limb-girdle weakness, waddling gait and exaggerated lumbar lordosis. Generalised areflexia was noted and stretch reflexes appeared after brief voluntary muscle contraction. There were no features of bulbar/ respiratory muscle weakness or dysautonomia. NCS showed reduced amplitude of evoked motor response (EMR) from the abductor pollicis brevis (APB), and post-exercise facilitation of 296.7%. RNS at 3Hz showed decrement 48.8%, while RNS at 20Hz showed an increment of 148%. MuSK antibodies were detected while AChR antibodies were absent. CT scanning of thorax and abdomen was normal. She was diagnosed to have LEMS-MG overlap and treated with steroids and azathioprine. At four months follow up, she reported 75% improvement in function.

Conclusions:: We report a rare patient with clinical and electrophysiological features of MG-LEMS overlap. The unique feature was presence of MuSK antibodies. MG, LEMS and overlap syndromes represent a continuum of disorders linked by antibodies to antigens in neuromuscular junction.
AN UNCOMMON CAUSE OF PARAPARESIS: THYROTOXIC HYPOKALEMIC PERIODIC PARALYSIS

Debora Pezzini¹, Beatrice Labella¹, Loris Poli², Angelo Costa³, Mauro Magoni³, Alessandro Padovani¹
¹University of Brescia, Department Of Clinical And Experimental Sciences - Neurology Clinic, Brescia, Italy, ²Spedali Civili of Brescia, Department Of Clinical And Experimental Sciences - Neurology Clinic, Brescia, Italy, ³Spedali Civili of Brescia, Department Of Clinical And Experimental Sciences - Vascular Neurology, Brescia, Italy

Background and Aims:: Thyrotoxic hypokalemic periodic paralysis (THPP) is an uncommon emergency mainly affecting Asian men. Stress, infections, high carbohydrate diet, steroids, physical activity are triggers. The classic triad for diagnosis is thyrotoxicosis, hypokalemia and paralysis. The typical presentation consists of symmetrical proximal muscle weakness (with legs more affected than arms, with extensor muscle more involved than flexors), promptly solved by the correction of hypokalemia.

Methods:: Case presentation A 56-year-old male from the Philippines presented to the emergency department with a sudden onset of weakness and pain of lower limb. He reported six months history of heart palpitations and hands tremors. Neurological examination revealed mild symmetrical paraparesis, hyperreflexia, fasciculations, hands tremors, without sensory or cranial nerve involvement. Systemic symptoms were fever and profuse sweating, along with new-onset atrial fibrillation. Magnetic resonance imaging of spinal cord and nerve conduction studies were normal and ruled out infections or inflammatory neuropathies. Laboratory data showed potassium 2,7 mmol/l (normal value 3,4 - 4,5), thyroid stimulating hormone < 0,005 mIU/L (normal value 0,270 - 4,200), thyroxine 65,3 ng/L (normal value 9,3 - 17,0), and triiodothyronine 16,0 ng/L (normal value 2,0 - 4,4), TSH receptor antibody 11,1 IU/L (normal value < 1,8) and anti thyroperoxidase > 600,0 kIU/L (normal value < 34,0).

Results:: He was treated with potassium supplementation, Propranolol, Methimazole and Propylthiouracil with favorable evolution.

Conclusions:: Thyroid function must be evaluated in differential diagnosis for acute paraparesis with normal electrophysiological and imaging studies. Management of THPP includes potassium supplementation, nonselective beta-blockers and achievement of euthyroid state.
TARGETED PHARMACOTHERAPY FOR TRAFFICKING DEFECTIVE CLC-1 MUTATIONS IN MYOTONIA CONGENITA

Concetta Altamura¹, Elena Conte², Giulia Maria Camerino², Francesco Girolamo³, Carmen Campanale¹, Maria Rosaria Carratu¹, Paola Imbrici², Jean-François Desaphy¹
¹University of Bari Aldo Moro, Dept. Of Biomedical Sciences And Human Oncology, Bari, Italy, ²University of Bari Aldo Moro, Dept. Of Pharmacy - Drug Sciences, Bari, Italy, ³University of Bari Aldo Moro, Dept. Of Basic Medical Sciences, Neurosciences And Sense Organs, Bari, Italy

Background and Aims:: A delayed muscle relaxation after a voluntary contraction is the main clinical feature of myotonia congenita (MC). MC is a skeletal muscle channelopathy caused by loss-of-function mutations in the ClC-1 chloride channel, which impair channel function or plasma membrane expression. To date, no direct activator of ClC-1 channel is known. A potential strategy may be to restore surface expression of trafficking-defective ClC-1 mutants by using pharmacological chaperones. Thus, we tested the ability of niflumic acid (NFA), a reversible inhibitor of ClC-1, to restore membrane expression of MC ClC-1 mutants (A531V, V947E, G411C).

Methods:: The HEK293 cells transfected with wild-type (WT) or MC ClC-1 channels, incubated in control conditions or in presence of 50 µM NFA, were used for patch-clamp recording, biotinylation assay, and confocal imaging.

Results:: Trafficking defect induced an absence (as for G411C) or marked reduction (as for A531V and V947E) of ClC-1 chloride currents. Incubation of transfected cells with NFA enhanced A531V and V947E chloride current density more than three-fold, thereby restoring WT-like currents. NFA incubation also improved V947E protein expression on the plasma membrane, as assessed by biotinylation assay. In contrast, NFA did not restore G411C chloride currents, suggesting lack of chaperone effect or G411C inability to conduct currents. The G411C channel surface expression was rescued by the proteasome inhibitor MG132 but no chloride current was recorded, indicating that G411C produces nonfunctional ClC-1 channels.

Conclusions:: NFA could be repurposed to MC patients carrying trafficking-defective ClC-1 channel mutations, designing a mutation-driven precision medicine in MC.
A NEW CYS1678TYR MUTATION RESPONSIBLE OF LGMD2B IDENTIFIED IN A FAMILY FROM SOUTHERN ITALY

Patrizia Spadafora, Antonio Qualtieri, Francesca Cavalcanti, Pierluigi Lanza, Olivier Gallo, Gemma Di Palma, Luigi Citrigno
Institute for the Biomedical research and Innovation, National Research Council, Mangone, Italy

Background and Aims:: Mutations in the gene DYSF encoding dysferlin are responsible for dysferlinopathies. Dysferlin is mainly expressed in cardiac and skeletal muscle and appears to play an important role in the repair of the plasmalemma. Intra- and inter-family phenotypic variability has been reported in the literature for mutations in the DYSF gene. A new Cys1678Tyr mutation responsible of LGMD2B has been identified in a family from southern Italy.

Methods:: Genomic DNA was extracted from peripheral blood lymphocytes of all family’s affected and unaffected subjects using standard protocol. We developed a panel comprising 40 genes involved in LGMDs. The sequencing process was conducted on Ion Torrent PGM platform, annotation of variant calling by WANNOVAR. All the variations founded were confirmed by direct resequencing ABI PRISM 3130xl Genetic Analyzer.

Results:: Molecular analysis of three patients from a southern Italian family allowed the identification of a new G5036A mutation in the DYSF gene responsible for LGMD 2B. This mutation determining the replacement of a cysteine in position 1678 with a tyrosine predicted to be deleterious by PolyPhen and silico SIFT analysis. Moreover, Swiss model pipeline analysis showed that this mutation causes the breaking of a strong disulfide bridge with important consequences on the protein activity.

Conclusions:: The identification of new mutations responsible for LGMD2B and the study of several affected families will contribute to the identification of additional genetic, epigenetic, environmental factors responsible for the intra and inter-family variability reported in the literature. Furthermore, this will determine the development of new therapeutic targets and personalized medicine.
Background and Aims:: With the advent of new therapies, early diagnosis in spinal muscular atrophy (SMA) is essential. The aim of this study is to analyze the various components of the all too prevalent diagnostic delay.

Methods:: Patients with a confirmed molecular SMA diagnosis (types I, II, III) were included. We studied among other parameters age and first presenting sign, as well as interval between clinical onset and confirmed diagnosis. Telephone or face-to-face interviews were conducted by neuromuscular neurologists and supplemented when necessary with medical records' reviews.

Results:: Cohort included 112 patients. SMA I n=40, SMA II n=48, SMA III n=24. Mean age (months) at first reported sign was (X): SMA I 2.2±2.2, SMA II 9.7±4.1, SMA III 32.7±42.2. The first signs were noticed by parents 75 to 85% of the times in all three types. Time elapsed (in months) between the first sign and first medical consultation was on average less than a month for SMA I and II and 2.3 months for SMA III. Time elapsed between the first sign and confirmed diagnosis for SMA I: Me: 2 (IQR:1-4) (R:0-11); for SMA II: Me: 10 (IQR:16-25) (R:3-46) and for SMA III, Me: 31.5 (IQR:14.25-98.25) (R:4-288).

Conclusions:: There is significant diagnostic delay in SMA, shortest in type I and longest in type III and possibly related to several factors such as the severity of the disease, the healthcare system and the lack of treating physician's recognition of "tell-tale" signs.
Background and Aims:: The spinal muscular atrophy (SMA) landscape has changed over the last few years with the appearance of different therapeutic approaches. However, limited information is available about physicians' therapeutic decisions. The aim of this study is to assess how pediatric neurologists make decisions on treatment initiation, switch, and discontinuation in SMA applying principles of behavioral economics.

Methods:: The DECISIONS-SMA is a multicenter, non-interventional, cross-sectional, web-based study. Pediatric neurologists involved in the care of patients with SMA will be invited to participate in the study by the Spanish Society of Pediatric Neurology (SENEP). Participants will complete a survey on risk preferences and management of eleven simulated case-scenarios mimicking the current treatment landscape. Case scenarios will assess attitude, enablers and barriers to initiate, switch or withdraw treatments in patients with SMA types I-III. Motor, respiratory, and patient-centered outcomes (quality of life and activities of daily living) will be explored. Concomitant behavioral characteristics that could be associated with decision making will be assessed, including: therapeutic inertia, care-related regret, herding, and occupational burnout.

Results:: Recruitment will begin in May 2021 with a planned total sample of 50 pediatric neurologists throughout Spain.

Conclusions:: The study results are expected to enhance our understanding about decision making, therapeutic goals and expectations among pediatric neurologists caring patients with SMA.
BACKGROUND AND AIMs: Becker muscular dystrophy (BMD) is a dystrophinopathy due to in-frame mutations in the dystrophin gene determining a reduction of dystrophin. It is characterized by a wide clinical spectrum as to motor disability, progression and cardiac involvement. Standardized motor scales are commonly used to quantify motor impairment. Muscle magnetic resonance (mMRI) has become a non-invasive tool for diagnosis and follow-up, along with cardiac magnetic resonance (cMRI) to monitor cardiomyopathy. Here we present a two-years prospective evaluation of ten adult BMD patients, through standardized functional scales, mMRI and cardiological assessment.

METHODS: We recruited ten patients (aged 25-63; eight with a 45-x deletion, one 47-48, one 48), evaluated at baseline with the 6MWT, NSAA and W&GM scale, and then after one and two years. Muscle MRI was performed at baseline and then after two years. Each patient underwent cardiological assessment with echocardiogram, NT-pro-BNP measurement and in a subgroup of 5 patients, cMRI.

RESULTS: Three asymptomatic patients at baseline showed no disease progression, while the other patients presented a declining trend in motor functions measured by motor scales; notably the W&GM scale was stable overtime. Muscle MRI paralleled the clinical picture overtime. Cardiologic evaluation revealed pump impairment in the majority of patients and cMRI detected alterations in all the tested patients.

CONCLUSIONS: To date, longitudinal cohort studies evaluating BMD natural history are not available. Our study describes disease progression rate in adult BMD subjects affected by different forms of disease - from asymptomatic to moderate-severe impairment. Multiparametric studies on a larger cohort are needed to expand our understanding of disease progression towards trial readiness for BMD.
Background and Aims:: Glioblastoma can be histologically determined by the presence of neoplastic cells with astrocytic characteristics. Therefore, researchers become interested to improve the therapy for GBM either by novel nano delivery systems or by new therapeutics or by supplementing existing therapy.

Methods:: The study involves the fabrication of lomustine-loaded biodegradable nanofibres prepared by electrohydrodynamic (EHD) techniques which utilize electrostatic forces as the driving force to fabricate nano-range nanofibres. The prepared nanofibres formulation were characterized using surface morphology analysis techniques such as by AFM, SEM, TEM analysis, dug release, in-vitro and elution method and a HPLC assay were employed to characterize the in vitro and in vivo release behaviors of drug in Albino Wistar Rats bearing tumors from the electrospun nanofibres and also cytotoxicity of nanofibers was evaluated by MTT assay in U87 MG Brain tumor cell line.

Results:: In vivo results shows primary tumor resection decreased in treated with oral administered nanofibers, compared with the blank nanofibres, systemically administered drug, and the control group. Furthermore, better drug transport is achieved without interfering with the normal function of the brain. No inflammation reactions were observed in histological examination of the cerebral tissues.

Conclusions:: The experimental results show that the biodegradable nanofibres released high concentrations of drug with high drug loading and drug-releasing efficiency after oral formulation in the cerebral cavity of rats showing excellent biocompatibility. It also reveals that adopting drug-eluting nanofibres may result in sustained delivery of anti-tumor drug in the cerebral cavity in order to attain the enhanced therapeutic effect of Glioblastoma tumors treatment.
HOW LONG AND HOW FREQUENT FOLLOW-UP CARE SHOULD BE FOR LOWER-GRADE GLIOMAS? RETROSPECTIVE STUDY ON PATIENTS WITH LGGS AT NEUROLOGICAL INSTITUTE BESTA OF MILAN

Matilde Leonardi¹, Fabrizio Tagliavini², Antonio Silvani³, Elena Lamperti³, Silvia Schiavolin¹, Fabiola Silvaggi¹
¹Neurological Institute C. Besta IRCCS Foundation, Neurology, Public Health And Disability Unit, milan, Italy, ²Neurological Institute C. Besta IRCCS Foundation, Scientific Direction, milan, Italy, ³Neurological Institute C. Besta IRCCS Foundation, Neuro-oncology Unit, milan, Italy

Background and Aims:: Glioma is the most common primary brain cancer in adults. Survival varies significantly by grade across glioma subtypes. The recent developments have led to the new term "lower-grade glioma" (LLG) to designate both grades II and III gliomas. These gliomas are best treated with a multidisciplinary team approach, including specialists from neurosurgery, radiology, pathology, radiation oncology, and neuro-oncology. In Italy, it is unclear how long follow-up care should last and whether the primary care sector is either willing or able to take this on. The aim is to determine pathways of follow-up care for LGGs and evaluate the professional attitude of doctors to prescribe to patients visits and exams after surgery.

Methods:: A retrospective study was performed on patients with LGGs who underwent surgery at tertiary care Neurological Institute Besta of Milan (FINCB) from 2012 to 2020. Data were collected through electronic medical records and inserted in an ad hoc developed database.

Results:: Three pathways have been identified: a common preliminary pathway (from the pre-operative visit to surgery) for all patients undergoing surgery for Gliomas II and III and two follow-up pathways (with or without second surgery).

Conclusions:: FINCB has developed care pathways that are sometimes personalized according to the doctor’s expertise and attitude to prescribe new examinations. Given the lack of guidelines on this issue, we can cautiously conclude that it is necessary to identify whether, in addition to standard care, personalized supportive care intervention.
PROLONGED REMISSION OF A PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA (PCNSL) AFTER CORTICOSTEROID THERAPY: A CASE OF VANISHED LYMPHOMA WITH LESIONS' SIDE CHANGE

Andrea Botturi, Paola Gaviani, Giorgia Simonetti, Veronica Redaelli, Antonio Silvani
Fondazione IRCCS Istituto Neurologico C. Besta, Neuro-oncology, Milano, Italy

Background and Aims:: PCNSL is a rare form of non-Hodgkin lymphoma, accounts for 1 – 3% of adult intracranial neoplasm. Clinical and neuroimaging presentation may mimic progressive neurologic disorders. Corticosteroids (corts) can produce a quite variable apoptotic effect on PCNSL: partial volume reduction until its disappearance (vanishing lymphoma). Corts sensitivity of PCNSL is reported in 20 – 60% of cases. The aim of the study is to evaluate corts response in PCNSL patient in order to plan the timing of the biopsy.

Methods:: CASE REPORT A 73-year-old woman developed visual delusion and left hemiparesis. Neuroimaging showed multiple cerebral alterations in the right hemisphere. She underwent a needle biopsy after corts therapy, but the specimen was not diagnostic. She continued corts treatment with clinical improvement and complete regression of the lesion. There were not target for another biopsy for 18 months; then, she developed psychomotor retardation and right hemiparesis. TC scan showed multiple lesions in the left side of the brain. The patient underwent a new biopsy that showed B cell lymphoma.

Results:: Our patient with a history of vanished lymphoma showed a peculiar localization of lesions, first located in the right hemisphere, then in the left one. She had an extreme sensitivity to corts that caused the lesions to disappeared completely with a disease-free interval for about one year.

Conclusions:: PCNSL is a capricious tumor whose clinical course can be extremely rapid and, at other times, indolent, complicating the diagnostic choices, especially in organizing the brain biopsy and the use of corts.
TWO CASES OF PARANEOPlastic NEUROlogical SYNDROMES ASSOCIATED WITH non-Hodgkin LYMPHOMA.

Alessandro Dinoto, Marta Cheli, Arianna Sartori, Paolo Manganotti
University of Trieste, Neurology Unit, Department Of Medical, Surgical And Health Sciences, Cattinara University Hospital, Asugi, Trieste, Italy

Background and Aims:: Lymphoma-associated paraneoplastic neurological syndromes (PNS) are a rare and ill-defined disorders. 

Methods:: We report two rare cases of PNS associated with non-Hodgkin lymphoma (NHL) from our single-center experience. Clinical, demographic data, treatments and outcomes are reported. 

Results:: A 72-years old female was admitted for subacute onset of gait instability and repeated falls. MRI showed cerebellar atrophy while 18F-FDG PET showed avid captation of laterocervical, mediastinal and para-aortic lymph nodes. Onconeural antibodies tested negative, type III oligoclonal bands were detected. Lymphnodes biopsies was consistent with small lymphocytic lymphoma. She was diagnosed with cerebellar paraneoplastic degeneration(PCD). She was treated with high-dose steroids and immunoglobulins without benefit. Her conditions rapidly worsened and she died of intercurrent infection. A 65-years old male was previously diagnosed with nodal marginal zone lymphoma and treated with rituximab-bendamustine. He was admitted for agitation, hallucinations, confusion and anterograde memory deficit followed by progressive tetraparesis with painful paresthesias in lower limbs. Brain and spinal MRI was negative. EMG showed sensory neuronopathy and lower motor neuron involvement. Onconeuronal antibodies tested negative. CT scans showed mild NHL progression. Paraneoplastic encephaloneuromyelitis was diagnosed and he was treated with high dose steroids, plasma-exchange and immunoglobulins with minimal improvement. The patient died of sepsis. 

Conclusions:: NHL-associated PNS are rare conditions that bear an unfavorable prognosis and they usually present in later stages of oncological disease. PCD is rare in NHL, while motor neuron involvement is peculiar. Our patients were seronegative for onconeural antibodies and had a poor response to immunotherapy. Negative onconeural testing should not mislead the diagnosis.
KI-67 EXPRESSION AS A PROGNOSTIC FACTOR OF GLIOMA IN INDONESIAN POPULATION

Ery Kus Dwianingsih¹, Sofia Pranacipta¹, Emilia Theresia¹, Rusdy Malueka²
¹Faculty of Public Health and Nursing, Universitas Gadjah Mada, Department Of Anatomical Pathology, Yogyakarta, Indonesia, ²Faculty of Medicine, Public health and Nursing, Universitas Gadjah Mada, Neurology, yogyakarta, Indonesia

Background and Aims:: Introduction: The most common neoplasms in the human brain is glioma that consisted of gial cells. The subjectivity in interpretation of glioma and difficulties to identify mitosis will affect the determination of tumor grade, therapy and prognosis of the patients. Immunostaining of Ki-67 represents the ability of tumor cells to proliferate and related to survival of the patient. Objective: The purpose of this study is to reveal the association of the Ki-67 expression and survival of glioma patients in Indonesia.

Methods:: Methods: Seventy eight sampels were obtained from formalin-fixed embedded parrafin (FFPE) samples in Dr. Sardjito General Hospital. Ki-67 labeling index (LI) was calculated as the percentage of labeled nuclei per 1000 cells using 40x objective lens in the same random area, evaluated by 2 independent observers. The expression of Ki67 and Overall Survival (OS) was statistically analyzed using Kaplan-Meier analysis.

Results:: Results: Based on univariate analysis, age ≥60 years, high-grade tumors, infratentorial gliomas, and Ki-67 LI ≥10% were associated with poorer overall survival. However, in multivariate analysis, only infratentorial tumors and Ki-67 LI ≥10% were statistically significant as independent prognostic indicators of gliomas.

Conclusions:: Conclusion. Ki-67 LI ≥10% is associated with shorter overall survival in Indonesian glioma patients.
PARAVERTEBRAL NEUROBLASTOMA WITH SPINAL CORD COMPRESSION AND BREAST METASTASIS IN A CHILD

Sirine Belghuith, Khadija Sonda Moalla, Nouha Farhat, Olfa Hdiji, Salma Sakka, Nadia Bouattour, Sawsan Daoud, Mariem Damak, Chokri Mhiri
habib bourguiba hospital, Neurological Department, sfax, Tunisia

Background and Aims:: Spinal cord compression is a rare but serious complication of malignancy in the children. Neuroblastoma (NB) presented with spinal cord compression and breast metastasis is uncommon.

Methods:: We report here the first case of paravertebral NB in an adolescent girl with bilateral metastatic deposits in the breast.

Results:: A 13-year-old girl was admitted for acute weakness in the lower limbs and urinary retention. Neurological examination showed a flaccid paraparesis and thermo-painful anesthesia with sensory T8 level. General examination showed bilateral breast masses. A spinal MRI was performed, which revealed a large right paraspinal mass at the thoracic spine levels from T7 to T10. This lesion extended through multiple neural foramina causing severe spinal cord compression. The CT guided biopsy of the paraspinal lesion as well as the ultrasound-guided breast biopsy concluded to NB associated to N-Myc gene amplification. The child was referred to oncologist and combined chemotherapy was given.

Conclusions:: Up to 15% to 30% of pediatric malignant spinal cord compressions were due to NB. Management of NB involvement of the spinal canal requires prompt diagnosis and early treatment to relieve spinal cord compression because neurological manifestations of less than 4 weeks can generally have complete recovery, but longer period of symptoms without treatment often leads to long-lasting or even irreversible problems. Metastasis to the breast from an extramammary malignant neoplasm, including NB, is exceptional. Only three reported cases of high stage olfactory NB with unilateral metastasis to the breast have been previously described in the literature.
MULTIPLE CRANIAL NERVE PALSIES AS THE PRESENTING SYMPTOM OF DIFFUSE LARGE B CELL LYMPHOMA

Dulmini Weerathunga¹, P Manokaran², Arjuna Fernando², Nethini Wijesinghe², Gamini Pathirana²
¹National Hospital of Sri Lanka, Neurology, Colombo, Sri Lanka, ²National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

Background and Aims: Cranial neuropathies in Large B Cell Lymphoma (DLBL) is rare, but could occur at any stage of the disease. Third and seventh nerves are the most affected cranial nerves. Direct lymphoid infiltration and leptomeningeal spread are the main identified causes for this involvement. We report a patient presented with rapid onset bilateral third, left sided sixth and seventh cranial nerve palsies, whom later diagnosed with DLBL.

Methods: Case A 65-year-old patient with back pain for 3 months presented with insidious onset isolated right sided complete medical Oculomotor nerve palsy. His MRI brain and orbits were normal except an incidental finding of Faix meningioma (fig.1). 10 days later he again presented with rapidly progressed left sided third, sixth and upper motor seventh cranial nerve palsies. 3T-MRI brain and orbit with contrast only revealed mild enhancement in left sided third and seventh cranial nerves. (fig.2) His MRI spine done for back pain showed Para spinal soft tissue mass (fig.3) and biopsy done from the mass revealed the histological diagnosis of DLBL. Meanwhile his CSF had elevated protein with 8 lymphocytes and moderate number of atypical cells with large irregular nuclei.
Results: This patient's MRI evidence of possible meningeal deposits of Lymphoma with abnormal CSF may suggest leptomeningeal spread of lymphoma causing cranial neuropathies.
Conclusions: Cranial nerve involvement of DLBL is infrequent and can happen rarely in early stages of the disease. Isolated cranial nerve palsies must be evaluated thoroughly. Treatable neoplasms are one of the important differentials to be considered in the workup.
ACUTE UNILATERAL OCULOMOTOR NERVE PALSY REVEALING A PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA IN AN IMMUNOCOMPETENT PATIENT

Rim Smaoui1, Sawsan Daoud1, Nouha Farhat2, Salma Sakka1, Khadija Sonda Moalla1, Olfa Hdi1, Mariem Damak1, Chokri Mhiri1
1Universal Hospital Habib Bourguiba, Neurology, Sfax, Tunisia, 2Universal Hospital Habib Bourguiba, Neurology, sfax, Tunisia

Background and Aims:: Primary central nervous system lymphoma (PCNSL) is a rare (5% of PCNS tumors) and aggressive extranodal non-Hodgkin lymphoma arising within the brain, eyes, leptomeninges, or spinal cord in the absence of systemic lymphoma at the time of diagnosis.

Methods:: A case report of an uncommon presentation of PCNSL to highlight its increasing incidence in immunocompetent patients.

Results:: A 63 years old woman with no medical history consulted for acute onset binocular diplopia. Neurological examination showed a partial palsy of the left extrinsic commun oculomotor nerve. Brain MRI showed a mesencephalo-thalamic hypersignal-lesion on T2 and diffusion with an intense enhancement after gadolinium administration and no restricted diffusion. There was no clinical or biological sign for systemic disease and the cytological and immunological study of the cerebro spinal fluid was normal. She received corticosteroids with total amelioration. A control imaging performed 01 month later has shown persistence of the lesion which was enhanced after gadolinium, hyper-perfused with a lipid peak and an increase in the choline/N-acetyl-aspartate ratio. A stereotaxic biopsy was performed showing a large B cell lymphoma. Bone marrow biopsy, ophthalmological examination and a thoraco-abdominal-pelvic CT were performed and were normal. Our patient received induction chemotherapy with high-dose methotrexate, followed by consolidative chemotherapy.

Conclusions:: The revelation of LPSNC by an oculomotor disorder is rare and it was reported in only 21 cases. It should be evoked in the immunocompetent subject, given both the increasing frequency and the absence of pathognomonic radiological sign.
DIFFERENTIAL DIAGNOSTIC DIFFICULTIES OF LYMPHOMA PRESENTING WITH NEUROLOGICAL SYMPTOMS

Maria Cholakova, Nikolay Mihnev, Ivan Staikov
Acibadem City Clinic MHAT Tokuda, Neurology, Sofia, Bulgaria

Background and Aims:: Lymphoma of the central nervous system (CNS), both primary and secondary, represents a rare subset of non-Hodgkin lymphoma. Incidence in immunocompetent patients is approximately 51 cases per 10,000,000 per year.

Methods:: Neurological examination, laboratory tests including flow cytometric (FCM) immunophenotyping of cerebrospinal fluid (CSF), magnetic resonance tomography of the head (MRI), biopsy.

Results:: We present three different clinical cases of patients with lymphoma of nervous system. First case is of a 44-year-old male admitted to the emergency department with meningo radicular irritation syndrome. Patient was with history for peripheral facial nerve palsy and MRI showing extra axial tumor formation in the left cavernous sinus area (image 1). Biopsy was performed 3 months earlier showing partially hyalinized connective tissue. Examination of CSF showed lymphocytic pleocytosis, atypical ones in different phase of mitosis. FCM of CSF gave the diagnose T-lymphoblastic lymphoma. The second case is of 50-year-old female with complaints of weakness and decrease sensation in lower limbs, dysphagia and facial nerve palsy. MRI of the brain was without lesions (image 2). The patient was with suspicion for Guillain-Barre but CSF examination showed lymphocytic pleocytosis (47% atypical). FCM of it gave the diagnose B-lymphoblastic lymphoma. The third case is of a 63-year-old male with right hemiparesis and progressive cognitive impairment. Several CTs and MRIs of the brain was performed with diffuse lesions in both hemispheres (image 3). It was discussed ischemic stroke, tumor, CNS infectious disease. Examination of CSF and trepan biopsy of bone marrow were without pathological changes. Patient was diagnosed with diffuse large B-cell lymphoma after brain tissue biopsy.

Conclusions:: CNS lymphoma is a rare disease. FCM of CSF and brain biopsy could help to make the right diagnose.
ATYPICAL PRESENTATION OF MENINGIOMA WITH CAVERNOUS HEMANGIOMA: CASE REPORT

Paula Fala¹, Pavel Gavriliuc¹, Alexandru Andrusca¹, Victor Andronachi¹, Eugen Melnic¹, Christian Mawrin²
¹State University of Medicine and Pharmacy "Nicolae Testemitanu", Neurology, Chisinau, Moldova, ²Otto-von-Guericke-University, Neuropathology, Magdeburg, Germany

Background and Aims:: The investigation of choice for meningioma diagnosis is MRI and it usually offers a high degree of reliability especially when the tumor has a typical location and appearance such as: iso-/hyointense to grey matter in T1 weighted imaging that shows homogeneous enhancement of contrast (T1 C + Gd) and iso-/hyointense to grey matter in T2 weighted imaging; other characteristic signs that help with the imaging diagnosis are the dural tail, the white matter buckling sign or the spoke-wheel appearance of the vessels. Atypical presentation such as inhomogeneous enhancement due to cystic degeneration or coexisting of the meningioma with other tumors is rare and can frequently lead to misdiagnosis.

Methods:: We present a 40-years old female patient diagnosed with a fibrous meningioma (World Health Organisation grade I) with alterations of the neurofibromatosis type 2 gene (NF2) and a cavernous hemangioma that showed an unusual perilesional swelling with higher density than the cerebrospinal fluid on MRI and signs of contrast of the peritumoral lesion at computer tomography angiography (CTA) more suggestive of a hemangioma.

Results:: Patient underwent surgery under the neuronavigational electrophysiological protocol. At 3-month follow-up MRI showed almost complete resection with restant tumor in the lateral wall of the SSS.

Conclusions:: The association between meningioma and cavernous hemangioma is extremely rare. There is little data on molecular alterations in such associations. Whether it affects treatment prognosis should be seen.
ASSOCIATION OF SMOKING WITH IDH1 MUTATION IN GLIOMA

Rusdy Malueka¹, Ery Kus Dwianingsih², Ibnu Argo¹, Maria Alethea¹, Kusumo Dananjoyo¹, Ahmad Asmedi¹, Rachmat Hartanto³
¹Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada, Neurology Department, Yogyakarta, Indonesia, ²Faculty of Public Health and Nursing, Universitas Gadjah Mada, Department Of Anatomical Pathology, Yogyakarta, Indonesia, ³Faculty Of Medicine, Public Health, and Nursing Universitas Gadjah Mada, Neurosurgery Division, Surgery Department, Yogyakarta, Indonesia

Background and Aims:: Mutation of the IDH1 gene plays an important role in gliomagenesis and in determining glioma prognosis. Previous studies had shown an association between smoking and IDH1 mutation in lung cancer. However, this association in glioma is unclear. This study aimed to find an association between smoking and IDH1 mutation in Glioma patients.

Methods:: Genomic DNA was extracted from fresh glioma tissues or from formalin-fixed paraffin-embedded (FFPE) samples. Mutation analysis was performed using Polymerase Chain Reaction-Restriction Fragment Length Polymorphism (PCR-RFLP) or DNA sequencing. Data regarding smoking was obtained from the medical record.

Results:: This study included 110 glioma patients. IDH1 mutations were found in 21 (19.1%) of the patients. As many as 30 patients (27.3%) had a history of smoking (current or former smokers). As many as 33.3 % of smokers had IDH1 mutations. This percentage was higher than in the non-smoking group (13.8%). This difference was statistically significant (p=0.02). Smoking was also associated with glioma grading. There was a higher proportion of high-grade glioma (WHO grade III and IV) in the smoking group compared to the non-smoking group (81.5% vs. 55.6% respectively, p=0.018).

Conclusions:: Smoking is associated with IDH1 mutations and grading in glioma patients.
NUMB CHIN SIGN: THINK OF THE OMINOUS!

Biswamohan Mishra¹, Ayush Agarwal¹, Anup Thacker²
¹AIIMS, New Delhi, Neurology, Delhi, India, ²Medanta Medicity, Neurology, Lucknow, India

Background and Aims:: Numb chin sign (NCS) is defined as reduced or absent sensation in an area of the chin and lower lip within the distribution of the mental or inferior alveolar nerves. NCS may be the preliminary symptom of malignancy or recurrence/metastasis in patients with cancer. Therefore, the occurrence of NCS warrants careful examination and monitoring of such patients and we aim to highlight the same through this case.

Methods:: We describe a 19-year girl, without any comorbidities, who presented with intermittent fever, 5 kilograms weight loss since the past 2 months and sudden onset numbness of chin for 20 days. Apart from haematological and biochemical evaluation, appropriate imaging and biopsy were performed to arrive at the diagnosis.

Results:: Examination was non-revealing apart from a numb chin (A). Routine blood investigations and cerebrospinal fluid examination (including malignant cytology sent twice) were normal. Magnetic resonance imaging of her brain (with contrast) revealed enlargement, along with contrast enhancement of the left Meckel’s cave (B). Bone marrow biopsy revealed hypercellular marrow with sheets of medium sized atypical cells consistent with acute leukemia of B lymphoid origin (C). She was treated with chemotherapy for the same but unfortunately succumbed to the illness.

Conclusions:: Presentation with numb chin, especially in young individuals should raise alarm bells and lead to a thorough search for an underlying malignancy.
Background and Aims: Diffuse midline glioma’s (DMGs) include central nervous system tumors, containing a characteristic H3K27M mutation and found in the midline location of brain and spinal cord. To determine the clinical, pathological, radiological & surgical outcome, disease severity of DMG patients who have undergone surgery and to find better therapeutic options.

Methods: 29 diffuse midline glioma patients were recruited. Clinical, pathological, radiological & surgical outcomes were noted and correlated with survival.

Results: KI67% was compared between <18 and >18yrs age groups, it was found that KI67% was higher in <18yrs age group (24.92±13.66, p = 0.08) compared to >18yrs age group (16.47±10.19) and found to have trend towards significance and it was also found that KI67% was significantly low in the population with >6months disease duration (12.2±4.712mnths, p=0.012) compared to <6months disease duration population (21.58±12.79mnths). Survival duration was significantly high in patients with age >18years (232.06±265.75days; p=0.02) compared to <18years age (50.16±47.79days). The patients who were taken the radiation therapy found to show significantly higher survival rate (341.25±318.05 days, p=0.05) compared to those who were not taken (69.89±71.5). Patients who required shunt placement found to have significantly lower survival duration (43.6±30.35 days, p=0.02) compared to patients who did not require shunt placement (215.56±263.55 days). Patients with improved post op outcome (10.8±4.08, p = 0.002) were having significantly low level of KI67% compared to not improved cases (21.87±12.58) and KI67% was negatively correlated with survival duration (r=-0.40; p=0.0358).

Conclusions: Our study conclude that KI67% and H3K27M serves as the markers and are correlated with survival duration.
POEMS SYNDROME ASSOCIATED WITH INTRAMEDULLARY PLASMACYTOMA MIMICKING ATYPICAL CIDP

Chulika Makawita, Sudath Ravindra, Kasun Udenika, Tharuka Herath, Bimsara Senanayake
National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

Background and Aims:: POEMS syndrome (Polyneuropathy, Organomegaly, Endocrinopathy, M protein, Skin changes) is a rare plasma cell disorder associated with sclerotic bone lesions and demyelinating neuropathy. It can present similar to CIDP (Chronic inflammatory demyelinating polyneuropathy), hence causing a diagnostic difficulty

Methods:: We present a case of 42-year-old gentleman with diabetes who presented with progressive limb weakness for 3 months causing him to be bed bound. He had bilateral symmetrical motor and sensory neuropathy with global areflexia, pedal oedema, skin pigmented and splenomegaly with liver parenchymal changes.

Results:: Nerve conduction study revealed sensory motor demyelinating neuropathy. CSF protein was high with no cellular reaction. These findings supported CIDP. Conventional treatments with immunoglobulin and plasmapheresis proved to be ineffective. MRI spine, sural nerve biopsy, bone marrow biopsy, CECT chest abdomen and viral screening were normal. His initial serum protein electrophoresis (SPE) was normal. The atypical nature of his demyelinating neuropathy lead to further investigations with radiology showing intramedullary infiltrating, lytic bony neoplasm in left pelvis which was biopsy proven to be an intramedullary plasmacytoma. Repeated SPE demonstrated abnormal monoclonal band confirming diagnosis of POEMS syndrome.

Conclusions:: Erroneous diagnosis of polyneuropathy due to CIDP in such cases could be costly. Prolonged treatment with IVIG and plasma exchange only is expensive and ineffective. Poor response to treatment and presence of other peripheral features should raise the possibility of other underlying causes such as paraproteinemia. Though POEMS syndrome is known to have osteosclerotic bone lesions plasmacytoma associated POEMS syndrome may cause lytic bone lesions.
CONTRIBUTION OF COMPARATIVE GENOMIC HYBRIDIZATION (CGH) TO THE CLASSIFICATION OF DIFFUSE GLIOMAS

Souhir Guidara¹, Marc Barritault², Eudéline Alix¹, Damien Sanlaville³, David Meyronet⁴
¹hopitaux est de Lyon, Genetic, Lyon, France, ²hopitaux est de Lyon, Anapath, Lyon, France, ³hopitaux est de Lyon, Genetic, Lyon, France, ⁴hopitaux est de Lyon, Anapath, Lyon, France

Background and Aims:: Diffuse gliomas are the most common primary malignant tumors of CNS in adults. These tumors are classified based on the recommendations WHO 2016 and cIMPACT-NOW. This classification results in an “integrated histo-molecular diagnosis” with better clinical correlation. In fact, it takes into account the results of genetic analyzes. The objective of our work is to discuss the contribution and limitations of CGH to classify diffuse gliomas and describe a cohort of patients with this tumor.

Methods:: It is a descriptive study of diffuse gliomas whose DNAs were sent to the cytogenetics service of the Lyon Hospices Civils for CGH. For each patient we collected age of tumor discovery, sex, tumor location and results of histological, immunohistochemical and genetic analyzes. In regards to CGH, we have tried to adapt this technique to DNA extracted from FFPE tissues.

Results:: We collected 16 patients. The age of discovery of the disease is on average 60 years. Tumor locations are variable. CGH’s technique has been validated in all cases. Based on the latest recommendations of WHO and cIMPACT-NOW, the gliomas were divided into 1 oligodendroglioma, 6 IDH mutant astrocytomas grade II or III, 3 IDHwt diffuse gliomas grade II or III and 6 glioblastomas.

Conclusions:: CGH is an efficient and in some cases essential tool to evaluate the prognosis and to adapt the treatment of gliomas. In view of this work, we wish to follow the evolution of our patients for a possible genotype prognosis correlation and to interpret all the anomalies observed in CGH.
INVOLVING PATIENTS AND CAREGIVERS IN THE PRODUCTION OF GUIDELINES FOR PALLIATIVE CARE IN PRIMARY BRAIN TUMOURS: IDENTIFICATION OF INTERVENTION PRIORITIES

Andrea Pace¹, Alessandra Solari², Ludovica De Panfilis³, Barbara Lissoni⁴, Edoardo Pronello⁵, Roberta Rudà⁶, Antonio Silvani⁷, Andrea Salmaggi⁸, Rossella Merli⁹, Ugo De Paula¹⁰, Elisabetta Bertocchi¹¹, Marina Verza¹², Simone Veronese¹³

¹IRCCS Regina Elena Cancer Institute, Neuroncology, Rome, Italy, ²Fondazione IRCCS Istituto Neurologico Carlo Besta, Unit Of Neuroepidemiology, Milano, Italy, ³Azienda USL-IRCCS di Reggio Emilia, Unit Of Bioethics, Reggio Emilia, Italy, ⁴ASST Ospedale Niguarda, Psicologia Clinica, Milano, Italy, ⁵University and City of Health and Science, Turin, Division Of Neuro-oncology, Turin, Italy, ⁶Castelfranco Veneto Hospital, Treviso Hospital, Department Of Neurology, Treviso, Italy, ⁷Neurological Institute C. Besta IRCCS Foundation, Neuro-oncology Unit, Milan, Italy, ⁸Manzoni Hospital, Neurology Unit, Lecco, Italy, ⁹ASST PGXXIII, Neurosurgery Unit, Bergamo, Italy, ¹⁰AO S Giovanni, Radiotherapy, Rome, Italy, ¹¹Azienda USL - IRCCS di Reggio Emilia, Palliative Care Unit, Reggio Emilia, Italy, ¹²IRENE Onlus, Patient’ Association, Rome, Italy, ¹³FARO Charitable Foundation, Research Unit, Turin, Italy

Background and Aims:: Involving patients and caregivers is an important component of clinical guideline development. The three main Italian scientific associations for neurology, neuro-oncology and palliative care (SIN-AINO-SICP) recently appointed a joint task force (TF) of clinicians and researchers to develop specific guidance on palliative care of people with primary brain tumours, following the GRADE approach. To identify clinical questions meaningful to the patients and caregivers, a qualitative approach was used.

Methods:: Based on the existing literature and on consensus, the TF identified nine intervention areas, whose relevance was apprised by patients (via personal semi-structured interviews) and bereaved caregivers (via focus groups, FGs) from five tertiary neuro-oncology centres. Participants were prompted to provide their personal disease-related experience, and were asked to elicit the areas that mostly impacted their own lives. Interviews and FGs were audio-recorded, transcribed and analysed using thematic analysis.

Results:: Twenty interviews and five FGs (28 caregivers) were completed between late 2020 and early 2021. Preliminary findings show that all the pre-specified areas were defined as important by participants. Most discussed topics were communication, organization and service satisfaction, cognitive and psychological issues, and advance care planning (ACP). Caregivers focused their discussions on the need for patient psychological support, difficulties experienced with symptoms control (e.g. epileptic seizures, behavioural changes), communication and organizational issues.

Conclusions:: Participation of Italian patients with brain tumours and family caregivers was high and information-rich. All of the nine guideline intervention areas were considered important, communication, care organization, symptom control and ACP being the most discussed.
MONITORING OF COGNITIVE FUNCTIONS AND QUALITY OF LIFE, IN GLOBLASTOMAS TREATED WITH REGORAFENIB

Allegra Carpaneto¹, Federica Franchino², Alessia Pellerino², Francesco Bruno², Erminia Muscolino¹, Roberta Rudà³, Riccardo Soffietti²
¹University and City of Health and Science Hospital, Department Of Neuro-oncology, Turin, Italy, ²University and City of Health and Science, Turin, Division Of Neuro-oncology, Turin, Italy, ³Castelfranco Veneto Hospital, Treviso Hospital, Department Of Neurology, Treviso, Italy

Background and Aims:: Standard treatment for progression in glioblastomas is represented by nitrosureas and bevacizumab. Since January 2020, regorafenib has been added. An Italian randomized study suggested a potential advantage of regorafenib over standard therapy. However, the impact of regorafenib on cognitive functions is not known. The aim of this study is to evaluate the impact of regorafenib on the cognitive functioning and quality of life of adult with glioblastoma.

Methods:: Patients with early progression to MRI after radiotherapy and chemotherapy are included in the study. They are monitored every 3 months using a 30-minute neuropsychological battery of ad hoc tests as follows: long-term verbal memory (Hopkins Verbal Learning Test-Revised), executive functions (Controlled Word Association Test) and visual attention, ideomotor speed, spatial research (Trial Making Test). Quality of life is assessed using the European Organization Research Treatment Cancer (EORTC) quality of life questionnaires for brain tumors (C30, BN20). The timing of the assessment is before regorafenib (baseline), after three and six months of treatment.

Results:: Since February 2021, ten patients, six males and 4 females with an age range of 24-74, were eligible to enter the study and have started cognitive and quality of life monitoring. The study is ongoing.

Conclusions:: The expected results concern the trend of cognitive functioning and quality of life (improvement vs stability vs deterioration) and the identification of the types of cognitive functions most involved. Progression represents a critical issue for the study, as some of these patients could drop out during the monitoring phases.
THE ASSOCIATION BETWEEN IDH1 MUTATION AND MGMT PROMOTER METHYLATION IN INDONESIAN GLIOMA PATIENTS

Dina Hudiana1, Rusdy Malueka2, Kusumo Dananjoyo3, Ahmad Asmedi2, Ery Kus Dwianingsih4
1Department of Neurology, Faculty of Medicine, Public Health and Nursing UGM/Dr. Sardjito General Hospital, Yogyakarta, Neurology, Yogyakarta, Indonesia, 2Faculty of Medicine, Public health and Nursing, Universitas Gadjah Mada, Neurology, yogyakarta, Indonesia, 3Faculty of Medicine, Public health and Nursing, Universitas Gadjah Mada, Neurology Department, Yogyakarta, Indonesia, 4Faculty of Medicine, Public health and Nursing, Universitas Gadjah Mada, Anatomical Pathology, yogyakarta, Indonesia

Background and Aims:: Gliomas are one of the most common brain tumors in adults. IDH mutation occurs in approximately 80% of all lower-grade glioma (LGG) and secondary GBMs. MGMT promoter methylation is an important marker to predict response to temozolomide chemotherapy. IDH1 mutation has been shown to be associated with MGMT promoter methylation. However, data about this from Indonesian glioma patients is very limited. Here we assessed the association between IDH1 mutation and MGMT promoter methylation status in Indonesian glioma patients.

Methods:: This was a retrospective study involving patients with glioma in Dr. Sardjito General Hospital and the affiliated hospitals. Genomic DNA was extracted from fresh glioma tissues or formalin-fixed paraffin-embedded (FFPE) samples. Mutation analysis was performed using Polymerase Chain Reaction-Restriction Fragment Length Polymorphism (PCR-RFLP) or DNA sequencing. MGMT promoter methylation status was identified using methylation-specific quantitative real-time PCR.

Results:: In total, 121 patients were included in this study. There were 29 patients with mutations in the IDH1 gene and 34 patients with MGMT promoter methylation. There was a higher proportion of MGMT methylation in the IDH1 mutant group than the IDH1 wild-type group (58.6% vs. 18.5%, p< 0.001).

Conclusions:: There was a significant association between IDH1 mutation and MGMT promoter methylation in Indonesian glioma patients.
ABDUCENS NERVE SCHWANNOMA: A CASE REPORT

Salma Naija, Emna Jarrar, Nesrine Amara, Anis Hassine, Sana Ben Amor
Service De Neurologie CHU SAHLOUL, Neurology Departement, SOUSSE, Tunisia

Background and Aims: Abducens schwannomas are rare tumors, representing less than 1% of all intracranial schwannomas in the literature. The tumor may be located within the cavernous sinus or more commonly at the prepontine region.

Methods: We reported a case of patient referred to the neurology department in Sahloul Hospital, Tunisia diagnosed with Abducens schwannomas;

Results: A 50-year-old woman presented with one month history of horizontal diplopia and headache. Right abducens nerve paresis was noted on neurologic examination. Facial sensation and corneal reflex were normal. The remainder of the physical examination was normal. Magnetic resonance imaging revealed a 6 x 5 mm sized heterogeneously enhancing mass in the right cerebellopontine angle. Although schwannoma was suggested, given the small size of the tumor, surgery was not indicated.

Conclusions: Intracranial schwannomas are benign, slow-growing tumors accounting for 6% to 8% of primary brain tumors. However, the majority has involved vestibular nerve and, less commonly, trigeminal nerve. Schwannomas of the cranial nerves involved with ocular motility are uncommon. Comprehensive radiographic evaluation together with the aid of advanced exquisite imaging technique can provide much more information on accurate diagnosis and microsurgical anatomy regarding the relationship of cranial nerves and microvasculature. Although MRI findings in the present case was considered consistent with schwannoma. In such cases, with no invasion of the cavernous sinus, radical tumor resection with preservation of the abducens nerve can be performed via a simple suboccipital retrosigmoid approach. Abducens schwannoma, although rare, should be taken into account for differential diagnosis of the cerebellopontine angle tumors.
CASE REPORT: GLIOSARCOMA IN PATIENT WITH SJOGREN SYNDROME

Viola Maharani1, Silvia Lumempouw2, Chairunnisa Baziad3, Dwi Rejeki4, Melita Melita5, Selfy Oswari6, Rini Andriani7
1Mahar Mardjono National Brain Center Hospital, Neurooncology, East Jakarta, Indonesia, 2Mahar Mardjono National Brain Center Hospital, Neurobehavior, Jakarta, Indonesia, 3Pusat Otak Nasional Prof. dr. Mahar Mardjono Hospital, Neurology, East Jakarta, Indonesia, 4Mahar Mardjono National Brain Center Hospital, Pathology, Jakarta, Indonesia, 5Mahar Mardjono National Brain Center Hospital, Radiology, Jakarta, Indonesia, 6Mahar Mardjono National Brain Center Hospital, Neurosurgery, Jakarta, Indonesia, 7Dharmais National Cancer Hospital, Neurology, Jakarta, Indonesia

Background and Aims: We describe a patient with Sjogren syndrome with rapidly progressive dementia due to gliosarcoma.

Methods: Female, 48 years old, presented with a memory dysfunction for 6 months and getting worse over time. The patient had complained about extreme fatigue, xerostomia, xerophthalmia, dysphonia, swallowing difficulty and diagnosed with Sjogren Syndrome for 3 years. She was then diagnosed with Rapid Progressive dementia and underwent MRI. The first MRI in September 2020 showed a hyperintense lesion in T2 and FLAIR along bilateral lateral periventricular, and contrast-enhanced diffuse nodules lesion in the left frontal lobe concluded as a demyelinating process. The second MRI in 2020 November 2020 showed a multiple solid-cystic lesion, with contrast enhancement on the solid part in cortical and subcortical of the bilateral frontal lobe, corpus callosum, and insulae. The lesions showed increased perfusion in CBV and CBF.

Results: Surgery was taken to resect the mass, and the pathology reveals the mass as gliosarcoma, WHO grade IV. Temozolomide 120 mg was given for 5 days and radiotherapy was given 8 times out of plan 33 times and was discontinued because of severe thrombocytopenia dan cardiomyopathy.

Conclusions: Gliosarcoma is a rare variant of a primary tumor of the central nervous system which very rarely shows rapid progressive dementia as an early clinical manifestation. In Sjogren’s syndrome, cognitive dysfunction can be also founded in some cases. This patient initially showed an MRI image that resembled a demyelinated lesion which was probably related to her Sjogren’s syndrome which was later found to be a malignancy.
A CASE OF STROKE AS THE FIRST PRESENTATION OF UNDERLYING PROSTATIC MALIGNANCY

Salma Naija, Emna Jarrar, Oussema Landolsi, Nesrine Amara, Anis Hassine, Sana Ben Amor
University Hospital Sahloul, Neurology Departement, SOUSSE, Tunisia

Background and Aims: Both ischemic and hemorrhagic stroke are well-recognized as complications of cancer and may be its initial manifestation. Pancreas, gallbladder, stomach, colon and gynaecological malignancies have all been associated with stroke.

Methods: We present ischemic stroke as the initial manifestation of prostatic cancer.

Results: A 62-year-old male with no medical history was admitted to our department after sudden onset left hemiplegia. Initial examination showed dysarthria, left homonymous hemianopia, left hemiplegia and purpuric skin lesions on his trunk and extremities. MRI brain demonstrated infract in the territory of the right middle cerebral artery. The etiological investigations: a cardiac ultrasound, 24hours ECG Holter and CT angiography of supra-aortic trunks showed no etiology. Laboratory investigations were suggestive of disseminated intravascular coagulation. CT abdomen and pelvis demonstrated enlarged heterogeneous prostate. Prostate specific antigen was raised more than 1000000ng/ml. A bone radionuclide imaging showed extensive metastasis. Prostate biopsy revealed an adenocarcinoma. The patient presented severe anemia and thrombopenia with hemorrhagic complication. He was initially treated by blood transfusion, then he was referred to oncology departement to start hormonotherapy.

Conclusions: Physicians should consider an underlying cancer as a potential explanation for a cryptogenic ischemic stroke particularly if the stroke is associated with abnormal blood studies. Authors recommended that etiological investigations should include a thoracic, abdominal and pelvic CT-Scan. Many mechanisms may explain the relation between ischemic stroke and active cancer as the disseminated intravascular coagulation, non-bacterial thrombotic endocarditis, secondary infections or direct tumor invasion. Early detection of underlying malignancy remains an essential driver of improved prognosis.
CORRELATION OF NEUTROPHILS LYMPHOCYTE RATIO WITH FUNCTIONAL OUTCOME IN INTRACRANIAL TUMOUR

Indah Youlpi¹, Alfansuri Kadri², Irina Nasution²
¹University of Sumatera Utara, Neurology, Medan, Indonesia, ²University of Sumatera Utara, Neurology, Medan, Indonesia

**Background and Aims:** Background and aims: Intracranial tumors are one of the causes of high rates of morbidity and mortality in neurology patients. Currently required laboratory markers can be used and correlated with functional outcome. Neutrophils Lymphocyte Ratio (NLR) is an inflammation marker used as a parameter of prognosis in various tumors. Increased of NLR have been known before its significant relationship with immediate survival rate in intracranial tumour by functional outcome. This study want to determine the correlation of neutrophils lymphocyte ratio with functional outcome in intracranial tumour.

**Methods:** This study uses a cross-sectional design. Sampling was conducted at Adam Malik General Hospital Medan. Samples were taken as many as 40 subjects consecutively. Blood laboratory and functional outcome were checked on days 1 and day 12. Data analysis used the spearman test and Pearson correlation test.

**Results:** Results of the study: Demographic characteristics of the study subjects were an average age 40-59 years, females 60% and 40% males, high school education level, housewife occupation. As many as 52.5% were primary brain tumors and 47.5% were metastatic brain tumors. There was significant relationship between NLR with NANO score in intracranial tumour for day 1 (p=0.001, r=0.646) and day 12 (p=0.001, r=0.656). There was significant relationship between NLR with KPS in intracranial tumour for day 1 (p=0.001, r=-0.617) and day 12 (p=0.003, r=-0.451).

**Conclusions:** Conclusion: There was significant relationship between NLR with functional outcome in intracranial tumour by NANO score and KPS.
COGNITIVE DEFICITS IN CHILDREN WITH BRAIN TUMOURS: A PROJECT TO CREATE A SOFTWARE FOR COGNITIVE TRAINING.

Angela Mastronuzzi¹, Domitilla Elena Secco¹, Beatrice Laus¹, Andrea Carai¹, Alberto Tozzi¹, Roberto Premuselli¹, Francesco Dellipriscoli², Antonio Pietrabissa², Alessandro Giuseppe², Danilo Menegatti²,₃, Eloisa Rizzotto¹, Giacomo Garone¹, Francesco Sciancalepore⁴, Eleonora Lacorte⁴, Leonardo Tariciotti⁵,₆, Giulia Remoli⁴, Nicola Vanacore⁴, Umberto Raucci⁷

¹Bambino Gesù Children's Hospital, Irccs, Rome, Italy, ²University of Rome "La Sapienza", Department Of Computer Science, Rome, Italy, ³Onlus, Il Laboratorio Di Chiara, Rome, Italy, ⁴National Institute of Health, National Center For Disease Prevention And Health Promotion, Rome, Italy, ⁵Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Neurological Surgery, Milan, Italy, ⁶University of Milan, Oncology And Hemato-oncology, Milan, Italy, ⁷Bambino Gesù Children's Hospital, IRCCS, Irccs, Rome, Italy

Background and Aims:: Brain tumors are the main cause of cancer-related death in children. These tumors and related treatments, in particular radiotherapy and high dose chemotherapy, are often associated with cognitive deficits that can cause mood and behavioral impairments. The aim of this study was to characterize cognitive impairments in children with brain tumors with the aim of creating a specific software for cognitive training to improve life expectancy and quality.

Methods:: The project had 3 phases: 1) defining the clinical and neuropsychological characteristics of children with brain tumors, 2) performing two systematic reviews on types of cognitive deficits and types of electronic devices available for cognitive rehabilitation 3) designing a software for cognitive training.

Results:: Between 2010 and 2020, 911 children with brain tumors were diagnosed by the Bambino Gesù Children's Hospital. Of these, 164 children (94 males; mean age 89±52 months, range 4-211), were consecutively enrolled by the emergency room. At a mean follow-up of 42±26 months (range 0-135) 12 patients had remitted, 36 were stable, 70 progressed, 44 died, and 2 were lost at follow-up. The histological diagnoses of the most frequent tumors were low-grade glioma (n=55), medulloblastoma (n=31), and ependymoma (n=16). In a preliminary evaluation of 9 children with medulloblastoma the general quotient score at diagnosis with the Griffiths Developmental Scale was 89± 16 (range 52-102).

Conclusions:: The identification and characterization of cognitive impairment over time are essential to define a specific technology for training (i.e. gaming app).
THE CORRELATION BETWEEN BRAIN TUMOR LOCATION AND ONSET OF NEUROOPHTHALMIC SYMPTOMS IN BRAIN TUMOR PATIENTS IN ADAM MALIK GENERAL HOSPITAL MEDAN

Citra Mega Kharisma, Cut Aria Arina, Kiki Mohammad Iqbal
Faculty of Medicine University of Sumatera Utara, Neurology, Medan, North Sumatera, Indonesia

Background and Aims:: Brain tumor is one of the tenth leading cause of death. Brain tumor can cause visual impairment by affecting the visual pathway. Important predictors for visual impairment are the tumor location (supratentorial or infratentorial) and elevated intracranial pressure. Patients with brain tumor often meet their ophthalmologist first. The signs and symptoms of neuroophthalmic can be one of suspicion to diagnose brain tumor. This study want to determine the correlation between brain tumor location and onset of neuroophthalmic symptoms in brain tumor.

Methods:: This study used a cross sectional design. Sampling was conducted at Ruang Rawat Inap Terpadu (Rindu) H. Adam Malik General Hospital Medan. Samples were taken as many as 30 subjects consecutively. Neurological examination and neuroophthalamic examination was performed in patients. Data analysis used the contingency coefficient test.

Results:: Demographic characteristics of the study subjects were in age >50-60 years, females>males, high school education level, housewife occupation. As many as 83,3% were primary brain tumors and 16,7% were secondary brain tumors. As many as 76,7% were located in supratentorial, 66,7% with onset ≥4,5 months and the most common neuroophthalmic symptoms was secondary headache due to raised intracranial pressure as many as 83,3%. There was significant relationship between brain tumor location with onset of neuroophthalmic symptoms in brain tumor (p=0,003).

Conclusions:: There was significant relationship between brain tumor location and onset of neuroophthalmic symptoms in brain tumor.
Background and Aims:: Paraneoplastic syndromes are rare, heterogeneous and might make the diagnosis of the underlying tumor. Although most clinical presentations are well described, some are atypical. Our aim is to establish a correlation between paraneoplastic neurological syndromes and the corresponding antibody, in a Tunisian series in comparison with the findings of the literature.

Methods:: Retrospective-descriptive study including patients with a confirmed diagnosis of a neurological paraneoplastic syndrome according to the Graus 2004 criteria. Epidemiology, clinical features and evolution were precised.

Conclusions:: Our study illustrates that the clinical spectrum of some onconeural antibodies exceeds the classical paraneoplastic syndromes (ex: anti-YO). In addition, positivity to more than one antibody is not exceptional. Some clinical presentations are unusual: multifocal presentation, Miller Fisher syndrome, multiple cranial nerve palsy. Screening for onconeural antibodies in these cases is mandatory if preliminary results are inconclusive. Diagnostic criteria might need to be updated and well established guidelines on the management of paraneoplastic syndromes are needed.
ATYPICAL INTRACRANIAL EXTRAMEDULLARY HEMATOPOIESIS AS A RARE COMPLICATION OF CHRONIC MYELOMONOCYTIC LEUKEMIA

Lucia Triguero Cueva, Virginia Guillen Martinez
Hospital Universitario Virgen de las Nieves de Granada, Neurologia, Granada, Spain

Background and Aims:: Extramedullary hematopoiesis (EH) in adults is rare and generally considered a compensatory mechanism in patients with chronic anemia and can occur in the course of myelodysplastic diseases. Cerebro-meningeal localization of EH is unusual and when it is present it is usually in the form of intracranial masses and it can course with neurological focus and epileptic seizures.

Methods:: We describe an unusual cerebro-meningeal EH case with history of chronic myelomonocytic leukemia and myelofibrosis criteria.

Results:: Male-67-years-old treated by idarubicina and citarabina 3 weeks ago, who presented an acute self-limited episode of disorientation with motor dysphasia and hypersalivation. The electroencephalogram showed no epileptic activity. Laboratory analysis showed pancytopenia (hemoglobin 8 g/dL, leukocytes 7880/µL, platelets 9000/µL) and mild hypertransaminasemia as unique remarkable findings. The brain magnetic-resonance (MRI) showed T1-hyperdensity and pachymeningeal enhancement with some nodulations; T2-hyperdensity was also seen at the supraorbital and left tempo-occipital sulcal level; the findings suggested extramedullary hematopoiesis at the meningeal level, with mild sulcal subarachnoid hemorrhage at the tempo-occipital level. Lumbar puncture could not be performed due to persistent thrombopenia. The control brain-MRI performed 2 weeks later showed partial resolution of lesions despite no specific treatment.

Conclusions:: EH is due to abnormal location of myeloid tissue in other organs than bone marrow. It is uncommon the cerebro-meningeal localization of EH secondary to chronic myelofibrosis. We describe a rare presentation with infiltrative pachymeningeal involvement and nodulations. Clinical evolution and succesives MRI can be useful to define the etiology in cases without possibility of pathological study.
THE INCIDENCE OF CHEMOTHERAPY-INDUCED PERIPHERAL NEUROPATHY AND COGNITIVE IMPAIRMENT IN PATIENTS WITH GASTROINTESTINAL TRACT CANCER

Haleh Ghavami1, Nasrin Taghizadeh1, Rasool Gharaaghaji Asl1, Mohsen Mansoori2
1Urmia University of Medical Sciences, Nursing And Midwifery Faculty, Urmia, Iran, 2Urmia University of Medical Sciences, Imam Khomeyni Teaching Hospital, Urmia, Iran

Background and Aims:: While there are many anti-cancer drugs used with widely varying mechanisms of action, there appear to be a common set of symptoms induced by many of these agents which include fatigue, cognitive dysfunction, and peripheral neuropathy. Indeed, these symptoms can be so severe that physicians may be forced to deviate from the optimal treatment strategy for a patient, which can directly influence survival. This research aimed to determine the incidence of chemotherapy induced peripheral neuropathy and cognitive impairment in patients with gastrointestinal tract cancer.

Methods:: This prospective descriptive study conducted on 100 patients with gastrointestinal tract cancer randomly selected, based on the including criteria. We used a demographic form, modified Total Neuropathy Score (mTNS), and Functional Assessment of Cancer Therapy Cognitive (FACT-Cog3) questionnaire for data collection.

Results:: The mean age of patients was 58.59 ±10.13 years .The majority of them were male (70%), with gastric cancer (36%).In this study 63% of patients had chemotherapy induced peripheral neuropathy and 80% of them had chemotherapy induced cognitive impairment. The results of chi-square test showed peripheral neuropathy and cognitive impairment were significantly associated with the type of chemotherapy agents used. Unlike peripheral neuropathy, cognitive impairment had a statistically significant relationship with patients' gender.

Conclusions:: The findings of the present study indicate a high incidence of chemotherapy induced peripheral neuropathy and cognitive impairment among cancer patients treated with cytotoxic drugs. The type of chemotherapy drugs can also be used as predictors of peripheral neuropathy and cognitive impairment.
THE INFLUENCE OF POSTOPERATIVE INFECTIONS ON THE SURVIVAL OF GLIOMA PATIENTS

Luisa Barbera\textsuperscript{1,2}, Friederike Schmidt-Graf\textsuperscript{2}, Claire Delbrdige\textsuperscript{3}, Jens Gempt\textsuperscript{4}
\textsuperscript{1}Charité, Berlin, Department Of Pediatric Pulmonology, Immunology And Critical Care Medicine, Berlin, Germany, \textsuperscript{2}Klinikum Rechts der Isar, Technische Universität of München, Department Of Neurology, München, Germany, \textsuperscript{3}Technische Universität München, Department Of Neuropathology, München, Germany, \textsuperscript{4}Klinikum Rechts der Isar, Technische Universität München, Department Of Neurosurgery, München, Germany

Background and Aims:: Glioblastoma remains the most common and lethal brain tumor in adults with a poor prognosis. Thinking about immunological influences, the question if postoperative infections have any efforts on survival arises consistently. Of our knowledge, this is the first study to evaluate a large group of glioma patients with postoperative infections, itemized by intracranial, extracranial and systemic infection.

Methods:: We analyzed retrospectively 267 patients with glioma for any infection over 2 months after brain surgery and identified WHO-grade, age, treatment and survival times from 2008 to 2013 with follow-up until 2016. We classified into intracerebral, extracerebral and systemic infections.

Results:: We identified 87 patients with infections over 2 months after brain surgery and 180 patients without. Age and WHO-grading were comparable in both groups. Patients with infections had shorter median survival than without (19.1 vs. 41.1 months, \(p=0.022\)). Patients with glioblastoma and infection had a shorter median survival time than patients without (12.9 vs. 16.4 months, \(p=0.017\)). Itemized by the location of the infection there was no statistically significant difference between the median survival of the non-infectious and the intracranial infection group (16.4 vs. 17.4 months, \(p=0.349\)). Patients with extracranial or systemic infection had a much lower life expectancy (1.4 and 1.8 months).

Conclusions:: There was no survival advantage for patients having suffered a postoperative infection, but the location of the infection made a vast difference in survival time. Immunological mechanisms may play a role in future local therapeutic strategies, but have no positive effects, even sometimes negative, in normal patient treatment postoperatively.
AN UNUSUAL CASE OF RELAPSING LONGITUDINALLY EXTENSIVE TRANSVERSE MYELITIS

Srinath Rajeevan¹, Lakshminarayanapuram Viswanathan², Madhu Nagappa³, Doniparthi Seshagiri³, Arimappan Arivazhagan², Vani Santosh⁴, Rose Bharath⁵, Sanjib Sinha⁶
¹National Institute of Mental Health and Neurosciences, Neurology, Bangalore, India, ²National Institute of Mental Health and Neurosciences (NIMHANS), Department Of Neurology, BENGALURU, India, ³National Institute of Mental Health and Neurosciences (NIMHANS), Neurology, Bangalore, India, ⁴National Institute of Mental Health and Neurosciences, Department Of Neuropathology, Bangalore, India, ⁵National Institute of Mental Health and Neurosciences (NIMHANS), Neuroimaging And Interventional Radiology, Bangalore, India

Background and Aims:: Etiologies of longitudinally extensive transverse myelitis (LETM) include demyelination, granulomas and infections. We describe an uncommon cause of LETM with a relapsing course.

Methods:: The clinical and imaging profile and laboratory investigations of a 17-year-old male were reviewed.

Results:: The patient developed intermittent low-grade fever, sub-acute paraparesis and urinary retention. Spine MRI showed LETM from dorsal cord to conus, and leptomeningeal enhancement. Cerebrospinal fluid (CSF) showed polymorphonuclear pleocytosis (180 cells), elevated protein (115 mg%), and reduced glucose (17 mg%). He was empirically treated with anti-tubercular therapy (ATT) and steroids. He recovered completely over five months and steroids were stopped at seventh month. At 11th month, he developed acute progressive paraplegia, sensory level at T4 and double incontinence. ATT was continued and steroids were re-initiated. At 18th month, weakness progressed to involve upper limbs and sensory level ascended to C7. At 22nd month, he developed holocranial headache, vomiting, diplopia, ptosis, nystagmus and tongue fasciculations. At 24th month, he developed hydrocephalic attacks and underwent ventriculo-peritoneal shunting. At 25th month, he developed respiratory distress and cyanosis necessitating mechanical ventilation. MRI showed appearance of new enhancing lesions in anterior corpus callosum, periaqueductal region, brainstem and bilateral dentate nucleus. Serial CSF analysis showed persisting pleocytosis and elevated protein. Evaluation for vasculitis, sarcoidosis, neuromyelitis optica and tuberculosis were negative. Bone marrow study was normal. Vario-guided biopsy of dentate lesion showed diffuse large B-cell lymphoma.

Conclusions:: Lymphoma of spinal cord is rare. Protracted course in this patient with ‘relapses’ could be attributed to modification of disease course by steroid therapy.
GARCIN SYNDROME: A RARE MANIFESTATION OF NASOPHARYNGEAL CARCINOMA

Hissam Musanip¹, Meldi Anuta², Arthur Gregori Lui³, Sunshine Lariego¹
¹Southern Philippines Medical Center, Internal Medicine, Davao City, Philippines, ²Southern Philippines Medical Center, Neurology, Davao City, Philippines, ³Southern Philippines Medical Center, Oncology, Davao City, Philippines

Background and Aims:: This is a case of a 38-year-old male with chronic ear pain, tinnitus, hearing loss, and effusion. The pain progressed with sudden multiple ipsilateral craniopathies. He was diagnosed with nasopharyngeal carcinoma as the primary cause of the Garcin syndrome. Literature on nasopharyngeal carcinoma presenting as Garcin Syndrome is very limited. Treatment and prognosis depend on the underlying pathology. Surgical option for nasopharyngeal carcinoma is usually limited to biopsy. Mainstay of treatment is combined chemotherapy and radiotherapy. Prognosis of nasopharyngeal carcinoma depends on the stage during diagnosis and the histology of the tumor. Our patient was given combined chemotherapy with cisplatin, 5-Fluorouracil and radiotherapy. Recommendations on appropriate management and prognosis is limited due to scant literature on the case.

Methods:: Case Report

Results:: Multiple cranial palsies can have many etiologies. A systematic approach to the case beginning with an exhaustive history taking and thorough physical examination complemented with radiologic workups is essential to a correct diagnosis and management. Extensive knowledge of the symptomatology and course of disease entities can help rule out intra-cranial and infectious pathologies and narrow our differential diagnoses. CT scan, MRI, and angiogram studies eliminated the vascular causes. Our radiologic work ups showed a mass lesion in the nasopharyngeal area with extension to the cranium and multiple cervical lymphadenopathies. Biopsy of the mass revealed nasopharyngeal carcinoma.

Conclusions:: Garcin syndrome is a rare cause of multiple cranial palsies. Garcin syndrome secondary to a nasopharyngeal carcinoma is even rarer. The appropriate management and prognosis of this case depends on the underlying pathology.
Background and Aims:: Cerebral venous thrombosis is a rare disease in children, but is one of the most serious complications of leukemia acute infantile lymphoblastic. We report the case of a child with acute childhood lymphoblastic leukemia, treated with L-asparaginase, who developed cerebral venous thrombosis.

Methods:: 12-year-old child with acute lymphoblastic leukemia, having received in the induction phase: methotrexate, purinol, endoxan, aracytine, and lastly asparaginase combined with corticosteroids. Three weeks later, the child presented with generalized serial tonic-clonic seizures. Examination: four-limb pyramidal syndrome predominant on the left. Brain MRI: bilateral frontal hemorrhagic infarction with thrombosis of the superior sagittal sinus (fig1) The child was put on keppra without anticoagulant, the child no longer had epileptic seizures.
Results: In acute lymphoblastic leukemia, the onset of thrombosis is due to the combination of different risk factors: the disease itself, the therapeutic attitude, the infections. This is the case of this child with this disease, treated with several molecules including L-asparaginase combined with corticosteroid therapy. L-asparaginase induces a state of hypercoagulability. Systematic and regular monitoring of fibrinogen and anti-thrombin III levels is therefore recommended. The administration of low molecular weight heparin followed by a relay with anti-vitamin K (3 to 6 months) is the recommended treatment.

Conclusions: The use of L-asparaginase requires careful clinical and laboratory monitoring. Cerebral thrombosis should be raised in the slightest doubt, requiring the temporary discontinuation of this drug, associated with specific management of the thrombosis, as well as a substitution on a case-by-case basis.
LANGERHANS CELL HISTIOCYTOSIS: CASE REPORT

Mariane Ferreira, Letícia Rigoti, Carlos Rodrigues, Eduardo Pessoa Júnior, Caroline Rincolato, Gustavo Bauer, Eloisa Neres, Leomara De Oliveira, Kevin Zilnyk, Marina Coronetti, Jaisla Colombi, Caio Goulart, Eugênio Da Silva, Fernanda Nacke, Luana Massarotto
Universidade Estadual do Oeste do Paraná, Ccs Centro De Ciências Da Saúde, Francisco Beltrao, Brazil

Background and Aims:: Langerhans Cell Histiocytosis (LCH), is characterized by expansive and erosive accumulations of Langerhans cells, which can occur in single or multiple tissues. The disease is rare, identified in approximately 0.5 per 100,000 children up to 2 years of age, shows a diverse clinical presentation, pathological commitment, and outcomes. Those factors make diagnosis and treatment difficult in LCH.

Methods:: We describe a case of Histiocytosis X in a male patient, aged 1 year and 6 months, with normal weight, height, and neuropsychomotor development for his age, who presented a tumor in the right temporal region and erythematous-squamous skin lesions with yellowish color on the scalp and trunk since his four months of age.

Results:: First, cranial Computed Tomography (CT) and temporal lesion biopsy were requested. The cranial CT revealed intense osteoclastic activity. Histopathological examination suggested LCH, confirmed by an Immunohistochemistry test that demonstrated CD1a-positive and S100-positive. To investigate systemic LCH, chest, abdomen, pelvis, and myelogram radiographs were requested, all without visible alterations. In addition, the patient's whole-body bone scintigraphy was requested, which identified multiple osteogenic reactions. The research proceeded with bone marrow biopsy, which showed infiltration by LCH, concluding the diagnosis of multisystem LCH. The patient had a favorable evolution to corticosteroid therapy associated with chemotherapy and has been monitored annually for recurrence research, the segment is maintained indefinitely.

Conclusions:: The case reported is notorious since its initial symptoms were discrete, with a single temporal tumor and skin lesions. This patients' LCH diagnosis occurred early, however, late diagnosis is common.
A CASE REPORT OF A BRAIN METASTATIC THYROID FOLLICULAR CARCINOMA SIMULATING A MENINGIOMA

Armando Cardoso¹, Augusto Brenner¹, Eduardo Anzolin², Deborah Shuha², Paulo Worm¹,²,³
¹Universidade Federal de Ciências da Saúde de Porto Alegre, Medicine, Porto Alegre, Brazil, ²Hospital Cristo Redentor, Neurosurgery, Porto Alegre, Brazil, ³Irmandade Santa Casa de Misericórdia de Porto Alegre, Neurosurgery, Porto Alegre, Brazil

Background and Aims:: Follicular thyroid carcinomas present intracranial metastases in about 1% of cases, usually consisting of intraparenchymal lesions. In less than 10% of cases, these lesions can be exclusively dural, being able to mimic meningiomas on imaging exams. The prognosis for thyroid carcinomas with distant metastases is poor, especially when the affected site is the brain, with a mean survival of less than one year. Our aim is to report a simulated meningioma by a brain metastatic thyroid follicular carcinoma.

Methods:: Case report of a 37-year-old woman presenting with a 6-month severe headache complaint and progressive bulging of the skullcap that sought medical assistance at our service.

Results:: Cranial MRI revealed an expansive intra and extracranial extra-axial mass in the left frontoparietal area that was causing a severe midline deviation. The lesion was isointense on T1, slightly hyperintense on T2, exhibited homogeneous enhancement post gadolinium administration, and a minimum halo of edema around the tumor on FLAIR, suggestive of meningioma. She underwent intracranial tumor exeresis and received hospital discharge 5 days after the procedure in good general condition, without neurological deficit. Pathological analysis and immunohistochemistry reported calvarial metastatic thyroid carcinoma of follicular pattern. The patient was submitted to thyroidectomy and radioiodine therapy about 1 month later. After 8 months, she underwent cranioplasty, without intercurrence. At the moment the patient is being followed-up by the oncology team.

Conclusions:: Considering that the metastatic follicular subtype of thyroid carcinomas tends to be more aggressive, our patient had an outstanding outcome, with a successful surgical resection therapy to date.
VISION LOSS RELATED TO COVID-19 INFECTION: A CASE SERIES OF ATYPICAL OPTIC NEURITIS

Nilufer Kale¹, Sami Omerhoca², Nurhan Kaya Tutar², Sebatiye Erdogan²
¹Bagcılar Training and Research Hospital, Neurology, İstanbul, Turkey, ²Bagcılar Training and Research Hospital, Neurology, İstanbul, Turkey

Background and Aims:: The Covid-19 outbreak, which was declared a global pandemic, has affected large human populations in many countries since March 2020. Although SARS-CoV-2 is a respiratory infection agent, various neurological syndromes, ranging from mild to severe, that may be associated with COVID-19 have been reported. Acute onset vision loss, optic neuritis (ON), cranial neuropathies, and Miller Fisher syndrome have been reported as covid-19-associated neuroophthalmological diseases. Objectives: In this case series, we aim to describe the clinical features of ON associated with COVID-19.

Methods:: We described the clinical laboratory and MR findings of our 3 patients who were diagnosed with COVID-19-associated ON after their application to our clinic.

Results:: Case 1: 18-year-old female patient presented with severe vision loss in the left eye. Examination showed visual acuity of finger movement from 40 cm and a left afferent pupillary defect with central scotoma. SARS-CoV-2 realtime polymerase chain reaction (RT-PCR) analysis of nasopharyngeal exudate and immunological testing was positive for IgM, suspicious for a possible active infection. Orbital magnetic resonance imaging (MRI) confirmed a left-sided optic nerve lesion on T2 weighted images. She was treated with IVMP treatment. Case 2: 56-year-old patient presented with blurred vision 1 month ago, he was diagnosed with COVID-19 and was treated with favipiravir. Visual acuity was 20/20 in the right eye and hand motions in the left eye. Cranial and orbital MRI were normal, patient was treated with IVMP. Case 3: 23-year-old patient presented with blurred vision in her left eye. Lymphopenia and SARS-CoV-2 PCR analysis of nasopharyngeal exudate were positive. Contrast-enhanced cranial and orbital MRI were normal, patient was treated with IVMP for 5 days.

Conclusions:: These 3 cases suggest that Covid-19 plays a role in the development of ON. The responsible mechanism may not be related to the direct infectious effect of the virus but rather a trigger role in autoimmune processes. Further studies are warranted.
CASE SERIES ABOUT DISJUNCTIVE NYSTAGMUS

Eunjin Kwon¹, Hyo-Jung Kim², Jeong-Yoon Choi³, Ji-Soo Kim³
¹Chungnam National University Hospital, Neurology, Daejeon, Korea, Republic of, ²Seoul National University Bundang Hospital, Research Administration Team, Seongnam-si, Korea, Republic of, ³Seoul National University Bundang Hospital, Neurology, Seongnam, Korea, Republic of

Background and Aims:: The mechanism and neural structures responsible for the disjunctive (disconjugate) nystagmus especially for divergence remain to be elucidated.

Methods:: We describe two patients with divergence nystagmus in association with lesions involving the dorsal pons and midline cerebellum.

Results:: Case 1. A 27-year-old woman was consulted for neuro-otologic evaluation three days after resection of cerebellar pilocytic astrocytoma mostly occupying the middle portion of the midline cerebellum around the fourth ventricle. Neurologic examination showed spontaneous divergence nystagmus during visual fixation, gaze-evoked nystagmus (GEN) during lateral gazes, more to the left, and limitation of abduction in the left eye. Convergence was intact. Video-oculography (VOG), seven days after the surgery, documented divergence nystagmus during visual fixation. Case 2. An 18-year-old woman visited the emergency department with acute dizziness for two days probably due to a large cavernoma involving the right cerebellum and pons. She additionally developed diplopia right after the visit. Examination showed right esotropia with limited abduction of the right eye along with rightward gaze palsy. She also showed spontaneous nystagmus beating outward in each eye and conjugate upbeat nystagmus with a clockwise component in the right eye and counterclockwise component in the left eye. After the emergent operation due to intracranial hypertension, the pathologic finding was consistent with cavernous hemangioma. Three days after the surgery, follow-up examination with VOG showed a resolution of the divergence nystagmus along with improved headache, dizziness, and nausea.

Conclusions:: Divergence nystagmus supports an active neural innervation for divergence, rather than passive relaxation after convergence.
Background and Aims:: Idiopathic intracranial hypertension (IIH) can cause disabling and permanent vision loss if it is not diagnosed and managed early. These findings are applicable only once the secondary causes of raised ICP are ruled out. Here we describe a patient of raised ICP secondary to severe iron deficiency anaemia causing vision loss.

Methods:: A 28 year old female presented to us with 6 months history of progressive holocranial headaches, associated with progressive bilateral loss of vision from 3 months. She had bilateral grade V papilledema and a visual acuity of counting finger (CF) till 1 meter in the left eye and 6/36 in the right eye (Fig.). The visual fields showed a generalised constriction of visual fields sparing a central island of vision (Fig.). Her Magnetic resonance imaging (MRI) of brain with venogram showed signs of raised ICP (Fig). Her CSF pressure was elevated > 400cms of water. She also had severe anaemia haemoglobin 6.8 g/dL with a low S.Ferritin levels of 15ng/mL. She was transfused 2 units of packed red blood cells (PRBCs). After 2 days of transfusion she noticed improvement in her visual fields.

Results:: She was discharged on oral haematinics, Acetazolamide 1000mg/dL and Topiramate 50 mg/day. A month after therapy her haemoglobin had increased to 8.8 g/dL, visual fields had cleared up (fig.) and visual acuity recovered to 6/6 in the right eye and 6/9 in the left eye.

Conclusions:: The diagnosis of IIH merits ruling out secondary treatable causes which might obviate surgery.
THE SPECTRUM OF OPTIC PERINEURITIS- A CASE SERIES

Aastha Takka¹, Sarath Aleti¹, Karthik Mahesh¹, Ramandeep Singh², Chirag Ahuja³, Vivek Lal⁴
¹PGIMER, Neurology, Chandigarh, India, ²PGIMER, Ophthalmology, Chandigarh, India, ³Postgraduate Institute of Medical Education and Research (PGIMER), Neuroradiology, Chandigarh, India, ⁴Postgraduate Institute of Medical Education and Research (PGIMER), Neurology, Chandigarh, India

Background and Aims:: Optic perineuritis (OPN) is an uncommon “inflammatory disorder” involving the optic nerve sheath. The term might be figuratively similar to Optic Neuritis (ON) which is an inflammation of optic nerves (and not the optic nerve sheath). We aim to describe the important clinical and radiological findings in patients with OPN.

Methods:: Where association of ON with demyelinating syndromes (Multiple sclerosis/ Neuromyelitis optica) is well known; OPN commonly presents with a background of Orbital inflammatory syndromes. The involvement of other orbital structures can be an important clue while diagnosing OPN. Neuroimaging usually clinches the diagnosis.

Results:: We provide a series of seventeen patients with varied causes of OPN. Clinical presentation, neuro-ophthalmological hallmarks and prognosis of patients with OPN need to be kept in mind while considering the prognosis.

Conclusions:: OPN is a comparatively rare localized form of orbital inflammatory diseases. It needs to be differentiated from ON because of different therapeutic and prognostic implications. The involvement of other ocular/orbital structures can be an important clue while diagnosing OPN. Secondary causes of OPN should always be borne in mind while investigating these patients.
WALL - EYED MONOCULAR INTERNUCLEAR OPHTHALMOPLEgia (WEMINO): CASE REPORT

Lina Carazo Barrios¹, Minerva Mañez Sierra¹, Olmo Leon Plaza², Carlos De La Cruz Cosme³
¹University Hospital Virgen de la Victoria, Neurology, Málaga, Spain, ²Hospital Universitario Virgen de la Victoria, Neurology, Málaga, Spain

Background and Aims:: Internuclear Ophthalmoplegia (INO) is a disorder of ocular motility caused by the damage to the Medial Longitudinal Fasciculus (MLF), which allows coordinated eye movements towards a horizontal direction. Wall-Eyed Monocular Internuclear Ophthalmoplegia (WEMINO) is an uncommon clinical presentation of INO that associates ipsilateral exotropia; the underlying pathophysiology of the syndrome is not yet fully understood.

Methods:: Case report of a patient with WEMINO due to pontine stroke.

Results:: A 73 year old man with previous medical history of hypercholesterolemia, diabetes mellitus and ischemic cardiomyopathy, smoker of 20 cigarettes per day and under treatment with acetylsalicylic acid, metformin and rosuvastatin, presented to the ER referring acute onset diplopia and vertigo. Initial neurological examination showed exotropia of the right eye, adduction paresis of the right eye, abducting nystagmus of the left eye, upbeat bilateral nystagmus and paresis of convergence of the right eye (video-filmatino available). Brain Magnetic Resonance revealed acute ischemic infarction in the right upper paramedian pontine tegmentum adjacent to the 4th ventricle, in the area of MLF. Basilar artery showed mild atheromatosis. The patient was diagnosed with Wall-Eyed Monocular Internuclear Ophthalmoplegia (WEMINO), and treated accordingly. Three months later the diplopia and eye deviation had disappeared completely.

Conclusions:: The case we present depicts a very uncommon clinical presentation of INO. The precise mechanisms underlying ipsilateral exotropia are not yet fully understood, but the few clinical reports suggest WEMINO is caused by damage confined to the MLF. Clinicians must be aware of this disorder in order to promptly identify and treat it.
ATYPICAL NON-PARANEOPLASTIC AUTOIMMUNE RETINOPATHY WITH ANTI-RECOVERIN ANTIBODIES: A CASE REPORT

Lina Carazo Barrios, Mariam Afkir Ortega, Alba Aguilar Monge, Javier Pinel Ríos, Agustin Rodriguez Belli, Carlos De La Cruz Cosme
University Hospital Virgen de la Victoria, Neurology, Málaga, Spain

Background and Aims:: Autoimmune retinopathy (AIR) is caused by antiretinal antibodies damaging the retinal tissue, classified as paraneoplastic or non-paraneoplastic. Non-paraneoplastic AIR usually presents as a rapidly progressive and often asymmetrical visual loss with an unfavorable visual prognosis. Only a few cases of non-paraneoplastic AIR associated with anti-recoverin antibodies have been described in literature.

Methods:: We describe an atypical case of non-paraneoplastic autoimmune optic neuropathy with anti-recoverin antibodies.

Results:: A 44 year old woman had in 2017 an acute episode of painful rapidly progressive visual loss in her left eye. Funduscopic examination showed mild alterations of the retinal pigment epithelium and optical coherence tomography showed papilledema. She received treatment with oral corticosteroids and the visual impairment resolved completely. She consulted one year later. Visual - Evoked Potentials (VEP) revealed a demyelinating left optic neuropathy. Brain and spinal cord magnetic resonance (MRI) were normal. NMO and MOG antibodies were negative. A lumbar puncture detected oligoclonal IgG bands in CSF. In 2019 the patient reported visual loss through her right eye and was treated with corticosteroids. New VEP showed axonal right optic neuropathy. A full autoantibody panel was performed, testing positive for anti-recoverin antibodies. Malignancy screening was negative. Although the patient reports nyctalopia and occasional blurred vision, her visual acuity returned to normal.

Conclusions:: The case illustrates how heterogeneous non-paraneoplastic AIR can be. We report an atypical clinical course, presenting as a recurrent optic neuropathy responsive to corticosteroid treatment associated with mild retinal alterations. In this case, the early corticosteroid treatment could have prevented further visual loss.
HORNER'S SYNDROME DUE TO HASHIMOTO'S THYROIDITIS

Antigoni Koukkouli1, Alisa Pham2, Zeinab Atieh2
1PANTHEO EYE CENTER, Ophthalmology, Limassol, Cyprus, 2St George's University of London, Department Of Medicine, Nicosia, Cyprus

Background and Aims:: Horner’s syndrome is characterized by ptosis, ipsilateral miosis, anhidrosis and occasionally apparent enophthalmos. Amongst the diverse neoplastic and non-neoplastic causes of acquired Horner’s in children, thyroid disease is rare. We present a case in which Horner’s syndrome was a consequence of the mass effect from a substantially sized goiter due to Hashimoto’s thyroiditis.

Methods:: A 13-year-old male presented with anisocoria and partial right eye ptosis. Following ophthalmic assessment and with the aid of pharmacological tests the diagnosis of acquired Horner’s syndrome was made. The patient was otherwise fit and healthy with no other symptoms. In view of the young age, MRI of the brain, orbits, neck and upper mediastinum was conducted which identified the enlarged thyroid. Fine-needle aspiration was compatible with lymphocytic thyroiditis. In our case, it is probable that the oculosympathetic tract injury present occurred in the pre-ganglionic region.

Results:: The diagnosis of Hashimoto’s thyroiditis was made. The patient was referred to an endocrinology team and was started on oral carbimazole. A year later, the goitre had almost resolved and his thyroid function returned to normal. The ptosis and anisocoria showed little improvement.

Conclusions:: It is important to exclude neuroblastoma as it is amongst the most common childhood tumours causing acquired Horner’s in young children. In rare circumstances, thyroid disorders may be associated with Horner’s syndrome and benign diseases predominate. Although the thyroid disorders associated with Horner’s are mostly benign diseases, it is imperative that appropriate investigations and treatment approaches are conducted timely to exclude the potential of a malignancy.
INCIDENCE OF MITOCHONDRIAL MUTATIONS IN COHORT OF PATIENTS WITH ETHAMBUTOL-INDUCED OPTIC NEUROPATHY

Prabhjit Kaur¹, Aastha Takkar², Kathirvel S.³, Biman Saikia⁴, Ramandeep Singh⁵, Paramjit Singh⁶, Vivek Lal⁷
¹Post Graduate Institute of Medical Education and Research (PGIMER), Neurology, Chandigarh, India, ²PGIMER, Neurology, Chandigarh, India, ³Post Graduate Institute of Medical Education and Research, School Of Public Health And Community Medicine, Chandigarh, India, ⁴Post Graduate Institute of Medical Education and Research, Immunopathology, Chandigarh, India, ⁵PGIMER, Ophthalmology, Chandigarh, India, ⁶Post Graduate Institute of Medical Education and Research, Radiodiagnosis And Imaging, Chandigarh, India, ⁷Postgraduate Institute of Medical Education and Research (PGIMER), Neurology, Chandigarh, India

Background and Aims:: Background: Ethambutol-induced Optic Neuropathy (EtON) is a devastating complication of the Anti-tubercular therapy (ethambutol-based regime) which is a cornerstone for the treatment of Tuberculosis. Though the etiology of the disease is unknown yet it has been postulated to be mitochondrial associated for a long time. It is intriguing to understand the basis which will aid in recognizing the “at-risk” population. Aim and Objective: To assess the association of mitochondrial mutations in the cohort of patients with Ethambutol-induced Optic Neuropathy (EtON)

Methods:: Patients who are on ATT (Ethambutol-based regime) and developing Ethambutol-induced Optic Neuropathy are being recruited. From the collected blood sample, mitochondrial DNA will be amplified after the isolation of whole genomic DNA. PCR- RFLP method will be used to further detect the presence of three mitochondrial mutations i.e. G3460A, T14484C, and G11778A.

Results:: Association of the mitochondrial mutations with Ethambutol-induced Optic Neuropathy and with the visual prognosis of the patients will be assessed. Recognition of high-risk groups may help isolate individuals in whom a longer duration of ethambutol can be avoided.

Conclusions:: Conclusion: A subset of patients who have a high predisposition to develop EtON upon the long duration of the drug will be isolated. The exposure of the drug ethambutol may be shortened in these patients.
TO ASSESS THE LEVEL OF CYTOKINES AND CHEMOKINES IN PATIENTS OF IDIOPATHIC INTRACRANIAL HYPERTENSION (IIH)

Kirandeep Kaur1, Aastha Takkar2, Kathirvel S.3, Chirag Ahuja4, Biman Saikia5, Ramandeep Singh6, Vivek Lal7
1Postgraduate Institute of Medical Education and Research, Neurology, Chandigarh, India, 2PGIMER, Neurology, Chandigarh, India, 3Post Graduate Institute of Medical Education and Research, School Of Public Health And Community Medicine, Chandigarh, India, 4Postgraduate Institute of Medical Education and Research (PGIMER), Neuroradiology, Chandigarh, India, 5Post Graduate Institute of Medical Education and Research, Immunopathology, Chandigarh, India, 6PGIMER, Ophthalmology, Chandigarh, India, 7Postgraduate Institute of Medical Education and Research (PGIMER), Neurology, Chandigarh, India

Background and Aims:: Background: Idiopathic intracranial hypertension (IIH) is a disorder characterized by elevated intracranial pressure (ICP) without an identifiable etiology. While, Headache, double vision and subsequently visual loss are the common symptoms, it is probably the commonest neurological cause of reversible blindness. The pathogenesis of idiopathic intracranial hypertension (IIH) remains unclear and as such it remains a diagnosis of exclusion. Aim: To measure the levels of pro and anti-inflammatory cytokines in serum and CSF of patients with IIH and study the association between inflammatory cytokines with neurological, ophthalmological and radiological profile of these patients.

Methods:: The diagnosis of IIH is being made after detailed neurologic, ophthalmic and radiological examination. 35 IIH patients and 10 controls were screened for the levels of cytokines and chemokines in the cerebrospinal fluid and serum using BD™ Cytometric Bead Array (CBA).

Results:: Result: Cytometric Bead Array showed elevated levels of IL-6, TNF α, IL-2, IL-17A, IL-10 in serum and IL-6, IL-2, IL-17 A in CSF in IIH patients compared with the controls.

Conclusions:: Conclusion: This study demonstrates differences in cytokine expression in the serum and CSF in IIH patients compared with controls. Since, the pathogenesis of IIH is unclear, the heterogeneity of the cytokine expression reported here may help understand the pathogenesis of this condition and further help in diagnosis of the disease.
CASE REPORT: A SURPRISING CAUSE OF ACUTE VISION LOSS

Dhawal Narang¹, Ritu Shree², Vivek Lal³
¹Apollomedics Superspeciality Hospital, Neurology, Lucknow, India, ²Postgraduate Institute of Medical Education and Research, Chandigarh, Neurology, Chandigarh, India, ³Postgraduate Institute of Medical Education and Research (PGIMER), Neurology, Chandigarh, India

Background and Aims:: Methanol poisoning is a common problem because of accidental ingestion of methanol or drinking adulterated liquor containing methanol. Exposure apart from ingestion is rare. Here we present a case in which acute vision loss occurred after inhalation.

Methods:: A 32y/o gentleman, worker in a chemical factory, presented to medical emergency with acute onset painless bilateral vision loss progressing to complete loss of light perception in 4 hours. He had inhaled fumes while working which made him feel dizzy. On presentation, he had fixed and dilated pupils and visual acuity was reported as no perception of light. Fundus examination showed bilateral optic atrophy. MRI of the brain showed hemorrhagic necrosis in bilateral putamina. Hemoglobin 14.8gm%, TLC 7300/mm³, DLC N91L8M2, Platelet count 158000/mm³, Urea 15mg/dL, Cr 1.12mg/dL, Sodium 134meq/L, Potassium 3.88meq/L, Chloride 107meq/L, Total Bilirubin 1.26mg/dL, Conjugated Bilirubin 0.23mg/dL. CSF showed 8 cells/mm³, N25L75, glucose 73mg/dl, protein 164mg/dl. He was given I.V. Methylprednisolone 1gm dailyx3 days followed by oral prednisone 1mg/kg weekly taper, high dose vitamin b12, folic acid and thiamine. His vision status did not change after 3 months of follow up.

Results:: He did not gain any useful vision even after 3 months of treatment.

Conclusions:: Poisoning by methanol even by inhalation could cause severe neurological symptoms especially severe vision loss.
Background and Aims:: Sub-acute visual loss together with optic disc oedema and macular star is referred to as neuroretinitis. Several conditions are known to masquerade as neuroretinitis. Idiopathic intra-cranial hypertension (IIHT) is one of them.

Methods:: A 35-year-old female, with a body mass index of 30.3 kg/m² presented with gradual loss of vision on the right eye over 2 weeks. She also complained of a long standing non-specific headache. Examination showed reduced visual acuity of 6/60 on the right eye with optic disc oedema and a macular star. The left eye was normal. No other neurological deficits were noted. Her blood pressure was normal. Her MRI-brain and orbits were normal. However, the CSF opening pressure was 330 mm.H₂O with normal constituents. The blood and CSF cultures were negative. The inflammatory markers were normal. Toxoplasma and HIV serology were negative. Bartonella serology was not available. She was initially treated with a combination of high-dose steroids and IV ciprofloxacin. This did not lead to a significant improvement in her visual impairment. However, following the discovery of elevated CSF opening pressure, she was commenced on acetazolamide and topiramate. This led to an improvement in the visual acuity on the affected eye to 6/24 and the optic disc oedema and macular star had reduced in size, two weeks after discharge.

Results::
Conclusions:: IIHT can rarely present with unilateral disc oedema and a macular star, mimicking neuroretinitis and cause a reduction in visual acuity, even at CSF pressures around 300 mm.H₂O.
Background and Aims:: Background: Chronic Relapsing Inflammatory Optic Neuropathy (CRION) is a rare and still poorly defined entity. Optic Coherence Tomography may improve diagnosis.

Methods:: Case report.

Results:: A 60 year old woman presented with subacute blurred vision, dyschromatopsia and pain on the right eye. Past medical history was unremarkable. On the first neurological examination pupils were equal and reactive to light, right VA was 9/10, fundus oculi examination was normal. After one month she experienced a dramatic worsening with great impairment of VA, counting fingers at 1 meter on the right. Right RAPD was present. Retinal nerve fiber layer (RNFL) was mildly increased bilaterally, VEP showed increased latency and reduced amplitude on the right, CSF electro focusing demonstrated type IV pattern. Orbit and brain MRI were normal. Anti NMO and anti MOG antibodies were negative. Doppler ultrasound of the temporal artery was negative. The patient was treated with high dose iv steroids with dramatic clinical response and RNFL thickness reduction. During steroid tapering she experienced a relapse on the right eye. OCT scan demonstrated increased RNFL thickness and GCL atrophy. The patient required continuous immunosuppression. CRION is a form of steroid responsive inflammatory optic neuropathy, which may belong to the growing family of NMOSD. Our patient experienced a subacute visual loss which developed over 2 months, with sudden acute worsening and dramatic recovery after steroids. OCT was consistent with inflammatory optic neuritis and was supportive in diagnosis.

Conclusions:: OCT may be a useful tool in diagnosing and monitoring inflammatory optic diseases.
HOMONYMOUS HEMIANOPIA IN MULTIPLE SCLEROSIS

Antigoni Koukkouli, Smriti Sasikumar, Chrisostomos Muwonge
1PANTHEO EYE CENTER, Ophthalmology, Limassol, Cyprus, 2St George’s University of London, Department Of Medicine, Nicosia, Cyprus

Background and Aims:: Ophthalmic manifestations are a prominent feature of multiple sclerosis (MS). Compared with optic neuritis retrochiasmal visual symptoms, such as homonymous hemianopia, are rare. We present an unusual case of homonymous hemianopia secondary to demyelinating process.

Methods:: A 40-year old female presented with sudden onset painless bilateral visual loss. The patient had been diagnosed with MS thirteen years earlier and had never received treatment. She had remained asymptomatic for several years. She also suffered from discoid lupus and migraines. On examination, best-corrected visual acuity was right eye 6/18 and left eye 6/9. Extra-ocular movements were normal and there was no relative afferent pupillary defect or colour vision loss. Dilated fundoscopy was unremarkable. Visual fields to confrontation suggested right homonymous hemianopia which was confirmed on automatic perimetry.

Results:: Magnetic resonance imaging on the day of presentation revealed multiple demyelinated lesions in the supratentorial region with no obvious contrast enhancement. Within days her right visual acuity reduced to counting fingers and now had a right relative afferent pupillary defect and colour vision impairment. Repeat imaging nine days following presentation, showed a lesion of the optic chiasm to the right with high T2/FLAIR signal intensity and mild contrast enhancement which was extending to the ipsilateral proximal optic tract. The patient was immediately pulsed on intravenous methylprednisolone 1gr for five consecutive days. She demonstrated excellent response to the treatment and was subsequently commenced on an immunomodulator.

Conclusions:: Homonymous hemianopia is uncommon in multiple sclerosis (0.5%-3.5%) and usually carries a favorable prognosis unlike other etiologies.
EYE BLOOD SUPPLY STUDY USING COLORED ULTRASONIC DOPPLEROGRAPHY

Alisher Hamidjonov, Alimardon Ismatov
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: The aim of the work is to study the state of blood circulation of the vessels of the eyeball in patients with atherosclerotic lesions of the carotid arteries of a hemodynamically significant nature, using the method of color Doppler ultrasound

Methods:: We examined 24 patients with atherosclerotic lesions of the carotid arteries of a hemodynamically significant nature (more than 70%) aged 51 to 74 years (16 men and 8 women)

Results:: It should be noted that the blood flow velocity obtained by us in the orbital artery and the central retinal artery was close to their results, then the maximum systolic blood flow velocity in the posterior short ciliary arteries, according to our data, significantly differs from those found by other authors, namely: from 8, 2 to 20 cm / s according to our data and 25.22 ± 4.53 cm / s. As for the final diastolic blood flow velocity, its values were close to the values obtained by the indicated authors, while maintaining a more pronounced tendency to decrease in the orbital artery. A few words about the resistance index

Conclusions:: The method of color Doppler ultrasound allows us to determine the blood flow velocity in the vessels supplying various parts of the eyeball that are inaccessible to direct observation, as well as a significant decrease in the blood flow velocity in a particular vessel feeding the eyeball
SHORT TERM AND LONG TERM VISUAL OUTCOMES IN PATIENTS OF IIH PRESENTING WITH BLURRING OF VISION

Ayush Dubey¹, Shubham Dubey²
¹Gandhi Medical College, Bhopal, Department Of Medicine, Bhopal, India, ²MMCH & RI, Department Of Neurology, Kanchipuram, India

Background and Aims:: Idiopathic Intracranial Hypertension (IIH) is a condition leading to raised intracranial pressure in the absence of any structural cause. Progressive blurring of vision is a complication of IIH and if not addressed, may lead to permanent blindness too. This study was done to assess the outcomes in patients of IIH presenting with blurring of vision to a tertiary care hospital in India.

Methods:: This was a retrospective study. Records of IIH patients presenting in last 5 years (1st January, 2016 to 31st December, 2020) with blurring of vision were assessed. Those who were regular in follow up were included in this study. The short term as well as long term visual outcomes with medical or surgical interventions were studied.

Results:: Out of 71 patients of IIH presenting to the hospital, 24 presented with blurring of vision. 3 out of 24 were lost to follow up. The remaining 21 patients were included in study. 16 patients responded to medical management (acetazolamide) whereas 5 patients required surgical procedure in addition to acetazolamide. Short term results (after 1 month therapy) showed improvement in vision in 14/16 patients on medical management and 3/5 patients on medical plus surgical management. Long term results (after 6 months of therapy) showed improved vision in all 16 patients on medicine and in 4 out of 5 patients in surgical group. 1 patient developed blindness in 2nd group.

Conclusions:: IIH is a disease having potential for permanent visual loss. Timely initiation of treatment with proper choice of treatment is required for improvement in the symptoms.
UNILATERAL OPTIC NEURITIS CAUSED BY SOLVENT. A CASE REPORT

Mariam Afkir Ortega¹, Carmen De Rojas Leal¹, Omar Hamad-Cueto², Olmo Leon Plaza³, Alba Aguilar Monge⁴, Virginia Delgado Gil⁵
¹Hospital Universitario Virgen de la Victoria, Neurology, Málaga, Spain, ²HOSPITAL CLINICO UNIVERSITARIO VIRGEN VICTORIA, Neurología, MÁLAGA, Spain, ³malaga, Neurology, Malaga, Spain, ⁴University Hospital Virgen de la Victoria, Neurology, Málaga, Spain, ⁵malaga, Neurologia, Málaga, Spain

Background and Aims:: Optic neuritis is one manifestation of central nervous system inflammation with resultant demyelination. Inflammatory-type optic neuritis caused by solvent is a rare clinical entity. It presents as acute loss of vision attributable to the use of neurotoxic substances such as cleaning solvents for domestic use.

Methods:: we describe a rare clinical case of unilateral optic neuritis caused by solvent.

Results:: A 41-year-old woman in January 2021 had an acute episode of painful and rapidly progressive visual loss in her left eye after the use of solvent for cleaning the bathroom a few days before. She consulted and complementary tests were performed. The rest of the neurological examination was normal. Funduscopic examination showed effacement of the left eye papilla and optical coherence tomography showed diffuse thickening of the optic nerve. In the blood analysis, an acute deficiency of folic acid was highlighted. NMO and MOG antibodies were negative. The MRI showed hypercaptation in both tear glands. The patient improved without treatment until she recovered ad integrum in five days.

Conclusions:: Inflammatory-type optic neuritis caused by solvent is an entity rarely described in the literature. We present a clinical case with acute onset of symptoms after use of solvent with spontaneous resolution after eight days. Faced with optic neuritis, we must carry out a broad differential diagnosis, insisting on the anamnesis for the use of substances, even days before. The deficit of folic acid can guide us to toxicity as a cause.
MISSING TISSUES IN EYE AND HEART WITH FACIAL PALSY - CASE REPORT OF CHARGE SYNDROME WITH LATE PRESENTATION AS HEART FAILURE

Alex Rebello¹, Ann Rodrigues², Anupriya Kaliyaparan³
¹Postgraduate Institute of Medical Education and Research (PGIMER), Neurology, Chandigarh, India, ²Giridhar Eye Institute, Ophthalmology, Kochi, India, ³Jawaharlal Institute of Postgraduate Medical Education and Research, General Medicine, Puducherry, India

Background and Aims:: CHARGE syndrome is a rare multisystem genetic disorder. Mutation in CHD7 gene was seen in around 58-64% of cases. It is usually diagnosed in infancy or childhood owing to the characteristic clinical features. However, there are occasionally late presentations, especially in resource limited settings where the clinical features may be ignored by the patients and there is delay in seeking medical care. We report a case of CHARGE syndrome with late diagnosis presenting with heart failure.

Methods:: CASE PRESENTATION: A 24-year-old male presented with exertional breathlessness, orthopnea and paroxysmal nocturnal dyspnea for 1-month duration. He was born out of non-consanguineous marriage and had normal antenatal and perinatal periods. He had mild developmental delay in motor milestones and difficulty in vision. However, he did not get evaluated earlier. There was no significant family history. On examination, he had short stature, microcornea, coloboma of iris and retina, external ear anomaly, prognathism, hockey-stick palmar crease and left facial palsy. Cardiac system examination suggested heart failure.

Results:: Routine blood investigations were normal. Echocardiography showed ostium secundum atrial septal defect and features of pulmonary artery hypertension. He was diagnosed as having CHARGE syndrome based on the clinical findings. Genetic studies couldn't be done due to financial constraints. He was treated with diuretics for cardiac failure and planned for atrial septal defect closure.

Conclusions:: It is a disease which needs early diagnosis as it involves multiple systems and requires early multi-modality intervention. The characteristic clinical features, which if recognized early will help in early diagnosis and management of this condition.
VISUOCOGNITIVE IMPAIRMENT IN MULTIPLE SCLEROSIS: THE RELATIONSHIP BETWEEN NEUROPSYCHOLOGICAL AND EVOKED POTENTIAL MEASURES

Christian Cordano¹,², Luca Mazzella³, Carla Ogliastro², Maria Cellmerino², Lucilla Vestito², Fabio Bandini⁴
¹UCSF, Neurology, San Francisco, United States of America, ²University of Genova, Department Of Neurology, Genova, Italy, ³P.A. Micone Hospital-ASL 3 Genovese, Ccdc/parkinson Center, Genova, Italy, ⁴ASL 3 Genovese, Neurology, Genova, Italy

Background and Aims::
Visual evoked potentials (VEPs) and event-related potentials performed with visual stimulation (VERPs) can be recorded non-invasively from different regions of the scalp. To compare simultaneously recorded VEPs and VERPs in MS patients without visual impairment.

Methods::
We performed a study of simultaneously recorded “primary” (VEPs) and “cognitive” (ERPs) visual evoked potentials in a group of MS patients who have no signs or symptoms of visual dysfunction. Two unidimensional Gabor patches of 1 cycle per degree of spatial frequency, differing in the orientation of the gratings, were presented in an “odd-ball” paradigm to 30 patients with MS and 30 age-matched control subjects. We measured latencies and amplitudes of N70, P100, and P300 components, deriving the “normalized” measures of P300-N70 latency difference (Central Processing Time - CPT70), the P300-P100 latency difference (CPT100), and the P300 amplitude responses normalized to either N70 and P100 amplitude.

Results::
We evaluated the relationship between primary and cognitive processing abnormalities. Then we investigated whether or not patients with orientation-dependent VEP changes, which are thought to be due to cortical pathology, have VERPs abnormalities. Third, we investigated if individual orientation-specific VEPs and VERPs results correlate with selective neuropsychological test scores for visuoperceptual or visuospatial skills. A wide battery of neuropsychological tests was performed. We found a significant correlation (r=066, p<0.01) only between the Stroop test and the raw and normalized (CPT) P-300 results.

Conclusions::
Simultaneously recorded VEPs and VERPs in MS patients are a promising tool for the study of cognitive function in MS.
ATYPICAL VISUAL IMPAIRMENT ASSOCIATED TO CEREBRAL SINUS STENOSIS RELATED TO COVID 19 THROMBOSIS

Mona Rekik¹, Omar Ayadi¹, Khadija Sonda Moalla², Imene Kaibi¹, Amira Ben Moula¹, Salma Gargouri¹, Amira Trigui¹, Chokri Mhiri²
¹Habib Bourguiba Hospital, Ophtalmology Department, Sfax, Tunisia, ²Habib Bourguiba Hospital, Neurology Department, Sfax, Tunisia

Background and Aims:: Cerebralvenoussinus stenosis (CVSS) may further complicate cerebral venous thrombosis(CVT) which is a rare thromboembolic complications in COVID-19 patients. We report a case of post COVID 19 CVT-related CVSS associated to intracranial hypertension (ICH). We discuss the possible mechanisms of highly asymmetric visual repercussions of ICH.

Methods:: A 45-year-old woman presented with complains of isolated visual loss in the right eye (RE). Her medical history included COVID-19 CVT for the past month. Visual acuity was 2/10 in the RE and 10/10 in the left eye. Fundus examination revealed bilateral papilledema, more important in the RE. The ultrasound examination showed right ON calcifications. Brain MRI showed features of raised intracranial pressure and revealed incidentally an extra axial meningioma surrounding the left ON in its retrobulbar portion. Brain MRA showed right lateral sinus stenosis. Lumbar puncture revealed significantly elevated intracranial pressure. Endovascular stenting was proposed.

Results:: CVSS can cause chronically-ICH. Patients may have no neurological symptoms other than visual impairment, secondary to bilateral papilledema. In this case, the visual repercussions of ICH were highly asymmetric. Compartmentalized cerebrospinal fluid would be a possible mechanism for asymmetric papilledema. The meningioma of the left ON could protect optic fibers from increased intracranial pressure. The ON head drusens of the RE would be an aggravating factor.

Conclusions:: Clinicians should consider the risk of CVT in the COVID-19 pandemic. Ocular symptoms could be the initial signs of CVSS. Correctly recognizing this condition is very important to avoid delayed treatment and complications.
**Background and Aims:** Mycoplasma pneumoniae (MP) is an atypical bacterium that can cause a variety of respiratory infections as well as neurological and ocular involvement such as conjunctivitis, third or sixth nerve palsies, uveitis and rarely optic neuropathy (ON).

**Methods:** A 38-year-old woman had a typical retrobulbar ON of the right eye, treated with corticosteroid therapy at high doses. Visual acuity improved to 16/20 after 5 days. One week later, she consulted for visual loss of the same eye at 6/20 associated with conjunctivitis. Neurological examination and brain MRI showed no abnormalities. A history of neglected respiratory infection was found with no evidence of other infection or auto-immune disease. The diagnosis of MP infection was established due to the presence of MP specific IgM antibodies. The patient was treated with corticosteroids and fluorquinolones. Outcome was favorable with complete regression of symptoms, and no recurrence after a follow-up of 4 years.

**Results:** The pathologic mechanism of extra-pulmonary involvement of MP remains unclear but is thought to be the result of direct invasion of the central nervous system, or a post infectious immune response. The coexistence of respiratory and visual symptoms with high levels of MP specific IgM antibodies underlines the possibility that the two infectious and auto-immune mechanisms are concomitant. This suggestion could justify antibiotic and steroid combination therapy and may explain initial improvement with corticosteroids in our case.

**Conclusions:** Atypical optic neuritis in a young adult should prompt consideration of a serologic testing for MP infection especially in endemic regions.
TOLOSA-HUNT SYNDROME: A RARE ENTITY

Mona Rekik¹, Sonda Kammoun¹, Khadija Sonda Moalla², Mariem Mariem Abdelhed³, Takwa Sammouda¹, Sofien Affes¹, Salma Gargouri¹, Amira Trigui¹, Chokri Mhiri²
¹Habib Bourguiba Hospital, Ophtalmology Department, Sfax, Tunisia, ²Habib Bourguiba Hospital, Neurology Department, Sfax, Tunisia

Background and Aims:: Tolosa Hunt syndrome (THS) is an inflammatory process adjacent to the cavernous sinus or within the superior orbital fissure and/or orbital apex. It is a rare entity well-defined clinically but of unknown etiopathogenesis.

Methods:: A 26-year-old woman presented with painful eye movements and diplopia. Examination revealed left ophthalmoplegia, ptosis with exophthalmos. Visual acuity was 7/10 in the left eye, 10/10 in the right eye. Fundoscopic examination was normal in both eyes. The remainder of the neurologic examination was unremarkable. Brain MRI revealed left orbital apexitis with diffusely enhancing left orbital apex extending to the anterior cavernous sinus and oculomotor muscles. The immunological and infectious assessments were negative. The diagnosis of THS was made, and the patient received corticosteroids. Outcome was favorable with complete regression of oculomotor symptoms after few days of treatment.

Results:: The clinical diagnostic criteria of THS include an episode or episodes of unilateral orbital pain; paralysis of one or more of the third, fourth, and sixth cranial nerves; and resolution of symptoms within 72 hours after corticosteroid therapy, with exclusion of other causes. MRI findings show inflammatory changes within anterior cavernous sinus, with or without involvement of the internal carotid artery, superior orbital fissure, orbital apex and optic nerve.

Conclusions:: Although THS is often a benign condition, it may lead to optic nerve involvement and blindness. Therefore, it is important to recognize the clinical features of this disease and provide immediate treatment to preserve visual function.
DRAMATIC TRAUMATIC OPTIC NEUROPATHY: A RARE ENTITY

Salma Gargouri, Omar Ayadi, Khadija Sonda Moalla, Mona Rekik, Takwa Sammouda, Kmar Maaloul, Sonda Kammoun, Amira Trigui, Chokri Mhiri

1Habib Bourguiba Hospital, Ophtalmology Department, Sfax, Tunisia, 2Habib Bourguiba Hospital, Neurology Department, Sfax, Tunisia

Background and Aims:: Traumatic optic nerve (ON) avulsion corresponds to the disinsertion of the ON from the eyeball at the level of the lamina cribrosa. We report clinical and multimodal imaging findings in partial (ON) avulsion following head trauma.

Methods:: An 11-year-old boy presented with complains of sudden vision loss of the left eye (LE) following blunt trauma with a wooden stick.

Results:: Examination of the LE found visual acuity limited to counting fingers and an afferent pupillary defect. Fundus examination showed superficial and deep peripapillary hemorrhages as well as retrohyaloid hemorrhages. A deep depression with empty space at the inferior pole of the ON head was noted. Brain MRI was without abnormalities. Kinetic perimetry found a superior altitudinal deficit in the LE. Optical coherence tomography (OCT) showed an interruption of axons at the inferior-temporal edge of the ON head with thinning of retinal nerve fiber and ganglion cell layers.

Conclusions:: In ON avulsion, the ON is disinserted from the retina, and the lamina cribrosa is retracted from the scleral rim. This is a rare and dramatic form of direct traumatic optic neuropathy. ON avulsion usually results from sudden extreme rotation or anterior displacement of the globe following head trauma. The diagnosis is evident in fundoscopy. OCT could reveal the disruption of ON axons at the scleral rim. The prognosis for this disease remains very poor. Its therapeutic management remains to date non-consensual.
**A RARE PRESENTATION OF MYASTHENIA GRAVIS FOLLOWING BOTULINUM TOXIN INJECTION**

Antigoni Koukkouli, Chrisostomos Muwonge, Anna Komarova, Smriti Sasikumar

1PANTHEO EYE CENTER, Ophthalmology, Limassol, Cyprus, 2Charles University, Faculty Of Medicine, Prague, Czech Republic, 3St George's University of London, Department Of Medicine, Nicosia, Cyprus

**Background and Aims::** Botulinum toxin drugs have an excellent safety profile. Adverse events are most often related to the local diffusion of the toxin and are usually mild and transient. However, there are cases where the clinical manifestations following the injection cannot so easily be explained. We describe a case of myasthenia gravis following periocular botulinum injection.

**Methods::** The patient presented with sudden onset diplopia ten days after botulinum toxin injection. There was also mild right sided ptosis which the patient first noticed five years earlier. The symptoms were initially attributed to the local diffusion of the drug, but her diplopia persisted beyond three months. Further, the diplopia constantly fluctuated requiring frequent revision of her Fresnel prisms.

**Results::** MRI orbits and brain and routine blood investigations were all normal. The blood test for antibodies (Ab) against acetylcholine receptor (AChR) and muscle-specific kinase (MUSK) were done: AChR Ab was negative and MUSK Ab was positive. Computer tomography showed no thymoma and spirometry was normal. In view of the emerging clinical picture and blood results, a diagnosis of myasthenia gravis with MUSK Ab was made. A year later, she remains well controlled on treatment, and even her ptosis has improved, but her symptoms occasionally relapse during her menstrual cycles.

**Conclusions::** Botulinum toxin injection may unmask subclinical generalized myasthenia gravis, therefore clinicians should be vigilant of this possibility. In patients with pre-existing neuromuscular pathology or signs of muscle weakness such as the ptosis in our patient, botulinum toxin should be used with caution.
OCULAR ISCHEMIC COMPLICATIONS FROM RETINAL MIGRAINE

Oana Dumitrascu¹, Cumara O’Carrol¹, Odette Houghton², Marie Acierno², Chia-Chun Chiang³
¹Mayo Clinic, Neurology, Scottsdale, United States of America, ²Mayo Clinic, Ophthalmology, Scottsdale, United States of America, ³Mayo Clinic, Neurology, Rochester, United States of America

Background and Aims:: Retinal migraine is defined by ICHD 3rd edition as fully reversible monocular visual phenomena, accompanied, or followed within 60 minutes by headache. We report two patients with persistent visual phenomena that complicated with either severe disabling visual loss or permanent visual field defect. We emphasize the importance of retinal migraine acute and preventive management.

Methods:: Case-series

Results:: Case 1. 57-year-old man with longstanding history of bi-annual retinal migraines and hypertension controlled on a calcium-channel blocker, presented with painless monocular visual loss. Initial symptoms were reminiscent of his typical retinal migraines, however progressed over 4 days to right eye finger-count vision. Intravenous fluorescein angiography (IVFA) showed paracentral acute middle maculopathy at 48-hours, and combined central retinal vein and central retinal arterial occlusion at 96-hours after onset. He was prescribed preventative daily nortriptyline and magnesium, and acute sublingual nitroglycerin should he experience contralateral visual auras. Case 2: 21-year-old man with history of one retinal migraine and family history of migraines, presented with a 24-hour persistent right eye supero-temporal scotoma after a retinal migraine. Visual acuity was normal; a right relative afferent pupillary defect and right supero-temporal visual field defect were noted, consistent with ischemic optic neuropathy. Daily migraine preventive therapy was recommended.

Conclusions:: Retinal migraines are not benign conditions, as they can complicate with retinal or optic nerve infarction. Migraine prophylactic therapy should be recommended to prevent disabling visual loss even in subjects with infrequent retinal migraines, especially with monocular vision. Patients should have a low threshold to self-administer early acute migraine therapy.
PROFILE OF DISC ATROPHY IN CIPTO MANGUNKUSUMO NATIONAL HOSPITAL

Lenny Naulita, Ni Nengah Ariarini, Freddy Sitorus, Dinda Diafiri
Faculty Faculty of Medicine University Indonesia- Cipto Mangunkusumo hospital, Departement Of Neurology, Jakarta, Indonesia

Background and Aims:: Disc atrophy is the end stage of the degeneration of the optic nerve. It is divided into primary and secondary disc atrophy. This study aimed to describe the etiologies and the characteristics of disc atrophy in Neurology Outpatient Clinic, Cipto Mangunkusumo Hospital, Jakarta.

Methods:: This retrospective cross-sectional study performed in Neuroophthalmology-Neurootology Diagnostic Clinic of Cipto Mangunkusumo Hospital, Jakarta, 2014-2019. Statistical analysis of Chi-square/Fisher exact test and Mann-Whitney test

Results:: Of 1,821 patients included in this study, 278 patients (6.5%) presented with disc atrophy. Primary disc atrophy proportion was 81.7% and usually unilateral whereas secondary disc atrophy was 20.8% and bilateral. Both primary and secondary disc atrophy showed a pupillary abnormality, a severe degree of visual acuity impairment, and visual field defect. The visual acuity tends to be a blindness in primary optic atrophy (72.6%) and secondary optic atrophy (80.7%). The severity of visual acuity was significantly more severe in secondary optic atrophy (Logmar 2.24±0.95 vs 1.94±0.99, p 0.005). Moreover, the proportion of complete visual field defects was significantly higher in secondary disc atrophy (90.5% vs 52.3%, p 0.00). CNS tumor commonly found as an etiology in secondary disc atrophy than primary (54.9% vs 28.2%, p 0.001). Ischemic optic neuropathy (13.7%, p 0.002) and multiple sclerosis/NMO (8.4%, p 0.03) were found only in primary disc atrophy.

Conclusions:: Different characteristics and etiologies occurred in primary and secondary disc atrophy. The visual acuity impairment and visual field defect were more severe in secondary disc atrophy. In regard to the etiology, CNS tumor found commonly in secondary disc atrophy, whereas ischemic optic neuropathy and multiple sclerosis/NMO found commonly in primary disc atrophy.
Background and Aims:: Fundoscopy is a useful tool in diagnosing neuro-ophtalmology disorders, especially for detecting papilledema and optic disc edema. However, there is a risk of airborne transmission that should be considered before doing the examination. Some clinical characteristics may help in deciding to do a fundoscopy examination.

Methods:: We analyzed a retrospective database consisting of 973 patients that were examined in a neuro-ophtalmology clinic at dr. Cipto Mangunkusumo Hospital, the national referral hospital of Indonesia, during the period of 2016-2019. Statistical analysis was done using SPSS.

Results:: Optic disc edema was found in 1.3% of patients. The visual complaint was more likely to be impaired visual acuity (p=0.005) and often accompanied by orbital pain (p=0.012). The most likely etiology was ischemic optic neuropathy (38%, p<0.001). Papilledema was found in 10.3% of patients. Visual complaints in patients with papilledema were more likely to be diplopia (p=0.031), persistent (p=0.004), and accompanied by a focal neurological deficit (p=0.008). The most frequent etiologies causing papilledema were brain tumor (51%, p<0.001) and CNS infection (7%, p=0.019). There was no significant difference of visual loss distribution (unilateral or bilateral) and onset, both in disc edema and papilledema.

Conclusions:: Some clinical characteristics and known etiologies can help neuro-ophtalmologists to prioritize patients for fundoscopy examination, particularly in office settings amid the COVID-19 pandemic.
POST COVID-19 OPTIC NEURITIS: TWO EGYPTIAN CASE REPORTS

Ayat Allah Farouk¹, Amira Elgohary²
¹kasralainy cairo university, Clinical Neurophysiology, cairo, Egypt, ²Cairo University, Clinical Neurophysiology, cairo, Egypt

Background and Aims:: The exact incidence of neurological complications from coronavirus disease 2019 (COVID-19) infection is still unknown. Neurological symptoms are more common with severe form of the disease. Through neuro-invasion, the virus can affect both neurons and glial cells and induce wide range of neurological pathologies. CNS symptoms are more common representing 91% of all neurological patients with 9% only with PNS. PNS manifestations showed variable results, where visual impairment and nerve pains were more frequent in the severe COVID-19 category of patients.

Methods:: This is a two-case report of post COVID optic neuritis, both after severe COVID infection and hospitalization, they developed acute onset visual affection mostly one and a half month in the first case and two months in the second one after almost complete cure. The first case had delayed perception of vision, the second one had complete visual loss of one eye of unexplained causes.

Results:: All neurological and ophthalmological investigations were normal apart from pattern visual evoked potentials that showed small amplitude P100 response bilaterally in the first case and absent pattern and flash VEP responses on the clinically affected side in the second case.

Conclusions:: This supports what was stated in a study based on murine models of other CoVs, which stated that viral-induced optic neuritis secondary to autoantibody production against neuroretina should also be considered and suggested that infected patients should be monitored for signs of neuroretinal degeneration on the long term.
PHARMACOACUPUNCTURE THERAPY FOR DIZZINESS IN TRADITIONAL KOREAN MEDICINE: A SYSTEMATIC REVIEW

Eui Ju Lee
Kyung Hee University Korean Medicine Hospital, Stroke Center, Seoul, Korea, Republic of

Background and Aims: This systematic review aimed at briefly exploring how effective pharmacoacupuncture therapy for dizziness is.

Methods: We searched publications in Medline, EMBASE, Cochrane Library, KoreaMed, China National Knowledge Infrastructure (CNKI), Cinii, DBpia, KSI, Kiss, KMBase, NDSL and RISS. We included randomized controlled trials and well-designed non-randomized controlled trials that compared the effects of only pharmacoacupuncture or pharmacoacupuncture and usual therapies with any controls for dizziness.

Results: The risk of bias was assessed using the Cochrane tool. Three studies have been included with eligibility criteria (Fig 1). Risk of bias assessments showed mostly “unclear” because the included study reported the results poorly (Fig 2). This review found the evidence that pharmacoacupuncture therapy was effective as add-on therapy to acupoint therapy, physiotherapy and had additional benefits in increasing of CER for cervical vertigo. Also, it was recommended that pharmacoacupuncture therapy was effective as add-on therapy to western medicine and had additional benefits in increasing of CER for vasovagal syncope (Table 1).

QUALITATIVE STUDY EXPLORING CLINICIANS’ EXPERIENCE OF PARTICIPATING IN A FEASIBILITY TRIAL INVESTIGATING BENIGN PAROXYSMAL POSITIONAL VERTIGO IN TRAUMATIC BRAIN INJURY

Bithi Sahu¹, Rebecca Smith², Caroline Burgess³, Jonathan Marsden⁴, Barry Seemungal⁵
¹Imperial College London, Student, London, United Kingdom, ²Imperial College London, Division Of Brain Sciences, London, United Kingdom, ³Kings College London, Population Health Sciences, London, United Kingdom, ⁴Plymouth University, Neurological Rehabilitation, Plymouth, United Kingdom, ⁵Imperial College London, Neuro-otology, London, United Kingdom

Background and Aims:: This is a multi-centre qualitative study embedded within a larger multiphase feasibility study investigating the management benign paroxysmal positional vertigo (BPPV) in acute traumatic brain injury (TBI). Evidence has shown qualitative methods have a place in feasibility studies as they can improve validity of a future trial. Our primary objective was to explore the acceptability of trial processes such as recruitment, randomisation and interventions. A secondary objective was to identify any facilitators or barriers to implementing a more definitive randomised controlled trial (RCT).

Methods:: A qualitative approach was utilised as it provides an interpretive view of context-related phenomena. We used the theoretical domains framework to inform our topic guide and provide a theoretical lens into factors affecting behaviour. Participants from the research team across two major trauma hospitals in London, UK were recruited using purposive sampling. Semi-structured, individual interviews were used as the data collection method. Data was transcribed verbatim and analysed using Framework analysis.

Results:: Eight clinicians participated: four research nurses, three physiotherapists and one occupational therapist. Concerns were raised surrounding the randomisation of BPPV patients to the usual care treatment arm. Reported facilitators included a split clinical-research post, which enabled therapists to complete study specific research activities without significant impact on their clinical workload.

Conclusions:: This work provides insight into clinicians’ perspectives of trial processes and demonstrates the importance of gaining such views. These data will inform the design of a future RCT and will help shape targeted theory-based implementation strategies for clinical behaviour change, with potential to translate into improved patient outcomes.
Galvanic Vestibular Stimulation Improves Spatial Cognition After Unilateral Labyrinthectomy in Mice

Thanh Tin Nguyen1,2,3, Gi Sung Nam1,4, Jin Ju Kang1,5, Kyu Cheol Han6, Ji-Soo Kim7, Marianne Dieterich8,9,10, Sun Young Oh1,2,5

Background and Aims:: The present study was aimed to investigate the contributions of unilateral vestibular deafferentation to spatial cognition and the efficacy of galvanic vestibular stimulation (GVS) for recovery of these deficits using a unilateral labyrinthectomized (UL) mouse model.

Methods:: Thirty-six male mice were divided into 3 groups comprising a control group and two UL groups with (GVS group) and without GVS intervention (non-GVS group). After surgical UL, locomotor and cognitive behavioral recoveries on postoperative days (PODs) 3, 7 and 14 were assessed by open field (OF), Y maze, and Morris water maze (MWM) tests.

Results:: Locomotion and spatial cognition were significantly impaired after UL (non-GVS group) compared to the control group. GVS intervention after UL significantly improved locomotion compared to control and non-GVS groups at PODs 3 and 7 in the OF and Y maze tests. Spatial working memory assessed by the Y maze were also significantly improved in the GVS group compared to the non-GVS group at POD 3. In addition, the recovery of long-term spatial navigation deficits during the MWM, as indicated by the escape latency and the probe trial, was significantly better in the GVS group compared to the non-GVS group 2 weeks after UL. (Please see the attached file)

Conclusions:: Acute unilateral peripheral vestibular lesions cause deficits in spatial cognition and motor coordination. Our study provides evidence that an early intervention with GVS was effective in improving spatial memory and navigation as well as locomotor function, implying a promising potential to rehabilitate these impairments in patients with acute unilateral vestibular failure.
SUDDEN UNILATERAL HEARING LOSS AND VERTIGO DUE TO POSTERIOR INFERIOR CEREBellar ARtery TERRITORY hypoperfUSION BY VERTEbral ARtery DISsection

Hak Seung Lee
Wonkwang University Hospital, Neurology, Iksan-si, Korea, Republic of

Background and Aims:: Sudden hearing loss and vertigo are the typical presentation of anterior inferior cerebellar artery infarction, but may occur in posterior inferior cerebellar artery (PICA) infarction. However, it is known that it is very rare that hearing loss and vertigo occur due to perfusion deficits without the occurrence of infarction. Here I describe a patient who presented with sudden hearing loss in left ear and vertigo due to PICA territorial hypoperfusion without infarction by vertebral artery (VA) dissection.

Methods:: case report

Results:: A 51-year-old man presented to emergency room complaining that he had suddenly lost hearing in his left ear. He had also noted vertigo and imbalance. On examination he had vibration induced right-beating nystagmus and left-beating nystagmus after head shaking test. Also he had left-beating nystagmus in right roll test and right-beating nystagmus in left roll test. The head impulse test was normal. Brain MRI showed left PICA territorial perfusion deficits without infarction. Brain MRA and conventional angiography revealed occlusion of left post-PICA intracranial VA with flow arrest and multifocal stenosis of right intracranial VA suggesting both VAs dissection.

Conclusions:: In this case, there was sudden hearing loss and severe vertigo in the early stages. If MRI/A including perfusion image was not performed, the diagnosis and treatment of cerebellar ischemia may have been delayed. Therefore, it is necessary to consider the possibility of a central cause in patients with sudden hearing loss and vertigo, and it is important to confirm through brain MRI/A including perfusion weighted image.
MENIERE’S DISEASE-LIKE SYMPTOMS IN 22Q11.2 DELETION SYNDROME

Hyunsung Kim¹, Jae-Hwan Choi¹, Eun Hye Oh¹, Kwang-Dong Choi², Jeong-Yeon Kim², Sang-Ho Kim³, Seung-Han Lee⁴
¹Pusan National University Yangsan Hospital, Neurology, Yangsan, Korea, Republic of, ²Pusan National University Hospital, Neurology, Busan, Korea, Republic of, ³Dong-A University Hospital, Neurology, Busan, Korea, Republic of, ⁴Chonnam National University Hospital, Neurology, Gwangju, Korea, Republic of

Background and Aims:: 22q11.2 deletion syndrome (22q11.2DS) caused by a microdeletion on the long arm of chromosome 22, is characterized by congenital heart disease, hypoparathyroidism, immunodeficiency, developmental delay, and velopharyngeal insufficiency. Anatomic malformations of the middle and inner ears are frequently present, leading to high prevalence of hearing impairment. We present a first case of 22q11.2DS showing fluctuating hearing loss with recurrent vertigo attacks, resembling Ménière’s disease.

Methods:: We described clinical features and neuro-otological findings of a 38-year-old male known to have 22q11.2DS who presented recurrent vertigo, tinnitus, and fluctuating hearing loss. We also performed delayed 3D-FLAIR MRI sequences to evaluate endolymphatic hydrops of inner ears.

Results:: The patient developed recurrent vertigo, tinnitus, and fluctuating hearing loss in the left ear during a 10-year follow up period. During vertigo attack, he had spontaneous left-beating nystagmus with downbeat components, but bithermal caloric and video head impulse tests showed normal vestibulo-ocular reflex functions. Sequential pure tone audiograms demonstrated fluctuating sensorineural hearing loss (SNHL) in both ears, which finally progressed to permanent hearing loss in the left ear. Computed tomography imaging of the temporal bone exhibited bilaterally malformed lateral semicircular canals, and delayed 3D-FLAIR sequences revealed cochlear endolymphatic hydrops with dilation of the scala media in the left ear.

Conclusions:: This case shows that acute vertigo with SNHL can be one of the audiovestibular presentations in 22q11.2DS caused by disturbance of endolymphatic flow.
ISOLATED VESTIBULAR SYNDROME WITH “DOUBLE-PANDA” SIGN IN CNS LYMPHOMA

Jeong-Yeon Kim, Kwang-Dong Choi
Pusan National University Hospital, Neurology, Busan, Korea, Republic of

Background and Aims:: Here we report two patients with CNS lymphoma of whom showed “double-panda” sign on MRI and developed isolated vestibular syndrome.

Methods:: Case 1: A 65-year-old male presented with acute dizziness for 3 days. He revealed bilateral horizontal GEN and catch-up saccades during bedside HITs. Brain MRI showed “double-panda” sign. Whole-body F-18 FDG PET was normal. CSF analysis exhibited mild lympho-dominant pleocytosis with elevated protein level and normal glucose ratio. One month later, he readmitted with sudden decreased mentality and received external ventricular drain due to obstructive hydrocephalus. Case 2: 77-year-old male with known DLBCL developed progressive diplopia and gait disturbance for 1 month. He showed horizontal GEN during rightward gaze and catch-up saccades during bedside HITs. Brain MRI showed “double-panda” sign. Cerebrospinal fluid analysis revealed lympho-dominant pleocytosis with markedly elevated protein level.

Results:: Both patients had horizontal GEN during bilateral (patient 1) or rightward (patient 2) gaze, and impaired horizontal smooth pursuit bilaterally. Video HITs revealed decreased VOR gains of both horizontal and posterior (patient 1) or all (patient 2) SCCs with corrective catch-up saccades. Ocular VEMPs were decreased during right ear stimulation, while cVEMPs were symmetric. Patient 2 had a canal paresis of 44.1% in the right ear on bithermal caloric tests and diagnosed with diffuse large B-cell lymphoma, histopathologically.

Conclusions:: Our cases are unique since they showed “double-panda” sign and presented isolated vestibular syndrome with characteristic findings involving the vestibular nucleus, which has been rarely described in CNS lymphoma.
ETIOLOGIC DISTRIBUTION OF DIZZINESS AND VERTIGO IN A REFERRAL-BASED DIZZINESS CLINIC IN SOUTH KOREA

Hyo-Jung Kim¹, Ja-Ok Lee², Jeong-Yoon Choi³, Ji-Soo Kim⁴
¹Seoul National University Bundang Hospital, Research Administration Team, Seongnam-si, Korea, Republic of, ²Seoul National University Bundang Hospital, Department Of Neurology, Seongnam-si, Korea, Republic of, ³Seoul National University Bundang Hospital, Neurology, Seongnam, Korea, Republic of, ⁴Seoul National University College of Medicine, Neurology, Seongnam, Korea, Republic of

Background and Aims:: This study aimed to determine the etiologic distribution of dizziness/vertigo according to age and sex in Koreans by analyzing the diagnoses with dizziness/vertigo in a referral-based dizziness clinic run by neurologists in South Korea.

Methods:: We analyzed the diagnoses of 21,166 consecutive dizzy patients (12,691 women, mean age = 57.9±15.7, age range = 3-97) seen from 2003 to 2019 using a registry and medical records.

Results:: Overall, dizziness and vertigo were more common in women (60.0%) than in men without a difference in age (57.7±15.5 vs. 58.1±16.1, p=0.094). Benign paroxysomal vertigo (BPPV, 24.1%) was the most common cause of dizziness/vertigo, followed by psychiatric or persistent postural perceptual dizziness (20.8%), vascular disorders (12.9%), vestibular migraine (10.2%), Meniere’s disease (7.2%), vestibular neuritis (5.4%). These six disorders comprised more than 80% of all disorders. The etiology could not be determined in 5.0%, and more than one etiology were found in 14.1%. Vestibular migraine was the most common disorder in children and adolescents (<19 years), psychiatric or persistent postural perceptual dizziness (26.3%) in the adults (19-64 years), and BPPV (28.2%) in the elderly (≥ 65 years).

Conclusions:: Our study showed various causes of dizziness/vertigo in a referral-based dizziness clinic in South Korea, but only six disorders accounted for more than 80% of all diseases. This etiologic distribution is similar to that reported in another country, and indicates no significant differences in the proportion of diseases causing dizziness and vertigo across different ethnic groups. This study provides valuable information to establish healthcare policy for dizziness and vertigo.
MOTION SICKNESS SUSCEPTIBILITY AND ANXIETY/DEPRESSION MAY INFLUENCE THE ABILITY TO UPDATE ORIENTATION IN THE HORIZONTAL PLANE IN HEALTHY SUBJECTS

Monica Alcantara Thome, José Miguel Puga, Kathrine Jauregui-Renaud
INSTITUTO MEXICANO DEL SEGURO SOCIAL, Unidad De Investigación Médica En Otoneurología, CIUDAD DE MEXICO, Mexico

Background and Aims:: To assess the ability to update orientation after passive rotations in the horizontal plane of young and middle-aged adults, considering individual factors.

Methods:: After ethical approval, 81 subjects (mean age 40.0± standard deviation 11.0 years), with no history or evidence of otology/neuro-otology/neurology disease, participated in the study. They completed an in-house general health/habits questionnaire, the motion sickness questionnaire by Golding and the Hospital Anxiety and Depression Scale (HADS). Blindfolded and wearing headphones, they were exposed to 10 manually driven whole-body rotations (45°, 90° & 135°) in a small square room with distinctive features on the walls, in such a way that the features and corners subtended 45° with respect to the subject. After each rotation, subjects reported which wall or corner they were facing. To calculate the error of estimation, the perceived rotation was subtracted from the actual rotation.

Results:: The motion sickness total score was from 0 to 27 (4.8±5.2) and the HADS score was from 0 to 30 (6.4 ±6.7). The mean estimation error was 16.6°±9.4° and the mean of correct estimations was 6.5±1.8. The performance was unrelated to age, gender, occupation, education, tobacco/alcohol consumption or sleep hours. However, factorial regression showed independent correlation of the motion sickness and HADS scores with both the mean estimation error and the total correct estimations (R= 0.37 & 0.39 respectively, p<0.01).

Conclusions:: In young and middle-aged healthy adults, motion susceptibility and anxiety/depression symptoms may influence the ability to update orientation after passive rotations in the horizontal plane.
ATTENTIONAL NETWORK DYSFUNCTION IN VESTIBULAR MIGRAINE

Angela Bonsu¹, Zelie Britton¹, Zara Asif¹, John Golding², Adolfo Bronstein³, Diego Kaski⁴, Qadeer Arshad⁵
¹Imperial College London, Brain Sciences, London, United Kingdom, ²University of Westminster, Social Sciences, London, United Kingdom, ³Imperial College London, Division Of Brain Sciences, London, United Kingdom, ⁴University College London, Centre For Vestibular And Behavioural Neuroscience, Department Of Clinical And Movement Neurosciences, Institute Of Neurology, London, United Kingdom, ⁵University of Leicester, Neurosciences, Leicester, United Kingdom

Background and Aims:: Despite vestibular migraine being amongst the commonest causes of episodic vertigo, the pathophysiology remains largely unknown. Given the common complaint of spatial disorientation in vestibular migraine patients, we postulated that this may be mediated by a dysfunctional attentional network.

Methods:: We used the Attentional Network task, where participants were instructed to indicate the direction (right/left) of a target arrow in the upper or lower visual hemifield presented on a laptop screen placed 25cm away. Targets were preceded by 1 of 4 possible cue types: none, double, central, or spatial and participants were required to detect the direction of a “target arrow” that allows interrogation of three attentional networks, alerting, orienting and executive control.

Results:: Vestibular dysfunction induces a global deficit in attentional processing as reflected by significantly increased reaction time, irrespective of stimulus condition, when compared to controls. Furthermore, a clinically relevant and domain specific deficit is observed within the executive control network of VM patients.

Conclusions:: Our findings revealed a specific and clinically relevant deficit in the executive control network of vestibular migraine patients.
VIDEO HEAD IMPULSE TEST FINDINGS IN PATIENTS WITH AMYOTROPHIC LATERAL SCLEROSIS

Zeljka Calic1,2, Milorad Vujnic3,4, Aleksa Palibrk5, Stojan Peric5,6, Ivo Bozovic5, Zorica Stevic5,6, Miriam Welgampola7,8,9

1Liverpool Hospital, 2170, Australia, Department Of Neurophysiology, Liverpool, Australia, 2University of New South Wales, South Western Sydney Clinical School, Sydney, Australia, 3School of Medicine, University of Banja Luka, Department Of Pathophysiology, Banja Luka, Bosnia and Herzegovina, 4Institute of Physical Medicine and Rehabilitation "Dr Miroslav Zotovic" Banja Luka, Emng Laboratory, Banja Luka, Bosnia and Herzegovina, 5University Clinical Centre of Serbia, Neurology Clinic, Belgrade, Serbia, 6University of Belgrade, School Of Medicine, Belgrade, Serbia, 7Ingham Institute for Applied Medical Research, Ingham Institute For Applied Medical Research, Liverpool, Australia, 8Royal Prince Alfred Hospital, Institute Of Clinical Neurosciences, Camperdown, Australia, 9Central Clinical School, Sydney Medical School, University Of Sydney, Camperdown, Australia

Background and Aims:: Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disorder affecting upper and lower motor neurons. We examined vestibulo-ocular reflex (VOR) characteristics in ALS as examined by the video-head impulse test (v-HIT).

Methods:: We performed three dimensional vHIT in 16 patients with definite ALS (mean age 62.0±7.3 years) and 16 age-matched healthy controls. VOR gain, refixation saccade prevalence and the first-saccade amplitude, onset-latency, peak velocity and duration were examined and compared against controls.

Results:: The mean disease duration was 1.6±2.0 years and 56.2% of patients had bulbar onset. 6/16 (37.5%) patients reported history of gait imbalance resulting in recurrent falls in 3/16 (18.7%). Mean ALS-functional rating scale (ALS-FRS) score was 37.1±7. Horizontal, anterior and posterior canal (HC, AC, PC) v-HIT gains for ALS were 1.07±0.1, 0.90±0.2, 0.80±0.1 and for controls were 0.98±0.1, 0.87±0.1, and 0.85±0.1. Refixation saccade prevalence for HC, AC, PC were 67%, 20%, 70% in ALS, and 65%, 18% and 25% in controls. PC VOR gain was reduced (mean-2SD) in 6/16 (37.5%) of patients. The first-saccade amplitude and peak velocity were higher in HC and PC plane in patients with ALS compared to controls (p<0.05). There was no significant association between reduced VOR gain and ALS-FRS score.

Conclusions:: Reduction in the Posterior-Canal VOR gain with a higher than normal prevalence of refixation saccade observed in patients in ALS may represent brainstem involvement. Larger studies in patients with predominantly bulbar presentations will clarify the utility of VOR testing in ALS.
FRONTAL WHITE MATTER INTEGRITY AND IDIOPATHIC DIZZINESS IN CEREBRAL SMALL VESSEL DISEASE

Richard Ibitye, Patricia Castro, Josie Cooke, John Allum, Louisa Murdin, Joanna Wardlow, Diego Kaski, David Sharp, Adolfo Bronstein

1Imperial College London, Brain Sciences, London, United Kingdom, 2Imperial College London, Brain Sciences, London, United Kingdom, 3University Hospital Basel, Otolaryngology Department, Basel, Switzerland, 4Guy’s and St Thomas’ NHS Foundation Trust, Ent, RT, United Kingdom, 5University of Edinburgh, Clinical And Brain Sciences, Edinburgh, United Kingdom, 6University College London, Centre For Vestibular And Behavioural Neuroscience, Department Of Clinical And Movement Neurosciences, Institute Of Neurology, London, United Kingdom, 7Imperial College London, Division Of Brain Sciences, London, United Kingdom

Background and Aims:: Three in ten older people (>60 years) complain of persistent dizziness which often remains unexplained despite specialist assessment and vestibular tests. The pathophysiology of such idiopathic dizziness in older people has remained unclear. We investigated if idiopathic dizziness was associated with vascular injury to white matter tracts relevant to balance or vestibular self-motion perception in sporadic small vessel disease.

Methods:: We prospectively recruited 38 vestibular clinic patients with idiopathic dizziness (median 77 years) and 36 asymptomatic controls (median 76 years) who underwent clinical, cognitive, balance, gait and vestibular assessments, and structural and diffusion brain MRI.

Results:: Patients had more vascular risk factors, poorer balance and worse executive cognitive function in association with greater white matter hyperintensity in frontal deep white matter, and lower fractional anisotropy in the genu of the corpus callosum and the right inferior longitudinal fasciculus. Tracts with lower fractional anisotropy in idiopathic dizziness overlapped with those in which lower fractional anisotropy correlated with worse balance across participants. More vestibular symptoms correlated with worse balance in patients. Vestibulo-ocular reflex and perceptual vestibular function was similar in patients and controls, though a white matter network involved in vestibular perception had lower connectivity in patients.

Conclusions:: Our results show a relationship between lower microstructural integrity in frontal balance-relevant white matter tracts in cerebral small vessel disease, poorer balance and idiopathic dizziness. This suggests cerebral small vessel disease may be involved in the pathogenesis of dizziness in some older people.
Background and Aims:: To examine the hypothesis that small vessel disease disrupts postural neural networks in older adults with unexplained dizziness in the elderly (UDE).

Methods:: Simultaneous electroencephalography and postural sway measurements were undertaken in upright, eyes closed standing, and sitting postures (as baseline) in 33 older controls and 36 older patients with UDE. Older adults underwent magnetic resonance imaging to determine whole brain white matter hyperintensity volumes, a measure of small vessel disease. Linear regression was used to estimate the effect of instability on electroencephalographic power and connectivity.

Results:: Ageing increased theta and alpha desynchronisation on standing. In older controls, delta and gamma power increased, and theta and alpha power reduced with instability. Dizzy older patients had higher white matter hyperintensity volumes and more theta desynchronisation during periods of instability. White matter hyperintensity volume and delta power during periods of instability were correlated, positively in controls but negatively in dizzy older patients. Delta power correlated with subjective dizziness and instability.

Conclusions:: Neural resource demands of postural control increase with age, particularly in patients with UDE, driven by small vessel disease. Compensatory postural strategies saturate in older adults with UDE, offering a neurophysiological basis to this common neurological syndrome.
SACCADES MATTER: REDUCED NEED FOR CALORIC TESTING OF COCHLEAR IMPLANT CANDIDATES BY JOINT ANALYSIS OF V-HIT GAIN AND CORRECTIVE SACCades

Constanza Fuentealba Bassaletti, Babette Van Esch, Jeroen Briaire, Peter Paul Van Benthem, Erik Hensen, Johan Frijns
Leiden University Medical Center, Ent, Leiden, Netherlands

Background and Aims:: Video head impulse test (v-HIT) is a quick and non-invasive test to evaluate vestibular function compared to the caloric test. The latter is, however, needed to decide on the optimal side for cochlear implantation to avoid inducing a bilateral vestibular areflexia. This study evaluates the effectiveness of using v-HIT to select cochlear implant (CI) candidates who require subsequent caloric testing before implantation.

Methods:: We used the v-HIT mean gain, MinGain_LR, the gain asymmetry (GA), and a newly defined parameter, MGS (Minimal Gain&Saccades) as models to detect the patients that would need the caloric test to decide the ear of implantation. The MGS model was defined as the MinGain_LR, except for the cases with normal gain (both sides ≥0.8) without corrective saccades. In the latter case, MGS was defined to be 1.0 (ideal gain value).
Results: The receiver operating characteristics curve showed a very good diagnostic accuracy with an area under the curve (AUC) of 0.81 for MGS. The mean gain, the minimal gain and GA had a lower diagnostic capacity; AUC of 0.70, 0.72 and 0.73, respectively. Using MGS, caloric testing could be avoided in 38 cases (a reduction of 46%), with a test sensitivity of 0.9 (i.e., missing 3 of 28 cases).
Conclusions: The newly developed model MGS balances the sensitivity and specificity of the v-HIT better than the common parameters: mean gain, MinGain_LR and GA. Therefore, considering the presence of corrective saccades in the evaluation of the v-HIT gain can considerably reduce the proportion of CI candidates requiring additional caloric testing.
ROLE OF TRANSCRANIAL MAGNETIC STIMULATION (TMS) COMBINED WITH ELECTROENCEPHALOGRAPHY (EEG) IN DISORDERS OF CONSCIOUSNESS (DOC)

Vincenzina Lo Re¹, Erica Varoli², Gabriel Hassan³, Federica Avorio¹, Giuseppe Mamone¹, Simona De Salvo⁴, Nunzio Muscarà⁴, Francesco Corallo⁴, Angela Comanducci⁵, Angelo Quartarone⁶, Silvia Marino⁴, Lila Bonanno⁴, Silvia Casarotto³, Leonor J Romero Lauro⁷
¹IRCCS-ISMETT, Diagnostic And Therapeutic Services, Palermo, Italy, ²IRCCS ISMETT, Department Of Research, Palermo, Italy, Palermo, Italy, ³University of Milan, Department Of Biomedical And Clinical Sciences "l. Sacco", Milan, Italy, ⁴IRCCS Centro Neurolesi "Bonino-Pulejo", Messina, Italy, ⁵IRCCS Fondazione Don Gnocchi ONLUS, Milan, Italy, ⁶University of Messina, Department Of Clinical And Experimental Medicine, Messina, Italy, ⁷University of Milan-Bicocca, Department Of Psychology, Milan, Italy

Background and Aims:: The gold standard for the differential diagnosis between unresponsive wakefulness syndrome (UWS) and minimally conscious state (MCS) is the coma recovery scale-revised (CRS-R). However, severely brain-injured patients can be unresponsive but still retain consciousness. To deal with this issue, we applied TMS-EEG as an objective brain-based tool to assess consciousness in DOC patients.

Methods:: 4 UWS and 2 MCS patients in acute and chronic stage were enrolled and underwent CRS-R and TMS-EEG recordings. Perturbational Complexity Index maximum (PCIₘₐₓ) was compared to the empirical cut-off PCI* (=0.31), which showed high sensitivity in detecting consciousness.

Results:: In chronic patients, PCIₘₐₓ values were consistent with the clinical diagnosis with >PCI* in MCS and ≤ PCI* in UWS patients. Interestingly, one UWS (PCIₘₐₓ=0.31) and one MCS (PCIₘₐₓ=0.45) patient achieved the same CRS-R score of 6, though with a different diagnosis based on visual fixation, a fluctuating clinical sign. PCI was highly sensitive to longitudinal changes, as it changed in an acute UWS patient as soon as his diagnosis rapidly upgraded to MCS.

Conclusions:: PCI confirmed the clinical diagnosis from CRS-R, providing an objective brain-based measure of consciousness, even when the behavioral responses were fluctuating or difficult to assess. Furthermore, PCI was able to longitudinally track the recovery of consciousness in an acute patient who shifted from UWS to MCS in a short time. These results are in line with previous large-scale validation studies in chronic patients, and also confirm the reliability of PCI in acute patients.
THE IMPORTANCE OF SINGLE-FIBER ELECTROMYOGRAPHY IN MYASTHENIA GRAVIS DIAGNOSIS AND PROGNOSIS: A SYSTEMATIC REVIEW

Catarina De Marchi Assuncao¹, Henry Taques Grein²
¹University of Louisville Hospital, Neurology, Louisville, United States of America, ²Universidade Federal do Parana, Medicine, Curitiba, Brazil

Background and Aims: Myasthenia gravis (MG) is a serious neuromuscular impairment in the communication between nerve cells and muscles. It causes weakness in skeletal muscles, hindering their movement and control. A single-fiber electromyography (SF-EMG) is the most sensitive test for diagnosing MG. The diagnosis is confirmed with an altered SF-EMG of a clinically weak muscle. We have systematically reviewed the current application of SF-EMG techniques in the diagnosis of myasthenia gravis.

Methods: We searched PubMed to identify studies focusing on SF-EMG and its associated analytical methods in the diagnosis, prognosis and monitoring of myasthenia gravis patients.

Results: The search yielded 17 studies. Six of these were able to correlate increased SF-EMG jitter to increased severity of the disease. Mean increased jitter is a sensitive measure of severity in MG and has a potential role as a biomarker, both in terms of absolute mean jitter value or as a percentage change in those values. It does suffer in terms of specificity, though. Although SF-EMG was unable to correctly distinguish a true case of MG from a case where the patient developed Myasthenia gravis-like symptoms due to a rare mitochondrial mutation in some of the studies, SF-EMG was of primordial importance in confirming the disease when the associated AChR, striational muscle and MuSK antibodies were altogether absent from the serum.

Conclusions: Single-fiber electromyography offers significant practical and analytical flexibility compared to more invasive techniques, such as muscle biopsy. As evidenced, SF-EMG can provide the missing confirmatory link between a myriad of symptoms and MG.
Null
NEURODEGENERATION AND NEOANGIOGENESIS IN THE CEREBELLAR CORTEX IN PENTYLENETETRAZOL (PTZ)-KINDLED RATS TREATED WITH AXITINIB AND RAPAMYCIN

Leonid Godlevsky¹, Mykhailo Pervak¹, Olesya Poshyvak², Kirill Latypov¹, Kseniya Prybolovets¹
¹Odesa National Medical University, Department Of Biophysics, Informatics And Medical Devices, Odesa, Ukraine, ²Danylo Halytsky Lviv National Medical University, 2pharmacology Department, Lviv, Ukraine

Background and Aims:: Morphological changes induced in pentylenetetrazol (PTZ)-kindled rats create the basis for the resistance of chronic brain epileptization. Cerebellar contribution to kindling seizures development was shown (Godlevsky L.S.et al., 2020). To investigate histological characteristics of the cerebellar paleocortex in PTZ-kindled rats under conditions of axitinib and rapamycin administration.

Methods:: For kindling induction, we used PTZ administrations (35.0 mg/kg, i.p.) for three weeks. Axitinib (2.0 mg/kg, i.p.) and rapamycin (0.56 mg/kg, i.p.) administered during ten days. Light microscopy was performed on hematoxylin and eosin painted slices (x200 magnification). Data presented as +S.E., ANOVA Fisher test used for statistics and differences at p<0.05 are presented.

Results:: The thickness of the molecular layer decreased in kindled rats from 238.5±18.3 to 168.6±15.6 μM. The number of PC cells per 1 mm in lobule VI reduced from 65.0±2.2 to 38.0±1.5. The square of stellate cell nuclei reduced from 16.43±0.93 to 10.27±0.72 μM². The thickness of granular cells decreased from 230.2±17.7 to 156.8±13.4 μM. The density of microvessels increased in kindled rats from 25.5±2.2 to 40.7±2.8 per 2500 μM². Treatment with axitinib and rapamycin prevented kindled generalized seizure in 8 out of 11 rats. After treatment, the thickness of the molecular layer was 185.0±19.3 μM, the number of PC per 1 mm of length was 53.0±3.2 per 1 mm, the number of microvessels was 34.7±3.0, which was not different from the control (P>0.05).

Conclusions:: PTZ kindling resulted in neurodegeneration in all layers of the cerebellar cortex and increased neoangiogenesis. Treatment with axitinib and rapamycin prevented kindling-induced morphological deteriorations.
BLINK REFLEX RECOVERY CYCLE DISTINGUISHES PATIENTS WITH IDIOPATHIC NORMAL PRESSURE HYDROCEPHALUS FROM ELDERLY SUBJECTS

Background and Aims:: The R2 component of blink reflex recovery cycle (R2BRrc) is a simple neurophysiological tool to detect the brainstem hyperexcitability commonly occurring in several neurological diseases such as Parkinson’s disease and atypical parkinsonisms. In our study, we investigated for the first time the usefulness of R2BRrc to assess brainstem excitability in patients with idiopathic Normal Pressure Hydrocephalus (iNPH) in comparison with healthy subjects.

Methods:: Eighteen iNPH patients and 25 age-matched control subjects were enrolled. R2BRrc was bilaterally evaluated at interstimulus intervals (ISIs) of 100, 150, 200, 300, 400, 500 and 750 ms in all participants. We investigated the diagnostic performance of R2BRrc in differentiating iNPH patients from control subjects using ROC analysis. Midbrain area and Magnetic Resonance Hydrocephalic Index (MRHI), an MRI biomarker for the diagnosis of iNPH, were measured on T1-weighted MR images, and correlations between R2BRrc values and MRI measurements were investigated.

Results:: Fourteen (78%) of 18 iNPH patients showed an enhanced R2BRrc at ISIs 100-150-200 ms, while no control subjects had abnormal R2BRrc. The mean amplitude of bilateral R2BRrc at the shortest ISIs (100-150-200 ms) showed high accuracy in differentiating iNPH patients from controls (AUC=0.89). R2BRrc values significantly correlated with midbrain area and MRHI values.

Conclusions:: This study represents the first evidence of brainstem hyperexcitability in iNPH patients. Given its low cost and wide availability, R2BRrc could be a useful tool for selecting elderly subjects with mild gait and urinary dysfunction who should undergo an extensive diagnostic work-up for the diagnosis of NPH.
SPINAL EXCITABILITY AND PLASTICITY IN HEREDITARY SPASTIC PARAPARESIS: A NEUROPHYSIOLOGICAL STUDY

Alessandro Zampogna¹, Andrea Guerra¹, Francesco Asciv, Antonio Funcis¹, Claudia Celletti², Filippo Camerota³, Alfredo Berardelliv, Antonio Suppaiv,²
¹Sapienza University of Rome, Department Of Human Neurosciences, Rome, Italy, ²IRCCS Neuromed, Irccs Neuromed, Pozzilli, Italy, ³Sapienza University of Rome, Department Of Physical Medicine And Rehabilitation, Rome, Italy

Background and Aims:: Pure hereditary spastic paraparesis (HSP) is a neurodegenerative disorder characterized by corticospinal pathway impairment leading to progressive lower limb weakness and spasticity. The pathophysiological role of spinal excitability and plasticity in HSP is currently unknown. This study aims to investigate spinal excitability and plasticity in HSP.

Methods:: Fifteen patients with pure HSP (SPG4) and ten controls (HS) were enrolled. Patients were clinically assessed through standardized scales (i.e., spastic paraparesis rating scale, modified Ashworth scale, Barthel scale). To examine spinal excitability, we evaluated the H reflex (HR) and reciprocal inhibition (RI) curve, at seven interstimulus intervals (ISIs), in the soleus (SO) muscle of the dominant limb. To investigate spinal plasticity, we assessed long-term changes in HR amplitude and RI curve, before and after a specific spinal cord plasticity-inducing protocol (i.e., 30-minutes of focal muscle vibration -fMV over the SO).

Results:: When considering excitability, HSP patients showed higher HR amplitude and lower HR inhibition at 2, 3 and 20 ISIs of the RI curve than HS. Concerning plasticity, HS showed significant long-term depression of the HR amplitude at 5 and 30 minutes after fMV. Conversely, in HSP patients, fMV left the HR amplitude and RI curve unchanged.

Conclusions:: HSP patients have abnormal spinal excitability (e.g., increased motoneuron excitability and decreased excitability of RI pathways). Also, the reduced modulation of the HR and RI curve following fMV demonstrates abnormal spinal plasticity. Overall, these findings suggest that abnormal spinal excitability and plasticity contribute to the pathophysiology of motor disorders in HSP.
PROLONGED DISTAL MOTOR LATENCY OF MEDIAN NERVE DOES NOT IMPROVE DIAGNOSTIC ACCURACY FOR CIDP

Emanuele Spina1, Pietro Doneddu2, Fiore Manganelli1, Eduardo Nobile-Orazio2
1University of Naples "Federico II", Department Of Neurosciences, Reproductive And Odontostomatology, Naples, Italy, 2IRCCS Humanitas Clinical and Research Institute, Rozzano, Milan, Italy, Neuromuscular And Neuroimmunology Service., Milan, Italy

Background and Aims:: Compression of the median nerve at the carpal tunnel can give demyelinating features and result in distal motor latency (DML) prolongation fulfilling the EFNS/PNS demyelinating criteria for chronic inflammatory demyelinating polyneuropathy (CIDP). Accordingly, being carpal tunnel syndrome (CTS) common in the general population, the EFNS/PNS guidelines recommend excluding the DML of the median nerve when DML prolongation may be consistent with median neuropathy at the wrist from CTS. The main aims of this study were to verify whether the inclusion of DML of the median nerve could improve electrophysiological diagnostic accuracy for CIDP and if the median nerve at the carpal tunnel (CT) was more prone to demyelination.

Methods:: We analyzed electrophysiological data from 499 patients included into the Italian CIDP Database.

Results:: According to the EFNS/PNS criteria, 352 patients had a definite, 10 a probable, and 57 a possible diagnosis of CIDP, while 80 were not-fulfilling the diagnostic criteria. The inclusion of DML prolongation of median nerve did not improve significantly the diagnostic accuracy for CIDP; overall diagnostic class changed in 6 out of 499 patients (1.2%) and electrodiagnostic class of CIDP changed from not-fulfilling to possible in only 2 patients (2.5% of not-fulfilling patients). Moreover, the median nerve at the CT was not more prone to demyelination in CIDP.

Conclusions:: Concluding, we can infer that excluding DML prolongation of median nerve does not increase the risk of missing a diagnosis of CIDP. On the other hand, importantly for clinicians, a diagnosis of CIDP based only on median DML prolongation is unlikely.
Background and Aims:: Chronic inflammatory demyelinating polyneuropathy (CIDP) is a chronic case of polyneuropathy, commonly caused by immunological factors that attack the peripheral myelin sheath. This disease has peripheral neuropathy characteristics, predominantly motoric and symmetrical, with clinical manifestation proximal and distal weaknesses. Complications of CIDP are mostly severe motoric weakness, and respiratory failure, which is mostly found in the acute inflammatory process, is uncommon.

Methods:: Data were obtained from the medical registry in the Department of Neurology, Saiful Anwar General Hospital, Malang, Indonesia, in December 2020.

Results:: A 20-year-old woman came to ER with the chief complaint of dyspnea in the last 2 days before admission, with weakness in inferior extremities and followed by weakness in superior extremities 1 day later. There were glove and stocking paresthesia, limb ataxia, and a history of diarrhea 3 days before admission. 6 months before, patients already came with the same weakness and were diagnosed with Guillain Barre Syndrome. The patient was diagnosed with CIDP Relapse Phase, intubated in ICU, and had plasma exchange 5 times. Patient show improvement in respiratory failure but no improvement in motor power.

Conclusions:: Respiratory failure is a rare feature of CIDP complications. CIDP Relapse Phase, which presents with acute and sub-acute manifestations, resembles GBS and may require ventilator assistance because of phrenic nerve palsy involvement. Immunotherapy treatment in the form of induction and maintenance phases has been carried out in the patient, with clinical improvement results.
VisuAl evOKed pOTENTIALS (VEP) in demyelinating disease

Shahdevi Nandar Kurniawan, Firda Aushi, Sri Budhi Rianawati, Masrurah Rahayu, Machlusil Husna
Faculty of Medicine Brawijaya University/ Saiful Anwar General Hospital, Department Of Neurology, Malang, Indonesia

Background and Aims:: Optic neuritis (NO) is an acute inflammatory demyelinating disease of the optic nerve. The optic nerve's demyelination is the most common symptom found in Multiple Sclerosis (MS) and Neuromyelitis Optica (NMO). Visual Evoked Potentials (VEP) can provide additional information regarding the integrity of the anterior visual pathway from the retina to the visual cortex. Until now, VEP examination is still rarely performed, so further research is needed on the characteristics of demyelinating disease with optic neuritis.

Methods:: Data were obtained from the medical registry in the Department of Neurology, Saiful Anwar General Hospital, Malang, Indonesia, from February 2021 until March 2021.

Results:: Three cases were reported; the first patient is a patient with Secondary Progressive MS, with decreased visual acuity and bilateral optic atrophy, and VEP showed mild bilateral optic neuropathy. The second patient was a Relapse Remitting MS Patient with decreased visual acuity and bilateral optic atrophy, but the VEP results were normal. The third patient with Neuromyelitis Optica had severe visual impairment and bilateral optic atrophy, showed severe bilateral optic nerve neuropathy in VEP and RFNL thinning in Optic Coherence Tomography (OCT).

Conclusions:: VEP examination aims to determine the condition of optic neuritis in the patient. Visual disturbances can occur due to inflammatory processes, demyelination, and axonal degeneration of the visual pathways. In MS, generally, the VEP test results will show prolonged latency of P100 with normal amplitude, and in NMO with severe optic neuritis, will result in the absence of P100 in both eyes.
THE INFLUENCE OF THE ENVIRONMENT ON MOTOR MEMORY OF FIRST YEAR MEDICAL STUDENTS

Maysah Arabi1, Pedro Carmo1, Mariana Silva1, Iago Pirani1, Rafael Dell' Antonia1, Karen Vida1, Renan Iegoroff2, Arnaldo Godoy1
1Sao Caetano do Sul University, Sao Paulo, Neurology, Sao Paulo, Brazil, 2University City of Sao Paulo, Neurology, Sao Paulo, Brazil

Background and Aims:: Memorizing a sequence of movements is of great importance for several human activities. We evaluated medical students motor memory in different environments.

Methods:: Twenty-four medical students from the first and 37 from the fourth year agreed to volunteer, with written approval. Half of the students from each group were tested in a calm environment: chromotherapy colors and meditation sounds. The other was in a bustling room: flashing lights and stressful sounds. They watched twice a video of 6 movements to make a surgical knot. Each volunteer was, then, asked to repeat the movements. They were recorded. The percentage of students which performed correctly each movement was calculated.

Results:: The percentages of first year medical students tested in the bustling room that made the correct movement (M) were: M1: 50%; M2: 62.5%; M3: 100%; M4: 0%; M5: 62.5% and M6: 87.5%. The percentages for volunteers in the calm environment (CE) were: M1: 81.2%; M2: 69.7%; M3: 37.5%; M4: 0%; M5: 75% and M6: 81.2%.

Conclusions:: The students performed better M1 in CE and did worse M3. We conclude that a stressful environment affects initiation of a sequence of movements, slowing the activation of neuronal circuits responsible for calling attention. The difficulty to remember correctly the third movement in CE suggests a rapid habituation of the neuronal activity. Submitting first year medical students to tests of motor memory can help to identify the “natural” skillful ones and help to plan trainings focusing on a particular step of a sequence of movements.
EEG PECULIARITIES TO HPT BY AGE AND GENDER IN PATIENTS WITH NEUROLOGICAL DISORDERS

Irma Khachidze¹, Manana Gugushvili², Maia Advadze³
¹Beritashvili Centre of Experimental Biomedicine, Caucasus University, SEU University, Human Psychology, Tbilisi, Georgia, ²Beritashvili Centre of Experimental Biomedicine, Human Psychology, Tbilisi, Georgia, ³Beritashvili Centre of Experimental Biomedicine, Georgia National University (SEU), Medicine, Tbilisi, Georgia

Background and Aims:: Introduction: Hyperventilation provocation tests (HPT) has been applied in patients for the detection of hidden disorders of the nervous system (NS) especially the pathological forms of Central NS. HPT is a relevant and useful for the study of electroencephalography (EEG). The various types of abnormal EEG response to HPT provoke different interpretation, while the research of these phenomena is still subject of investigation. The study aimed classified pathological EEG responses to HPT be age and gender of patients.

Methods:: The EEG of 985 outpatients with various functional disorders of the CNS was examined. Study classified of pathological EEG responses to hyperventilation (PERH), take into account, the age (3-6, 7-12, 13-18, 19-30, 31-50, 50<), and biological sex (mail. female) of the patients.

Results:: The disorganization of basic EEG rhythm in the first, second and third minutes of HPT shown in all age and sex groups. The all 3 types of PERH (disorganization of basic rhythm, paroxysmal discharges, epileptic activity) in the first minute were revealed in all ages, which were not observed in the second and third minutes. The all three types of PERH in the first and the second minutes were found only in women.

Conclusions:: Conclusion: We assume specificity electrical activity of the brain response to HPT depending on the time, age, and sex. PERH Shown Sex Differences, males and females are impacted differently to HPT by CNS diseases. Remember those differences play roles during examination and treatments of patients.
MEDICAL REASONING: NOT SUSTAINED ACTIVATION OF NEURONAL CIRCUITS

Thais Azevedo¹, Monai Oliveira², Renan Iegoroff³, Arnaldo Godoy⁴
¹Sao Caetano do Sul University, Neurology, São Paulo, Brazil, ²Sao Caetano do Sul University, Neurology, São Paulo, Brazil, ³University City of Sao Paulo, Neurology, Sao Paulo, Brazil, ⁴Sao Caetano do Sul University, Neurology, Sao Paulo, Brazil

Background and Aims:: For a physician, it is essential to extract relevant information from a patient’s history and identify abnormal findings of the physical examination to select exams for an accurate diagnosis. We checked the performances of medical students in different steps of the clinical reasoning.

Methods:: Twenty-five medical students that finished the first two years of basic training, gave us written approval and were tested. We presented 3 different clinical cases: colon cancer (CC), pneumonia (Pn) and stroke (St). For each case, 4 findings of the history and 2 of the examination were informed. They had to choose 2 supplementary exams. Then, we asked which other 2 exams they would require. Finally, diagnosis was required.

Results:: For CC, 52% chose the blood count and 44% a scopy as the first exams. The other exams: scopy (32%) and blood count (28%). Diagnosis: CC (36%) and lower gastrointestinal hemorrhage (12%). For Pn, 92% chose Chest X-ray or tomography and 38% blood count. Further exams were: gasometry (54%) and blood count (29%). Diagnosis: Pn (54%) and COVID-19 (33%). For St, 79% chose Head tomography and 54% blood count. The other exams: blood glucose (37.5%) and electrolytes (29%). Diagnosis: St (88%) and brain tumor (4%).

Conclusions:: Our data show that, no matter the clinical case, the students strongly disagree the second set of exams they would ask to make a diagnosis. Data from the medical consultation can activate neuronal circuits on a standardized way at an initial step of the clinical reasoning, but that activation cannot be sustained.
EFFECT OF PANDEMIC ON VISUAL MEMORY

Katharina Goto¹, Vitor Godoy², Arnaldo Godoy³
¹FCMSCSP, Medicine, São Paulo, Brazil, ²FMABC, Medicine, São Paulo, Brazil, ³Sao Caetano do Sul University, Sao Paulo, Neurology, Sao Paulo, Brazil

Background and Aims:: In pandemic era, people spend more time indoor. It is not known if their perception of the reality has changed. We decided to evaluate the visual memory of inhabitants of a city when they were exposed to outdoor pictures.

Methods:: Twenty-seven volunteers aged 25 (average) were tested. We got their written approval. They saw three pictures: P1, elements of nature, P2, elements of a city and P3, “natural” plus “human made” elements. After each picture they answered the questions: Q1: Among 3, choose one image like one you saw; Q2: Among 3, choose the image you have not seen; Q3: We asked if one element of the picture was or was not seen; Q4: We questioned if one element not present was or was not seen.

Results:: As for P1, 70% answered Q1 correctly; 81% Q2; 62% Q3 and 62% Q4. In case of P2: 44% chose the correct answer of Q1, 59% of Q2, 92% of Q3 and 62% of Q4. For P3: 59% answered correctly Q1, 62% Q2, 100% Q3 and 96% Q4.

Conclusions:: The volunteers got the best performances of Q1 and Q2, in case of P1 (70% and 81%, respectively) and the worst performances (44% and 59%) for P2. When asked if they had seen a shown object, 62% answered correctly for nature (P1). As for visual memory, our data suggest being indoor did not decrease the ability to compare elements of the nature, but did damage recall the image of an object in a non-comparative way.
MEDICAL STUDENTS' MEMORY FOR FACES: COMPARING THE INFLUENCES OF A NON-NATURAL FEATURE AND EMOTION

Vinicius Figueiredo¹, Monai Oliveira¹, Mayara Nunes¹, Pietro De Aguiar¹, Bianca Andrade¹, Renan Iegoroff², Arnaldo Godoy¹
¹São Caetano do Sul University, São Paulo, Neurology, São Paulo, Brazil, ²University City of Sao Paulo, Neurology, Sao Paulo, Brazil

Background and Aims:: The influence of emotion in the process of memorizing faces is still under discussion. We tested the medical students’ memory when they saw professional actors expressing feelings.

Methods:: Fifty-one volunteers, aged 18-30, were tested virtually. We got written approval. Twelve actors (M) and 12 actresses (F) pictures, wearing (WG) and not wearing glasses (NG) were taken: with happy (H), angry (A) and emotionless (E) faces. Ten slides containing photos of 5 actresses and 5 actors were shown. The volunteers answered 5 questions (Q1-Q5): neutral faces were presented. We asked if they were wearing or not glasses. Then, other 2 questions: to choose, among three E faces, the one wearing (Q6) and not wearing glasses (Q7).

Results:: Percentages of correct answers: Q1 (FHNG): 70%. Q2 (MHNG): 90%. Q3 (FHWG): 60%. Q4 (MANG): 92%. Q5 (MHWG): 94%. Q6 (MAWG): 57%. Q7 (MANG): 80%.

Conclusions:: The performance was greater when they saw a man, regardless his emotion and wearing or not glasses. The scores were lower if the volunteer had to choose among 3 faces. The percentage of students answering correctly which one was wearing glasses, when they saw 3 faces, was lower than when they had to choose the man not wearing it. The data suggest that to wear or not wear an accessory is more important than the facial expression for memorization in case of choosing among 3 faces. Other significant element that influences the memory for faces is gender. A non-natural feature of a face can decrease neuronal activity of the limbic system.
MULTIDIMENSIONAL ANALYSIS OF ELECTROENCEPHALOGRAPHIC TRACES

Gioacchino Aiello¹, Rossini Michela², Merati Silvia², Toti Pia¹
¹PRIVATE OUT PATIENTS, Neuropsychophysiology, BERNAREGGIO, Italy, ²PRIVATE OUT PATIENTS, Neuropsychophysiology, MONZA E DELLA BRIANZA, Italy

Background and Aims:: The central nervous system can be evaluated through multiple systems of analysis, in the time domain and in the frequency domain.

Methods:: Today, all these methods allow us to take a deeper look at the organization of EEG oscillations, allowing we to expand the amount of information obtainable from the EEG traces. This also does not increase costs and does not change the low invasiveness of the EEG. Our center for many years has been oriented to carry out complex analyses of the different activities of the nervous system. The following softwares are used to perform all the analyses described: MICROMED ANALYSIS OF EEG, BQEVOQUE for the analysis of evoked potentials, NOTEPAD, LORETA SOFTWARE, DATAPLORE.

Results:: In our presentation we will present in detail the different stages of EEG signal processing

Conclusions:: We describe with detailed data clinical examples of different clinical pictures
EFFECTS OF TRANSCRANIAL ULTRASOUND STIMULATION ON TRIGEMINAL BLINK REFLEX EXCITABILITY

Donato Colella¹, Andrea Guerra², Edoardo Vicenzini¹, Ettore Cioffi¹, Antonio Cannavacciuolo¹, Silvia Pozzi², Barbara Caccia², Giulia Paparella², Giulia Di Stefano², Alfredo Berardelli¹,², Matteo Bologna¹,² ¹Sapienza University of Rome, Department Of Human Neurosciences, Rome, Italy, ²IRCCS Neuromed, Irccs Neuromed, Pozzilli, Italy, ³Istituto Superiore di Sanità (ISS), National Center For Radiation Protection And Computational Physics, Rome, Italy

Background and Aims:: Recent evidence indicates that transcranial ultrasound stimulation (TUS) modulates sensorimotor cortex excitability. However, no study has assessed possible TUS effects on the excitability of deeper brain areas, such as the brainstem. In this study, we investigated whether TUS delivered on the substantia nigra, superior colliculus, and nucleus raphe magnus modulates the excitability of trigeminal blink reflex, a reliable neurophysiological technique to assess brainstem functions in humans.

Methods:: The recovery cycle of the trigeminal blink reflex (interstimulus intervals of 250 and 500 ms) was tested before (T0), and 3 (T1) and 30 min (T2) after TUS. The effects of substantia nigra-TUS, superior colliculus-TUS, nucleus raphe magnus-TUS and sham-TUS were assessed in separate and randomized sessions.

Results:: In the superior colliculus-TUS session, the conditioned R2 area increased at T1 compared with T0, while T2 and T0 values did not differ. Results were independent of the interstimulus intervals tested and were not related to trigeminal blink reflex baseline (T0) excitability. Conversely, the conditioned R2 area was comparable at T0, T1, and T2 in the nucleus raphe magnus-TUS and substantia nigra-TUS sessions.

Conclusions:: Our findings demonstrate that the excitability of brainstem circuits, as evaluated by testing the recovery cycle of the trigeminal blink reflex, can be increased by TUS. This result may reflect the modulation of inhibitory interneurons within the superior colliculus.
STUDY OF MOTOR RESONANCE DURING MOVEMENT OBSERVATION IN PARKINSON DISEASE ASSESSED BY FUNCTIONAL NEAR-INFRARED SPECTROSCOPY (F-NIRS)-EEG CORECORDING

Giuliana Conca1, Katia Ricci1, Eleonora Gentile1, Eleonora Vecchio2, Filippo Tamma2, Giovanni Iliceto1, Marina De Tommaso1

1University of Bari “Aldo Moro”, Basic Medical Sciences, Neurosciences And Sense Organs, Bari, Italy, 2“F.Miulli” General Hospital, Neurology Unit, Acquaviva delle Fonti, Italy

Background and Aims:: In previous neurophysiological studies, mu-rhythm event-related desynchronization during observed movement, an indicator of activity in mirror neuron system (MNS), resulted impaired in Parkinson Disease (PD), even at early stages of the disease. This study tested the hypothesis of a dysfunction in MNS in PD investigating EEG activity and changes in oxy- and deoxyhaemoglobin concentration in motor cortical areas at rest and during movement observation and execution, in PD patients and healthy subjects, by EEG and fNIRS simultaneous recording.

Methods:: We enrolled 20 healthy subjects and 20 PD patients, all right-handed. Patients came from two Apulian Parkinson centers and met these inclusion criteria: age 40-80, MMSE>23, normal or corrected-to-normal visual acuity, diagnosis of Idiopathic PD at Hoehn-Yahr stage I-II. The experiment consisted of two sessions. In observation session participants observed videos in which a woman grabbed a flat or a sharp tip object and videos where the agent’s hand stopped before grabbing them. In execution session participants had to tap the space bar at the time of touch. For recording, we used 20 fNIRS channels, with probes placed on motor areas and high-density EEG with 61 scalp electrodes.

Results:: We found some differences between early PD and normal controls, with a tendency through hypermetabolism and hypersynchronization of motor cortex during coherent action observation. Detailed data about quantitative EEG analysis, oxygen metabolism and neuropsychological evaluation will be presented.

Conclusions:: Motor resonance mechanisms could compensate the abnormal motor planning in early PD, supporting specific rehabilitation strategies such as Action Observation.
Background and Aims:: Memorizing words is of great importance for physicians. The aim of this study is to explore the auditory memory of medical students through the evaluation of their ability to identify the words’ positions when said in a pre-established order.

Methods:: One hundred-twenty medical students volunteered to participate. Written approval was granted. Three different intonations of the same twelve words were recorded in equal order: neutral, happy and sad. The volunteers were separated into three subgroups (N, H and S) and answered 4 questions (Q) after hearing them. Q1 and Q2: Respectively, what was the second and eleventh word that you heard? Q3 and Q4: what was the position of the words “white” and “papaya”?

Results:: The percentages of students who answered correctly were: Subgroup H (SH): Q1: 89.2%; Q2: 62.2%; Q3: 97.3%; Q4: 86.5%. Subgroup S (SS): Q1: 83%; Q2: 56.1%; Q3: 58.4%; Q4: 78%. Subgroup N (SN): Q1: 78.6%; Q2: 54.8%; Q3: 66.7%; Q4: 73.8%.

Conclusions:: SH had a better performance remembering the word’s position, compared to SS and SN. SH and SN performed better when the word was given and the position was asked of them (Q3 and Q4), than when the position was given, and the word was asked of them (Q1 and Q2). SS had a tendency of performing better in the Q1 and Q2. For first and fourth year medical students, words in a sequence with “happier” connotations activated the memory neural circuit more than words with “sadder” connotations.
HEMISPHERIC SHIFT OF THE BRAIN ACTIVATION IN MEDICAL STUDENTS: THE ROLE OF PERIPHERAL VISION STIMULI

Brenda Silva¹, Priscila Almendra¹, Isabela Lombardi¹, Luana Campelo¹, Nadia Cevallos¹, Renan Iegoroff², Arnaldo Godoy²
¹São Caetano do Sul University, Memory Institute, São Paulo, Brazil, ²São Caetano do Sul University, São Paulo, Neurology, São Paulo, Brazil

Background and Aims:: Memorization of objects located in the peripheral vision field is not well known. We chose to check it in medical students from different years.

Methods:: Thirty-two first year medical students (FY), aged 18-46 (average: 23.3), and thirty-two third year medical students (TY), aged 21-43 (average: 24.8), were volunteers with written approval. They saw 3 objects at the left peripheral vision field (two of them medical ones) and 3 at the right peripheral vision field (one medical). Then, answered the question (Q): which object most called your attention?

Results:: As for FY: 59.4% chose shown objects (SO) and 31.2% not shown objects (NSO). In SO subgroup, 73.7% of the objects were on the left; 68.4% chose medical objects. As for TY: 65.6% chose SO and 18.8% NSO. In SO subgroup, 71.4% of the objects were on the left and 57.1% chose medical objects.

Conclusions:: We checked whether object position and meaning influence in peripheral vision memorization. As medical objects were better recalled, meaning is of importance. As there were medical objects in both sides and the right answers varied, position on the left was of uttermost importance. In case of non-medical objects, for FY, side was also important, but objects at right. As for TY, did not influence. Our hypothesis is that the right cerebral hemisphere is important for meaningful objects memorization. On the other hand, the left hemisphere was triggered for not meaningful objects, but its activity decreases as a medical student gets trained.
VISUAL BRAIN CORTEX ACTIVATION AND SURGICAL TRAINING

Nadia Cevallos¹, Isabela Lombardi¹, Luana Campelo¹, Brenda Silva¹, Priscila Almendra¹, Renan Iegoroff², Arnaldo Godoy²
¹São Caetano do Sul University, Memory Institute, São Paulo, Brazil, ²São Caetano do Sul University, São Paulo, Neurology, São Paulo, Brazil

Background and Aims:: Visual memory is essential for several professionals. We decided to check it in medical students to plan a training for future surgeons.

Methods:: Thirty-two first year medical students, average age 23.3, were volunteers. We got written approval. They answered questions (Q) of two visual memory tests. The first one: 3 objects at their left peripheral vision field (2 medical). The second test: 3 objects at the right peripheral vision field (one medical). The questions were about: Q1: All seen objects; Q2: Meaningful object; Q3: Objects seen on the right; Q4: Objects seen on the left; and Q5: the lower right position object.

Results:: As for Q2: 59.4% chose shown objects (SO). Among them, 52.6% chose objects located in an intermediate position, 31.6% in the upper and 15.8% in the lower position; 73.7% on the left, 26.3% on the right. In case of Q5: 18.8% chose the correct object (mask), 75% told they did not remember.

Conclusions:: Parameters as side, meaning and position of an object may influence the peripheral vision memorization of objects. Brain activation of the visual areas of first year medical students was greater when they saw objects in an intermediate position, secondly in a high position. This finding is of importance to plan surgical trainings.
ACTIVATION OF NEURONAL CIRCUITS AND MANIPULATION OF THE PERIPHERAL VISION: A TOOL FOR MEDICAL TRAINING

Raphael Fanin¹, Karina Ferreira¹, Renan Iegoroff², Arnaldo Godoy³
¹Sao Caetano do Sul University, Sao Paulo, Neurology, -, Brazil, ²University City of Sao Paulo, Neurology, Sao Paulo, Brazil, ³Sao Caetano do Sul University, Sao Paulo, Neurology, Sao Paulo, Brazil

Background and Aims:: The peripheral vision (VP) field is favorable for the identification of scenes. To improve memorization of VP objects can be useful to train future surgeons. We checked medical students’ ability to pay attention in peripheral elements.

Methods:: Thirty-two first year medical students were volunteers for an online test. We got written approval. They stayed between 15 and 25 centimeters from the screen, so that the objects would be in their VP fields. The tests were recorded. We asked the students to focus a central marker. Three different thematic sequences: T1 (black and white), T2 (medical) and T3 (colorful) with 4 scenes each. There was a progressive increase in the number of elements. After each scene they answered the question (Q): among 3 options which did you see?

Results:: For T1, the percentages of students who answered correctly were 71.9% (Q1); 37.5% (Q2); 31.3% (Q3) and 28.1% (Q4). For T2, they were 65.6% (Q1); 59.4% (Q2); 9.4% (Q3) and 18.1% (Q4). For T3, the percentages were 87.5% (Q1); 34.4% (Q2); 34.4% (Q3) and 56.3% (Q4).

Conclusions:: In case of a low number of elements, the performance was greater for T3. When there was a slight increase in quantity, the highest score was for T2. Nevertheless, there was a significant decrease in that score with an even greater number. Considering the final scenes, again, the performance was the highest for T3, but very low for T2. The increase of colored elements activates neuronal circuits related to the excitation of the cones, in a reverberating way.
INFLUENCE OF EMOTIONS IN MEDICAL STUDENTS: FOCUSING ON THE MEMORY OF RECOGNITION OF WORDS

Tereza De Brito¹, Alice Lee¹, Franciny Kelly¹, Vhirginea Helena De Oliveira Staut Federle¹, Enrico Da Silva¹, Renan legoroff², Arnaldo Godoy³
¹Sao Caetano do Sul University, Sao Paulo, Neurology, Sao Paulo, Brazil, ²Sao Caetano do Sul University, Sao Paulo, Neurology, Sao Paulo, Brazil, ³Sao Caetano do Sul University, Neurology, Sao Paulo, Brazil

Background and Aims:: The relation between auditory memory and emotions needs to be further explored. The aim of this study is to explore the auditory memory of medical students through the evaluation of their ability to recognize words that were said from words that were not said.

Methods:: One hundred-twenty medical students volunteered to participate. Written approval was granted. Three different intonations of the same twelve words were recorded in equal order: neutral, happy and sad. The volunteers were separated into three subgroups (N, H and S) and answered 8 questions (Q) after hearing them. Q1-Q4: among the 3 words, which word did you hear? Q5-Q8: among the 3 words, which word did you not hear?

Results:: The percentages of students who answered correctly were: Subgroup H: Q1: 100%; Q2: 100%; Q3: 97.3%; Q4: 94.6%. Q5: 94.6%; Q6: 94.6%; Q7: 97.3%; Q8: 97.3%.Subgroup S: Q1: 100%; Q2: 92.7%; Q3: 92.6%; Q4: 97.6%; Q5: 90.2%; Q6: 97.6%; Q7: 92.7%; Q8: 100%. Subgroup N: Q1: 97.6%; Q2: 100%; Q3: 90.5%; Q4: 97.6%; Q5: 95.2%; Q6: 95.2%; Q7: 95.2%; Q8: 95.2%.

Conclusions:: Considering the ability of remembering words that were or were not said, there were more than 90% of correct responses for all intonations. SH and SN performed better with words that were said than the words that were not said. SS had a tendency to perform better with words that were said. Our hypothesis is that activation of auditory neuronal circuits and of the limbic system depends on the emotion perceived by the listener.
THE INFLUENCE OF THE ENVIRONMENT ON MOTOR MEMORY OF FOURTH YEAR MEDICAL STUDENTS

Karen Vida¹, Rafael Dell’Antonia¹, Iago Pirani¹, Mariana Silva¹, Pedro Carmo¹, Maysah Arabi¹, Renan Iegoroff², Arnaldo Godoy¹
¹Sao Caetano do Sul University, Sao Paulo, Neurology, Sao Paulo, Brazil, ²University City of Sao Paulo, Neurology, Sao Paulo, Brazil

Background and Aims:: Motor memory is essential in medical education. To evaluate the influence of the environment in motor memory, we tested the surgical skills on fourth year students in different sets.

Methods:: Twenty-four medical students from the first and 37 from the fourth year agreed to volunteer, with written approval. Half of the students from each group were tested in a calm environment: chromotherapy colors and meditation sounds. The other was in a bustling room: flashing lights and stressful sounds. They watched twice a video of 6 movements to make a surgical knot. Each volunteer was, then, asked to repeat the movements. They were recorded. The percentage of students which performed correctly each movement was calculated.

Results:: The percentages of fourth year medical students tested in the bustling room that made the correct movement (M) were: M1: 82.4%; M2: 70.6%; M3: 52.9%; M4: 28.6%; M5: 47.1% and M6: 94.1%. The percentages for volunteers in the calm environment (CE) were: M1: 95%; M2: 80%; M3: 65%; M4: 20%; M5: 75% and M6: 85%.

Conclusions:: The environment significantly influences the performance of motor memory, demonstrated by better performance in CE. Regardless the environment, movement 4 was difficult to be made. Scores were higher in first 3 and last 2 movements, demonstrating that performing motor tasks in a sequence, at a certain step, a habituation occurs. Submitting fourth-year students to motor memory tests highlights the importance of skills training for future surgeons, which facilitates motor learning.
RELATION BETWEEN VISUAL AND AUDITORY NEURONAL CIRCUITS ACTIVATION: ITS INFLUENCE ON THE LIMBIC SYSTEM

Fernanda Garcia Passos¹, Matheus Martins¹, Rafael Lago¹, Tainá Oliveira¹, Renan Iegoroff², Arnaldo Jose Godoy³
¹Sao Caetano do Sul University, Sao Paulo, Neurology, Sao Paulo, Brazil, ²University City of Sao Paulo, Neurology, Sao Paulo, Brazil, ³Sao Caetano do Sul University, Medicine, Sao Paulo, Brazil

Background and Aims:: It is important to compare the memory of medical students for scientific knowledge. For that, we used a test of visual memorization and concentration with music to evoke feelings.

Methods:: Forty-eight first and third medical students were volunteers. We got written approval. We showed Slide 1 with 2 objects from each of the categories: kitchen, school and medical, in 6 different action neutral scenes (one object per scene). Slide 2: the objects were in scaring scenes. While seeing the first slide they listened to a “calm and happy” music. As for the second slide they listened to a “sad and fearful” music. After that, the volunteers answered the questions (Q) 1: Which objects did you see on slide 1? and Q2: Which objects did you see on slide 2? Q3: Do you think the music on slide 1 correlates with the images? Q4: Do you think the music on slide 2 correlates with the images?

Results:: The percentages of students that remembered all objects (4) were: for Q1, 43.8% and for Q2, 58%. In case of Q3: 50% answered “yes” and 50% answered “no”. Q4: 66.7% answered “yes” and 33.3% answered “no”.

Conclusions:: The ability of remembering an object in a scaring scene listening to a fearful music was greater than the one in a neutral scene. However, the difference was not as significant as one might expect. When a high percentage of volunteers found a correlation between the emotions related to the music and the scenes, their working memory was better.
DIFFERENTIATING MULTIFOCAL ACQUIRED DEMYELINATING SENSORY AND MOTOR NEUROPATHY (MADSAM) WITHOUT SENSORY LOSS FROM MULTIFOCAL MOTOR NEUROPATHY (MMN): A CASE STUDY

Hasini Munasinghe¹, Bimsara Senanayake², Ishani Rajapakshe², Sudath Ravindra², Sudath Gunasekara¹, Chulika Makawita²
¹National Hospital of Sri Lanka, Colombo, Clinical Neurophysiology, Colombo, Sri Lanka, ²National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

Background and Aims:: MADSAM is a CIDP variant where patients present with asymmetrical motor weakness in distal limbs with sensory symptoms and signs. The differentiation of MADSAM from MMN can be challenging when there is lack of sensory involvement in the former. We report a case of MADSAM without sensory signs or symptoms, which was differentiated from MMN using SSEP.

Methods:: A 48-year-old man presented with asymmetric, gradual onset distal lower limb weakness which progressed to involve distal upper limbs after one and a half years. His sensory system examination was normal.

Results:: The NCS showed motor conduction blocks in clinically affected nerve segments with normal sensory conduction. The CSF analysis revealed elevated proteins at 57mg/dl with no cells. Due to the suspicion of a CIDP variant, SSEPs were performed. SSEPs of the affected segments were delayed confirming proximal sensory involvement. The diagnosis was made as MADSAM. Patient was treated with intravenous immunoglobulin followed by long-term oral prednisolone. He responded to treatment with evidence of clinical and neurophysiological improvement in the previously affected nerve segments at 10 months follow up.

Conclusions:: MADSAM with pure motor symptoms and motor predominate neurophysiological findings, can be misdiagnosed as MMN. Therefore, CSF analysis and recording of SSEPs are mandatory.
INTRAOPERATIVE MAPPING AND MONITORING OF THE OPTIC PATHWAY

Francesco Vergani¹, Jose Lavrador¹, Prajwal Ghimire¹, Asfand Mirza¹, Hannah Keeble², Noemia Pereira², Ana Mirallave-Pescador³, Ashkan Keyoumars¹, Richard Gullan¹, Ranjeev Bhangoo¹
¹King's College Hospital, Neurosurgery, London, United Kingdom, ²Inomed, Neuromonitoring, London, United Kingdom, ³King's College Hospital, Neurophysiology, London, United Kingdom

Background and Aims:: The identification of the visual pathway during surgery for tumours in visual areas is challenging. We present our experience in visual pathway mapping and monitoring, describing the role of direct mapping of the optic radiations and different techniques of VEPs monitoring, employing both Scalp Recording (SR) and the use of strip electrode positioned over the primary visual cortex for Direct Cortical Recording (DCR).

Methods:: Single-centre prospective cohort study of patients admitted for surgery of intra-axial visual eloquent lesions. Pre-operative mapping – tractography – and intraoperative monitoring (surface – SR - and direct cortical recordings - DCR) and mapping (subcortical stimulation) data were collected along with demographic and clinical information and correlated with extent of resection, surgical technique and visual outcome

Results:: 34 patients were included (20 males, 14 females; mean age of 54.91±2.81 years). 19 (55.88%) patients had homonymous quadrantanopia or hemianopia. Occipital and Parietal location had the larger extent of resection – GTR in 91.67% and 84.62%, respectively, p=0.023 - and the occipital location was related with the better visual outcome - 83.33% patients remained stable and 15.38% improved (p=0.006). DCR was predominantly used in occipital lesions (p=0.002), SR in temporal and parietal lesions (p<0.0001) and positive subcortical stimulation was achieved in parietal and occipital lesions (p=0.007). The DCR was better in metastasis than in gliomas (p=0.040) and was related with the visual outcome (p=0.019).

Conclusions:: Direct cortical recording of VEPs and subcortical stimulation of the optic radiations are reliable techniques to monitor and map the visual pathways in asleep patients.
Background and Aims: The peripheral vision (VP) field is favorable for the identification of scenes. We checked medical students’ ability to pay attention in peripheral elements.

Methods: Fifty-two medical students (first [G1] and third years [G2]) were volunteers for an online test. We got written approval. They stayed between 15 and 25 centimeters from the screen, so that the objects would be in their VP fields. The tests were recorded. The students had to focus a central marker. Three different thematic sequences: T1 (black and white), T2 (medical) and T3 (colorful) with 4 scenes each. There was a progressive increase in the number of elements. After each scene they answered the question (Q): among 3 options which did you see?

Results: G1 for T1, the percentages of students who answered correctly were 71.9% (Q1); 37.5% (Q2); 31.3% (Q3) and 28.1% (Q4). For G2, they were 70% (Q1); 45% (Q2); 20% (Q3) and 25% (Q4). G1 for T2, 65.6% (Q1); 59.4% (Q2); 9.4% (Q3) and 18.1% (Q4). For G2, they were 75% (Q1); 60% (Q2); 15% (Q3) and 50% (Q4). G1 for T3, the percentages were 87.5% (Q1); 34.4% (Q2); 34.4% (Q3) and 56.3% (Q4). For G2, they were 95% (Q1); 55% (Q2); 50% (Q3) and 60% (Q4).

Conclusions: The G2 had better results when medical elements were shown. In the other themes, this advantage was lower. However, there are similar curves of variation in both groups. The longer the period of training, the easier was the ability to recall a seen element.
Background and Aims:: Visuospatial and association skills are of great importance for human relationship. In pandemic times we do not know if and how much they have been damaged. We propose an easy method to check them. Inhabitants of a big city were tested.

Methods:: Twenty-seven volunteers aged 25 (on average) had their visuospatial and association skills tested. All of them gave us a written approval. They saw three pictures: P1: natural objects, P2: human-made objects and P3: both kinds. After each scene they had to choose a professional they would include in the seen picture. The options were: a garbage collector, a physician, a teacher, a musician, and a delivery biker. It was possible to choose more than one.

Results:: As for P1, 55% chose the inclusion of a garbage collector and the same percentage would choose a musician. In case of the picture of the city (P2), 74% would include a delivery biker. For the mixed scene (P3), 48% would include a garbage collector and 48% a delivery biker.

Conclusions:: Half of the volunteers were worried about cleaning and the same percentage was interested in a musician when they saw natural objects. Three fourths chose a delivery worker when they saw human-made objects. The data suggest that staying indoors too long called much attention to cleaning (even in scenes with no garbage) and to pleasant activity (in a nature scene but not in a street scene). The activation of neuronal circuits important for association between visual stimuli and their meanings seems to be impaired.
Background and Aims:: The amnestic type of mild cognitive impairment (aMCI) carries an increased risk of conversion to Alzheimer disease (AD) and therefore its early identification is relevant for the development of disease-modifying treatments. Considering non-invasive simple diagnostic methods, we focused on visual evoked potentials (VEPs) as putative biomarker of cholinergic disfunction. We thus studied patients with MCI and AD by means of paired-pulse flash-visual evoked potentials (paired-F-VEPs). This technique, recently revived, analyses the overall excitability of visual system as detected from the cortical occipital signal.

Methods:: We enrolled 12 adult patients with aMCI and 12 with AD. Fourteen normal subjects of similar age and sex acted as controls. Stimuli were single flashes, intermingled at random to flash pairs at critical interstimulus intervals (ISIs, 16.5 to 125ms) with closed eyes. The “single” (unconditioned) F-VEP was split into a “main complex” (50 to 200ms after the flash) and a “late response” (200 to 400ms). As for paired stimulation, the “test” F-VEP emerged from electronic subtraction of the “single” F-VEP to the “paired” F-VEP. Its size was expressed as “test”/”single” F-VEP*100.

Results:: Patients with aMCI did not show the size reduction (at ISIs 50 and 62.5ms) which was typical among both the controls and AD (p<0.016), when the “late response” was considered. No changes of the “main complex” were detected.

Conclusions:: Paired-F-VEPs document a defective neural inhibition in the visual system of patients with aMCI. Paired-F-VEPs may warrant inclusion in future clinical studies, to evaluate its potential role in the pathophysiology and management of aMCI.
CONTRIBUTION OF DIFFERENT SOMATOSENSORY AFFERENT INPUT TO SUBCORTICAL SOMATOSENSORY EVOKED POTENTIALS IN HUMANS

Massimiliano Valeriani¹, Paolo Mazzone², Domenico Restuccia³, Angelo Insola⁴
¹Ospedale Pediatrico Bambino Gesù, Neuroscience, Rome, Italy, ²CTO Hospital, Neurosurgery, Rome, Italy, ³Catholic University, Neurology, Rome, Italy, ⁴CTO Hospital, Neurophysiology Unit, Rome, Italy

Background and Aims:: Cortical projection of the somatosensory fibers of different modalities has been studied in humans. The aim of this study was to investigate the subcortical somatosensory evoked potentials (SEPs) to electrical stimulation of either muscle or cutaneous afferents.

Methods:: SEPs were recorded in 6 patients suffering from Parkinson’s disease who underwent electrode implantation in the pedunculopontine (PPTg) nucleus area. We compared SEPs recorded from the scalp and from the intracranial electrode contacts to electrical stimuli applied to: 1) median nerve at the wrist, 2) abductor pollicis brevis motor point, and 3) distal phalanx of the thumb. Also the high-frequency oscillations (HFOs) were analysed.

Results:: After median nerve and pure cutaneous (distant phalanx of the thumb) stimulation, a P1-N1 complex was recorded by the intracranial lead, while the scalp electrodes recorded the short-latency far-field responses (P14 and N18). On the contrary, motor point stimulation did not evoke any low-frequency component in the PPTg traces, nor the N18 potential on the scalp. HFOs were recorded to stimulation of all modalities by the PPTg electrode contacts.

Conclusions:: Our study showed that: a) the scalp N18 wave can be evoked by the cutaneous input, while the pure stimulation of the muscular afferents does not evoke it; b) both presynaptic and postsynaptic HFOs can be recorded at level of the cuneate nucleus after all stimulation modalities. These results suggest that the stimulus processing within the cuneate nucleus depends on modality, since the reverberation mechanism producing the scalp N18 potential is triggered only by the cutaneous but not the muscular input.
ENVIRONMENTAL TRIGGERING EMOTIONS: ENHANCING MEDICAL STUDENTS VISUAL MEMORY

Carolina Hemeque, Rafaela Rodrigues Souza, Larissa Abreu, Giovanna Silva, Arnaldo Jose Godoy
Sao Caetano do Sul University, Sao Paulo, Medicine, Sao Paulo, Brazil

Background and Aims:: Memorization of details of a scene depends on different brain neuronal circuits. We decided to study how emotions influence visual memories.

Methods:: Fifty-one third year medical students were selected (21 to 30 years) and divided into two groups: with emotion (WE: 23) and with no emotion (NE: 28). They were in two classrooms. Four images were projected: a bedroom, a classroom, an operating room, and a kitchen. Then they had to answer four questions (Q) after each image: the color of the wall (Q1,5,9,13), which object they saw (Q2,6,10,14), which object was not in the scene (Q3,4,7,8,15,16). In the room where were NE students they saw the pictures and listened to no music. In the other room (WE): four musics were played with each image, respectively: happy, angry, sad, and relaxing ones.

Results:: In the NE: 75% got right answers for Q1 and 89% for Q3, 86% for Q6, Q9 and Q12. For WE: 61% got right answers for Q1 and 66% for Q3, 66% for Q6, 100% Q9 and 96% Q12.

Conclusions:: Students in a non-medical (NM) emotional environment had lower performance memorizing details of a scene. However, in case of the medical (M) environment emotion facilitated memorization. In a NM neutral environment volunteers got higher scores memorizing objects than color. On the other hand, in M those scores were similar and higher. Our data support that visual memory neuronal circuits were overactivated by the combination of long term stored emotions (the vision of an operating room) and present emotions (musics).
Background and Aims:: To evaluate serum antidiuretic hormone (ADH) its receptors and renin levels in Cerebral salt wasting (CSW) in tuberculous meningitis (TBM).

Methods:: Patients diagnosed with definite (n=30) or probable TBM (n=47) who developed hyponatremia (CSW, SIADH or miscellaneous causes) were included. Sequential measurement of Serum ADH, ADH-R and renin activity by enzyme linked immunosorbent assay was done and correlated with serum sodium level, urinary output and fluid balance

Results:: Out of 79 TBM patients, CSW was observed in 36, SIADH in four and miscellaneous hyponatremia in eight patients. CSW patients had a longer hospital stay (P<0.001), lower GCS score (P<0.007), higher MRC grade (P<0.007) and a lower serum Na (P<0.001) compared to non-CSW TBM patients. In severe CSW patients, Serum ADH and ADH-R were correlated with hyponatremia and returned to baseline on correction, however, serum renin levels remained elevated. Serum ADH was related to hyponatremia but ADH-R and renin were not. ADH -R and renin levels did not significantly differ in CSW and SIADH

Conclusions:: CSW is the commonest cause of hyponatremia in TBM, and correlates with disease severity. ADH is related to hyponatremia, but ADH receptor and renin are not
UNCLASSIFIED SUBTYPE OF GUILLAIN-BARRÉ SYNDROME IS ASSOCIATED WITH QUICK RECOVERY

Keiko Ohnari1, Kazumasa Okada1, Kosuke Mafune2, Susumu Kusunoki3

1University of Occupational and Environmental Health, Neurology, Kitakyushu, Japan, 2University of Occupational and Environmental Health, Mental Health, Institute Of Industrial Ecological Science, Kitakyushu, Japan, 3Kindai University, Neurology, Osaka-sayama, Japan

Background and Aims:: Electrophysiological classification of Guillain-Barré syndrome (GBS) is important for predicting its clinical course. However, few reports discuss GBS patients who do not fit into the acute inflammatory demyelinating polyneuropathy (AIDP) or acute motor axonal neuropathy (AMAN) classifications of GBS. Therefore, the present study focused on the features of unclassified types of GBS and compared these to AIDP and AMAN.

Methods:: We compared clinical symptoms, nerve conduction, and laboratory data among patients with AIDP, AMAN, and unclassified subtypes of GBS, according to criteria developed by Rajabally, Hadden, and Ho.

Results:: According to the Rajabally criteria, the F wave frequency of the upper and lower extremities in the unclassified subgroup was higher than that of AIDP and AMAN. However, according to the Hadden and Ho criteria, the frequency of the F wave in only lower extremities in the unclassified subgroup was higher than that in other subgroups. The unclassified subgroups showed better prognosis using the Rajabally criteria.

Conclusions:: Classification with the Rajabally criteria is a useful tool for predicting prognosis and determining treatment in patients with GBS, and unclassified patients exhibit quick recovery.
DISTINCT NEURONAL CIRCUITS TO MEMORIZE FACES: MODULATION OF THE LIMBIC SYSTEM

Monai Oliveira¹, Pietro De Aguiar¹, Mayara Nunes¹, Vinicius Figueiredo¹, Bianca Andrade¹, Renan Iegoroff², Arnaldo Godoy¹
¹São Caetano do Sul University, São Paulo, Neurology, São Paulo, Brazil, ²University City of Sao Paulo, Neurology, Sao Paulo, Brazil

Background and Aims:: Memorizing faces is especially important for physicians. We analyzed the effect of gender-linked features and emotion for that memorization in medical students.

Methods:: Fifty-one students, aged 18-30 were tested online, with written approval. Pictures from 12 actors (M) and 12 actresses (F) were taken: with happy (H), angry (A) and emotionless (E) faces. The men were with (Mu) and without a mustache (wMu) and the women using (uL) or not using lipstick (nL). We showed ten slides of 5 actresses and 5 actors, wearing or not accessories. They answered 6 questions (Q1-Q6): in each, an E face. We asked if they were wearing mustache or using lipstick. Other questions, to choose among three E faces, the one using lipstick (Q7) and the one not wearing mustache (Q8).

Results:: Percentages of correct answers: Q1 (FAuL): 78%, Q2 (MHwMu): 39%, Q3 (FHnL): 54%, Q4 (FAnL): 86%, Q5 (MHMu): 67%, Q6 (FHuL): 84%, Q7 (FEuL): 49%, Q8 (MAwMu): 74%.

Conclusions:: After the students saw faces with gender-linked accessories (mustache and lipstick) it was easier to remember female’s faces (Q4 and Q6). The performance of the volunteers was greater when they saw angry faces, no matter the gender or the presence of accessories (Q1, Q4 and Q8). Male or female’s happy faces were easier to be recalled when they were with accessories (Q2, Q3, Q5 and Q6). Our data strongly suggest that gender, emotion, and accessories affect the memorization for faces in specific ways. Therefore, the neuronal circuits important for that kind of memory are distinct.
WHOLE PLANTAR NERVE CONDUCTION STUDY: AN USEFUL TOOL IN DIAGNOSIS OF DIABETIC POLYNEUROPATHY

Dario Ricciardi, Vincenzo Todisco, Gioacchino Tedeschi
University of Campania Luigi Vanvitelli, Dept. Of Neurology, Naples, Italy

Background and Aims:: Whole plantar nerve (WPN) allows the registration of a summation sensory action nerve potentials (SNAPs), simultaneously recording from both lateral and medial plantar nerves. Thus, WPN may be useful in length-dependent polyneuropathy, as well as diabetic peripheral neuropathy. We aimed to assess the reliability of whole plantar nerve (WPN) conduction study in diabetic subjects.

Methods:: This single-center prospective observational case-control study involved 70 type II diabetes mellitus patients and 62 healthy controls referred to I Division of Neurology of the University of Campania “Luigi Vanvitelli” between October 2019/October 2020. All subjects performed validated screening tests of neuropathy, nerve conduction study (NCS) of the sural nerve, WPN and sympathetic skin response (SSR).

Results:: Median SNAPs amplitude (2.10µV vs 4.9µV, p=0.001) and sensory conduction velocity (SCV) (40µV vs 42.7µV, p=0.013) recorded by WPN were significantly lower in type II diabetes mellitus patients. Likewise, proximal sural nerve conduction revealed that both SNAPs amplitude (6.4 [3.48 – 12.4] µV vs 11.25 [6.2 – 16.7] µV, p=0.001) and SCV (50.1 [45.68 – 54.9] m/s vs 53.6 [49 – 57.6] m/s, p=0.006) were significantly lower in the diabetic group, as compared to HC.

Conclusions:: Our data support WPN conduction study reliability in characterizing lower limbs’ most distal sensory nerve fibers. Thus, WPN may represent a useful tool for diabetic PN studies.
PRECLINICAL MARKERS OF NEUROPATHIC DAMAGE IN TYPE 1 DIABETES MELLITUS

Laura Rapisarda¹, Concetta Irace², Rita Nisticò³, Alessia Giugno⁴, Stefania Barone⁵, Martina Parise², Marianna Crasà⁶, Domenico Nicoli⁴, Antonio Gambardella¹, Paola Valentino⁷
¹AOU Mater Domini, Magna Graecia University, Department Of Medical And Surgical Sciences, Institute Of Neurology, Catanzaro, Italy, ²Magna Graecia University, Metabolic Diseases Unit, Department Of Clinical And Experimental Medicine, Catanzaro, Italy, ³National Research Council, Neuroimaging Research Unit, Institute Of Molecular Bioimaging And Physiology, Catanzaro, Italy, ⁴Magna Graecia University of Catanzaro, Institute Of Neurology, Department Of Medical And Surgical Sciences, Catanzaro, Italy, ⁵Institute of Neurology, Department Of Medical And Surgical Sciences - Magna Graecia University, Catanzaro, Italy, ⁶University Magna Graecia, Neuroscience Research Centre, Catanzaro, Italy, ⁷catanzaro, Neurology, catanzaro, Italy

Background and Aims:: Diabetic neuropathy (DN) is the most common neurological complication of diabetes mellitus (DM). Although DN has been related to long-lasting disease, early signs might be appreciable after a few years from DM onset. Our study aimed to detect with clinical and multimodal neurophysiological tests the presence of DN in a group of patients with DM type 1.

Methods:: Fifty-six patients affected by DM type 1 attending the Metabolic Disease Unit of Magna Graecia University of Catanzaro underwent to clinical screening for DN through Michigan neuropathy screening instrument (MNSI) and multimodal neurophysiological tests including electroneurography, laser evoked potentials and neurovegetative function tests (skin sympathetic response and evaluation of heart rate variation).

Results:: Among 56 patients with mean age of 41±15 and disease duration of 20±11, 42.8% had symptoms and 51.8% had clinical signs of DN. Neurophysiological tests showed that 82.2% presented a DN: 19.6% have only large fiber neuropathy, manifesting mainly with demyelinating and/or axonal length-dependent polyneuropathy or entrapment neuropathy; 17.6% had only small fiber neuropathy; whereas 44.6% had both small and large fibers involvement. About a third of patients with DN resulted negative for MNSI test. Comparison with demographic data and continuous glucose monitoring parameters revealed a significant association between presence of DN with or without clinical sign and symptoms and age, disease duration and time below range.

Conclusions:: this study showed that multimodal neurophysiological tests are more sensitive to identify DN than traditional clinical tests. Further studies are needed to investigate the relationship between DN and continuous glucose monitoring parameters.
EP1303 / #2801

PUPIL SIZE IS INFLUENCED BY TRANSCUTANEOUS VAGAL NERVE STIMULATION UNDER SPECIFIC STIMULATION INTENSITY AND ILLUMINANCE CONDITION

Francesco Motolese, Fioravante Capone, Fabio Pilato, Mariagrazia Rossi, Vincenzo Di Lazzaro
Campus Bio-Medico University of Rome, Neurology, Neurophysiology And Neurobiology Unit, Department Of Medicine, Roma, Italy

Background and Aims:: Pupil size has gained attention as a promising biomarker of vagal activation in different studies on animal models. Locus Coeruleus (LC) is the main noradrenergic nucleus of the central nervous system and plays a key role in regulating pupil diameter. Transcutaneous vagal nerve stimulation (taVNS) is a non-invasive technique used to stimulate cutaneous auricular afferent branch of the vagus nerve at the external ear. Cervical taVNS is a currently approved treatment for primary headache. However, taVNS mechanisms of action are still not known even if animal studies have reported a potential effect of taVNS on LC. Our aim was to investigate the effects of taVNS on pupil diameter in healthy subjects.

Methods:: All subjects (n = 12) received taVNS at the left external acoustic meatus and control stimulation at the left earlobe during the same experimental session. Different intensities and illuminance conditions (scotopic, mesopic, photopic) for both conditions were tested.

Results:: In scotopic illuminance condition real taVNS at 2 mA was capable of inducing a larger pupil dilatation, in comparison to baseline and 2 mA control stimulation.

Conclusions:: Our study demonstrates that taVNS induces pupil dilation under specific illuminance condition and at a specific stimulation intensity. Pupil dilation during taVNS could be used as an online and easy-to-use indicator of the effectiveness of the stimulation, in order to optimize therapeutic applications of this technique, also in neurodegenerative diseases in which the activity of the LC-noradrenergic network is supposed to play a role in the pathogenesis.
POSTSYNAPTIC NEUROMUSCULAR JUNCTION DEFECT IN A PATIENT WITH MILLER FISHER SYNDROME

Steno Rinalduzzi, Susanna Almonti, Francesca Gragnani, Isabella Pestalozza, Antonella Biasiotta, Francesca Gilio
Ospedale Sandro Pertini, Emergenza Urgenza, Rome, Italy

Background and Aims:: Miller Fisher syndrome (MFS) is an acute immune-mediated neuropathy. To date only few studies reported a possible overlap of Myasthenia Gravis (MG) and MFS in patients with acute ophthalmoplegia. We report the case of a patient diagnosed as MFS with a coextistent neuromuscular junction defect.

Methods:: A 77-year-old Chinese female, without significant previous neurological history, presented in our Emergency Department with acute ophthalmoplegia after recent fever and faringodinia. Neurological examination revealed clinical signs (areflexia, complete ophthalmoplegia and ataxia) consistent for MFS.

Results:: Instrumental tests (neuroimaging, CSF, nerve conduction studies, serum antibodies tests) were performed and the patient was diagnosed with MFS. Repetitive nerve stimulation also showed coextistent significant decremental motor response suggesting an overlapping postsynaptic neuromuscular transmission defect. Patient underwent plasmapheresis with a progressive improvement until full clinical recovery.

Conclusions:: Although the overlap of MG and MFS is very rare, it should be considered in the differential diagnosis in neuro-ophthalmic diseases. Our findings emphasize the importance of electrophysiologic tests for neuromuscular transmission also in MFS in order to build a spectrum of clinical, serological and electrodiagnostic characteristics and better understand the mechanisms that determine ophthalmoplegia and the treatment response. We encourage other studies to collect further related data.
PATIENTS WITH UNRESPONSIVE WAKEFULNESS SYNDROME PRODUCE HIGH-AMPLITUDE AUDITORY STEADY-STATE RESPONSE

Shun-Ichiro Hirano
Osaka University of Comprehensive Children Education, Department Of Neurology, Osaka City, Japan

Background and Aims: The unresponsive wakefulness syndrome (UWS) is one of the unfavorable states that are characterized by a condition of arousal without signs of awareness. Most UWS patients are unresponsive to external stimuli. However, they often open their eyes and are capable of swallowing. In addition, most cases preserve their sleep-wake cycles. These symptoms make it difficult to understand the symptom. The author studied the electrophysiological response of UWS patients, and found a unique means to describe the syndrome.

Methods: Ten cases with UWS were studied. I examined their electroencephalogram (EEG), auditory brainstem response (ABR) and auditory steady-state responses (ASR) simultaneously. Ally ASR data set were processed by the fast Fourier transformation method, and a power spectrum around the 40 Hz-frequency band was calculated. These records were compared to the data obtained from normal volunteers.

Results: All patients exhibited low-voltage EEG less responsiveness to external stimuli. In contrast, they showed a significantly high-amplitude ASR. Waveforms and each peak’s latency of their ABR records were almost normal. These findings suggested deteriorated cerebral function and preserved brainstem activity. The ASR records may indicate dysfunction of cerebral inhibition system in the neural activity of the brainstem reticular formation.

Conclusions: Findings from the electrophysiological examinations revealed cerebral hypofunction and preservation of brainstem activity. In addition, the results of the ASR examination suggested malfunction of the cortical inhibitory system against brainstem neural activity. This result is thought to be a unique feature in the UWS patients and may help to understand the pathophysiology of UWS.
OVERT AND COVERT EFFECTS OF COGNITIVE FATIGUE ON ATTENTION NETWORKS

Caterina Pauletti, Daniela Mannarelli, Andrea Maffucci, Alessia Petritis, Francesco Fattapposta
Sapienza University of Rome, Human Neurosciences, Rome, Italy

Background and Aims:: Cognitive fatigue refers to a variation of the psychophysiological state during or after prolonged periods of mental activity that requires work efficiency, and could lead to temporary deterioration of attentional functioning, especially top-down attention and cognitive control. The present study aims to verify the effects of cognitive fatigue on attention in the context of the three attentional networks described by Posner, by using behavioral and psychophysiological measures, to detect variations in overt and covert responses respectively.

Methods:: Thirty young healthy subjects were enrolled in the study, 15 in the “fatigue” and 15 in the control group. Cognitive fatigue was provoked by a continuous arithmetic task lasting 1 hour, and the EEG recordings were conducted before and after the task, while subjects were performing the attention network test. The N1, N2 and P3 components were analyzed for the alerting, orienting and conflict networks, in conformity with behavioral analysis.

Results:: No difference emerged between groups in networks’ efficiency scores and in N1 and P3 amplitudes related to the alerting network. As regards the orienting network, P3 amplitude was significantly reduced in the fatigue group alone (p=0.02), while no differences emerged in N1 amplitude. As regards the conflict network, both N2 and P3 amplitudes were significantly reduced in the fatigue group alone and selectively for the incongruent target (p<0.001; p=0.001 respectively).

Conclusions:: Our results suggest that, in young healthy subjects, cognitive fatigue interferes with goal-driven attention especially when the task demand is higher, sparing the bottom-up attention control mechanisms and in absence of any overt observable effect.
CEREBELLUM IN TIMING CONTROL: EVIDENCE FROM CONTINGENT NEGATIVE VARIATION AFTER CEREBELLAR TDCS.

Alessia Petritis, Daniela Mannarelli, Caterina Pauletti, Andrea Maffucci, Chiara Panzini, Francesco Fattapposta
Sapienza University of Rome, Human Neurosciences, Rome, Italy

Background and Aims: Timing control is defined as the ability to quantify time. The temporal estimation of supra-seconds range is generally seen as a conscious cognitive process, while the sub-seconds range is a more automatic cognitive process. It is accepted that cerebellum contributes to temporal processing, but its function is still debated. The aim of this research was to better explore the role of cerebellum in timing control. We transitorily inhibited cerebellar activity and studied the effects on CNV components in healthy subjects.

Methods: Sixteen healthy subjects underwent a S1-S2 duration discrimination motor task, prior and after cathodal and sham cerebellar tDCS, in two separate sessions. In S1-S2 task they had to judge whether the duration of a probe interval trial was shorter (Short-ISI-trial:800ms), longer (long-ISI-trail:1600ms), or equal to the Target interval of 1200ms. For each interval trial for both tDCS sessions, we measured: total and W2-CNV areas, the RTs of correct responses and the absolute number of errors prior and after tDCS.

Results: After cathodal tDCS a significant reduction in total-CNV and W2-CNV amplitudes selectively emerged for Short (p<0.001; p=0.003 respectively) and Target-ISI-trial (total-CNV: p<0.001; W2-CNV:p=0.003); similarly, a significant higher number of errors emerged for Short (p=0.004) and Target-ISI-trial (p=0.07) alone. No differences were detected for Longer-ISI-trials and after sham stimulation.

Conclusions: These data indicate that cerebellar inhibition selectively altered the ability to make time estimations for second and sub-second intervals. We speculate that cerebellum regulates the attentional mechanisms of automatic timing control by making predictions of interval timing.
INTRAOPERATIVE NEUROPHYSIOLOGICAL MONITORING URGENT SYMPTOMATIC EXTRAĆTRANIAL INTERNAL CAROTID ARTERY DESOBLITERATION.

Svatopluk Ostrý1,2, Milan Nevšímal3, Miroslava Nevšímalová2, Martin Reiser2, Jiří Fiedler3,4
1First Faculty of Medicine, Charles University in Prague and Military University Hospital Prague., Department Of Neurosurgery And Neurooncology, Prague, Czech Republic, 2Hospital České Budějovice, a.s., Neurology, České Budějovice, Czech Republic, 3Hospital České Budějovice, a.s., Neurosurgery, České Budějovice, Czech Republic, 4Faculty of Medicine in Plzeň , Charles University in Prague, Neurosurgery, Plzeň, Czech Republic

Background and Aims:: Background: Surgical recanalization extracranial internal carotid artery (ICA) occlusion is an off-label acute stroke therapy because of conflicting results. Common carotid artery (CCA) cross-clamp might be the main cause of intraoperative ipsilateral stroke and unacceptably high rate of poor outcome. Intraoperative median somatosensory evoked potentials (SEP) monitoring is an established tool for selective shunting and intraoperative stroke prevention. Aim: Rate of necessary interventions induced by intraoperative SEP changes during urgent ICA recanalization.

Methods:: Acute ischemic stroke with extracranial ICA occlusion within 24 hours from last seen normal with no contraindications for urgent recanalization therapy. Prospectively recruited 33 patients, 30 males (90.1 %), average age 70.4 ± 8.9 years (52-88). Symptomatic side on left in 22 (66.7%), NIHSS median 6.0, interquartile ratio (2.0-12.0). Prestroke modified Rankin scale (mRS) 0, 1 and 2 were in 30 (91.9 %), 1 and 2, respectively.

Results:: Recanalization was achieved in 32 (96.7%). SEP amplitude dropped after CCA crossclamp in 6 patients (18.2%). SEP recovered after mean arterial pressure increase >100 mmHg, shunt insertion and final flow restoration in 3, 2 and 1 patient, respectively. Surgical complications were in 6 (18.2%) patients. Four haematomas were resolved after urgent surgical revision. Four ipsilateral cranial nerve lesions recovered spontaneously within 3 months. 3month mRS-3M 0-1, 2, 4-5 and 6 were 23 (69.7%), 5, 2 and 3, respectively. Overall permanent morbidity and mortality was 5 (15.2%).

Conclusions:: Intraoperative SEP during urgent ICA desobliteration seems to be valuable because of intraoperative brain ischemia prevention and permanent morbidity and mortality reduction.
A NEW, SENSITIVE BIOMARKER FOR ABNORMAL CORTICAL EXCITABILITY: SINGLE TRIAL BASED SYNCHRONIZATION AND DESYNCHRONIZATION WITH CORTICAL MYOCLONUS

Haruo Yamanaka1, Maya Tojima1, Takefumi Hitomi2, Katsuya Kobayashi1, Masao Matsuhashi3, Kiyohide Usami2, Akihiro Shimotake1, Ryosuke Takahashi1, Akio Ikeda4

1Kyoto University Graduate School of Medicine, Neurology, Kyoto-shi Sakyo-ku, Japan, 2Kyoto University Graduate School of Medicine, Clinical Laboratory Medicine, Kyoto-shi Sakyo-ku, Japan, 3Kyoto University Graduate School of Medicine, Department Of Epilepsy, Movement Disorders And Physiology, Kyoto-shi Sakyo-ku, Japan, 4Kyoto University Graduate School of Medicine, Epilepsy, Movement Disorders And Physiology, Kyoto-shi Sakyo-ku, Japan

Background and Aims:: Giant somatosensory evoked potentials (SEPs), i.e., enlarged cortical components of SEPs, represent abnormal cortical excitability such as cortical myoclonus (CM). Recently, we reported high-frequency oscillations (HFOs) with a part of giant SEPs specifically observed in benign adult familial myoclonus epilepsy (Tojima et al., 2021). However, no clear HFOs after N33 were observed. We herein hypothesized, in CM patients, late cortical abnormal excitability may be poorly synchronized in average method and thus only detectable by single trial, event-related synchronization (ERS) and desynchronization (ERD). We also compared ERS/ERD between CM patients and healthy controls (HCs).

Methods:: This retrospective study included patients from 2017 to 2020 showing CM and giant SEPs to median nerve stimulation, and all single-trace data were available. We investigated time-frequency analysis using single-trace data and defined significant power increase and decrease compared to baseline activities as ERS/ERD. Occurrence rates of ERS/ERD in CM patients and those in SEP of age-matched HCs were compared.

Results:: In 46 giant SEPs to one arm in 23 patients and 33 SEPs in 17 HCs, ERS/ERD up to 1000Hz were observed between 20-150ms commonly. Occurrence rate of ERS (83% vs. 30%, p<0.01) and ERD (59% vs. 15%, p<0.01) was significantly higher in CM patients.

Conclusions:: Time-frequency analysis of single-trace data revealed ERS/ERD after N33 in CM patients. It indicates that oscillatory activity was totally obscured in the background of averaged SEP. It could be a new sensitive biomarker for abnormal cortical excitability of CM, beyond “averaged” giant SEPs.
Background and Aims:: A growing body of literature has investigated the use of nonlinear analysis of electroencephalographic (EEG) signal and particularly the Hurst exponent as a method for studying EEG dynamics. In this paper we make an emphasis on investigation of the Hurst exponent in slow frequency bands in children during the first two years of life

Methods:: Retrospective cross-sectional study. The high-density EEG (128-channel) was recorded during wakefulness in one group typically developing infants in the following age points: 5 months (N=20 (F=7), mean age (ma)= 5.8 (0.2)), 10 months (N=18 (F=5), ma = 10.7 (0.3)), 14 months (N=18 (F=10), ma= 14.5 (0.5)).

The Hurst exponent ranges was calculated in MATLAB R2020a for delta (0.5-3.9 Hz) and theta (3.9-8 Hz) frequency band (0.1 Hz steps) in the next regions of interest (channels): frontal (3,4,5,6,10,11,12,13,16,18,19,20,23,24,27,28,29,111,112,117,118,123,124), central (7,10,30,31,35,36,37,41,55,80,87,104,105,106,110), temporal (34,40,46,47,51,58,59,91,96,97,98,102,109,116) and occipital (65,66,67,70,71,72,75,77,76,83,84,90).

Results:: The remarkable result of our study is identification of significant decrease of H values at 3.9-4.0 Hz for the estimated frequency bands in all regions of interest and in all age points.

Conclusions:: Results obtained from this study are similar to previously reported data (Hernan Diaz M. et al., 2015) indicating to sudden non-proportional decrease of H values of theta (> 4 Hz) frequency range, despite the discrepancy between chronological age of subjects and methodology of studies. However, this intriguing result is not clear from the point of view of its neurophysiological interpretation.
CORRELATION BETWEEN THE OCCURRENCE OF SEIZURES AND EEG RESULTS

Machlusil Husna¹, Sri Rianawati¹, Zamroni Afif¹, Yulia Damayanti²
¹Faculty of Medicine Brawijaya University/ Saiful Anwar General Hospital, Department Of Neurology, Malang, Indonesia, ²Universitas Brawijaya, Neurology Resident, Neurology Department, Malang, Indonesia

Background and Aims:: Epilepsy is a state of electrical signal disturbance in the brain that manifests as seizures. Diagnosis of epilepsy with history, physical examination, and investigations. One of the investigations that help diagnose epilepsy is electroencephalography (EEG). The EEG result is abnormal if there are epileptogenic and non-epileptogenic waves such as sharp waves, spike waves, and amplitude abnormalities. This study aims to determine the relationship between seizure frequency and EEG result.

Methods:: This type of research used in this research is observational analytic using the chi-square test. The data collection technique was carried out using the purposive sampling technique. The sample used in this study amounted to 300 samples that met the inclusion and exclusion criteria. This study's data were received through secondary data from the patient register by recording electroencephalography (EEG).

Results:: From 300 patients, the prevalence of patients with recurrent seizures would give a picture of abnormal EEG results compared to patients with one or two seizures. A firm agreement did obtain with the chi-square test between the seizure frequency and the EEG results (p = 0.050).

Conclusions:: There is a significant relationship between seizure frequency and EEG results.
Carpal Tunnel Syndrome: Prospective and Observational Study of 458 Cases. Diagnosis Accuracy of Clinical Symptoms and Their Correlation with ENMG Findings

Basma Marzouk¹, Ikrame Mouhi², Bouchra Kably², Leila Ergguig², Reda Ouazzani², Nazha Birouk²
¹Hôpital des Spécialités, Department Of Clinical Neurophysiology, Rabat, Morocco, ²Hôpital des Spécialités, Department Of Clinical Neurophysiology, Rabat, Morocco

Background and Aims:: Electroneuromyography (ENMG) studies are the gold standard for carpal tunnel syndrome diagnosis (CTS). The main objective of this prospective study was to identify the clinical data and their concordance with ENMG test results in the first large series of CTS in Morocco.

Methods:: This study enrolled 249 patients diagnosed with CTS from February 2019 to December 2020.

Results:: This study concerned 458 cases of CTS, 93.2% females and 6.8% males with a mean age of 53 years. The average of symptoms duration until diagnosis was 33.43 months. CTS concerned especially housewives (48.19%). The associated comorbidities were found in 34.9%. The main complaint was pain and paresthesia in the territory of the median nerve in 79.98%, isolated ulnar nerve territory in 0.98% and isolated radial nerve territory in 1.22%. The Tinel's and Phalen's tests indicated moderate sensitivity (39.7% and 27.69% respectively) and high specificity (88.8% and 89.38% respectively). According to ENMG test results, 11% was normal including transcarpal comparisons, while 408 had median nerve entrapments in carpal tunnel (85% bilateral, 11.8% in the right and 2.7% in the left), 10.29% had very severe CTS with reduced CMAP amplitudes and abolished sensory potentials; 70.58% had moderate to severe CTS with abnormal motor nerve conduction and decreased sensory response; 18.13% had a CTS demonstrable only in sensory nerve conduction tests. There was a significant correlation between the duration of the disease and the severity of CTS.

Conclusions:: ENMG studies are valuable tools in diagnosis and severity assessment of CTS, it should be performed after clinical examination.
HEREDITARY NEUROPATHY WITH LIABILITY TO PRESSURE PALSY PRESENTING AS BILATERAL FOOT DROP

Ismail Koc¹, Guray Koc², Zeki Odabasi³
¹Gulhane Training and Research Hospital, Neurology, Ankara, Turkey, ²Istanbul Kartal Dr. Lutfi Kirdar City Hospital, Neurology, Istanbul, Turkey, ³University of Health Sciences, Gulhane Medical School, Department Ofneurology, Ankara, Turkey

Background and Aims:: Hereditary neuropathy with liability to pressure palsy (HNPP) is a rare, autosomal dominant disorder that typically present with episodic, multifocal neuropathy and recurrent transient pressure palsies. However HNPP can be underdiagnosed or misdiagnosed due to its heterogeneity in clinical and electrophysiological presentation. We herein present a case of HNPP presenting with bilateral foot drop.

Methods:: A 22-year-old man developed a sudden onset of painless muscle weakness in his both legs. On neurological examination, he was found to have bilateral foot drop. Normoactive deep tendon reflexes and acute onset history was interpreted as a transvers myelitis mistakenly. Magnetic resonance imaging of the brain and whole spine, extensive blood tests and investigation of cerebrospinal fluid were all normal. Then, electromyography was performed.

Results:: Nerve conduction study showed sensory and motor polyneuropathy associated with multiple entrapment neuropathies including conduction block of the bilateral peroneal nerves at fibular head. These electrophysiological findings were compatible with HNPP but also sural sparing was observed. Genetic testing was performed and PMP22 gene analysis showed the typical deletion, 1.5 Mb in the distal region of the locus 17p.11.2.

Conclusions:: In this study we describe a case of HNPP misdiagnosed as transvers myelitis initially. Interestingly, electrophysiological studies showed sural sparing that is classical finding of autoimmune polyradiculoneuropathies.
SEASONAL VARIATION OF GUILLAIN-BARRÉ SYNDROME IN IRANIAN PATIENTS: A RETROSPECTIVE STUDY

Elham Dirandeh¹, Hossein Hatami², Farzad Fatehi³, Ramin Heshmat⁴
¹Tehran University of Medical Sciences, Neurology Resident, Department Of Neurology, Shariati Hospital, Tehran, Iran, ²Shahid Beheshti University of Medical Sciences, Professor Of Infectious Diseases And Public Health (mph), Department Of Public Health, School Of Public Health And Safety. And Environmental And Occupational Hazards Control Research Center, Tehran, Iran, ³Tehran University of Medical Sciences, Associate Professor Of Neurology, Department Of Neurology, Shariati Hospital And Department Of Neurology, Iranian Center Of Neurological Research, Tehran University Of Medical Sciences, Tehran, Iran, ⁴Tehran University of Medical Sciences, Research Associate Professor Of Epidemiology, Chronic Diseases Research Center, Endocrine Population Sciences Institute, Endocrinology And Metabolism Research Institute, Tehran, Iran

Background and Aims:: It seems that the incidence of Guillain-Barré syndrome (GBS) has seasonal trends depending on weather as well as environmental and demographic factors such as upper respiratory tract (URI) and gastrointestinal (GI) infections as recent triggers, which might be higher in special weather conditions.

Methods:: The records of all admitted patients to all wards of Shariati Hospital with a probable diagnosis of GBS were investigated from March 2009 to March 2019 based on fulfillment of Brighton criteria and symptom onset during the recent 4 weeks.

Results:: Eighty-seven patients were included in this study of whom 63.2% were men. The mean age of the patients was 49.1±19.2 years, and 41.3% and 10.3% of the patients had recent URIs and GI infections, respectively. Most of the patients had acute inflammatory demyelinating polyneuropathy (AIDP) in electrophysiological study. The frequency of GBS in different seasons was 35.6% in the winter, 27.6% in the autumn, 19.6% in the spring, and 17.2% in the summer. The highest frequency was observed in January followed by September (16.1% and 14.9%, respectively). The lowest frequency was in July (3.4%). The most frequent electrophysiological subtype was AIDP in all seasons. The most common GBS disability score was 1. Mortality was 11.5% (6 men and 4 women). Six participants had acute motor sensory axonal neuropathy (AMSAN) and others had AIDP. No seasonal variation was detected.

Conclusions:: The highest and the lowest occurrence was seen in the winter and summer, respectively. AIDP was the most common electrophysiological subtype in all seasons.
MOVEMENT RELATED CORTICAL POTENTIALS AND MEANINGFUL DRAWING

Gaia Leandri¹, Caterina Leone², Silvia Stara¹, Massimo Leandri¹
¹University of Genova, Dinogmi, Genova, Italy, ²Università La Sapienza, Neuroscienze Umane, Roma, Italy

Background and Aims:: Movement related cortical potentials are usually studied employing single and well defined movements, thus lacking adherence to reality of complex gestures. Our research was aimed at investigating the possibility of triggering EEG recordings during natural freehand drawing and assessing if differences could be established between meaningful and meaningless movements.

Methods:: We used a digital drawing tablet to provide a trigger pulse every time a pen touched its surface. Five subjects were asked to execute a meaningful drawing or to simply draw meaningless curves. The EEG was recorded from C3-Au1 derivation and approximately 150 pen down events triggered the averaging of 600 ms before to 600 ms after trigger.

Results:: In meaningful drawing a slow negative deflection preceded the pen down event peaking at -140ms followed by a sharp and large positive to negative component with peaks few millisecond before and after the pen down. Slower components followed until about +400ms. The maximum peak to peak amplitude ranged between 6 and 4 microV across subjects. In meaningless drawing amplitude of the components occurring before pen down was reduced by approximately 70%, with little change in latency. No significant change in amplitude was detected after pen down.

Conclusions:: Our recordings demonstrate that it is possible to detect cortical events occurring before, during and after an event triggered by fast, natural and complex movements like freehand drawing. Cortical activity occurring before movement was remarkably increased by saliency.
SPECTRAL ANALYSIS OF HEART RATE VARIABILITY IN HUMAN FEAR LEARNING

Simone Battaglia¹, Stefano Orsolini², Sara Borgomaneri¹, Riccardo Barbieri³, Stefano Diciotti², Giuseppe Di Pellegrino¹
¹University of Bologna, Department Of Psychology, Bologna, Italy, ²University of Bologna, Department Of Electrical, Electronic And Information Engineering, Bologna, Italy, ³Politecnico di Milano, Department Of Electronics, Information And Bioengineering, Milano, Italy

Background and Aims:: Understanding transient dynamics of autonomic control during emotional learning is crucial to translate basic research into the treatment of psychopathology. Fear learning typically elicits short-latency bradycardia in humans. Yet, standard analyses of heart rate variability (HRV) fail to disentangle the contribution of parasympathetic and sympathetic activation, and to capture phasic changes of HRV during fear learning.

Methods:: To this aim, 50 healthy participants (mean age = 24 years) underwent a fear conditioning and extinction protocol. Two novel approaches were used to perform a frequency-domain analysis of HRV: short-time Fourier transform and instantaneous spectral estimation. Specifically, we tested whether the spectral components of the HRV, used as a non-invasive biomarker of sympathetic and parasympathetic activity, are able to distinguish between fear conditioned and neutral stimuli.

Results:: We found that learned fear elicited a profound heart rate deceleration in anticipation of noxious stimuli. More importantly, results revealed significant increases in spectral power in the high-frequency (0.15–0.40 Hz) band, indicating a specific vagal contribution, which robustly and reliably distinguished conditioned from neutral stimuli during fear learning.

Conclusions:: These results provide unique evidence of the direct involvement of the parasympathetic (vagal) component of the autonomic nervous system during fear learning. These laboratory findings can be readily translated into the clinical field, thereby providing a novel and accessible tool to evaluate several psychopathological processes, and quantify deficits of Vagus nerve modulation of HRV during emotional responding in humans.
Motor unit potential analysis in myasthenia gravis disease

Moram Yassin, Ammar Ahmed, Afraa Musa
Faculty of medicine University of Khartoum, Physiology Department, Khartoum, Sudan

Background and Aims:: Motor unit action potential (MUAP) analysis is a test used to evaluate neuromuscular diseases (myopathy, neuropathy and neuromuscular junction disorders). Myasthenia gravis is an autoimmune disease affects neuromuscular junction that is diagnosed by clinical, pharmacological, serological and electrophysiological tests. This study was conducted to estimate parameters of MUAP analysis test in myasthenic patients based on our own control values.

Methods:: MUAP test was done in twenty healthy subjects and thirty-three myasthenic patients using concentric needle electrode. Four muscles were tested (extensor digitorum communis (EDC), tibialis anterior, frontalis and orbicularis oculi) muscles.

Results:: Comparison of MUAP analysis parameters (amplitude, duration, phases and turns) between control and myasthenic patients showed no significant differences regarding (EDC, Tibialis anterior and Frontalis) muscles, except Orbicularis oculi muscle which showed significant difference in amplitude and duration between control and myasthenic patients (p value <0.02).

Conclusions:: MUAP parameters of myasthenic patients exhibited normal values in most of the tested muscles.

Background and Aims:: Body Mass Index (BMI) is a measuring instrument in determining of a person's nutritional status. Obesity and Overweight are the risk factors for Carpal Tunnel Syndrome (CTS). This study was conducted to determine the relationship between BMI and the severity level of CTS at RSUP Dr. M. Djamil Padang Period 2017-2018

Methods:: This type of research is analytic with cross-sectional design. The sample of this study was CTS patients in the Neurology Department of Dr. RSUP M. Djamil Padang and Electromyography (EMG) examination with a sample size of 34. Sampling was done by total sampling technique based on inclusion and exclusion criteria. The instruments of this study were medical records and EMG results of CTS patients at RSUP Dr. M. Djamil Padang. Data was analyzed using the fisher’s exact test.

Results:: The majority of CTS patients were female (85.3%). The majority age group is 46-55 years (32.4%). Bilateral CTS is the most common symptom of CTS (85.3%). The BMI of CTS patients was found to be obese (38.2%) and normal (38.2%). Severe CTS (38.2%) is the most degree of severity found. Bivariate analysis showed the value of p = 0.03 (p <0.05), where there was a significant relationship BMI and the severity of CTS.

TRANSCALLOSAL MOTOR DISINHIBITION TO TRANSCRANIAL MAGNETIC STIMULATION IN DE NOVO PATIENTS WITH CELIAC DISEASE

Francesco Fisicaro¹, Giuseppe Lanza², Carmela D’Agate³, Raffaele Ferri⁴, Mariagiovanna Cantone⁵, Luca Falzone⁶, Giovanni Pennisi⁷, Rita Bella⁷, Manuela Pennisi⁸
¹University of Catania, Department Of Biomedical And Biotechnological Sciences, Catania, Italy, ²University of Catania, Department Of Surgery And Medical-surgery Specialties, Catania, Italy, ³University Hospital “Policlinico G.Rodolico-San Marco”, Gastroenterology And Endoscopy Unit, Catania, Italy, ⁴Oasi Research Institute-IRCCS, Department Of Neurology Ic, Troina, Italy, ⁵Sant’Elia Hospital, ASP Caltanissetta, Department Of Neurology, Caltanissetta, Italy, ⁶Istituto Nazionale Tumori-IRCCS “Fondazione G. Pascale”, Epidemiology And Biostatistics Unit, Napoli, Italy, ⁷University of Catania, Department Of Medical And Surgical Sciences And Advanced Technologies, Catania, Italy

Background and Aims:: Celiac disease (CD) may present or be complicated by neurological and neuropsychiatric manifestations. Transcranial magnetic stimulation (TMS) non-invasively probes brain excitability, even in preclinical stages. We previously demonstrated an intracortical motor disinhibition and hyperfacilitation in de novo CD patients, which revert back after long-term gluten-free diet (GFD). In the present study we explored the intercortical excitability by transcallosal inhibition, which has never been investigated in CD.

Methods:: 15 right-handed de novo CD patients and 15 age-matched healthy controls were screened for cognitive and depressive symptoms to the Montreal Cognitive Assessment (MoCA) and the 17-item Hamilton Depression Rating Scale (HDRS), respectively. TMS consisted of resting motor threshold, latency and amplitude of the motor evoked potentials, latency and duration of the contralateral silent period (cSP). Transcallosal inhibition was evaluated as onset latency and duration of the ipsilateral silent period (iSP).

Results:: Patients had worse MoCA and HDRS scores. cSP and iSP durations were also shorter in patients, with a positive correlation between MoCA score and iSP duration.

Conclusions:: An intra- and intercortical disinhibition was observed in neurologically asymptomatic CD patients, suggesting the involvement of GABA-mediated intracortical and callosal circuitries. Early diagnosis and prompt GFD are needed to prevent cognitive and mood changes in CD.
INTER-ELECTRODE DISTANCE INFLUENCES SUBTHALAMIC LOCAL FIELD POTENTIALS RECORDINGS IN PARKINSON’S DISEASE

Alberto Averna¹, Sara Marceglia², Mattia Arlotti³, Marco Locatelli⁴, Paolo Rampini⁴, Alberto Priori¹, Tommaso Bocci³
¹Università degli studi di Milano, Centro Di Ricerca “aldo Ravelli” Per Le Neurotecnologie E Le Terapie Neurologiche Sperimentali, Dipartimento Di Scienze Della Salute, Milano, Italy, ²University of Trieste, Department Of Engineering And Architecture, Trieste, Italy, ³Newronika s.r.l., Newronika S.r.l., Cologno Monzese, Italy, ⁴Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, U.o. Neurochirurgia, Milano, Italy

Background and Aims:: The study of subthalamic (STN) local field potentials (LFPs) led to significant advancement in the understanding of the pathophysiology of Parkinson’s disease (PD). PD is associated with pathological spectral power in the β band (11–30 Hz range), and it is also characterized by β phase-high frequency (200-500Hz) amplitude coupling (PAC). Although both β band spectral power and PAC correlate with PD severity, whether their changes are consistent with different electrodes geometry is still a matter of debate. This study aims to assess the spectral power and PAC of two LFP signals captured from both wide- and close-spaced contact pairs (i.e. 0-3 and 1-2) of the same DBS electrode within the STN, before and after Levodopa administration.

Methods:: LFP12 and LFP03 were recorded from 20 PD patients. We evaluated oscillatory power, PAC and correlation with motor symptoms (UPDRSIII) between close- and wide spaced electrodes.

Results:: Before Levodopa, both LFP03 and LFP12 power in the α band correlated with UPDRSIII. Whereas the low-β (12-20Hz) band did not differ between the two contacts, lower frequency bands had higher power in LFP03 than in LFP12. After Levodopa, a modulation of the low-β power and an increased β-LFO (15-45Hz) PAC was found only for LFP12.

Conclusions:: These results may be relevant for the implementation of better control strategies for adaptive Deep Brain Stimulation (aDBS). LFP12 can be used to detect β power (i.e. bradykinesia), while LFP03 are optimal for low frequency oscillations (dyskinesias).
EFFECTS OF NEURAL STEM CELL-DERIVED EXOSOMES ON HFD-DEPENDENT IMPAIRMENT OF BRAIN PLASTICITY: MOLECULAR AND FUNCTIONAL EVIDENCE

Background and Aims:: Adult neural stem cells (NSC) release extracellular vesicles (exo-NSC) contributing to intercellular communication and potentially capable to influence brain cell activity and modulate brain plasticity. High fat diet (HFD) in C57BL/6 mice is a well-established experimental model of obesity and insulin resistance, almost completely resembling the hallmarks of metabolic syndrome and cognitive decline identified in humans. We investigated whether administration of exo-NSC prevented alterations of hippocampal synaptic plasticity and adult neurogenesis induced by insulin resistance.

Methods:: C57BL/6 mice were fed with standard diet or HFD and intranasally treated with vehicle or exo-NSC for 6 weeks. NSCs were cultivated in vitro with a medium containing insulin and palmitic acid (IPA) for 3 days to mimic insulin resistance. Biochemical and imaging techniques have been used to analyze IPA, HFD and exo-NSC effects on NSCs in vitro and in vivo.

Results:: Our data demonstrated that intranasal administration of exo-NSC was able to deliver the vesicles into the hippocampus of mice and to restore the HFD-dependent proliferation/senescence unbalance of neurogenic niche. Chronic exo-NSC administration also prevented HFD-induced memory impairment. Interestingly, exo-NSCs appear to differently modulate intracellular signaling cascades in mature neurons and NSCs. In particular, exosomal cargo containing neurotrophic factors (e.g., BDNF) reactivated CREB-dependent expression of synaptic plasticity-related genes in differentiated neurons. In addition, exo-NSC restored insulin signaling and epigenetically regulated FoxO-dependent transcriptional activity in NSCs.

Conclusions:: Our findings highlight the role of extracellular vesicle cargo in the regulation of brain plasticity and provide evidence of the potential therapeutic effect of exo-NSC against metabolic disease-related cognitive deficits.
HIPPOCAMPAL ERK1/2 ACTIVATION CONTRIBUTE TO SEX DIFFERENCES IN RETROACTIVE INTERFERENCE.

Marco Rinaudo\textsuperscript{1}, Fabiola Paciello\textsuperscript{1}, Francesca Natale\textsuperscript{2}, Francesco La Greca\textsuperscript{1}, Domenica Li Puma\textsuperscript{1,2,3}, Salvatore Fusco\textsuperscript{3}, Claudio Grassi\textsuperscript{1,3}
\textsuperscript{1}Università Cattolica del Sacro Cuore, Department Of Neuroscience, Rome, Italy, \textsuperscript{2}A. Gemelli IRCCS, Fondazione Policlinico Universitario, Rome, Italy, \textsuperscript{3}Università Cattolica del Sacro Cuore, Neuroscience, Rome, Italy

\textbf{Background and Aims::} Memory removal is a physiological function and little is known about its molecular and cellular underpinnings. One mechanism for removing stored information from the brain is retroactive interference, a phenomenon in which newly acquired information overwrites or interferes with the retrieval of previously stored memories. In this work, we investigated the behavioural and molecular differences in a retroactive interference paradigm between male and female mice.

\textbf{Methods::} For the novel object recognition interference paradigm (NOR-Int), C57Bl/6 mice underwent a 5 minutes training session with a couple of objects. One hour prior to the test with one new object and one training object, animals were exposed to a different couple of objects unrelated to the training or test objects (interference session). For immunohistochemical and molecular experiments, animals were sacrificed at different time points post-interference and c-fos expression and ERK1/2 activatory phosphorylation were assessed.

\textbf{Results::} In the NOR-Int paradigm, female mice were able to discriminate the novel object while male mice showed impaired memory performance. Immunohistochemical analysis of c-fos expression showed a stronger activation of female dorsal dentate gyrus post-interference compared to males. Western blot analysis revealed a higher level of ERK1/2 activatory phosphorylation in the hippocampus of female mice compared to male mice post-interference. Finally, injection of an ERK1/2 inhibitor into the dorsal hippocampus of female mice prior to the interference procedure rendered females susceptible to the interference-mediated memory removal.

\textbf{Conclusions::} Collectively, our data suggest that hippocampal ERK1/2 activation contribute to a pattern separation mechanism which reduces object-related retroactive interference in female mice.
CLINICOEPIDEMIOLOGICAL AND ELECTROPHYSIOLOGICAL STUDY OF PERIPHERAL NEUROPATHY IN HIV-INFECTED PATIENTS

Bethasiwi Purbasari¹, Shahdevi Nandar Kurniawan²
¹Faculty of Medicine, University of Miyazaki, Basic Medical Science, Division Of Cardiovascular Physiology, Miyazaki, Japan, ²Universitas Brawijaya / Saiful Anwar General Hospital Malang, Indonesia, Neurology Department, Malang, Indonesia

Background and Aims:: Peripheral neuropathy (PN) is one of the most prevalent neurologic complications of HIV infection and frequently inadequately treated in resource-limited settings. Despite substantial improvements in the general health of HIV-infected patients throughout HAART, PN continues to be a crucial aspect of patients' morbidity due to its severe impact on their quality of life. More than two-thirds of HIV patients may have an abnormality in electrophysiology study before their symptoms occurred. Hence, understanding the abnormality in electrophysiology study in HIV patients and the association with risk factors and degree of PN is imperative. Aim: To identify risk factors for PN in HIV patients and examine electrophysiological abnormalities concerning disease severity.

Methods:: The study used a cross-sectional design and lasted around one year. The study enrolled patients seen in the outpatient department of an antiretroviral therapy (ART) center. Selected individuals were evaluated for peripheral neuropathy-related signs and symptoms and underwent electrophysiological examination.

Results:: There was a strong association between CD4 nadir, smoking, and comorbidity with toxoplasma, CMV, tuberculosis, and hepatitis infection in PN. The most prevalent pathogenic feature of neuropathy was mixed neuropathy (both axonal and demyelination). In addition, there was a significant correlation between the severity of peripheral neuropathy and the results of electrophysiological studies in the sensory and motoric median nerves, as well as the motoric ulnar, tibial, and peroneal nerves.

Conclusions:: Addressing risk factor may help to minimize the incidence of PN. In addition, early detection and prompt treatment of HIV may help slow the progression of nerve damage in HIV patients.
PHYSIOTHERAPY WITH DUAL-TASKS IMPROVES COGNITION IN PARKINSON’S DISEASE WITH POSTURAL INSTABILITY AND GAIT DISORDERS

Michela Leocadi¹,², Elisa Canu², Elisabetta Sarasso¹,², Andrea Gardoni¹,², Veronica Castelnovo¹,², Noemi Piramide¹,², Maria Antonietta Volontè³, Massimo Filippi¹,²,⁴, Federica Agosta¹,²,³
¹Vita-Salute San Raffaele University, N/a, Milan, Italy, ²IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Milan, Italy, ³IRCCS San Raffaele Scientific Institute, Neurology Unit, Milan, Italy, ⁴IRCCS San Raffaele Scientific Institute, Neurology Unit, Neurorehabilitation Unit And Neurophysiology Service, Milan, Italy

Background and Aims:: To assess cognitive changes following a 6-week training associated with dual-task gait/balance exercises in PD patients with postural instability and gait disorders (PD-PIGD).

Methods:: 25 PD-PIGD patients were randomized into 2 groups: i) action observation training (AOT) and motor imagery (MI)+DUAL-TASK group performed a 6-week (W6) training consisting of AOT-MI combined with practicing observed-imagined gait and balance exercises; ii) DUAL-TASK-group performed the same exercises combined with landscape-videos observation. At baseline, W6 and W14, patients underwent neurological, computerized cognitive and motor evaluations. 23 healthy controls underwent a neuropsychological assessment at the study entry only. Cognitive changes in patients were monitored with the CANTAB (Cambridge Neuropsychological Test Automated Battery). Cognitive changes at each time point in the overall PD-PIGD sample and between groups (AOT-MI + DUAL-TASK and DUAL-TASK) were assessed.

Results:: At baseline, no cognitive differences were found between the two PD-PIGD groups. However, both PD groups performed worse than healthy controls in several cognitive domains. Over time, both PD groups improved in terms of gait velocity and balance. Regarding cognitive changes, at W6 and W14, all PD patients improved in terms of accuracy and reaction times in tests assessing attention switching and visuospatial localization abilities. No differences were observed between groups over time.

Conclusions:: A physiotherapy approach associated with dual-task gait/balance exercises can improve cognitive performances in PD-PIGD patients that persist at long term. This improvement is evident in specific cognitive domains, which are usually affected in PD-PIGD and can interfere with their motor performances.
A RANDOMIZED CONTROLLED TRIAL COMBINING COMPUTERIZED COGNITIVE TRAINING AND TRANSCRANIAL DIRECT CURRENT STIMULATION IN THE EARLY STAGES OF COGNITIVE IMPAIRMENT

Sara Bottiroli¹,², Sara Bernini³, Silvia Panzarasa⁴, Silvana Quaglini⁴, Claudia Rodella³, Marta Picascia³, Elena Cavallini⁵, Tomaso Vecchi⁵, Cristina Tassorelli²,⁵
¹Giustino Fortunato University, Faculty Of Law, Benevento, Italy, ²IRCCS Mondino Foundation, Headache Science And Neurorehabilitation Centre, Pavia, Italy, ³IRCCS Mondino Foundation, Clinical Neuropsychology Unit, Pavia, Italy, ⁴University of Pavia, Dept. Of Electrical, Computer And Biomedical Engineering, Pavia, Italy, ⁵University of Pavia, Department Of Brain And Behavioral Sciences, Pavia, Italy

Background and Aims:: The prevalence of neurodegenerative diseases is expected to increase over the next years, therefore new methods able to prevent and delay cognitive decline are needed. The aim of this prospective double-blind 2-arm Randomized Controlled Trial was to evaluate the effectiveness of a combined treatment protocol associating an computerized cognitive training with anodal transcranial direct current stimulation (tDCS).

Methods:: Thirty-three patients (14 females; mean age = 74.18, SD = 5.59) in the early stage of cognitive impairment (i.e. with a diagnosis of aMCI or mild AD) were enrolled and randomly assigned to the experimental group (CoRe + real tDCS) or control group (CoRe + sham tDCS). All patients were evaluated with an exhaustive neuropsychological assessment before (T0) and after (T1) treatment. A post-treatment follow-up visit was scheduled 6 months (T2) after the end of the treatment. Treatment consisted in 12 individual sessions of about 45 minutes of cognitive training with multi-domain CoRe combined with online tDCS. Being adaptive, CoRe allows the possibility to generate different patient-tailored exercises.

Results:: We found that patients who received the real stimulation improved in working memory and attention/processing speed at both T1 and T2. Moreover, they reported a stable global cognitive functioning (MMSE) at T2, while patients in the control group worsened. In addition, age, mood, and initial cognitive functioning resulted to play a role in predicting treatment effects.

Conclusions:: Our findings confirm the importance of adopting a combined (i.e. cognitive training + tDCS) multi-domain intervention, as it may facilitate the development of compensatory mechanisms.
COMPARISON OF THE EFFECTIVENESS OF MOTOR AND COGNITIVE REHABILITATION ALONE COMPARED TO THE COMBINATION OF THE TWO IN PATIENTS WITH MULTIPLE SCLEROSIS

Ornella Argento, Chiara Piacentini, Andrea Santamato, Carlo Caltagirone, Vincenzo Saraceni, Ugo Nocentini

1IRCCS, Behavioural Neuropsychology Laboratory, Rome, Italy, 2Fondazione “Turati”, Rehabilitation Center, Foggia, Italy, 3S. Lucia Foundation IRCCS Rome, Neurorehabilitation, Rome, Italy, 4Fondazione "Turati", Rehabilitation Center, Pistoia, Italy, 5IRCCS “Santa Lucia” Foundation, Neurorehabilitation Unit, Rome, Italy

Background and Aims:: Motor and cognitive impairments (CI) are the main clinical features of Multiple Sclerosis (MS) with an incidence of around 85% for the former and 65 % for the latter. Aim of the present study was to compare three formats of cognitive and motor rehabilitation programs in order to understand which is the most efficient in reducing cognitive deficits in MS patients.

Methods:: A total of 48 patients were randomly assigned to one of the three rehabilitation conditions (two cognitive training/week-C1; one cognitive and one motor training/week-C2; two motor training/week-C3, for 12 weeks). All participants were submitted to a detailed neuropsychological and motor assessments before (T0) and after (T1) the treatment. The cognitive rehabilitation was focused on memory functioning and performed with Rehacom (http://www.emsmedical.net).

Results:: No significant differences in age, sex, education and disease course was found between the three conditions. In the C1 condition we found a decrease in the total cognitive impairment score. In C3 no statistical difference was found between T0 and T1 for any cognitive or motor variable. Conversely, patients in the C2 group showed an improvement in both gait and the 2 memory tasks.

Conclusions:: These preliminary data confirm that MS patients may benefit more from a combined approach (cognitive and motor) than from separate single training conditions (C1 and C2). Rehabilitation programs combining motor and cognitive treatments could give a stronger advantage in the improvement of cognitive impairment due to MS.
EFFECT OF EXTRACORPOREAL SHOCK WAVE THERAPY AND BOTULINUM TOXIN INJECTION ON NERVE REGENERATION IN EXPERIMENTALLY INDUCED SCIATIC NERVE INJURY RATS

Kiyeun Nam¹, Joonghyun Park²
¹Dongguk University College of Medicine, Goyang, Korea, Department Of Physical Medicine & Rehabilitation, Goyang-si, Gyeonggi-do, Korea, Republic of, ²Inje University College of Medicine, Department Of Neurology, seoul, Korea, Republic of

Background and Aims:: Extracorporeal shock wave therapy and Botulinum neurotoxin A have recently been studied as modalities for neural regeneration. The goal of this study is to investigate whether neural regeneration and functional recovery improved by using BoNT/A and ESWT as a non-surgical treatment.

Methods:: After crushing the sciatic nerve of 60 rats, intranerve delivery of BoNT/A or transcutaneous ESWT was applied. Two experimental groups and one control group were set up: the group 1(G1) received intranerve delivery of BoNT/A(15pg) and group 2(G2) received ESWT(400 impulses,4 Hz, 1 session). Both groups were treated immediately after nerve injury. A group 3(control, G3) received nerve injury only. Molecular biology and histological exams of the sacrificed rats were confirmed after 3, 6, and 10 weeks of experiment. The antibodies used were GFAP, GAP43, NF200, ATF3, S100 assessed by realtime PCR, Western blot, ELISA and Immunofluorescence. Neural regeneration of all rats was measured weekly by Sciatic Function Index(SFI) and nerve conduction study(NCS).

Results:: It was confirmed that G1 and G2 were more highly expressed in all five genes than in G3. In the NCS, G1 and G2 showed statistically significant differences compared to G3, and G1 showed the highest value. According to the SFI results, G1 and G2 improved gait pattern compared to G3 statistically significant at weeks 1, 2, 3 and 4.

Conclusions:: Collectively, these findings indicate that both ESWT and BoNT/A are helpful in neural regeneration and function improvement after peripheral nerve injury. And they are expected to be promising as the effective treatment modalities for neural regeneration.
"DEVELOPMENT OF VIDEOGAMES TO IMPROVE THE FUNCTIONALITY OF THE UPPER LIMB IN NEUROLOGICAL PATIENTS".

Mireya Burgos
Universidad Austral de Chile, Instituto Aparato Locomotor, Valdivia, Chile

Background and Aims:: Today, one of the challenges facing neurorehabilitation is that people who have suffered a neurological event can be completely independent in their daily life activities. One of the most frequent sequelae in these patients is the limitation of the movement of upper limb. The new technologies can improve functional independence. Objective: Develop a videogame to improve the functionality of the upper limb in the activity of feeding for adult and childhood neurological patients.

Methods:: A videogame was built that incorporates the movements required to put your hand to your mouth. The video game incorporates 9 mini-video games, which train different planes of movement with three levels of difficulty. To determine the reference values for the design of the video game, the reference values of normal range of motion and measurements of joint ranges obtained during the activity in neurological patients were used. A Kinect camera and the Unity web platform were used to capture movements. Finally, pilot tests were carried out with children and adults for the final version.

Results:: The videogame "My space travel" was developed, which allows the training of the affected upper limb in different planes of movement, considering the movement characteristics of people with neurological damage.

Conclusions:: The development of technologies in rehabilitation should consider not only the specific objectives that are to be achieved in this, but the population for which they are being designed, therefore, it is important that more and more rehabilitation professionals be involved in the design and elaboration of these.
Background and Aims:: Stroke is the leading cause of death, disability and hospitalization (> 65 years) in Chile. A large part of post-stroke patients remain with alterations of the upper limb, among them the involvement of property perception and sensitivity, which is why the need for the implementation of a specific program. Neurocognitive physiotherapy is a treatment little used in Chilean rehabilitation, which focuses on a sensory-motor reeducation to restore sensitivity and functionality. Objective: To determine the effectiveness of a neurocognitive physiotherapy intervention program in the sensitivity and functionality of the upper limb in patients with ACV in the subacute and chronic stage, belonging to the city of Valdivia.

Methods:: Quasi-experimental study with a study group, allocation for convenience, without masking. Eight participants were analyzed with LCA (med = 57.00, RIC [27-82].) The program was applied during 6 sessions of 45 minutes.

Results:: The neurocognitive intervention was able to obtain a significant difference in motor function (p = 0.01), sensitivity (p = 0.00), joint movement (p = 0.00). The rest of the variables did not show significant differences.

Conclusions:: Neurocognitive physiotherapy produces significant changes in upper limb function in acute and chronic stroke patients.
EFFICACY OF HIGH-INTENSITY LASER THERAPY ON MECHANICALLY INDUCED SCIATIC NERVE INJURY IN WISTER RATS.

Mohamed Alayat¹, Mohamed Basalamah², Wagih Elbarrany³, Naser El Sawy⁴, Ehab Abdel-Kafy¹
¹Umm Al-Qura University, Faculty of Applied Medical Science, Physiotherapy And Rehabilitation, Mecca, Saudi Arabia, ²Umm Al-Qura University, Faculty of Medicine, Department Of Pathology, Mecca, Saudi Arabia, ³Umm Al-Qura University, Faculty of Medicine, Anatomy And Embryology, Mecca, Saudi Arabia, ⁴Umm Al-Qura University, Faculty of Applied Medical Science, Laboratory Medicine, Mecca, Saudi Arabia

Background and Aims:: Background: Traumatic nerve injury (TNI) is a common source of motor disability. Early application of low-level laser therapy promotes the regeneration of nerves in TNI with a lack of evidence of high-intensity laser therapy (HILT) on nerve regeneration. Aim: The purpose of the study was to evaluate the efficacy of HILT in the treatment of mechanically induced sciatic nerve injury in Wister rats.

Methods:: A total of 60 male Wistar rats were randomized into three groups. Groups received no crushing-no laser, crushing without laser, and crushing plus HILT for control negative, control positive, HILT group respectively. At the thigh area, the left sciatic nerve was exposed, crushed, and received HILT (λ=1064 nm, 10.5 W, 20 Hz, 50 J/cm², 12 min.) five times/ week for three weeks. Gait and electrophysiological evaluations were measured weekly for three weeks by sciatic functional index (SFI), the amplitude of compound motor action potential (CMAP), and motor nerve conduction velocity (MNCV). The level of significance was set at p<0.05.

Results:: There were no significant effects of the measured variables after one week. After two weeks, there were significant increases in the amplitude of the CMAP and MNCV in the HILT group with non-significant changes in the control groups. A significant decrease in the SFI was observed after three weeks of HILT as compared to controls.

Conclusions:: HILT promotes the recovery of the sciatic nerve by increasing the amplitude of CMAP and MNCV and decreasing the SFI in mechanically induced sciatic nerve injury in Wister rats.
EFFECTS OF ISOMETRIC SCAPULAR EXERCISES ON THE SCAPULAR STABILITY IN PATIENTS WITH STROKE

Rabia Oz¹, Mehmet Duray², Nilufer Cetisli Korkmaz³  
¹Pamukkale University, School Of Physical Therapy And Rehabilitation, DENİZLİ, Turkey, ²Suleyman Demirel University, Faculty Of Health Sciences, Department Of Physiotherapy And Rehabilitation, Isparta, Turkey, ³Pamukkale University, School Of Physical Therapy And Rehabilitation, denizli, Turkey

Background and Aims:: Maintaining the scapular alignment and stability has a key role on upper extremity functionality in neurological disabilities. The aim of this study was to examine the effect of scapular exercises on the scapular stability in patients with stroke.  
Methods:: Patients (aged 50-85 years) with acute hemiparetic stroke were divided into two groups as control group and study group by simple randomization method. A physical therapist, who was blinded to which group they belonged, evaluated the participants before and after treatment. The exercises were applied by another physiotherapist. The patients in both group were treated with the exercise program according to the Bobath concept and isometric scapular exercises were applied to the study group in addition to these exercises. The evaluation instruments included measurement of scapular position.  
Results:: After 5 sessions, a significant improvement was found distance in protraction and distance between protraction and retraction at 90° of shoulder flexion, distance in protraction, retraction and distance between protraction and retraction at 90° of shoulder abduction within both groups and distance in protraction at 90° of shoulder flexion within only control group.  
Conclusions:: The increase in the ability of the scapula to contract isometric can also increase the quality of scapular movements by increasing the dynamic stability of the scapula.
EFFECT OF WHOLE-BODY VIBRATION ON FUNCTIONAL CAPACITY AND RESPIRATORY FUNCTIONS IN INDIVIDUALS WITH STROKE: A RANDOMIZED CONTROLLED STUDY

Mehmet Duray¹, Ugur Cavlak², Nilufer Cetisli Korkmaz³
¹Suleyman Demirel University, Faculty Of Health Sciences, Department Of Physiotherapy And Rehabilitation, Isparta, Turkey, ²Avrasya University, Faculty Of Health Sciences, Department Of Physiotherapy And Rehabilitation, TRABZON, Turkey, ³Pamukkale University, School Of Physical Therapy And Rehabilitation, DENİZLİ, Turkey

Background and Aims:: Decreased functional and pulmonary capacity are among the most frequently overlooked non-motor symptoms experienced in patients with stroke. The aim of this study was to determine the effects of 4-week whole body vibration (WBV) approach in addition to neurodevelopmental treatment (NDT) on functional capacity and respiratory functions in patients with stroke.

Methods:: Twenty-eight patients with stroke were divided into 2 groups as treated by NDT (control group) and NDT+WBV (intervention group). Patients’ pre and post-treatment results were evaluated with six-minute walking test (6MWT) for functional capacity, a microQuark® brand spirometer for respiratory volume and capacity, and chest circumference measurements for thoracic expansion ability.

Results:: The increase in walking distance and VO₂max levels in the NDT+WBV group were significantly higher than the NDT group (p<0.05). Both exercise approaches had a similar effect on both effort-related and non-effort-related developments in respiratory function’s flow and volume parameters, and chest circumference measurement results, except inspiratory capacity (p>0.05).

Conclusions:: Our results showed that the WBV applied in addition to NDT lead to gain more effective results for the treatment of the reduction in functional capacity and respiratory dysfunction observed in patients with stroke.
THE EFFECT OF WHOLE BODY VIBRATION ON SPASTICITY, DYNAMIC BALANCE AND SHOULDER PAIN IN PATIENTS WITH TAKAYASU ARTERITIS

Mehmet Duray¹, Nilufer Cetisli Korkmaz²
¹Suleyman Demirel University, Faculty Of Health Sciences, Department Of Physiotherapy And Rehabilitation, Isparta, Turkey, ²Pamukkale University, School Of Physical Therapy And Rehabilitation, DENİZLI, Turkey

Background and Aims: Takayasu arteritis is a chronic inflammatory arteritis which affects mainly the aorta and its major branches. Vascular, neurological, musculoskeletal, constitutional and cardiac problems can be seen related with Takayasu arteritis. The aim of this study was to evaluate the effectiveness of combined physical therapy (PT) and whole body vibration (WBV) on spasticity, dynamic balance and shoulder pain.

Methods: This case was a 55-year-old male who presented with balance impairment, shoulder pain, upper an lower extremity dysfunction. The patient completed 8 weeks of PT and WBV. After the recording demographic characteristic, baseline clinical measurements including Modified Ashworth Scale, Time up and go test and visual analog scale to assess the spasticity, dynamic balance and shoulder pain were applied to case, respectively. The assessments were repeated twice after the first and last session of treatment. Follow-up measurements will be performed in the third and sixth months after treatment.

Results: About 10% improvement on dynamic balance and more decreased spasticity degree of upper and lower extremity muscles was seen after the first episode of therapy than 8 weeks of treatment. After completing all sessions, the following changes were noted from baseline: 21% improvement on dynamic balance, 26% improvement on shoulder pain. Finger and wrist flexor and gastrocnemius muscles spasticity decreased from 3 to 2.

Conclusions: This case report suggests that combined of PT and TVV of Takayasu arteritis was effective in helping to improve dynamic balance and to decrease the spasticity, and shoulder pain.
SAFETY AND EFFICACY OF MLC601/MLC901 (NEUROAID) AMONGST PATIENTS WHO SUSTAIN SEVERE SPINAL CORD INJURY (SATURN STUDY)

Htwe Ohnmar¹, Ramesh Kumar², Azmi Baharudin³, Hisam Ariffin³, Muhindra Gsangaya⁴, Hezery Harun⁵, Khairrudin Kandar⁶, Maatharasi Balan⁴
¹Pusat Perubatan University Kebangsaan Malaysia, Rehabilitation Medicine Unit, Department Of Orthopaedic And Traumatology, Kuala Lumpur, Malaysia, ²University Kebangsaan Malaysia Medical Centre, Division Of Neurosurgery, Department Of Surgery, Kuala Lumpur, Malaysia, ³University Kebangsaan Malaysia, Department Of Orthopaedic And Traumatology, Kuala Lumpur, Malaysia, ⁴Hospital Serdang, Department Of Orthopaedics, Selangor, Malaysia, ⁵University Putra Malaysia, Department Of Orthopaedics, Selangor, Malaysia

Background and Aims:: Objective This pilot study aims to evaluate the safety and efficacy of MLC601/MLC901 among subjects with moderately-severe to severe SCI. Background Spinal cord injury has been considered an incurable condition and it often causes devastating sequelae. Hence the growing emphasis on the need for multimodal therapeutic approaches. MLC601/MLC901 (NeuroAid) are natural formulations demonstrated to enhance neurological recovery after injury and extensively studied in stroke and traumatic brain injury.

Methods:: Methods This prospective, phase I trial (ClinicalTrials.gov Identifier: NCT02537899) includes subjects with moderately-severe to severe SCI: American Spinal Injury Association (ASIA) Impairment Scale (AIS) grades A and B. Subjects received open-label MLC601/MLC901 for 6 months in addition to standard care and followed up for 24 months. Rates of adverse events, progression of neurological status (AIS) and functional outcome (SCIM), Short Form (SF-8) Health Survey were evaluated at month 1, 3, 6, 12, 18 and 24.

Results:: Results This analysis included 30 patients with the mean age of 42.2 years old, the median time from injury at 15.5 days, and median time to first dose at 16.5 days. The most common reasons for injury were Motor Vehicle Accident (MVA) (43.3%). SATURN met its primary endpoint of showing improvement in total motor score at 6 months compared to baseline (19.4 SD± 24.5, 95% CI, 9.1 to 29.7; P < 0.001). There were 4 patients (13.3%) who reported at least one adverse event.

Conclusions:: Conclusions MLC601/MLC901 shows remarkable promise as a safe adjunctive for aiding recovery in our cohort of subjects with moderately-severe to severe SCI.
MONITORING OF MOTOR DEFICITS DYNAMICS IN PATIENTS AFTER LUMBAR HERNIATED DISK REMOVAL.

Anton Shatokhin¹, Sergey Karpov¹, Sergey Bazhanov¹, Andrey Shatokhin¹, Irina Vyshlova², Alexey Kuzuberdin¹, Alexey Karpov¹

¹Stavropol state medical university, Neurology, Neurosurgery And Medical Genetics, Stavropol, Russian Federation, ²Stavropol state medical university, Neurology, Neurosurgery And Medical Genetics, Ставрополь, Russian Federation

Background and Aims:: According to the current literature, the neurological deficit after the removal of a disc herniation at the lumbar level in the postoperative period ranges from 22% to 39%. The aim. Objective evaluation of motor deficits in the distal lower extremities in patients operated on lumbar herniated disk using isokinetic dynamometry.

Methods:: Prospective study. In the period from 2018 to 2020, the results of surgical treatment of 66 patients with lumbar spine hernias with compression radiculopathy were analyzed. Men 34, women 32, average age 41.0+3.2 years. The strength and volume of the lower leg muscles were measured using the isokinetic dynamometer. The isokinetics, isometry in the concentric and the eccentric were evaluated, both in the affected limb and in the healthy one. The dynamics of the pic torque (PT) and the retention time of PT (TPT) were evaluated. The patients were examined before the operation, 14, 90 days after the operation.

Results:: Compression radiculopathy L5 was detected in 25 patients, S1– in 41. When assessing the muscle strength in the eccentric before surgery, the decrease in the concentric of the affected limb relative to the healthy one with the lesion of the L5 root was 41.7%, with the lesion of the S1 root-47.5%. Immediately after the operation, the strength in the lesion of m.tibialis anterior was restored- 84.9%, in the lesion of m. gastrocnemius to 81.7%.

Conclusions:: The use of isokinetic dynamometry is advisable in the objective assessment of muscle strength after the removal of root compression during the removal of a lumbar disc herniation.
THE EFFECTS OF NEUROREHABILITATION ON SEQUENCE EFFECT IN PARKINSON'S DISEASE PATIENTS WITH AND WITHOUT FREEZING OF GAIT

Michele Corrado, Roberto De Icco, Alessia Putorti, Marta Allena, Daniele Martinelli, Micol Avenali, Silvano Cristina, Gabriele Corrao, Valentina Grillo, Antonio Pisani, Cristina Tassorelli

1IRCCS Mondino Foundation - University of Pavia, Headache Science & Neurorehabilitation Center - Department Of Brain And Behavioral Sciences, Pavia, Italy, 2IRCCS Mondino Foundation, Headache Science And Neurorehabilitation Center, Pavia, Italy

Background and Aims:: Freezing of gait (FOG) represents a disabling symptom of Parkinson’s disease (PD). The sequence effect (SE), an amplitude reduction of repetitive movements, is a clinical feature of several tasks in PD. We studied the effects of an overground training rehabilitative program on SE in PD patients with and without FOG.

Methods:: Forty-three PD patients (30 males, 70.6±7.5 years old) were enrolled. The patients completed a 4-week in-hospital rehabilitation program, (6 sessions per week - 90 minutes each). At hospital admission (T0) and at the end of the rehabilitation (T1), the patients underwent instrumental gait analysis. SE was computed as a regression slope (β) of step length. The lengths of the last six steps ahead of the final stride were plotted against step number, and the linear regression slope (β) was calculated as a measure of SE.

Results:: Twenty-three patients were affected by FOG (PD-FOG: 19 males, 72.4±5.6 years) while the remaining 20 did not (PD-NO FOG: 11 males, 68.4±8.9 years). The SE was more negative in PD-FOG group (-0.80±0.6) when compared to PD-NO FOG group (-0.39±0.3) (p=0.007). The SE improved at the end of the rehabilitation period in the study population (T0: -0.63±0.5; T1: -0.23±0.4; factor TIME: p=0.001). A significant TIMExGROUP interaction (p=0.012) was consistent with a more pronounced improvement of SE in PD-FOG group when compared to PD-NO FOG group.

Conclusions:: SE is pronounced in PD patients affected by FOG. A 4-week rehabilitation positively modulated the SE in PD patients, specifically in the PD-FOG group.
Background and Aims:: There is a close connection between the central nervous system and the immune system. This balance can be impaired in the presence of severe brain damage, i.e. in case of stroke. The consequences of stroke on the balance between these two systems are cerebral inflammation and immunosuppression. The aim of this study is to verify whether lymphopenia may represent a negative prognostic index of functional recovery in the Neurorehabilitative setting.

Methods:: Fifty-six stroke patients (42 ischemic and 14 haemorrhagic), were enrolled. The patients completed a 8-week in-hospital rehabilitation program, (6 sessions per week; 90 minutes each). At hospital admission (T0) and at the end of the rehabilitation (T1), the patients underwent: neurological and functional physical evaluation examination, administration of clinical scales, and inertial gait analysis. In this study, 1500 lymphocytes/µl were used as cut-off for lymphopenia definition.

Results:: At T0, 17 patients (30.4%) had lymphopenia. At T0, they were older and more disabled than patients without lymphopenia. The percentage of infectious complications was significantly higher in the group with lymphopenia (58.8%) than in the group without lymphopenia (28.2%) (p=0.039). The presence/absence of lymphopenia was not a predictor of the effectiveness of the rehabilitation treatment, although outcome scores of patients without lymphopenia were still slightly better at hospital discharge (T1).

Conclusions:: In stroke patients, lymphopenia may represent a complication of the rehabilitative setting. Patients with lymphopenia were more disabled at hospital admission and discharge, even if the extent of improvement was comparable to non-lymphopenic patients. Lymphopenia was a strong predictor of infectious complications.
SUBACUTE PROGRESSIVE PARAPARESIS (FOIX-ALAJOUANINE SYNDROME) IN AN ELDERLY AFRICAN-AMERICAN MAN

Shri Mishra¹, Daniel Okobi², Shaweta Khosa¹
¹Olive View UCLA Medical Center, Department of Neurology, Sylmar, United States of America, ²UCLA, David Geffen School of Medicine, Neurology, Los Angeles, United States of America

Background and Aims:: First described in 1926 by Foix and Alajouanine, the Foix-Alajouanine syndrome is a rare congestive myelopathy typically arising secondary to dural arteriovenous (AV) fistulas, often of cryptogenic origin. We here present a case of the rare and overlooked Foix-Alajouanine syndrome.

Methods:: A 68-year-old African American male with past medical history of coronary artery disease, hypertension, hyperlipidemia, and diabetes presented with chief complaint of three months of urinary and fecal incontinence accompanied by slowly progressive left followed by right lower extremity weakness. The patient also reported new-onset low back pain with symptoms worse towards the end of the day.

Results:: Initial exam demonstrated diminished muscle bulk and weakness against resistance in both legs, left worse than right and distal worse than proximal. The sensory examination showed symmetric hyporeflexia in the legs. The Babinski sign was negative. Serum and CSF labs were normal, including various tests for other causes of myelopathy. MRI was notable for cord edema from T6 to the conus medullaris. A spinal angiogram revealed an epidural AV fistula at the left L3 radicular artery with marked venous congestion in neighboring levels. Because the lesion was not amenable to endovascular repair the patient underwent successful open repair one month later, followed by an extended rehabilitation course to regain ambulatory ability.

Conclusions:: This case demonstrates many typical features of Foix-Alajouanine syndrome. Generally subacute to chronic, there is a predilection towards males over 50. Open surgery is often necessary. Advanced myelopathy portends worse outcomes. Early detection and surgical repair are critical.
NEW OPPORTUNITIES FOR REHABILITATION OF COGNITIVE AND SPEECH DISORDERS IN PATIENTS WITH ISCHEMIC STROKE

Saule Turuspekova, Yerkyn Nurgujaev, Roza Nurzhanova, Elmira Atantaeva, Bayan Demesinova, Dmitry Mitrokhin
Asfendiyarov Kazakh National Medical University, Department Of Nervous Diseases With A Course Of Neurosurgery, Almaty, Kazakhstan

Background and Aims:: The provision of specialized psychological and speech therapy assistance contributes to a more effective rehabilitation of patients with Ischemic stroke (IS) Objective: to evaluate the effectiveness of articulatory logotherapy and ion-reflex phonophoresis with hypothalamic phospholipids in the rehabilitation of patients with IS in the early recovery period.

Methods:: 154 patients with cognitive and speech disorders on the background of IS at the age of 42-68 years were studied. Of these, 36 with motor aphasia, 15 sensory aphasia, 18 amnestic aphasia, 85 with dysarthria. The MMSE short scale, MoCA test, Barthel ADL index, Rivermead questionnaire were used. For the first time, we tested the Speech Impairment Scale (SPR) as a measure of effectiveness. 84 patients underwent a course of ion-reflex phonophoresis with hypothalamic phospholipids, longitudinal psychological fronto-occipital galvanization of the head, intrapersonal correction, a restorative integrative “I” image, articulatory gymnastics and articulatory massage. Control - 70 patients.

Results:: There was a positive dynamics of speech functions according to SRR data (48.8 ± 1.6 - 78.86 ± 1.5); control (48.6 ± 1.6 - 57.88 ± 1.6) dynamics of cognitive functions in the main group (20.13 ± 2.3 - 26.0 ± 2.3) - control (20.2 ± 2, 1 - 23.2 ± 2.1). The Barthel Index climbed 19 points and the Rivermead Index climbed 18 points.

Conclusions:: The articulation logotherapy and ion-reflex phonophoresis with hypothalamic phospholipids allows to can achieve effective rehabilitation in patients with IS in the early recovery period. The use of SPR showed the effectiveness of therapeutic methods in speech disorders.
IS THE INTELLIGENCEGYM AN EFFECTIVE TOOL TO IMPROVE COGNITIVE PERFORMANCE IN VASCULAR DEMENTIA?

Nina Trushkova¹, Olga Cochran¹, Natalia Ermolina², Giovanni Zelano³
¹Cognitive and Motor Education Center, Section Of Neurorehabilitation, London, United Kingdom, ²Astrakhan State University, Faculty Of Physical Training And Sports, Astrakhan, Russian Federation, ³Catholic University of Sacred Heart, Department Of Neuroscience, Roma, Italy

Background and Aims:: Several studies have shown that the capacity of working memory (WM) could be an indicator of performance in several other cognitive tasks: from simple attentional tasks to tasks requiring more compound capabilities. There are many cognitive training strategies, but none of them uses more different cognitive activities during the class. We hypothesized that by changing activities during the class we will have more efficacy to improve cognitive abilities including WM. This study investigated the effectiveness of WM training created by us (IntelligenceGym) to improve cognitive functions in older adults with mild vascular dementia (VaD).

Methods:: The study subjects were 108 VaD patients, 42 men and 66 women, with Mini-Mental State Examination (MMSE) scores of 19 to 23 at inclusion. All of them had initially reduced WM capacity level. We have created two groups: Dual-Task Group and IntelligenceGym Group, each 27 people. We proposed them to perform training one hour twice a week for 24 weeks. Cognitive performance was assessed before and after intervention included MMSE, Forward and Backward Digit Span Test, Rey’s Auditory Verbal Learning test (RAVLT), TMT-A, TMT-B.

Results:: The cognitive assessment showed statistically significant improvement in all two groups in all the scores tested (t-test performed). The results showed that participants of the IntelligenceGym Group had significantly higher performance in Backward Digit Span Test, RAVLT and TMT-B, than the Dual Task Group.

Conclusions:: Our findings indicate that the IntelligenceGym training is an efficient tool to improve cognitive performance in older adults with VaD.
INNOVATIVE MOTOR LEARNING TRAINING IMPROVES PARETIC ARM FUNCTION

Nina Trushkova¹, Olga Cochran¹, Natalia Ermolina², Giovanni Zelano³
¹Cognitive and Motor Education Center, Section Of Neurorehabilitation, London, United Kingdom, ²Astrakhan State University, Faculty Of Physical Training And Sports, Astrakhan, Russian Federation, ³Catholic University of Sacred Heart, Department Of Neuroscience, Roma, Italy

Background and Aims:: Several studies have shown that bilateral training in post stroke upper-limb rehabilitation is based on the premise that simultaneous movements of the nonparetic upper limb facilitate performance and recovery of paretic upper-limb function through neural coupling effects. We hypothesized that if we use not only bilateral arm movements but also coordinate and combine them with leg movements, both symmetrically and asymmetrically using motor learning tasks, then this could be the effective strategy for recovering the functionality and motor control of the paretic arm. The aim of the study was to evaluate efficacy of the Upper and Lower Limbs Coordination Training Strategy.

Methods:: Sixty-eight post-stroke (> 6 months) hemiparetic subjects (Brunnstrom recovery stage ≥ 3) were randomly divided into 2 groups: Upper and Lower Limbs Coordination (ULLC) training group (n=36) and Bilateral Upper Limb (BUL) training group (n=32). We proposed the 8-week intervention (5 sessions of 1 hour each, per week). Motor performance was assessed before and after intervention included the Fugl-Meyer assessment (FMA), the Wolf Motor Function Test (WMFT), Box and Block Test.

Results:: In both groups, the tests scores were significantly higher after the intervention, but the ULLC training group demonstrated greater improvement on the FMA test and the WMFT than the BUL training group. All assessments were executed by a blinded evaluator.

Conclusions:: The ULLC training strategy showed to be more effective than BUL training program in recovering the functionality and motor control of the paretic arm in post-stroke (> 6 months) hemi-paretic subjects.
CROSSFIT: A NEUROREHABILITATION PROPOSAL

Nolly Nataly Castañeda-Ibáñez
Corporación Universitaria Minuto de Dios - UNIMINUTO, Psychology, Bogotá, Colombia

Background and Aims:: CrossFit is a sport practice that generates a healthy and dynamic lifestyle based on functional movements, constantly varied and executed at a high intensity which contributes in multiple areas such as physical and mental health, allowing to potentiate well-being and the physical and mental functioning in relation to activities of the daily living. Objective: Design a rehabilitation program through the practice of CrossFit for people with mild cognitive impairment.

Methods:: A cross-sectional descriptive study, in order to know the neuropsychological functioning of those who do CrossFit and the benefits for those with mild cognitive impairment. Participants were 75 Adults, aged 18 and 60 living in Bogotá, Colombia. Healthy people, who have practice CrossFit for more than 3 months consecutively. A neuropsychological evaluation was required as baseline to know the possible cognitive functions who required attention, finding difficulties in the domain of executive functions (Table 1).

Note: The hierarchy of intervention according to the neuropsychological evaluation of the pilot study is based primarily on executive functions.

**Conclusions:** People who practice CrossFit at least 3 times a week for more than three months have noticed a favorable change in their health, helping to prevent problems caused by low rates of psychological well-being and quality of life, making this sports practice as a therapeutic alternative to physical and psychological problems related to mild cognitive impairment.
IS TRAINING WITH A FOCUS ON MOTOR LEARNING EFFECTIVE IN IMPROVING BODY COORDINATION IN CHRONIC POST STROKE PATIENTS?

Nina Trushkova¹, Olga Cochran¹, Natalia Ermolina², Giovanni Zelano³
¹Cognitive and Motor Education Center, Section Of Neurorehabilitation, London, United Kingdom, ²Astrakhan State University, Faculty Of Physical Training And Sports, Astrakhan, Russian Federation, ³Catholic University of Sacred Heart, Department Of Neuroscience, Roma, Italy

Background and Aims:: The central tenet in stroke rehabilitation is motor training which includes the interlimb coordination. Several studies robustly demonstrate that the learning of new motor skills is not abolished by stroke. Training of an unfamiliar skill task using either their hemiparetic or non-hemiparetic limbs represents a strategy to improve fine motor function in chronic stroke. We hypothesized that training with a focus on motor learning which includes coordination of all limbs, would be effective in improving motor coordination in patients.

Methods:: Fifty-six post-stroke subjects were recruited. Inclusion criteria: 1) age 40–70 years, 2) unilateral, first ever ischemic stroke more than 6 months before study enrollment, 3) mild to moderate hemiparesis with residual hand function sufficient for task performance, 4) sufficient cognitive function to comply with study requirements. We proposed the 8-week of the complex motor learning intervention (3 sessions of 1 hour each, per week). Motor and functional performance was assessed before and after intervention and included measures of independence in activities of daily living (ADL), the Fugl-Meyer Assessment (FMA), the Wolf Motor Function Test (WMFT), Box and Block Test.

Results:: The motor assessment showed statistically significant improvement in all participants in all the scores tested (t-test performed). The results showed that participants have had the greatest improvements on the FMA test (p < 0.011) and the ADL (p = 0.036).

Conclusions:: Our motor learning training is an effective tool in improving motor coordination and motor control in chronic stroke patients.
COGNITIVE TESTING IN INDIGENOUS POPULATIONS IN CAMEROON – CHALLENGES AND OPPORTUNITIES IN THE BAKA PYGMY AND MBORORO GROUPS

Wepnyu Yembe Njamnshi¹, Nicolas Ruffieux², Leonard Ngarka³, Joelle Chabwine², Claudio Straccia², Julius Fonsah¹, Helen-Marie Sani¹, Jean-Marie Annoni², Marie-Therese Obama¹, Alfred Njamnshi³, Helen-Marie Sani¹, Jean-Marie Annoni², Marie-Therese Obama¹, Alfred Njamnshi³
¹Brain Research Africa Initiative, Neuroscience Research, Yaounde, Cameroon, ²University of Fribourg, Neurosciences, Fribourg, Switzerland, ³c. Neurology Department, Central Hospital Yaoundé/Faculty of Medicine and Biomedical Sciences (FMBS), The University of Yaoundé I, Neurology, Yaoundé, Cameroon, ⁴d. Brain Research Africa Initiative (BRAIN), Yaoundé, Cameroon/Geneva, Switzerland, Administration, Bamenda, Cameroon

Background and Aims:: Cognitive testing is an important method of assessing brain function, in neurological disease. However, indigenous populations with cultural and educational specificities need adapted cognitive assessment tools. This project in the Baka and Mbororo ethnic groups, evaluated the feasibility of using selected cognitive tests from a normalized battery, compared their cognitive performance to urban counterparts and verified the effects of age, gender and education on cognitive performance

Methods:: From 3 indigenous villages in Cameroon, we carried out a community-based, cross-sectional study in 93 healthy children aged 6-16 years to assess fine motor skills and working memory/executive functions using a normalized neuropsychological battery. Demographic, clinical and cognitive data were collected in all participants.

Results:: The mean age was 10.62 years. We obtained descriptive data for cognitive performance per age group in indigenous populations. Large floor effects were observed in 40% of the normalized cognitive tests and thus were not feasible for use in these indigenous groups. Compared to urban children, indigenous children performed significantly better on fine motor assessment tests (p<0.001) and significantly lower on working memory/executive function tests (p<0.001). Applying multiple logistic regression, age and education significantly influenced neurocognitive performance (p<0.001), not gender.

Conclusions:: Our findings support the need for the adaptation of existing and/or development of new cognitive assessment tools integrating the educational, cultural and lifestyle specificities of indigenous groups in Cameroon. This will enhance brain research in these communities with limited access to healthcare and education.
IS LATEROPULSION REALLY RELATED WITH SPECIFIC LESION OF BRAIN?

Seong Hoon Lim¹, Kyoung Bo Lee², Bo Young Hong¹
¹St. Vinvent's Hospital, College of Medicine, The Catholic University of Korea, Rehabilitation Medicine, Suwon, Korea, Republic of, ²St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Rehabilitation Medicine, Suwon, Korea, Republic of

Background and Aims:: The lateropulsion (pusher syndrome) is an important barrier to standing and gait after stroke. Although several studies have attempted to elucidate the relationship between brain lesions and the lateropulsion, the effects of specific brain lesions on the development of lateropulsion remain unclear. Thus, the present study investigated the effects of stroke lesion location and size on lateropulsion in right-hemisphere stroke patients.

Methods:: The present retrospective cross-sectional observational study assessed 50 right-hemisphere stroke patients. The lateropulsion was diagnosed and evaluated using the Scale for Contraversive Pushing (SCP). Voxel-based lesion–symptom mapping (VLSM) analysis with 3T-MRI was used to identify the culprit lesion for SCP. We also performed VLSM controlling for lesion volume as a nuisance covariate, in a multivariate model that also controlled for other factors contributing to pusher behavior. VLSM, combined with statistical nonparametric mapping (SnPM), identified the specific region with SCP.

Results:: Lesion size was associated with lateropulsion. The precentral gyrus, postcentral gyrus, inferior frontal gyrus, insula, and sub-gyrual parietal lobe of the right hemisphere seemed to be associated with the lateropulsion, however, after adjusting for lesion volume as a nuisance covariate, no lesion areas were associated with the SCP scores.

Conclusions:: The size of the right hemisphere lesion was the only factor most strongly associated with lateropulsion in patients with stroke. These results may be useful for planning rehabilitation strategies of restoring vertical posture and understanding the pathophysiology of lateropulsion in stroke patients.
TRAUTMATIC AND ISCHEMIC SPINAL CORD INJURIES HAVE A COMPARABLE COURSE OF RECOVERY

Giorgio Scivoletto¹, Marcella Masciullo¹, Doris Maier², Floriana Pichiorri¹, Norbert Weidner³, Martin Schubert⁴, Ruediger Rupp⁵, Abel Rainer⁶, Yorck-Bernhard Kalke⁶, Jiri Kriz⁷, Marco Molinari¹, Armin Curt⁴

¹IRCCS Fondazione S. Lucia, Spinal Cord Unit, Rome, Italy, ²Berufsgenossenschaftliche Unfallklinik, Spinal Cord Unit, Murnau, Germany, ³Heidelberg University Hospital, Spinal Cord Injury Center, Heidelberg, Germany, ⁴University Hospital, Spinal Cord Injury Center, Zurich, Switzerland, ⁵Spinal Cord Injury Center, Spinal Cord Unit, Bayreuth, Germany, ⁶Orthopaedic Department Ulm University, Sci Centre, Ulm, Germany, ⁷University Hospital Motol, Spinal Cord Injury Center, Prague, Czech Republic

Background and Aims:: The relative rarity of ischemic compared with traumatic spinal cord injury limited comparison of the outcomes of these conditions. Objective. To investigate the neurological and functional recovery of ischemic compared with traumatic acute SCI.

Methods:: Data were derived from the European Multicenter Study Spinal Cord Injury database. Patients with ischemic (iSCI) or traumatic SCI (tSCI), 18 years or older were evaluated at different time points from lesion: 1 month, 3 months, 6 months. The neurological status was assessed at each point by the International Standards for Neurological Classification of Spinal Cord Injury and the functional status by the Spinal Cord Independence Measure. Walking ability was evaluated by Walking Index for Spinal Cord Injury, 10-Meter Walk Test, and 6-Minute Walk Test. Because of the imbalances of the 2 groups in respect to size and lesion severity, a matching procedure according to age, neurological level, and injury severity was performed. Outcomes evaluation was performed by means of a 2-way repeated-measures ANOVA.

Results:: The matching procedure resulted in 191 pairs. Both groups significantly improved from about 15 days after the lesion to 6 months. No differences were found in the course of neurological and functional recovery of iSCI compared with tSCI.

Conclusions:: This analysis from a representative cohort of participants revealed that from 15 days following the lesion, the outcomes after iSCI and tSCI are comparable. This finding supports the potential enrolment of patients with acute iSCI into clinical trials from that point in time after the event and an evaluation up to 6 months afterward.
IMPACT OF THE ONLINE COMPUTER GAME ON 18-24 YEARS OLD YOUNG PEOPLES' VISUAL SCANNING, ATTENTION AND MEMORY

Gokcen Akyurek, Irem Ulukaya
Hacettepe University Faculty of Health Sciences, Occupational Therapy, Ankara, Turkey

Background and Aims:: It is important to consider the potential benefits of games as much as their harms, because the nature of these games has changed dramatically over the last decade, becoming increasingly complex, diverse, realistic, and inherently social. The aim of this study is to compare the visual scanning, attention, and memory functions of young people between the ages of 18-24 according to their playing online computer games (First Person Shooter games).

Methods:: As the research group, fifty computer game players invited from the game site groups and as the control group, fifty participants who are similar age and gender with the research group were included in the study. Multitasking, Visual Search Task, and Corsi Block Test were applied to the participants. Analyzes were made using the Wisconsin test.

Results:: According to the analysis, it was found that there was a statistically significant difference between groups in the Visual Search Task (visual scanning) (p < 0.001). However, there was no statistically significant difference between the groups in Multitasking (attention) and Corsi Block Test (memory) (p > 0.05).

Conclusions:: As a result of this research, it was determined that playing online computer games (First Person Shooter games) has no effect on attention and memory, but on visual scanning. For this reason, it is important to examine this effect by using computer games in addition to the therapy to be applied for individuals with visual scanning problems.
WHAT IS DONE IS NOT ALWAYS WHAT SHOULD BE DONE: RESULTS OF AN ITALIAN SURVEY ON MANAGEMENT OF CRANIOPLASTY IN NEUROREHABILITATION

Fabio La Porta¹, Antonio De Tanti², Anna Estraneo³,⁴, Rita Formisano⁵
¹IRCCS Istituto delle Scienze Neurologiche di Bologna, Uo Medicina Riabilitativa E Neuroriabilitazione (sc), Bologna, Italy, ²S. Stefano Riabilitazione, Cardinal Ferrari Center, FONTANELLATO (PR), Italy, ³SM della Pietà General Hospital, Neurology Unit, nola, Italy, ⁴IRCCS Fondazione Don Carlo Gnocchi, -, Florence, Italy, ⁵IRCCS Santa Lucia Foundation, Post-coma Unit, ROME, Italy

Background and Aims:: Decompressive craniectomy (DC) is often performed in the acute phase of several acute severe Acquired Brain Injuries (sABI) conditions to control intracranial hypertension and reduce mortality. Cranioplasty (CP) is a neurosurgical procedure aiming to reconstruct the skull defect created by DC. While delayed DC may be associated with complications, there may be significant neurological improvements following CP. This work aims to take a snapshot of the management issues regarding DC/CP patients admitted to neurorehabilitation from the Italian Neuro-Rehabilitation Physicians’ (INRP) perspective.

Methods:: The Italian Neurorehabilitation Society Special Interest Group on sABI (SIRN-sABI-SIG) devised a simple questionnaire made of 21 questions. The first 16 explored INRP’s opinions in three main areas (clinical aspects, complications, clinical pathway), whereas the last five questions regarded epidemiological aspects. The survey was then distributed throughout the SIRN-sABI-SIG and other INRP’s mailing lists in April-May 2018.

Results:: The survey was responded to by thirty-eight neurorehabilitation centers, corresponding to 599 patients. Amongst these, the prevalences of DC, CP, and DC+CP were, respectively, 18.9%, 13.5%, and 32.4%. The analyses showed significant differences between INRP’s perceptions about DC/CP management compared to several recommendations of the 2018 International Consensus Conference for CP.

Conclusions:: DC/CP regards about one-third of neurorehabilitation patients in Italy. There is a substantial disagreement between the international recommendations regarding the neurosurgical management of DC/CP (what should be done) and the NPRI’s perception of what is done in practice. Future multicenter and trans-disciplinary prospective studies are warranted to explore and reconcile these controversies.
A FUNCTIONAL BIOMARKER FOR INTERMITTENT HYPOXIA-INDUCED WALKING RECOVERY IN PERSONS WITH CHRONIC SPINAL CORD INJURY

Randy Trumbower¹,², Chris Tuthill¹,², Stella Barth¹,²
¹Harvard Medical School, Physical Medicine And Rehabilitation, Boston, United States of America, ²Spaulding Rehabilitation Hospital, Physical Medicine & Rehabilitation, Charlestown, United States of America

Background and Aims:: Spinal cord injury (SCI) disrupts connections between the brain, spinal cord, and leg muscles, often causing lifelong walking deficits. Breathing modest bouts of low oxygen (acute intermittent hypoxia, AIH) is a promising strategy to elicit plasticity within spared motor pathways important for restoring walking after SCI. A prior study showed clinically meaningful improvements in walking speed occurred after a single session (D1) that persisted after daily (five consecutive days, D5) AIH in persons with chronic (>1 year), incomplete SCI. Despite the exciting finding, there remains considerable variability in patient responsiveness to AIH treatment. The purpose of this study is to examine the extent to which a single dose-response to AIH may predict long-term response to AIH in persons with SCI.

Methods:: We quantified the dose-dependent associations in walking speed improvements in 19 persons with chronic, motor-incomplete SCI. We computed odds ratios (OR) and 95% confidence intervals (CI) between D1, D5, and 2-weeks follow-up (F2).

Results:: A majority of participants (89.5%) who walked faster at D1 also walked faster at D5 and F2. 60.0±17.5% of participants responded at D1 and F2. Walking improvements at D1 persisted at F2 (OR=10.5; CI=1.1-96.6). The OR increased when associating gains at D5 and F2 (OR=12.0; CI=1.9-75.1).

Conclusions:: Daily AIH shows promise as a treatment to enhance walking function for many but not all persons with chronic, motor-incomplete SCI. Here, we found the early beneficial response to AIH treatment may serve as a functional biomarker for the long-term benefit of AIH treatment after SCI.
RTMS IN PATIENTS WITH ORGANIC AFFECTIVE DISORDER WITH COMORBID PARKINSON'S DISEASE

Simona Trifu¹, Antonia Vasile²
¹Carol Davila University of Medicine and Pharmacy, Clinical Neurosciences, Bucharest, Romania, ²Medical Military Institute, General Medicine, Bucharest, Romania

Background and Aims: Parkinson's disease, along with motor disorders, involves disorganized neural activity and association with organic affective disorder. Among the first studies performed with rTMS are those with implications in Parkinson's disease and major depression, the aim being the electrical activation of nerve cells and its correlation with increased blood flow in response to rTMS.

Methods: Explaining the results regarding the application of rTMS on 10 case studies that associated organic affective disorder with Parkinson's disease, both diagnoses being medically certified for at least 3 years. The application of rTMS was done 5 times a week in 35-minute sessions for 4 weeks. The measurement of the results was done comparatively by self and hetero-application, Hamilton scale versus Beck scale. In parallel, patients were treated with antidepressant and anti-Parkinson's medication.

Results: Stimulation was done in the left prefrontal cortex considered to be involved in depression. The initial increase in blood flow is followed by a longer period of decreased blood pressure, which stimulates certain functions (learning and memory) that are based on neural activity. Compared to the pharmacologically treated group, scores significantly improved on the motivation scales, self-esteem and subjective perception of quality of life. After 4 weeks, the rTMS group required lower doses of maintenance antidepressant medication.

Conclusions: The rapid change produced by the magnetic impulses that induce depolarization activates at the neuronal level causing the reorganization of the brain through axonal germination. The undamaged axons grow new terminations to fulfill their function.
THE USEFULNESS OF COGNITIVE TRAINING IN ORGANIC AMNESTIC SYNDROME (PATHOLOGY ASSOCIATED WITH ALCOHOLISM - EPILEPSY)

Simona Trifu¹, Arina Trifu², Ana Dragoi³
¹Carol Davila University of Medicine and Pharmacy, Clinical Neurosciences, Bucharest, Romania, ²Medical Military Institute, General Medicine, Bucharest, Romania, ³Alex. Obregia Clinical Hospital for Psychiatry, Psychiatry, Bucharest, Romania

Background and Aims:: We propose to present the results of a study conducted in the psychiatric clinic on a group of 30 patients diagnosed with chronic alcoholism, who in the first days of hospitalization presented epileptic seizures of grand mal type, later developing various psychiatric pathologies: delirium tremens in the following days, alcoholic psychoses with prolonged evolution, Wernicke Korsakoff type pathology, prolonged organic amnestic syndrome, organic personality disorder, organic affective disorders, mixed dementia (combined ethanolic background + epileptoid).

Methods:: Cerebral neuroimaging, withdrawal treatment, delirium treatment, antiepileptic treatment, neuroprotective, follow-up of GCS, gradual scale of adaptive disability, MMSE, neuropsychological evaluation tests in the area of mnesic prosexial functions and cognition, psychiatric treatment in reality and the retrieval of memories.

Results:: Of the 30 patients investigated, who had prolonged hospitalizations, the average being one month, only 7% developed complicated withdrawal with delirium tremens in the days following epileptic seizures. 75% of those in the study received a diagnosis of the disorder at discharge. organic personality disorder, a quarter of which also associate organic amnestic syndrome. Prolonged alcohol psychosis, which requires the combination of long-term antipsychotic medication, developed in 23% of patients, and in 57% were detected disorders specific to Wernicke Korsakoff syndrome. During hospitalization, a combined pharmacological approach and psychological tests of cognitive recovery were tried.

Conclusions:: Cognitive training related to psychiatric medication (Hasomed battery) ensures the reduction of damage in the area of early Korsakoff-type amnesia, as well as better protection in terms of prevention of prolonged amnestic syndromes or alcoholic psychoses post delirium tremens.
PSYCHIATRIC MORBIDITY AMONG THE PATIENT OF FIRST EVER ISCHAEMIC STROKE

Muhammad Sayed Inam
Sylhet MAG Osmani Medical College, Psychiatry, Sylhet, Bangladesh

Background and Aims:: Stroke is the most common cause of mortality worldwide and a serious cause of disability in the community. Stroke affects not only physical but also emotional, psychological, cognitive and social aspects of patients. Some of the neuropsychiatric disorders associated with stroke include post stroke depression (PSD), anxiety disorder, psychotic disorder. Aims and objectives: To evaluate psychiatric morbidity among the patients of first ever ischemic stroke.

Methods:: This cross sectional comparative study was carried out in the Department of Psychiatry, Sylhet MAG Osmani Medical College Hospital, Sylhet during the period from 1st July 2013 to 30th June 2014. Sixty six ischaemic stroke patients of first attack between 2 weeks to 2 years of stroke, aged above 18 years irrespective of sex and 66 accompanying healthy person of the patients and other patients without any kind of stroke matching age and sex fulfilling inclusion and exclusion criteria were taken in Group-A and Group-B respectively. Exclusion criteria were patients with transient ischaemic attack, haemorrhagic stroke, previous stroke, head injury, known psychiatric disorder, serious cognitive impairment and other chronic diseases that may cause psychiatric morbidity.

Results:: Co-morbid psychiatric disorder was found in 23 (34.8%) patients of ischaemic stroke and 9 (13.6%) control subject. The co-morbid psychiatric disorder was significantly higher in patients of ischaemic stroke than that of control subjects (p=0.004).

Conclusions:: Co-morbid psychiatric disorders are quite common among patients with first ever ischaemic stroke in the form of major depressive disorder and generalized anxiety disorder. Therefore, attention should be paid to the anxiety and depressive symptoms in stroke units.
EFFECTS OF PRIMING THERAPIES ON MOTOR IMPAIRMENTS AND IN CORTICAL EXCITABILITY ON STROKE SUBJECTS – SYSTEMATIC REVIEW

Hugo Santos, Isabel Baleia, Adeline Xavier, Daniela Branco, Joana Leal, Paulo Almeida
Alcoitão School of Health Sciences, Physiotherapy, Alcabideche, Portugal

Background and Aims:: Approximately 90% of the subjects with stroke have some type of functional limitation. Priming is an unconscious process associated with learning, in which previous exposure to one stimulus alters the response to another subsequent stimulus. When used successfully in conjunction with another therapeutic intervention, priming can result in a change in behaviour that appears to coincide with changes in neural networks. The aims of this study are to review and to analyse the effects of priming therapies on motor impairments and in cortical excitability on stroke subjects.

Methods:: A bibliographic search was carried out in the databases Pubmed, PEDro and CENTRAL. Only RCT whose intervention explicitly referred to the use of priming therapies, that were performed on subjects who suffered a stroke, were included.

Results:: After applying the eligibility criteria, 14 final studies were included. Of these, 4 used transcranial magnetic stimulation, 3 used transcranial direct current stimulation, 2 used imagery and action observation and 5 used motion-based priming as the main type of priming. Due to the clinical and methodological heterogeneity of the studies, it was not possible the realization of a meta-analysis.

Conclusions:: Of the studies which evaluate the effect of the priming motor recovery, 10 showed that priming associated with rehabilitation had significant improvements and 4 that there were no significant improvements between groups. This review was limited by the small sample of participants, a heterogeneity in methodological and clinical characteristics, only short-term conclusions and lack of consistency in the measured variables between all studies.
“EFFECTIVATE” DIGITAL COGNITIVE TRAINING: A THERAPEUTIC CANDIDATE FOR AGE-RELATED COGNITIVE DECLINE

Anna Izoutcheev, Yael Gilutz
Effectivate, Research And Development, Tel Aviv-Yafo, Israel

Background and Aims:: Even without reaching a pathological threshold, age-related cognitive decline may undermine wellbeing. As life expectancy increases, many individuals are in need of a solution for preserving cognitive abilities. While studies examining the effectiveness of computerized cognitive training showed mixed results, several recent meta-analysis studies concluded there are benefits in cognitive training. In order to address these unmet needs while building upon current findings, we developed "Effectivate", a computerized cognitive training program that focuses on attentional and memory functions. Our objective was to examine the influence of "Effectivate", a self-administered, commercial, cognitive training application, on older adults' attentional and memory functions.

Methods:: Data was collected from 275 "Effectivate" users at two time points, with an average of 52 days between baseline and post-training assessments. During that period, participants could perform one training a day, with a recommendation of 3 training sessions per week. Participants were then divided into 4 subgroups based on their median accumulated training duration and age. Attentional and memory functions were assessed in 4 tasks: processing speed, attentional control, object-location binding and working memory.

Results:: Processing speed task: we found an overall improvement in RTs, which was significantly higher for older participants. Attentional control: a significant Dosage by Assessment interaction was found. Object-location binding: an overall increase in accuracy was found under high visual load. Working memory: Older participants with below-median training dosage showed a decline, while the other subgroups showed no decline.

Conclusions:: These results suggest that the “Effectivate” protocol may support older adults’ cognitive state.
SENSORY-MOTOR AND COGNITIVE IMPROVEMENT BY REINTRODUCING POSTURAL AND BALANCE CONTROL FROM PARETIC BODY SEGMENTS IN STROKE AND TBI PATIENTS

Liisa Paavola¹, Mari Tynkkynen²
¹Oulu University Hospital, Department Of Neurology, OYS, Finland, ²Vasa Concept Global ry, Research Coordination, Savonlinna, Finland

Background and Aims:: Life after stroke is a key interest in neural rehabilitation. We need an integrating approach that combines the theoretical background of multidisciplinary rehabilitation sciences. Within this worldwide economic situation, every citizen need to give his social contribution to the common welfare. Our pilot study is based on Vasa Concept (VC), developed by Rajul Vasa. VC is a holistic approach to rehabilitate spasticity, motor deficiency, abnormal synergic grouping, subluxation of shoulder, aphasia and neuropsychological symptoms. In comparison with other methods (Beyaert et al., 2015), VC is based on the combination of physiological knowledge of the body functions to neuroscientific findings related to neuroplasticity and brain-derived behaviour. By reintroducing automatic control on local and global center of mass safety to paretic segments, the self-organized brain will recover. Physical and cognitive recovery emerges as by-product. Our aim is to describe in detail the rehabilitation of five patients with neurological symptoms. We also validate the most informative standardized tests for study of a larger patient sample. We will use the results for integrating the study protocol further. The follow-up study will include the evaluations of occupational-, speech-, physiotherapist and neuropsychologist.

Methods:: Standardized tests, measuring upper limb strength and function and balance were performed. Video analysis of motor pre-ambulatory skills and walking was also evaluated.

Results:: Results indicate that VC improves the recovery of motor performance. Significant changes were found in Berg balance test (mean change 4.8 p) and and Hand grip strength (mean change 4.31 kg).

Conclusions:: Pre-walking abilities should be noted more as a base of neurorehabilitation.
THE EFFECTIVENESS OF VIRTUAL REALITY IN THE NEUROREHABILITATION OF CHILDREN WITH HIV-ASSOCIATED NEUROCOGNITIVE DISORDER

Saida Saidkhodjaeva, Yakuthon Madjidova
Tashkent pediatric medical institute, Neurology, Tashkent, Uzbekistan

**Background and Aims:** The aim of the study was to evaluate the effectiveness of various neurorehabilitation programs, including the use of memantine hydrochloride and the virtual reality feedback method (NIRVANA) in children with HAND.

**Methods:** The study included 260 children with HIV-positive status and receiving highly active antiretroviral therapy (HAART) according to an individually selected scheme for at least 6 months. All the children included in the study showed signs of HAND. After the initial examination, all patients were divided into 4 groups: only HAART, HAART + memantine, HAART + NIRVANA and HAART + memantine + NIRVANA. The follow-up period was 3 months.

**Results:** In the groups of active neurorehabilitation, there were significant positive changes in the neurocognitive status. As a result, by the end of the 3rd month of follow-up in children taking memantine (HAART group+M and HAART +M+N) achieved a significantly lower IQ score compared to children who were only on HAART (p<0.001 for both comparisons). Also in children who received complex neurorehabilitation (HAART +M+N) by the end of the 3th month of observation, a significantly lower integral score of neurocognitive status assessment was achieved compared to children of the HAART group (p<0.05).

**Conclusions:** Thus, in the course of this study, it was found that children with HAND, despite the ongoing HAART, have a tendency to progress HAND. Children with HIV-associated dementia are most susceptible to progression. The use of active neurorehabilitation, especially a combination of memantine and virtual reality techniques, can significantly improve the indicators of neurocognitive status.
TREATMENT WITH A GAIT DEVICE USING TELEHEALTH DELIVERY IN STROKE SURVIVORS DURING THE CORONAVIRUS PANDEMIC

Brianne Darcy1, Lauren Rashford1, Tyler Shultz2, Nancey Tsai1, David Huizenga1, Stacy Bamberg1
1Moterum Technologies, Inc., Rehabilitation, Salt Lake City, United States of America, 2Wingate University, Doctor Of Physical Therapy Program, Wingate, United States of America

Background and Aims:: The coronavirus pandemic prompted healthcare providers to implement strategies to meet patient care needs remotely. This study investigates the feasibility of two adapted telehealth delivery models for remote gait treatment using a novel gait device in chronic stroke survivors.

Methods:: Participants included five individuals with chronic stroke (average age 72 years and 84 months post-stroke). Four of the participants had previously begun in-person treatment with the gait device but had their treatment interrupted by worsening pandemic conditions. These individuals transitioned to the telehealth delivery model to continue their gait treatment remotely. The fifth participant performed all activities (recruitment through follow-up) remotely. The telehealth treatment protocol included a virtual caregiver training session followed by three months of remote treatment with the gait device. To assess feasibility, we monitored safety, compliance, acceptability, and efficacy. Functional improvement was assessed using the 10-Meter Walk Test (10MWT), the Timed Up and Go (TUG) test, and the Six-Minute Walk Test (6MWT) after three months of remote treatment. Sensors were worn during all activities to monitor gait patterns and compliance.

Results:: No significant adverse events occurred and survey responses indicated a high level of acceptability for the remote treatment. Average improvement on the 10MWT, TUG, and 6MWT approached or surpassed twice the minimal clinically important difference or minimal detectable change value. Compliance neared 100% for treatment sessions and assessments.

Conclusions:: The feasibility of safe, remote treatment with the gait device appears promising and could be further evaluated by larger future studies.
EXPLORING THE OPINIONS OF PHYSICAL THERAPIST UNDERGRADUATE STUDENTS REGARDING APPLICABILITY OF TELEREHABILITATION IN STROKE SURVIVORS AND THEIR CAREGIVERS.

Ruchi Vispute, Nawaj Pathan
MGM School Of Physiotherapy, Aurangabad, Neurophysiotherapy, Auranagabad, India

Background and Aims:: Tele-rehabilitation (TeleRehab) is to facilitate rehabilitation procedures for patients suffering from neurological impairments. During this global pandemic, the majority of the Physiotherapists (PT) opted for the TeleRehab mode for their clients to consult and prescribe the protocols. The opinions of the therapists and applicability of TeleRehab in stroke and their primary caregivers have become essential.

Methods:: A qualitative study was designed using an online survey among PT Graduates. A brief structured and validated questionnaire was constructed and sent to PT graduates via What's app and mail.

Results:: The results stated that among n=22 participants, all the participants were familiar with this mode, and they were aware of this through their colleagues, research articles and various social media platforms. About 27% were unaware of its possible use in the Stroke population. A 90% agreed that there are benefits and uses of Tele-rehabilitation, but 81% also agree that this mode comes with several constraints and ethical issues. About 86% felt a prior training is required to use this mode. The major barriers were network connectivity, patient assessment and delivery of treatment.

Conclusions:: The majority of graduate PT noted, Telerehabilitation is a beneficial mode of rehabilitation and also appreciates its advantages and uses.
SARCOPENIA IN PATIENTS WITH NEUROLOGICAL DISORDERS

Maryna Bystrytska, Nataliia Grygorieva, Anna Musiienko
Dmitry F. Chebotarev Institute of Gerontology of the National Academy of Medical Sciences of Ukraine, Clinical Physiology And Pathology Of The Musculoskeletal System, Kyiv, Ukraine

**Background and Aims:** Muscular-skeletal disturbances are common in patients with neurological disorders (ND); however, the data about sarcopenia in they are insufficient. The aim was to determine the body composition particularity and sarcopenia frequency in patients with ND (Parkinson's disease (PD), stroke, and spinal cord injury (SCI)).

**Methods:** 410 subjects aged 23-79 years were included, being divided into two groups: the group of healthy subjects (group I, n=160) and a group of patients with ND (group II, n=250 (89 PD patients, 84 stroke patients, and 77 SCI subjects)). Body composition was measured using dual-energy X-ray absorptiometry. Sarcopenia was diagnosed according to the appendicular lean mass index (< 7.2 kg/m² for men and < 5.45 kg/m² for women).

**Results:** Sarcopenia had not been reported in PD patients. We did not find any significant differences in their lean mass index, however, the fat mass index in PD patients was probably lower – 18.4%. The lean mass was significantly lower in stroke patients than in group I, however, the fat mass did not differ significantly. The frequency of sarcopenia in stroke patients was 16.7%, among SCI subjects – 84.3% versus 6.5% in group I (p<0.0001), but their fat mass, on the contrary, was higher.

**Conclusions:** The study did not show common features of body composition for patients with neurological disorders. Sarcopenia is significantly more common in SCI persons and stroke patients, however, is not registered in subjects with PD. On the contrary, fat mass significantly lower in PD patients and higher in stroke and SCI subjects.
REPEETITIVE TRANSCRANIAL MAGNETIC CORTICAL STIMULATION FOR RESISTANCE DIABETIC NEUROPATHIC PAIN

Hussein Mousa, Sura Albaker
alsdr teaching hospital, Neurosurgery, basra, Iraq

Background and Aims:: No single treatment exists to prevent or reverse neuropathic changes or to provide total pain relief. Although medical treatment are useful, they produce a diversity of side effects and are occasionally ineffective. Repetitive transcranial magnetic stimulation (rTMS) safe, non-invasive and effective therapeutic opportunities for many neurogenic disorders. This study was designed to assess the efficacy rTMS for treatment resistance neuropathic pain (NP) in diabetic patients.

Methods:: forty six subjects had resistance NP, were divided equally real rTMS and sham rTMS. The NP level was scored on a visual analogue scale before and after a 20 sessions, each session had 20 minute 10 Hz rTMS over the side of the motor cortex corresponding to the on the painful side.

Results:: The percentage NP reduction was significantly greater real rTMS than sham rTMS, confirming that motor cortex rTMS was able to induce antalgic effects. These effects were significantly influenced by the origin and the site of pain. Across representation plasticity of cortical areas resulting from deafferentation could explain this discrepancy.

Conclusions:: Motor cortex rTMS achieved significant short-term pain relief of the NP.
HEMATOCRIT CHANGES DURING EARLY POST-STROKE REHABILITATION WITH ORAL HYDRATION AND WITHOUT

Lidjiya Maikut¹, Angelika Payenok¹, Marianna Yurchak²
¹Danylo Halytsky Lviv National Medical University, Department Of Neurology And Neurosurgery Fpge, Lviv, Ukraine, ²Municipal non-profit enterprise Lviv Clinical Emergency Hospital, Department Of Vascular And Minimally Invasive Neurosurgery And Neurology, Lviv, Ukraine

Background and Aims:: General blood test is the simplest and most accessible method of research, which provides sufficient information about the body. We aimed to find out if water consumption during the early rehabilitation stage can impact the blood hematocrit(HTC) level in patients with stroke.

Methods:: A total of 214 stroke patients were included, attending the early stage of rehabilitation program that consist of kinesitherapy and mechanotherapy daily. For each participant blood test was performed 15 minutes before and 10 minutes after session. The duration and intensity of physical activity were adjusted individually. During training 107 patients drank water and 107 did not.

Results:: We found differences between two groups. HTC level in water consumption group changed from 60.33% before exercise to 54.56% after, so it decreased by 5.77%. However, patients who did not drink water showed HTC increasing: 59.71% before exercise and 61.12%, therefore increased by 1.41%.

Conclusions:: Elevated hematocrit adversely affects the blood rheological properties, increasing the risk of thrombosis and recurrence of stroke. Therefore, drinking enough water is one of the key factors not only in rehabilitation improvement, but also in the prevention of unexpected complications.
MARCHIAFAVA-BIGNAMI DISEASE PRESENTING AS MIXED TRANSCORTICAL APHASIA.

Francesca Bartesaghi, Emma Scelzo, Chiara Rosci, Sara Sbaraini, Morena Tincani, Tommaso Bocci, Elisabetta Bernardi, Fabrizio Luiso, Alberto Priori

1III Clinical Neurology Unit, University of Milan, San Paolo University Hospital, ASST Santi Paolo e Carlo, Department Of Health Sciences, Milan, Italy, 2Neuroradiology Unit, ASST Santi Paolo e Carlo, Milan, Italy, Department Of Neuroradiology, Milan, Italy, 3“Aldo Ravelli” Center for Neurotechnolgy and Experimental Brain Therapeutics, University of Milan, Milan, Italy, Department Of Health Science, Milan, Italy

Background and Aims:: Marchiafava-Bignami disease (MBD) is a rare demyelinating and necrotic disorder of the corpus callosum, classically presenting with altered mental status. Increasing evidence shows that lesions can localize also in the subcortical white matter, presenting with focal symptoms and carrying a poorer prognosis. We describe the clinical and radiological findings of a patient with MBD presenting as mixed transcortical aphasia (MTA), remarkably improving after thiamine treatment.

Methods:: A 48-year-old male was admitted to our emergency department with clinical suspicion of stroke for the acute onset of aphasia. He had a 30-year history of alcohol abuse and recent poor feeding. He was slowed down on psychomotor level, confused, disoriented in time, space and on personal information. Neuropsychological evaluation revealed frontal lobe dysfunction and a marked language disturbance fitting the diagnosis of MTA. MRI showed marked diffusivity restriction in the corpus callosum, mainly in the splenium, and in the subcortical left fronto-parietal and occipito-temporal white matter, suggesting the diagnosis of MBD.

Results:: After treatment with high dose Thiamine we documented a definite improvement of his mental status and a partial regression of the callosal signal alteration, while aphasia persisted.

Conclusions:: To our knowledge, this is the first case of MBD presenting as MTA, a rare entity usually caused by infarctions that disconnect the left perisylvian area, thus sparing the arcuate fasciculum, Wernicke and Broca area. Focal symptoms at onset may sometimes delay the diagnosis of this treatable condition. We recommend considering MBD in the differential diagnosis of patients with malnutrition and alcoholism, independently from clinical presentation.
“CHASING THE DRAGON”: A RARE LEUKOENCEPHALOPATHY DUE TO HEROIN INHALATION TOXICITY

Federica Masuzzo¹, Davide Quartana¹, Sabrina Gasverde¹, Chiara Baima¹, Francesca Bisanti², Diego Maria Papurello¹
¹ASL TO 4 Cirié Hospital, Neurology, Cirié, Italy, ²ASLTO4 Chivasso Hospital, Chivasso, Italy, Radiology, Chivasso, Italy

Background and Aims:: Leukoencephalopathy due to heroin inhalation toxicity is a white matter disease, with an unclear aetiology, characterized by symmetric spongiform degeneration. The patients may progress through three defined clinical stages that could lead to death.

Methods:: Last year, in September, a 52 years-old patient with decreased level of consciousness and spastic quadriparesis occurred to our Emergency Department. Since her childhood she was drugs addict and few months before she required hospitalization for heroin abuse. She presented fever and she underwent an EEG (with interictal epileptiform discharges) and a lumbar puncture hypothesizing an encephalitic syndrome but chemical, bacteriological and virological exams were normal. A first CT scan was negative. Suspecting a catatonic state she was treated with high dose of Lorazepam without clinical results. During the hospitalization, she underwent a brain MRI that revealed symmetric hyperintensities on T2 weighted sequences involving cerebral white matter (particularly posteriorly), corticospinal tract and sparing of the subcortical white matter. We introduced baclofen, ubiquinone and vitamins supplement.

The patient’s condition slowly deteriorated because of vegetative seizures, treated with Lacosamide.
Results: For a month, she was aphasic and she layed in bed. After a long period of rehabilitation she walks with bilateral assistance and she pronounces simple sentences. At discharge time, she was still dysphagic and she needed a PEG (percutaneous endoscopic gastrostomy) to feed herself.

Conclusions: Although the heroin inhalation is not a frequent current practice, we should suspect toxic leukoencephalopathy when a “drugs addict” patient is admitted to the hospital for sudden decreased levels of consciousness.
B12 DEFICIENCY PRESENTING AS SENSORY NEURONOPATHY

Rishikesh Joshi, Santosh Sriram Andugulapati, Rahil Ansari, Sangeeta Ravat, Neeraj Jain, Piyush Anshu, Parag Maheshkar
SETH G.S MEDICAL COLLEGE AND KEM HOSPITAL, Neurology, Mumbai, India

Background and Aims: Vitamin B12 deficiency is a common but underdiagnosed condition and has protean manifestations affecting both central and peripheral nervous systems. Sensory ganglionopathy due to vitamin b12 deficiency is a seldom described but easily treatable condition which should be always be a part of the etiological differential diagnoses.

Methods: We describe 3 patients who presented with subacute onset of painful paresthesias over the feet followed by face, hands, with h/o wash basin ataxia, imbalance while walking. Clinical examination revealed impaired joint position, vibration, positive romberg’s test, asymmetric loss of pain, crude touch over hands and limbs, diffuse areflexia. 1st had knuckle hyperpigmentation, 2nd had familial premature greying of hair, 3rd was a daily alcohol abuser. Clinical diagnosis of sensory ataxia was made and evaluated.

Results: Investigations revealed raised MCV, low serum b12 levels, hyperhomocysteinemia. All 3 patients being omnivorous, search for etiology revealed positive Anti parietal cell antibodies in 2 patients. Electrophysiological study was s/o severe, asymmetrical, non length dependent sensory action potential attenuation with normal motor conduction parameters suggestive of possible sensory neuronopathy as per published diagnostic criteria. We ruled out classical causes of sensory neuronopathy. The patients received injection B12 and folate replacement. All patients showed remarkable improvement in both clinical and electrophysiological parameters at 3 month follow up.
Conclusions:: 50% of patients of sensory ganglionopathy are labelled idiopathic after evaluation of established causes. Vitamin B12 deficiency should be systematically ruled out even in omnivorous as this is an easily remediable & therapeutically rewarding cause of sensory neuronopathy.
RIBOFLAVIN IN NEUROLOGICAL DISEASES

Domenico Plantone¹, Matteo Pardini², Giuseppe Rinaldi¹
¹ASL Bari - Di Venere Teaching Hospital, Neurology Institute, Bari, Italy, ²University of Genova, Department Of Neurology, Genova, Italy

Background and Aims:: Accumulating evidence suggests that riboflavin has multiple effects on several cellular pathways, some of them relevant for mechanisms of neurodegeneration, shared by the main neurological diseases. In this review of the literature we analyze the therapeutic effects of riboflavin on the pathogenesis of different neurological diseases.

Methods:: To select the relevant literature for this narrative reviews the authors searched pubmed and google scholar databases as well as their personal article libraries using the following string: “Riboflavin” AND (“neurology” or “nervous system” or “myelin” or “brain” or “peripheral nervous system” or “neuropathology” or “deficiency”). Articles in languages different than English, published before the 1960s or reported only as abstracts were not considered suitable and were discarded.

Results:: Several successful trials testing riboflavin for migraine prevention were performed and this drug is currently classified as a Level B medication for migraine according to the American Academy of Neurology evidence-based rating. Brown-Vialletto-Van Laere syndrome and Fazio-Londe disease are now renamed as “riboflavin transporter deficiency”, because these are autosomal recessive diseases caused by mutations of SLC52A2 and SLC52A3 genes that encode riboflavin transporters. High doses of riboflavin represent the mainstay of the therapy of these diseases. Some mitochondrial diseases respond to supplementation with riboflavin. These include multiple acylCoA dehydrogenase deficiency (which is caused by ETFDH gene mutations in the majority of the cases), mutations of ACAD9 gene, mutations of AIFM1 gene, mutations of the NDUFV1 and NDUFV2 genes.

Conclusions:: Future studies need to elucidate whether and how riboflavin may be used as an add-on treatment in many neurological diseases.
CENTRAL PONTINE MYELINOLYSIS AS A CONSEQUENCE OF HYPEREMESIS GRAVIDARUM: A CASE REPORT.

Beatrice Labella¹, Marcello Giunta¹, Stefano Cotti Piccinelli², Giovanni Lodoli², Alberto Benussi¹, Alessandro Padovani¹
¹University of Brescia, Neurology Unit, Dept. Clinical And Experimental Sciences, Brescia, Italy, ²University of Brescia, Neuroradiology Unit, Dept. Diagnostic Imaging, Brescia, Italy

Background and Aims: Few cases of central pontine mielinolysis (CPM) are reported in the literature, mainly linked to hyperemesis gravidarum which may cause incorrect absorption of thiamine. In this report we described the case of CPM in a 17 weeks pregnant woman with hyperemesis gravidarum.

Methods: The patient underwent neurological examination which disclosed the hallmarks of a cerebellar syndrome (dysarthria, horizontal nystagmus, bilateral dysmetria, positive Romberg sign, abasia, gait disorder) and a paretic syndrome with mild piramidal signs (asymetric reflexes of lower limbs and inexhaustible Achilles clonus). No disturbaces in electrolytes were reported in previous routine pregnancy controls, whereas a severe recent weight loss merged. No history of alcol or drug abuse emerged.

Results: Initial laboratory tests showed moderate anemia and hypoglicaemia, without alteration of electronitical balance. Admitted with a CT scan showing central-pontine hypodensity, a subsequent brain MRI highlighted a pontine-centred focal signal alteration, hypointense in T1-weighted sequences, hyperintense in T2-weighted (FLAIR) sequences, with a diffusion restriction on diffusion-weighted images and increased ADC values. Radiological pattern matched features of CPM. According to the anamnestic and laboratory findings, a diagnosis of CMP due to Wernicke’s encephalopathy was made. Tiamine was administrated (500 mg/3 times/day for two days, then 250 mg/2 times/day) with an improvement of symptoms and neurological signs.

Conclusions: CPM in pregnancy is a rare but not negligible neurological complication, requiring a prompt intervention. While its occuring in isolation is not typical for Wernicke’s encephalopathy, this etiology should be taken into account in the differential diagnosis of suspected metabolic encephalopathy.
HEROIN INDUCED ACUTE MYELOPATHY, Rhabdomyolysis AND CHRONIC GLOBUS PALLIDUS ISCHEMIA: UNCOMMON COMPLICATIONS OF HEROIN ABUSE

Chulika Makawita1, Kasun Udenika1, Hasini Munasinghe2, Sudath Ravindra1, Bimsara Senanayake1
1National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka, 2National Hospital of Sri Lanka, Colombo, Clinical Neurophysiology, Colombo, Sri Lanka

Background and Aims:: Heroin or diacetylmorphine is widely consumed illegal opioid. Neurological manifestations of heroin include Spongiform lekoencephalopathy, ischemia, botulism, myelopathy, neuropathy and cerebral atrophy. Heroin myelopathy is a very rare manifestation seen in relation to first episode of heroin usage or following consumption after a period of abstinence. Neurovascular ischemia is the most common complication involving Globus pallidus, periventricular and subcortical regions. We describe a rare case of acute myelopathy, rhabdomyolysis and Globus pallidus ischemia in a chronic heroin user.

Methods:: A 41 year old Sri Lankan man presented with acute bilateral lower limb weakness, numbness and urinary retention followed by unconsciousness four hours after using inhaled heroin. He has consumed heroin after two years of abstinence. Examination revealed flaccid paraparesis with a sensory level at T7. Joint position senses were absent.

Results::

Haematology was abnormal with very high CPK (10431 U/L), hyponatremia (128 mmol/l), high creatinine (13.2 mg/dl) and positive urine myoglobin. MRI spine showed T2 FLAIR hyperintensities in cervical region involving anterior and central cord. There were T2 hypo intensities in Globus Pallidus with a central hyperintensity, mimicking a ‘tiger’s eye appearance’ along with contrast enhancement and blooming artifacts in SWI. T2 hyper intensities were noted in paraspinal muscles due to rhabdomyolysis. Heroin induced acute myelopathy was diagnosed along with rhabdomyolysis and kidney injury. Patient improved with hemodialysis and methylprednisolone pulse.
**Conclusions:**

Suggested mechanisms of acute heroin myelopathy include direct toxicity, hypersensitivity, vasculitis and hypotension. Globus Pallidus is the commonest brain structure to be affected in 5-10% of chronic heroin users.

---

**Figure 01:** T2, FLAIR hyperintensities in C2/3, C4/5 and C5/6 regions
Extra-pontine Osmotic Demyelination Syndrome and Membranous Nephropathy

Yousef Boobes¹, Fatima Alkindi², Noria Ghulam Nabi², Abdulla Al Kuwaiti³
¹Tawam Hospital, Nephrology, Al Ain, United Arab Emirates, ²Tawam Hospital, Internal Medicine Department, Al Ain, United Arab Emirates, ³Tawam Hospital, Neurology, Al Ain, United Arab Emirates

Background and Aims:: Rapid correction of hyponatremia can increase the risk of osmotic demyelination syndrome (ODS) involving the central pons and extrapontine (basal ganglia) brain areas. We described a patient who developed extrapontine ODS after rapid correction of profound hyponatremia in the setting of severe nephrotic syndrome (NS).

Methods:: Case Description:
A 45 years old male, previously healthy, presented with 8 days history of ataxia, slurred speech, vomiting and confusion. Laboratory showed severe electrolyte imbalances including profound symptomatic hypotonic hyponatremia of 96 mmol/l, hypokalemia (K : 2.1 mmol/l), with normal creatinine level and severe mixed alkalosis. He received hypertonic saline and fluids with rapid correction of hyponatremia to 124 within 24 hours. He also had hypoalbuminemia (10 g/l), massive proteinuria and mixed hyperlipidemia. Kidney biopsy revealed membranous nephropathy and secondary focal and segmental glomerulosclerosis with positive PLA2R-Ab. He was treated with Tacrolimus, prednisolone and atorvastatin. Two weeks later, he developed dysphagia, confusion and ataxia and MRI brain showed extra-pontine osmotic myelinosis. He required nasogastric tube for feeding and physiotherapy with gradual clinical improvement.

Results:: Discussion:
Conditions associated with increased risk of ODS include alcoholism, malnutrition, symptomatic hyponatremia below 105 mmol/l, liver disease and hypokalemia. The association of extrapontine myelinosis and nephrotic syndrome has been reported in a 6 years old girl. Our patient was diagnosed with primary membranous nephropathy and had other risks factors for developing ODS.

Conclusions:: Extrapontine myelinosis resulted from rapid correction of profound hyponatremia and hypokalemia. Severe nephrotic syndrome related to membranous nephropathy might be considered as a potential risk factor for ODS.
NON-ALCOHOLIC WERNICKE’S ENCEPHALOPATHY WITH ATYPICAL BRAIN MRI IN SETTING OF SEVERE SUBACUTE MALNUTRITION

Shri Mishra¹, Shaweta Khosa², Michael Connerney²
¹Olive View UCLA Medical Center, Department Of Neurology, Sylmar, United States of America, ²David Geffen School of Medicine UCLA, Department Of Neurology, Los Angeles, United States of America

Background and Aims:: Wernicke encephalopathy (WE) classically presents as encephalopathy, oculomotor dysfunction, and gait ataxia. WE usually occurs in the setting of chronic alcohol use and thiamine insufficiency. MRI imaging generally demonstrates edema of the periaqueductal region of the midbrain, mammillary bodies, and thalamus. Basal ganglia (BG) involvement, more commonly seen in pediatric WE, is classically thought to differentiate pediatric versus adult WE. However, we report a case of adult non-alcoholic WE with both thalamic and BG involvement.

Methods:: A 73-year-old woman with a past medical history of hypertension, diabetes mellitus, and unintentional 40 lbs weight loss presented with a chief complaint of acute onset double vision and gait instability. The patient underwent a recent esophagogastroduodenoscopy demonstrating a gastric mass leading to poor oral intake. The patient denied any alcohol use.

Results:: Neurologic examination was significant for bradyphrenia and bilateral ophthalmoplegia including inability to abduct with either eye as well as bilateral vertical nystagmus on upward gaze. Ataxic gait was noted. Laboratory examination showed low thiamine levels of 32nmol/L (ref 78-185nmol/L). MRI brain showed multifocal bilateral areas of old infarcts, diffusion restriction involving the bilateral medial thalami with abnormal FLAIR signal involving the basal ganglia bilaterally. Overall presentation was suggestive of atypical WE. Patient was treated with high-dose IV thiamine followed by oral supplementation.

Conclusions:: WE may present in cases of severe subacute malnutrition and poor absorption even in the absence of alcohol use. Although imaging with BG involvement is atypical in adults, this should not rule out WE if clinical presentation strongly suggests WE.
NEW PRESENTATION ON PILOCYSTIC ASTROCYTOMA (PA): A DISCUSSION FOR MECHANISMS OF DEATH

Omid Iravani, Ali Samanpour, Mohammadreza Nourian, Homa Ebrahimi
Legal Medicine Organization, Legal Medicine Research Center, Tehran, Iran

Background and Aims:: The most common causes of sudden unexpected death are cardiovascular diseases, followed by central nervous system (CNS), and respiratory and gastrointestinal diseases. Sudden death in persons with intracranial neoplasms is a rare mechanism of death detected in the forensic autopsies. Among the deaths due to intracranial neoplasms, sudden deaths due to polycystic astrocytoma (PA) are rarely reported in literature. In this case-report we discuss rare autopsy case of Pilocystic astrocytoma with unusual severe emaciation who was died from myocarditis.

Methods:: Full forensic examination of the body was performed with subsequent chemical and histological analysis.

Results:: Autopsy findings showed a small, solid cerebellar mass without any bleedings which was located on third ventricle brain and attached in choroid plexus. Histological diagnosis was PA, low-grade tumor. A slight accumulation of lipofushin pigments in the cytoplasm of myocytes, a focal chronic inflammatory cells infiltration predominantly lymphocytes with changes on degenerative on other myocytes were also seen in the heart.

Conclusions:: Rare cause of profound emaciation is tumores affecting the diencephalon. The clinical presentation may differ, depending on the location of the lesion and age of the patient. We hypothesize that PA induce generalized cachetic in a paraneoplastic fashion either by formation of antiadipocyte autoantibodies. In addition of, there is an unknown way to starting of myocarditis. We conclude that the diagnosis of brain tumor should be considered in young children presenting with generalized and severe unexplained cachexia with or without metabolic abnormalities. Forensic pathologists must keep in mind that sudden unexpected death caused by intracranial meningiomas, although extremely rare, may be encountered in the forensic setting.
PARKINSONISM AND CORTICOSPINAL TRACTS INVOLVEMENT IN HEPATIC ENCEPHALOPATHY

Lucia Manzo\textsuperscript{1}, Maurizio Morelli\textsuperscript{1}, Angelo Pascarella\textsuperscript{1}, Mariilisa Pasquale\textsuperscript{1}, Pietro Bruno\textsuperscript{1}, Paola Valentino\textsuperscript{1}, Ludovico Abenavoli\textsuperscript{2}, Antonio Gambardella\textsuperscript{1}, Stefania Barone\textsuperscript{1}
\textsuperscript{1}“Magna Graecia” University, Institute Of Neurology, Catanzaro, Italy, \textsuperscript{2}“Magna Graecia” University, Department Of Health Sciences, Catanzaro, Italy

Background and Aims:: Hepatic encephalopathy (HE) is characterized by cognitive, psychomotor and psychiatric symptoms due to liver failure and/or portal-systemic blood-shunting. Pathophysiology of HE is multifactorial, partially caused by brain accumulation of ammonia and other metabolites. Manganese is thought to be responsible of development of parkinsonism with typical bilateral symmetric T1-hyperintensity of basal ganglia at brain MRI. Moreover, T1-signal changes of white matter had been reported, but its clinical relevance is still debated.

Methods:: A 67-year-old male with exotossic cirrhosis, resolved HBV infection and history of HE in hyperammonemia developed acute lethargy, amnesia, disorientation in time and space and dysarthria since about 48 hours. Neurological examination showed diffuse hypo-elicitable reflexes, asterixis, postural and telekinetic tremor, dysmetria and mild rigidity at both upper limbs. He underwent blood analysis, EEG and brain MRI.

Results:: Ammonia was 97 μmol/l (normal range 21-50 μmol/l). EEG was unremarkable, while brain MRI showed bilateral T1-hyperintensity of substantia nigra, globus pallidus, posterior limb of internal capsules and corticospinal tracts. Diagnosis of HE was made. Treatment with hydration, branched-chain polyaminoacids, lactulose and rifaximin induced cognitive and motor improvement.

Conclusions:: Manganese accumulation in basal ganglia with development of parkinsonism in HE patients is well known. Manganese acts as neuronal MRI contrast agent: its ion (Mn\textsuperscript{2+}) is taken-up into intracellular space and diffuses throughout cytoplasm and axons transported by microtubules. Our findings of corticospinal tracts T1-hyperintensity could suggest manganese deposition in these structures too, even if no pyramidal sign was evident. Surely, this condition deserves a longer follow-up to detect potential long-term effects.
WERNICKE ENCEPHALOPATHY SECONDARY TO HYPEREMESIS GRAVIDARUM: THIRD LEVEL HOSPITAL EXPERIENCE

Khadija Saghir, Yahya Naji, Hasna Bentaher, Lamya Aballa, Nissrine Louhab, Najib Kissani, Mohamed Chraa
Neuroscience Research laboratory of Marrakech Medical School, University Hospital Mohammed VI, Neurology Department, Marrakech, Morocco

Background and Aims:: Vitamin B1 (thiamine) deficiency causes an acute neurological condition known as Wernicke encephalopathy (WE). In the developed world, WE is usually secondary to alcoholism. In some cases it may be secondary to hyperemesis gravidarum (HEG). In this paper, we report 5 cases of Wernicke’s encephalopathy secondary to hyperemesis gravidarum. Our aim is to highlight the importance of thiamine supplementation in cases of prolonged vomiting during pregnancy.

Methods:: We collected retrospectively the observations of all patients with Wernicke encephalopathy (WE) hospitalized in the Department of Neurology (Mohammed VI university hospital, Marrakech) during a period of 2 years (between September 2018 and September 2020). Each patient had benefited from magnetic resonance imaging of the brain (MRI) with venography, vitamin B1 screening was unavailable.

Results:: We found 5 cases of WE secondary to HEG, two of the five women were primi-gravidae, the mean age was 25.8 years. all the five women were non-alcoholic. One patient had hypothyroidism and had developed WE in her previous pregnancy, another one had depression. All the five patients had developed intractable vomiting early on in the first trimester. They all had a decreased level of consciousness, ataxia with concomitant dry beriberi.

Conclusions:: In countries, where religion forbids the consumption of alcohol, hyperemesis gravidarum (HG) may be the main cause of thiamine deficiency, consequently leading to WE. It is important to consider thiamine supplementation in cases of hyperemesis gravidarum or prolonged vomiting in pregnancy. A timely diagnosis of WE in pregnancy is important and its prevention in subsequent pregnancies is mandatory.
ANALYSIS OF THE TROPHIC STATUS OF PATIENTS WITH CORONAVIRUS DISEASE COMPLICATED BY CAVERNOUS SINUS THROMBOSIS.

Akmal Kholmuratov¹, Dilnoza Bobamuratova², Yokubjon Kurbanov²
¹Tashkent medical academy, Neurology, Tashkent, Uzbekistan, ²Tashkent Medical Academy, Otolaringology & Stomatology, Tashkent, Uzbekistan

Background and Aims:: It is known that Covid-19 disease is severe in obese and elderly people. The study once again proves the high risk of complications in these patients. Identification of risk factors based on an assessment of the trophic status of patients complicated by cavernous sinus thrombosis.

Methods:: In the multidisciplinary clinic of the Tashkent Medical Academy, in 36 patients with Postcovid syndrome complicated by thrombosis of the cavernous sinus. The average age of the patients was 60 ± 8 years, of which 26 women (57.8%) and 19 men (42.2%). All patients underwent an bioimpedancometry (Tanita BS-585, Japan)

Results:: Deviations from the ideal body weight were found in 87% of cases, body weight deficiency was noted in 14% of patients, an increase in adipose tissue mass in 73% of patients. The average values of the indicator of total and visceral fat mass were 23% higher than their characteristic physiological norm, lack of muscle mass from 13-25 kg was revealed. The total percentage of water in the body varied from 35 to 65%, since in overweight patients below normal - 42.2 ± 2.12 (p≤0.01). The calculated indicator of basal metabolism on average corresponded to 1 995.1 ± 50.34 kcal, which is 18% lower than the required value, but indicates a reduced physical activity

Conclusions:: According to bioimpedancemetric analyzes, the deviation of many indicators of the composition components of the body was interpreted, as it means a violation of the physical, metabolic status. Such patients have a high risk of complications, unfavorable outcome of the underlying disease.
CONCOMITANT HIGH OXIDATIVE STRESS AND POOR ANTIOXIDANT ENZYME ACTIVITY WITH DNA DAMAGE MAY UNDERLIE OBESITY AND REDUCED LONGEVITY IN WNIN/OB OBESE RATS

Jitendra Kumar Sinha1, Shampa Ghosh2, Manchala Raghunath2
1Amity University UP, Amity Institute Of Neuropsychology And Neurosciences, NOIDA, India, 2National Institute of Nutrition, Icmr, Hyderabad, India

Background and Aims:: Disequilibrium between the production of reactive oxygen and ability of an organism to readily detoxify the reactive intermediates or easily repair the resulting damage is termed as oxidative stress (OS). OS is believed to be involved in development of various pathologies like Alzheimer’s disease, cancer, accelerated aging and many others. On the other hand, OS itself arises from medical conditions like obesity. Wistar of National Institute of Nutrition Obese (WNIN/Ob) obese rats are the novel rat models presenting a link between obesity and ageing.

Methods:: We evaluated the oxidative stress parameters, C-reactive protein levels, DNA damage status and astroglial infiltration in the different brain regions.

Results:: Our studies clearly show the progression of OS and accumulation of DNA damage in brain at an early age causing accelerated aging in these rat models. Imbalance in the levels of trophic factors IGF1 and BDNF, both in plasma and brain, implies altered signaling which in turn leads to hyperphagic behavior and stress. The increased C-reactive protein levels and astroglial infiltration further give clues regarding increased cellular stress and damage in important brain areas like hypothalamus, hippocampus and cerebral cortex.

Conclusions:: Here the link between obesity and brain aging has been proposed with future directions of research. Ethical Statement: This study was performed in accordance with the protocols duly approved by the institutional animal ethical committee. Source of funding: Indian Council of Medical Research, New Delhi.
Background and Aims:: The neurological manifestations of celiac disease (CD) are rare, polymorphic and often severe. They can inaugurate the disease in 9.4% of CD. Our Aim is to illustrate this polymorphism via a case report and to approve that The gluten-free only improves peripheral lesions in the majority of cases while the central-lesions progress on their own.

Methods:: We present the case of a patient with CD and followed for mixed involvement of the central and peripheral nervous system.

Results:: Our patient is 55 years old, with CD, discovered 20 years ago, on a gluten-free diet badly observed. She presented with gait instability that is progressively worsening since 3 years. Neurological examination showed a static and kinetic cerebellar syndrome, a posterior cord syndrome and bone tendon reflexes abolished in the 2 lower limbs. The cytochemical analysis of the cerebrospinal fluid was normal. Absence of an oligoclonal band in the CSF. Thyroid analysis as well as the dosage of vitamins B12 and B1 were normal. The immunological analysis was negative (ANA, anti-intrinsic factor and anti-parietal cell antibodies). VS = 10, Electromyogram: sensory axonal neuropathy. Cerebral and spinal MRI showed a right temporal hypersignal, diffuse pontic and cerebellar atrophy. The patient was put on vitamin therapy in combination with a well-managed Gluten-free diet. We note only the amelioration of her neuropathy after 3 months with regular diet.
Conclusions: Cerebellar ataxia and peripheral axonal-sensory-neuropathy are the common neurological damage in CD. Cerebellar atrophy was proportional to the disease progression. The diagnosis should only be made after ruling out other differential-diagnoses.
A 60 DEGREE CELCIUS OF GASSERIAN GANGLION ABLATION WITH IMPROVEMENT ON PSORIASIS PATIENT WITH TRIGEMINAL NEURALGIA: A CASE REPORT

Rina Astuti¹, Yani Arlina², Savitri Shitarukmi³
¹Faculty of Medicine Diponegoro University/ Dr. Kariadi Hospital Semarang, Dept Of Neurology, Pain And Minimally Invasive, Semarang, Indonesia, ²Diponegoro Univ/ Dr. Kariadi Hospital Semarang, Department Of Neurology, Semarang, Indonesia, ³Faculty of Medicine Gadjahmada University, Department Of Medical And Bioethic Education, Faculty Of Medicine, Public Health And Nursing, yogyakarta, Indonesia

Background and Aims:: Scalp psoriasis is a chronic disease found in 45% to 58% of patients, while neuropathic symptoms are found in 26% to 56.3%. TN requires long-term treatment, and RFA is a treatment with satisfying improvement.

Methods:: A male, 39 years old, with right hemifacial pain (NRS 6-8) for 3 weeks, that corresponded to all branches of the trigeminal nerve. No head-face trauma was experienced, and since 2008 suffered from scalp-psoriasis. Brain MRI observed normally, while 3D Fiesta with right SCA and TN contacted (3.5 mm from the entry zone). Carbamazepine 600 mg and amitryptiline 25 mg were prescribed without improvement. Insertion of a 15 mm RF insulated needle was placed in Meckel's cavity after the local anesthetic, a single cycle of 60° C and 90 seconds is set after branches are confirmed together. A 0.2 mL of 10 mg triamcinolone injected gently before pulling out.

Results:: Clinical improvement on week 2 (NRS 2-3), and week 16 (NRS 0-1). Pain and itch are sensed by C-fibers of the DRG and trigeminal ganglion. Psoriasis might increase SP and CGRP, so lead to central trigeminal ganglion and peripheral sensitization.

GENETIC STUDY OF ITALIAN FAMILIES AFFECTED BY SMALL FIBRE NEUROPATHY IDENTIFIED VARIANTS IN PREDISPOSING PAIN PHENOTYPE

Kaalindi Misra, Silvia Santoro, Andrea Zauli, Margherita Marchi, Erika Salvi, Raffaella Lombardi, Daniele Cazzato, Filippo Martinelli Boneschi, Massimo Filippi, Federica Esposito, Giuseppe Lauria

1IRCCS San Raffaele Scientific Institute, Laboratory Of Human Genetics Of Neurological Disorders, Milan, Italy, 2Foundation IRCCS Carlo Besta Neurological Institute, Neurology Unit, Milan, Italy, 3Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Dino Ferrari Centre, Neuroscience Section, Department Of Pathophysiology And Transplantation, University Of Milan, Milan, Italy, 4University of Milan, Department Of Biomedical Sciences For Health, Milan, Italy, 5Vita-Salute San Raffaele University, Na, Milan, Italy, 6IRCCS San Raffaele Scientific Institute, Neurology Unit, Neurorhabilitation Unit And Neurophysiology Service, Milan, Italy, 7IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Institute Of Experimental Neurology, Division Of Neuroscience, Milan, Italy, 8IRCCS San Raffaele Scientific Institute, Neurophysiology Unit, Milan, Italy, 9University of Milan, Department Of Biomedical And Clinical Sciences “luigi Sacco”,, Milan, Italy

Background and Aims:: Peripheral Neuropathy (PN) affects 2.4% of people and almost 50% of general population is known to have pain-related symptoms. Genetic studies in painful PN (PPN) revealed that Voltage Gated Sodium Channels (VGSCs) genes are involved in pain amplification. Here we aimed to broaden the genetic aspect of PPN by using whole exome sequencing (WES).

Methods:: Six families with PPN were selected having at least one affected member, positive neurological examination and pain questionnaire result with numerical rating score ≥ 4. Variants were filtered with a manually curated gene panel, allele frequency (AF) and computational predictors. Segregation causative/protective models were applied according to pedigree and sharing models were applied after grouping probands of each family.

Results:: According to segregation causative and protective model, we found 129 and 112 variants respectively (AF≤10%) across families. Among genes shared between two families with causative approach, variants were observed in SCN9A, SV2C and DST, whereas protective variants in TRPM2 and LRP1. In shared model, we identified 21 variants and 53 genes shared across ≥ 3 probands. Among shared genes with predicted high-impact variants in probands were observed in SCN9A, SCN7A, P2RY4, P2RX7, TRPV4 and TRPM1.

Conclusions:: WES approach appears powerful in mutation detection and in revealing new genotype-phenotype association. In addition to VGSCs, other gene families including Transient Receptor Potential and Purinergic Receptor seem to play a role in pain modulation. The same approach will be replicated on new families already sequenced before proceeding with ad hoc functional experiments to deepen the role of genes in painful phenotype.
NEEDLE PHOBIA AND PAIN AMONG ELECTRODIAGNOSTIC SUBJECTS: PRELIMINARY SURVEY.

Philip Adebayo1, Rose Mwankabatika2
1Aga Khan University, Dar es Salaam, Internal Medicine, Dar es Salaam, Tanzania, 2Aga Khan Hospital, Clinical Neurophysiology, Dar es Salaam, Tanzania

Background and Aims: Needle phobia, otherwise known as trypanophobia, is seen in at least 10% of the general population. We evaluated the effect of needle phobia on the perceived and actual pain during electrodiagnostic procedures in this study.

Methods: Prospective subjects referred to our electrodiagnostic laboratory between July and August 2020 were interviewed. Demographic data, perceived pain score (using a visual analogue scale) for nerve conduction test (NCT) and electromyography were assessed. Needle phobia score (using a needle phobia scale) was collated and analyzed.

Results: Of the 38 subjects, 24 were male and 14 were females with mean age of 43.11±12.2 and 41.05±16.83 respectively (p=0.662). The needle phobia score was not different between female (13.25±15.43) and males (17.40±11.63), p=0.56. The mean perceived pain score for NCT was 4.73±2.93 while mean of actual pain score was 4.94±2.33 (p=0.028). The mean perceived pain score for EMG was 2.69±2.24 while mean post score was 4.25±3.31, (p=0.028). There was a direct correlation between pre and post NCT pain scores (correlation coefficient 0.457, p=0.007) and pre-EMG and post EMG pain scores (correlation c=0.558, p= 0.025). Trypanophobia index was positively correlated to the perceived pain but not actual pain on EMG.

Conclusions: Inquiry about needle phobia and treating them may ensure more cooperation and tolerability of electrodiagnostic procedure, especially electromyogram in high-risk subjects.
Background and Aims:: it is well known that brain derived neurotrophic factor (BDNF) can modulate pain symptoms in diabetic polyneuropathy (DPN). It is still not known which type of receptor mediates its hyperalgesic effects. Aim: to compare serum levels of BDNF and tropomyosin receptor kinase type B (trkB) in patients with a painful and painless forms DPN.

Methods:: we studied 56 patients with DPN divided into two groups: the 1st group of 30 patients with neuropathic pain, and the 2nd group of 26 patients without pain symptoms. Pain intensity was examined by PainDetect. Presence of DPN were assessed by neurological examination according to the Michigan neuropathy screening instrument (MNSI) and electroneuromiography (ENMG) of lower extremities. Serum levels of BDNF and TrkB were studied by enzyme immunoassay.

Results:: The comparison of clinical and ENMG data for both groups is presented in Figure 1.

The 1st group was characterized by the highest serum level of BDNF (4.38±1.55ng/ml) versus patients of 2nd group (2.35±1.24ng/ml, p=0.002). The highest level of TrkB was detected in the 2nd group (5.12±1.56ng/ml), versus the average levels of the 1st group (3.21±1.55ng/ml, p=0.001). The inverse dependence between serum TrkB and severity of pain by Pain Detect (R=−0.572, p=0.005) were revealed.

Conclusions:: Low serum level of TrkB testifies to relatively intact transmembrane receptor, which can
bind with an excess of BDNF and implements its hyperalgesic intracellular effects. On the contrary, severe DPN is associated with a high serum amount of non-functional TrkB, which can lead to painless form polyneuropathy.
TOPOGRAPHICAL AND DIPOLAR ANALYSIS OF LASER EVOKED POTENTIALS IN FIBROMYALGIC PATIENTS WITH NON LENGHT DEPENDENT SMALL FIBER NEUROPATHY

Silvia Giovanna Quitadamo¹, Eleonora Vecchio¹, Giuseppe Libro¹, Katia Ricci¹, Raffaella Lombardi², Giuseppe Lauria², Marina De Tommaso¹
¹University of Bari “Aldo Moro”, Basic Medical Sciences, Neurosciences And Sense Organs, Bari, Italy, ²Foundation IRCCS Carlo Besta Neurological Institute, Neuroalgology Unit, Milan, Italy

Background and Aims:: Research on Fibromyalgia (FM) is currently based on interesting pathogenetic hypothesis based on the involvement of the central and peripheral nervous system. Recent studies have shown an altered central processing of nociceptive inputs as well as a small fibers neuropathy (SFN) in a large number of fibromyalgic patients. Objectives: 1) to evaluate Laser Evoked Potentials (LEPs) in FM patients, taking into consideration skin innervation and comparison with control group 2) to identify cortical sources of LEPs in consideration of skin biopsy results.

Methods:: We evaluated 57 fibromyalgic patients already included in Vecchio et al. (2020) and 15 healthy age and sex matched controls. All patients were examined with multichannel LEPs and with skin biopsy as described respectively in de Tommaso et al. (2014) and in Vecchio et al. (2020). sLORETA software was used to localize generators of LEPs.

Results:: Skin biopsy showed in 22 patients proximal denervation (FMP), in 18 patients normal skin innervation (FMN) and in 7 patients SFN in proximal and distal crural sites (FMD). The sLORETA analysis highlighted a reduced activation of Brodmann area 32 in FMP and area 33 in FMD compared to controls after knee stimulation and a reduced activation of the dorsolateral cortex in the FMP and FMN groups in comparison to controls after foot stimulation.

Conclusions:: Denervation can cause a deactivation of the cingulate and the dorsal-latero-frontal area, which can determine altered pain modulation.
DIFFUSE NOXIOUS INHIBITORY CONTROL MODULATES THE N13 SPINAL COMPONENT OF SOMATOSENSORY EVOKED POTENTIALS

Giuseppe Di Pietro¹, Giulia Di Stefano¹, Caterina Leone¹, Andrea Di Lionardo¹, Emanuele Sgro¹, Eleonora Galosi², Gianfranco De Stefano¹, Pietro Falco¹, Nicoletta Esposito², Andrea Truini¹
¹Sapienza University of Rome, Department Of Human Neuroscience, Rome, Italy, ²La sapienza, university of rome, Human Neuroscience, Roma, Italy

Background and Aims:: The dorsal horn generator of the N13 component of somatosensory evoked potentials (SEPs) is not clearly understood. To verify whether wide-dynamic-range (WDR) spinal neurons in the dorsal horn are involved in the generation of the N13 SEPs; we tested the effect of diffuse noxious inhibitory control (DNIC), a modulator of WDR neurons, on N13 SEPs in healthy humans.

Methods:: Twelve healthy subjects (age 26.7±4 years, 5 males) were enrolled. The cold pressor test on the left foot was used as a heterotopic noxious conditioning stimulus to trigger DNIC. We tested the pressure pain threshold at the thenar muscles of the right hand to verify the effectiveness of our DNIC paradigm. We then recorded SEPs after right median nerve stimulation before, during, and after the cold pressor test.

Results:: The cold pressor test increased pressure pain threshold by 15% (p=0.04). The amplitude of the N13 SEPs component during the cold pressor test was significantly lower than that recorded at baseline (by 25%, p=0.04).

Conclusions:: We showed that a heterotopic noxious conditioning stimulus significantly reduced N13 SEPs amplitude, suggesting that the generators of this spinal SEPs component are sensitive to DNIC. This finding suggests that the N13 SEPs is generated by the segmental postsynaptic response of dorsal horn WDR neurons and support the use of N13 in the assessment of dorsal horn excitability during central sensitization.
Background and Aims:: Back pain is very common in the general population, but even more so among people with multiple sclerosis (MS), with a prevalence of up to 50%. But it is difficult to associate back pain with MS in most cases. These syndromes can have different nature and mechanisms of pain and sometimes their combination.

Methods:: 120 patients with MS were examined and their history was analyzed at the Lviv regional multiple sclerosis center. Standardized questionnaires VAS, PainDetect, HADS, SF-36 were used to assess the characteristics of pain, anxiety, depression, and quality of life in these patients.

Results:: During the last month, 28 patients (23,3%) had back pain associated with MS. 10(8,33%) patients had Lhermitte’s sign (LS), 4(3,33%) had back pain associated with postural abnormalities (PABP), 14(11,66%) patients had other back pain (OBP). 60% of patients with LS and 64,29% with OBP considered these pain syndromes as the most disturbing in the structure of MS. 90% of MS patients with LS were female and they had high rates of pain intensity and were characterized by the presence of a neuropathic component of pain and high levels of anxiety. For patients with PABP and OBP prevalence of the nociceptive component of pain was more typical. PABP occurs among patients with a longer duration of MS and they have lower levels of the physical component of quality of life.

Conclusions:: Understanding the structure and characteristics of back pain syndromes and their association with MS will improve the diagnosis and treatment of these patients.
SOUND-INDUCED FLASH ILLUSIONS SUPPORT CORTEX HYPEREXCITABILITY IN FIBROMYALGIA

Salvatore Iacono¹, Vincenzo Di Stefano², Andrea Gagliardo², Bruna Maggio³, Giuliana Guggino⁴, Massimo Gangitano², Roberto Monastero⁴, Nadia Bolognini⁵, Filippo Brighina³
¹Azienda Ospedaliera Universitaria Policlinico Paolo Giaccone, Department Of Biomedicine, Neuroscience And Advanced Diagnostic, Palermo, Italy, ²University of Palermo, Department Of Biomedicine, Neuroscience And Advanced Diagnostics, Palermo, Italy, ³University Of Palermo, Department Of Experimental Biomedicine And Clinical Neurosciences, Palermo, Italy, ⁴AOU Paolo Giaccone, University Of Palermo, Dibimis University Of Palermo, Palermo, Italy, ⁵NeuroMi, University Of Milano Bicocca, Department For Psychology, Milan Center For Neuroscience, Milano, Italy

Background and Aims:: Sound-induced flash illusions (SIFI) reflect visual cortical excitability. In this case-control study, we explored whether SIFI are perceived differently in patients affected by fibromyalgia, in healthy controls and in patients with fibromyalgia and migraine together.

Methods:: Forty-one patients affected by fibromyalgia (mean age 49.8±10.65 years; 38 females) and in forty-one healthy controls (mean age 47.26±4.9 years; 34 females) were enrolled and matched for gender and age. A single flash with multiple beeps was given to induce fission illusion (1F0B, 1F1B, 1F2B, 1F3B, 1F4B), whereas multiple flashes with a single beep were induced fusion illusion (2F0B, 2F1B, 3F0B, 3F1B, 4F0B, 4F1B). Finally, we compared the number of perceived flash in fission and fusion illusion using multivariate analysis of variance between groups.

Results::

Patients affected by fibromyalgia perceived fewer flashes than controls with reduction of fission illusion when a single flash was combined with multiple beeps (F₁F₁B=5.74, p=0.019, F₁F₂B=22.79, p<0.001; F₁F₃B=22.45, p<0.001; F₁F₄B=11.23, p=0.001). On multiple flash trials, fusion illusion was less consistently reported in both groups, but not completely disrupted for some trial conditions (F₃F₀B=4.254 p=0.043; F₄F₀B=4.39 p=0.04). Finally, the group fibromyalgia plus migraine reported fewer flashes than healthy controls and patients with only fibromyalgia in some experimental conditions (e.g., 1F₂B, 1F₃B, 1F₄B), without statistical significance (all p>0.05).

Conclusions:: The reduced illusory fission effects in fibromyalgia might indicate an increased cortical...
responsivity supporting the potential role of cortical hyperexcitability in fibromyalgia. Cross-modal illusions represent a valid tool for exploration of cross-sensory functional connectivity, which likely has an important role in the pathophysiology of fibromyalgia.
THERAPEUTIC EFFECT OF ONABOTULINUMTOXINA (BONT/A) IN PIRIFORMIS SYNDROME RESISTANT TO CONVENTIONAL THERAPY

Jose Ricardo Lopez Castellanos¹, Jose Lopez-Contreras²
¹University of Arkansas for Medical Sciences, Neurology, Little Rock, United States of America, ²Instituto Salvadoreño del Seguro Social, Clínica De Movimientos Anormales, Servicio De Neurología, San Salvador, El Salvador

Background and Aims:: Objective: To describe the therapeutic effect of OnabotulinumtoxinA in a case of piriformis syndrome. Background: Piriformis syndrome is due to entrapment of the sciatic nerve by the piriformis muscle, in the absence of a lumbar radiculopathy.

Methods:: We conducted open administration of 3 cycles of 50 units of OnabotulinumtoxinA (BoNT/A) injections in the piriformis muscle every 9 months in a patient with Piriformis Syndrome. Analgesic medication used by the patient was recorded periodically before and after of BoNT/A injections as well as patient subjective rating and Visual Analog Scale (VAS).

Results:: A 38-year-old man with 6 years of continuous pain in right buttock, pelvic pain and right leg that increased when attempting to walk (VAS: 9), causing a significant interference in activities of daily living. No improvement with analgesics, muscle relaxants and neuromodulators. After of each OnabotulinumtoxinA injection the patient had a significant subjective improvement in pain of 90% (VAS: 4) and his activities of daily living for 9 months, without side effects, and achieved a 92% of reduction in the use of medication compared to baseline.

Conclusions:: OnabotulinumtoxinA was effective to control pain in our patient with refractory piriformis syndrome, improving his quality of life.
CAN THE SONOGRAPHIC DISTAL VASTUS MEDIALIS THICKNESS BE A USEFUL MARKER TO REFLECT DISEASE PROGRESSION OF KNEE OA?

Sangrok Woo, Byunghoon Kang, Hamok Jeong, Soyeon Jang, Junhee Lee, Joonshik Yoon
Korea university Guro hospital, Rehabilitation Medicine, Seoul, Korea, Republic of

Background and Aims:: The objective of this study was to evaluate the correlations between radiologic staging and evaluated ultrasound results of the distal portion of VM muscle thickness in knee OA comparing with the previous mid-thigh level study.

Methods:: Knee OA was graded according to the Kellgren-Lawrence classification. We measured the femur length using the distance from the surface landmark of ASIS to the lateral border of the patella. Then the mid-level (50%), and distal 25% of the femur level were calculated. At the mid-level, thickness of the rectus femoris, vastus intermedius, and VM was measured, and at the distal 25% level, VM muscle thickness was measured (Fig 1).

Results:: We included 30 patients (20 women and 10 men) aged 20 to 80 years. The subgroup was divided into two groups according to the severity of knee OA (Group 1: K-L grade 0-1, Group 2: K-L grade 2-4). A significant negative correlation between the thickness of some anterior thigh muscle and stage of knee OA was noticed. When the body mass effect was considered, it showed a more significant result between groups 1 and 2 (Table 1). With subgroup analysis, a statistically significant difference was determined in every muscle we investigated (Table 2).

Conclusions:: Individual thigh muscle thickness showed a negative correlation with the progression of knee OA. With the easy accessibility and high reproducibility, exploring the thickness of the distal portion of VM can be a useful indicator for severe knee OA patients.
Background and Aims:: Pain is a highly disabling non-motor symptom of Parkinson’s disease (PD). In advanced PD stage, pain frequently occurs or is aggravated in the “off” state and ameliorates by increasing dopamine replacement therapy (DRT). Levodopa/carbidopa intestinal gel (LCIG) is useful in advanced PD patients with severe complications. LCIG may help optimizing the risk/benefit ratio of DRT and ameliorate quality of life (QoL) in advanced PD patients.

Methods:: Study of the clinical course of a PD patient candidate for LCIG and with painful dystonia.

Results:: A 77-year-old female was diagnosed with PD in 2004 and initiated DRT in 2005. In the last 2 years, she kept suffering from painful peak-dose dystonia, followed by severe “off” state; moreover, she was in “off” state for most night-time. She was proposed switching to LCIG. Along the 3-day test tube phase with 24-h infusion, dystonia almost disappeared, and the patient reported marked reduction of pain severity. After PEG-J positioning, the patient was discharged under 24-h infusion treatment. At 2-month follow-up visit, the patient was able to walk with assistance, night-time sleep was significantly improved and pain severity was greatly reduced. She reported moderate limb dystonia, occurring soon after tube cleansing.

Conclusions:: Non-motor symptoms may benefit from switch to LCIG. Here we show the benefit of switch to LCIG in a PD patient suffering from severe peak-dose levodopa-related dystonia. These findings strengthen the need for optimizing DRT with the aim of managing motor and non-motor symptoms to reduce disability and ameliorate QoL and autonomy.
CLINICAL SIGNS OF OPIOID OVERDOSE IN A PATIENT ON GABAPENTIN AND OXYCODONE

Evgenii Vladislavov
MU-Sofia, Neurology, Sofia, Bulgaria

Background and Aims:: The pain control in some chronic or acute conditions can be a difficult problem. A few levels model is often used for post-surgical patients. Oxycodone and gabapentin are used in many patients together. This combination may have some harmful potential in some circumstances.

Methods:: The patient had physical examination, imaging, blood tests.

Results:: We present a case of a patient who after 10 mg Oxycodone MR and twice given 300 mg gabapentin suffered worsening with a clinical picture of opioid overdose; the condition was successfully influenced with 400 mcg Naloxone. The patient had no significant problems further.

Conclusions:: The probable risk of combining gabapentin and oxycodone has already been described, but the mechanism remains still unclear.
LONG-TERM PAIN FREE EFFECT OF PLATELET-RICH PLASMA INJECTION IN A HIGHLY FREQUENT CASE OF SACROILIAC JOINT PAIN

Yusak Siahaan1,2, Pamela Tiffani1,2, Vinson Hartoyo1,2
1Siloam Hospital Lippo Village/Universitas Pelita Harapan, Neurology, Tangerang, Indonesia, 2Universitas Pelita Harapan, Neurology, Tangerang, Indonesia

Background and Aims:: Background Sacroiliac joint pain (SIJP) is one of the most common debilitating disorders that can affect an otherwise healthy productive person. This can be due to combination of inflexible sacroiliac joint structure and disregardable risk factors such as bad posture and prolonged immobility. Platelet-rich plasma (PRP) injection is one of the most recent, promising and less explored modalities, particularly in Indonesia. Aims To report a case of highly frequent relapse of SIJP.

Methods:: Case A 46-year-old, obese male with no other known risk factors other than prolonged position due to his occupation as a commercial pilot. He suffered from frequently relapsed (less than 6 months interval) intense radiating back pain down to left posterior thigh with pain score of 8/10 and 34% of Oswestry Disability Index (ODI). He had no prior history of trauma nor related back surgery. Physical examination revealed the pain was localized to the left posterior superior iliac spine (PSIS) with positive Faber and straight leg raising test. Lumbar imaging yielded mild disc degeneration of L5-S1 and spondyloarthrosis. He was previously treated with conservative (oral medication, physiotherapy) and interventional (corticosteroid injection) therapy. Single PRP intra-articular injection was done under C-arm guidance (Fig. 1).
Results: Despite no change in his modifiable risk factors, he is pain free for 3 years with 0/10 in numeral pain score and 2% of ODI in follow up.

Conclusions: Conclusion PRP is one of modalities in treating SIJP that can be considered in a highly frequent relapse case.
LONG-TERM EFFICACY OF SINGLE BOTULINUM TOXIN-A INJECTION IN A RELAPSING PIRIFORMIS SYNDROME CASE

Yusak Siahaan¹,², Amanda Tanasia², Pamela Tiffani¹,², Vinson Hartoyo¹,²
¹Siloam Hospital Lippo Village/Universitas Pelita Harapan, Neurology, Tangerang, Indonesia, ²Universitas Pelita Harapan, Neurology, Tangerang, Indonesia

Background and Aims:: Background Piriformis syndrome (PS) has been considered as a complex diagnosis thus often making its management become complicated. Management of PS ranges from conservative therapies to interventional including injection and surgeries. Among interventional methods, local anesthetic and steroid injections are more commonly practiced. However, due to its negative effect, serial botulinum toxin-A (BTX-A) injections has been proposed as an alternative therapy that can provide relief. Aims To report a long term relief of pain in case of persistent PS with single BTX-A injection.

Methods:: Case An otherwise healthy 41-year-old female weekly basis relapse of classic PS. She complained sharp radiating gluteal pain with no neurological deficits. Diagnosis of PS was confirmed from positive trigger point, provocative test (FAIR, Beatty and Pace maneuver) and diagnostic block. She was initially treated with combination of local anesthetic and corticosteroid injections but failed to provide long-term relief with relapsing 8/10 score of pain. Considering the negative effects from multiple local anesthetic and steroid injections, an alternative method of 100 IU BTX-A intra-muscular injection was done (fig. 1).
**Results:** Result She reported improvement in pain score from 8 to 3 in 15 minutes post injection, with further decrease in pain score to 0 after two weeks and no complications. Thus no additional injection was performed. She is now pain free for 1.5 years with no report of additional relapses.

**Conclusions:** Conclusion BTX-A injection can be considered as an alternative to provide a long term relief in a frequent relapse case of PS.
THE IMPACT OF SMALL FIBER DAMAGE ON SOMATOSENSORY DISTURBANCES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): A CLINICAL, NEUROPHYSIOLOGICAL AND SKIN BIOPSY STUDY.

Eleonora Galosi, Pietro Falco, Giuseppe Di Pietro, Gianfranco De Stefano, Nicoletta Esposito, Carmelo Pirone, Andrea Truini
La sapienza, university of rome, Human Neuroscience, Roma, Italy

Background and Aims:: Peripheral neuropathy is one of the most common neurological manifestations of SLE. Though patients with SLE often complain about painful somatosensory disturbances, the prevalence and clinical impact of nociceptive small fibers damage have been poorly studied in this condition. Our prospective study aims at assessing how small fibers damage impacts on painful symptoms and at disclosing clinical and diagnostic variables associated to small fibers impairment in patients with SLE.

Methods:: We consecutively enrolled 22 patients suffering from SLE with painful disturbances. Each patient underwent clinical examination, DN4, SFN-SIQ, NPSI, Pain Catastrophizing questionnaires, nerve conduction study, quantitative sensory testing (QST) and skin biopsy. Small fiber neuropathy was diagnosed by distal skin biopsy intraepidermal nerve fibers density (IENFD) reduction associated to at least one thermal detection threshold abnormality at QST.

Results:: 32% patients showed a pure small-fiber neuropathy, 10% a mixed neuropathy with both large and small fibers involvement. 75% showed both proximal and distal IENFD reduction at skin biopsy. Small fiber damage presence and IENFD reduction were associated to higher DN4 scores, pain hypoesthesia and higher QST mechanical pain threshold (MPT) at foot.

Conclusions:: Small fiber damage with a non-length dependent distribution is a common finding in patients with SLE and is significantly associated to pain of neuropathic quality as assessed by DN4 questionnaire. DN4 for distal pain, besides clinical and QST evaluation of the foot pain sensitivity, could be valuable diagnostic tools to screen for small fiber neuropathy in patients suffering from SLE.
EVALUATION OF DULOXETINE EFFECTIVENESS IN PAIN RELIEF FOR PARKINSON'S DISEASE PATIENTS

Kuzieva Shakhnoza, Shokhimardon Khudjanov
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims: To study effectiveness of duloxetine for relief of pain in Parkinson's disease.

Methods: A double-blind, placebo-controlled study was conducted for 3 months. Patients with Parkinson's disease were selected according to the following criteria: with chronic pain in stage I-III of Hoehn & Yahr scale. From this group of samples in a random order, patients were divided into placebo groups and duloxetine groups. In the second group, patients received 30 mg of duloxetine once a day with a gradual increase in dose up to 60 mg. Results were evaluated using of 11-point Visual Analogue Scale and Short-Form McGill Pain Questionnaire, as well as a miniature pain stimulus were used to determine the subjective threshold of pain sensitivity. Threshold of pain sensitivity for each of the subjects was established after the application of the "multiple random stairs" method.

Results: At the beginning of study, there was no statistically significant difference in demographic and clinical data between duloxetine group and placebo group. Quantitative improvements were observed in evaluations of the 11-point Visual Analogue Scale and Short-Form McGill Pain Questionnaire in favor of duloxetine group (p = 0.04). In the induced pain stimulus was noticeable increase in pain thresholds in the duloxetine group compared with the placebo group (p = 0.05).

Conclusions: The efficacy of duloxetine in pain relief was determined in patients with Parkinson's disease, further studies are needed to understand the effectiveness of duloxetine with prolonged use.
NEUROPHYSIOLOGICAL AND CLINICAL EFFECTS OF TSDCS IN PATIENT WITH CHRONIC PAIN

Matteo Guidetti1,2, Giada Aglieco3, Roberta Ferrucci4,5, Stefano Giannoni-Luza6, Anisia Naci3, Kevin Pacheco-Barrios7, Maurizio Vergari3, Sara Versace3, Alberto Priori1,8, Tommaso Bocci1,8

Neurophysiology, Milan, Italy, 4Università degli studi di Milano, Centro Di Ricerca “aldo Ravelli” Per Le Neurotecnologie E Le Terapie Neurologiche Sperimentali, Dipartimento Di Scienze Della Salute, Milano, Italy, 5ASST Santi Paolo e Carlo, Neurology Clinic III, Milan, Italy, 6Sensory-Motor Lab (SeMoLa), Department of Ophthalmology, Jules Gonin Eye Hospital-Fondation Asile des Aveugles, Lausanne University, Lausanne, Switzerland, 7Harvard Medical School, Neuromodulation Center, Spaulding Rehabilitation Hospital, Boston, United States of America, 8III Clinical Neurology Unit, University of Milan, San Paolo University Hospital, ASST Santi Paolo e Carlo, Department Of Health Sciences, Milan, Italy

Background and Aims:: Chronic pain (CP) is complex clinical condition, often devastating for patients and unmanageable with pharmacological treatments. Several findings indicate that transcutaneous spinal direct current stimulation (tDCS) might represent a complementary therapy in managing CP. In this randomized, double-blind, sham-controlled crossover study, we assess tDCS effects in CP patients.

Methods:: Sixteen patients (aged 65.06 ± 16.16 years, 8 women) with CP of different etiology underwent sham and anodal tDCS (anode over the tenth thoracic vertebra, cathode over the somatosensory cortical area - 2.5 mA, 20 min, five days for one week). As outcomes, we considered the Visual Analogue Scale (VAS), the Neuropathic Pain Symptom Inventory (NPSI), and the components of the lower limb flexion reflex (LLFR), i.e., RIII threshold, RII latency and area, RIII latency and area, FR total area. Assessments were conducted before (T0) and at the end of the treatment (T1), and after one week (T2) and one month (T3).

Results:: Compared to sham, anodal tDCS reduced RIII area at T2 by more than 50% (p=0.0043) and T3 by about 50% (p=0.0012); similarly, FR total area was reduced at T3 by about 50% (p=0.03). Clinically, anodal tDCS dampened VAS score at T3 by about 50% (p=0.015), and NPSI score at T1 (p=0.0012) and T3 (p=0.0015) by about 30%, compared to sham. Changes in VAS and NPSI scores linearly correlated with the reduction in LLFR areas (p=0.0004).

Conclusions:: Our findings suggest that anodal tDCS could modulate central nociceptive signal transmission and pain perception in CP conditions.
QUALITY OF LIFE AND PAIN IN PARKINSON DISEASE: A PROSPECTIVE STUDY

Yasmina Zakaria, Najib Kissani, Mohamed Chraa
university hospital Mohamed VI, Neurology, marrakesh, Morocco

**Background and Aims::** Introduction: Pain is a common non-motor symptom in Parkinson disease (PD), which can be disabling. The objective of this work is to describe the epidemiological aspects of pain in PD and its impact on the patient’s quality of life.

**Methods::** This is a prospective analytic study conducted in the neurology department of Mohamed VI hospital university in 80 patients suffering from PD. Demographics, clinical features and medication data were obtained using a structured questionnaire and the clinical classification of Ford.

**Results::** the analysis showed that the mean age was 62.92 (range from 42 to 90), pain was prevalent in 65% of PD patients, men were more affected than women (males 59.57%), five different types of pain were reported: musculoskeletal pain (42.5%), nerve/nerve root pain (38.8%), primary/central pain (16.3%), dystonic pain (12.5%) and akathisia (12.5). Fifty nine percent of the patients reported the pain on the off period, (1.92%) on the on period and (38.46) on both periods. There was no difference statistically significative in the distribution of depression depending on the presence or absence of pain. The quality of life was impacted with the presence of a musculoskeletal pain.

**Conclusions::** Conclusion: pain is a common non-motor symptom in Parkinson disease, but it is probably infradiagnosed. For a correct treatment, it must be well identified and clinically classified.
CHEMOTHERAPY-INDUCED PERIPHERAL NEUROPATHY: FROM SYMPTOMATOLOGY USING QUANTITATIVE SENSORY TESTING TOWARDS EFFECTIVE TREATMENT

Heleen Marynissen¹, Delphine Mergaerts¹, Hans Wildiers², Patrick Neven³, Eric Van Cutsem⁴, Jan De Hoon⁵
¹University Hospitals of Leuven, Center For Clinical Pharmacology, Leuven, Belgium, ²University Hospitals of Leuven, General Medical Oncology, Leuven, Belgium, ³University Hospitals of Leuven, Gynecology And Obstetrics, Leuven, Belgium, ⁴University Hospitals of Leuven, Gastrointestinal And Liver Diseases, Leuven, Belgium

Background and Aims:: Chemotherapy-induced peripheral neuropathy (CIPN) affects up to 80% of patients after treatment with e.g. paclitaxel or oxaliplatin. Preclinical research elicits sensitization of temperature- and mechanosensitive Transient Receptor Potential (TRP) channels as potential mechanism behind this debilitating pathology. The current study evaluates TRP involvement in human by assessing thermal and mechanical sensitivity in patients with CIPN.

Methods:: Quantitative Sensory Testing is performed bilaterally on the proximal phalanx of the index finger in patients previously treated with paclitaxel or oxaliplatin, and age-matched healthy controls. Von Frey hairs are used with an ascending-descending principle to determine the mechanical detection and pain thresholds. Heat and cold detection and pain thresholds are assessed with a thermal cutaneous stimulator using the method of limits, ranging from 0°C to 60°C.

Results:: Sixteen subjects have been included so far. Therefore, no statistical analysis has yet been performed. However, a trend towards higher heat detection thresholds (mean±SEM) can already be distinguished for paclitaxel and oxaliplatin versus healthy controls (41.6±1.9°C and 42.3±0.9°C vs. 37.0±0.7°C, respectively, Figure 1A). Also, paclitaxel reduces the mechanical pain threshold (mean±SEM) compared to healthy controls (84.1±41.7g vs. 168±28.9g, respectively, Figure 1B). By October 2021, approximately 60 subjects will have been included.

Conclusions:: Preliminary data suggest that paclitaxel and oxaliplatin induce heat hyposensitivity. Alterations in thermal or mechanical sensitivity may provide evidence for the involvement of temperature- or mechanosensitive TRP channels in CIPN in human. In the near future, linkage of such altered sensitivity to direct TRP functionality assessments will further support novel TRP-based medicines for CIPN.
HIGH BETA EEG FUNCTIONAL CONNECTIVITY IS DECREASED IN THE LEFT AMYGDALA OF FIBROMYALGIA PATIENTS IN CORRELATION WITH THE AFFECTIVE COMPONENT OF PAIN.

Soline Makowka1, Naima Mory1,2, Michael Mouthon1, Christian Mancini1, Jean-Marie Annoni1, Adrian Guggisberg2, Joelle Nsimire Chabwine1,2

1University of Fribourg, Neurology Unit, Medicine Section, Laboratory For Cognitive And Neurological Science, Department Of Neuroscience And Movement Science, Faculty Of Science And Medicine, Fribourg, Switzerland, 2Fribourg Hospital Meyriez/Murten, Neurorehabilitation Division, Fribourg, Switzerland, 3Geneva University Hospital, Division Of Neurorehabilitation, Department Of Clinical Neuroscience, Geneva, Switzerland

Background and Aims:: Fibromyalgia is a major chronic disease associating mainly pain, prominent affective dysfunction, sleep disorders and fatigue. Changes in neurotransmitters activity and in brain connectivity have been associated to pain in fibromyalgia, however, electrophysiological data on correlates of the affective dimension of pain lack.

Methods:: In this data analysis from a wider case-control study, we explored resting-state EEG connectivity (spectral analysis and coherence) in the beta domain (supposedly indexing the GABAergic neurotransmission highly involved in pain regulation), in 16 fibromyalgia patients and 11 age-matched healthy controls. In addition, we recorded affective and sensory pain components (patients), as well as mood and sleep descriptors (patients and controls).

Results:: A decrease in functional connectivity was noticed in the high beta (20-30 Hz) sub-band of patients (p=0.039) in the left laterobasal complex of the amygdala, correlated with the affective component of pain (r=0.50, p=0.049). An increase observed in the low beta (13-20 Hz) relative power in the left DLPFC and in the VLPFC of fibromyalgia patients (respectively p=0.001 and 0.033) was correlated with the ongoing pain intensity (r=0.54 and 0.71, p=0.032 and 0.002).

Conclusions:: For the first time, we showed a decreased connectivity related to the GABAergic system in the amygdala, associated with the affective component of pain (expected in this structure highly involved in the affective regulation of pain). The increased beta power in the prefrontal cortex could be compensatory of the overall GABAergic dysfunction in chronic pain.
MERALGIA PARESTHETICA ASSOCIATED WITH WEIGHT LOSS

Linda Jaffe  
Tripler Army Medical Center, Neurology, Honolulu, United States of America

**Background and Aims:** Belts and tight-fitting clothing, obesity, and pregnancy are all common causes of compression of the Lateral Femoral Cutaneous Nerve (LFCN) also known as Meralgia Paresthetica (MP). But the LFCN can be vulnerable to other sources of traction as it passes beneath the inguinal ligament. We sought to consider if MP, much to our surprise, could be caused by weight loss.

**Methods:** A review of the literature and commonly used references such as UpToDate was completed to search for the possibility that mechanical factors involved with loss of weight might contribute to Meralgia Paresthetica. This effort was undertaken when a 63 year old non-Diabetic man presented to our clinic with the classic features of LFCN syndrome without any of the commonly associated risk factors and rather than weight gain, he had lost 30 pounds during the recent pandemic.

**Results:** The most commonly identified risk factors for MP are obesity, diabetes mellitus, and older age, pregnancy, increased abdominal girth such as in ascites. Mechanical traction on the nerve due to prolonged leaning against a table or bench, carrying heavy objects supported by the groin, various exercises have also been associated. Postoperative MP is also cited as cause of the compressive neuropathy. But weight loss is not described.

**Conclusions:** Meralgia Paresthetica is a mononeuropathy of the LFCN and like other neuropathies, injury can be due to various causes with the ultimate result being local ischemia. We report on a case of such injury occurring due to mechanical effects from weight loss rather than weight gain, obesity, or other causes usually cited.
REFLEXOTHERAPY AND CHRONIC LOWER BACK PAIN

Irina Vyshlova, Sergey Karpov, Anton Shatokhin, Anastasia Raevskaya
Stavropol state medical university, Neurology, Neurosurgery And Medical Genetics, Stavropol, Russian Federation

Background and Aims:: Lower back pain (LBP) affects 90% of the population. Objective: to study the effect of acupuncture on the relief of exacerbations of chronic LBP.

Methods:: 100 patients with chronic LBP were divided into two groups. The main group - 50 patients (48.55 ± 14.4). Patients underwent reflexology daily for 10 days along with standard drug therapy. The control group consisted of 50 patients (47.92 ± 14.0) with standard drug therapy. Pain intensity was evaluated with numeric rating scale for pain, kinesiophobia on the Tampa Scale for Kinesiophobia, anxiety and depression on the hospital anxiety and depression scale.

Results:: pain intensity decreased by 57% from 6.61 ± 0.54 to 2.92 ± 0.31 points in the main group, by 14% from 5.72 ± 0.84 to 3.12 ± 0.50 points in the control group after 10 days of therapy. Kinesiophobia decreased by 11% in the main group and by 9% in the control group. The level of anxiety decreased from 8.66 ± 1.04 to 7.06 ± 1.32 points and from 9.24 ± 1.13 to 7.14 ± 0.82 points, the level of depression from 7.22 ± 0.88 to 6.18 ± 1.11 points and from 6.58 ± 0.79 to 5.84 ± 0.93 points respectively in the main and control groups after 10 days.

Conclusions:: Reflexotherapy is an effective method of short-term relief of exacerbation in patients with chronic LBP, but does not significantly affect the degree of kinesiophobia and manifestations of anxiety and depression.
CANCER-RELATED NEUROPATHIC PAIN (CRNP) IN EUROPE: WHAT ARE THE GAPS IN DIAGNOSIS AND TREATMENT FROM PATIENTS' PERSPECTIVE?

Martin Rakusa¹, Denis Dupoiron², Corien Eeeltink³, Femke Riel⁴, Begoña Barragán⁵, Dany Bell⁶, Gudula Petersen⁷, Sam Schofield⁸, Deirdre Ryan⁹, Silviu Brill¹⁰

¹University Medical Centre Maribor, Neurology, Maribor, Slovenia, ²Institut de Cancérologie de l’ouest, Département Anesthésie, Angers Cedex, France, ³Amsterdam UMC, Department Of Hematology, Amsterdam, Netherlands, ⁴Stichting Buddyhuis, Buddyhuis, Utrecht, Netherlands, ⁵Grupo Español de Pacientes con Cáncer, Grupo Español De Pacientes Con Cáncer, Madrid, Spain, ⁶Macmillan Cancer Support, Strategy Development, London, United Kingdom, ⁷Grünenthal, Governmental Affairs & Patient Engagement, Aachen, Germany, ⁸Grünenthal Ltd, Market Research, Stokenchurch, United Kingdom, ⁹Pain Alliance Europe, Presidency, Brussels, Belgium, ¹⁰European Pain Federation EFIC, European Pain Federation Efic, Brussels, Belgium

Background and Aims:: Cancer burden on individuals and society is high with 2.7 million new cancer cases per year in Europe. With effective treatments available, people with cancer live longer but often with sequelae such as neuropathic pain resulting from the cancer or its treatment. People with cancer experiencing neuropathic pain from 13 European countries shared their experiences with the diagnosis and management of their pain.

Methods:: An online survey, prepared, conducted and analysed with a team of experts including physicians, nurses and patients, was completed in June 2021. Adults consenting to participate and diagnosed with cancer were screened for symptoms of neuropathic pain. Respondents who met three or more of the DN4 (Douleur Neuropathique 4) criteria were enrolled and provided detailed information about their experiences relating to the diagnosis and management of CRNP.

Results:: Out of 24,733 screened respondents, 549 persons living with CRNP were recruited. Of those recruited, 88% were ≤ 65 years old, 32% experienced severe pain daily and 89% fulfilled ≥4 DN4 criteria. CRNP locations included arms/hands/fingers (63%), legs/feet/toes (60%), torso/chest/body/back (62%), and at surgical site (29%). Although CRNP symptoms were present, 40% had not received a formal diagnosis of neuropathic pain. Those with CRNP diagnosis were more likely to get pharmaceutical treatment (67% vs 44%) or physiotherapy (35% vs 22%) and were more likely to be satisfied with their treatment (67% vs 43%).

Conclusions:: Diagnosis of cancer-related neuropathic pain remains a challenge and many of those affected seem to remain unrecognised. Those without diagnosis are less likely to be treated for pain.
COMPARISON OF PATIENTS WITH L5-S1 INTRAVERTEBRAL DISK HERNIATION THAT EXPERIENCED ACUTE AND CHRONIC PAIN

Andriy Kulyk, Anzhelika Payenok
Danylo Halytsky Lviv National Medical University, Department Of Neurology And Neurosurgery Fpge, Lviv, Ukraine

Background and Aims:: Discogenic lower back pain remains a common and challenging problem to solve. The intervertebral disk can be a source of acute or chronic pain. It is still not clear what causes some people to suffer more than others, but there appear to be links to mechanisms of psychological and biological sensitization. This can be due to individual response to stress. Cortisol is frequently been associated with various stress related disorder.

Methods:: A total of 60 patients with L5-S1 intravertebral disk herniation were recruited. MRI of lower back was performed for all participants. The first group (30) included patients who experienced acute pain, and the second group (30) with pain that last more than 3 months. Both groups were assessed with morning serum cortisol level and DN4 questionnaire before the treatment.

Results:: The group with chronic pain showed significantly higher (p<0.05) level of morning serum cortisol level (1.34±0.25 mg/l) than acute pain group (0.51±0.32 mg/l). According to DN4 questionnaire we found that neuropathic type of pain is found in patients with acute pain (93%) statistically more often (p<0.05) than with chronic pain type (53%).

Conclusions:: In contrast to acute pain, people suffering from chronic pain report amplified rather than decreased pain over time. Recent theories have suggested that chronic pain could be partly maintained by the endocrine stress response. Results showed that patients with chronic back pain have higher levels of serum cortisol, which can possibly affect healing and prolong recovery time.
EFFECT OF BALANCE TRAINING WITH BOSU BALL ON SUBJECTS WITH CHEMOTHERAPY-INDUCED PERIPHERAL NEUROPATHY

Snehal Thakur  
MGM School Of Physiotherapy, Community Physiotherapy, Aurangabad, India

**Background and Aims::** Among patients undergoing chemotherapeutic regimens for cancer treatment chemotherapy-induced peripheral neuropathy (CIPN) is a common adverse effect, wherein patients experience symptoms like decreased proprioception, decreased sensation, reduced balance and weakness in lower extremities leading to increased risk of falls. The present study aimed to evaluate the effect of balance training with BOSU ball on balance in subjects with CIPN.

**Methods::** A total of 27 subjects (21 females, 06 males) with a modified total neuropathy score (m-TNS) score of >5 were included in the study. Pre and post-assessment scores were noted using the Berg balance scale (BBS), functional reach test (FRT) and one leg standing test (OLS).

**Results::** Paired ‘t’ test was used to analyze the important pre and post-scores BBS, FRT, OLS with p≤0.05 with physiotherapy intervention of 01-week significant improvements in BBS, FRT and OLS were noted (p <0.01).

**Conclusions::** Balance training with BOSU ball and exercises was demonstrated improvements in balance. However, similar study may be carried out in larger sample size to substantiate the evidence.
BOTULINUM TOXIN IN PAIN TREATMENT: ABOUT 100 PATIENTS

Massinissa Lounis, Hakim Si-Ahmed, Smail Daoudi
Nedir Moahammed Teaching Hospital, Neurology, Tizi ouzou, Algeria

Background and Aims:: Considered once the most toxic substance in the world, botulinum toxin (BTX) is presently under a more engaging day. Its medical use has gained an important extension that still support the validation of some clinical trials, this is the case of pain.

Methods:: We report a clinical experience with 100 patients who presented chronic pain phenomenon, such as migraine, tension headache, lower back pain, painful diabetic neuropathy, post herpetic neuralgia and trigeminal neuralgia. All patients presented a pain\(\geq 7/10\) on the visual numeric scale (VNS), with or without prior treatment. They were treated with BTX type A each 3 months and followed for 12 months. The doses and routes used were: Migraine (30u, 12 sites/4muscle groups); tension headache (30u, 6sites/2muscle groups); LBP (20u, 8 sites/2muscle groups); PHN and TN (0, 5-1u/cm2 intradermally) and PDN (1-2 u/cm2 subcutaneous).

Results:: The sex ratio (F/M) was 1.3 and the average age was 43.3 years with age limits of 11 and 79 years. It was noted 26% of TN, 23% PDN, 20% migraine, 15% LBP, 11% headache and 5% PHN. The average gain (decrease) on VNS was 4.11 points. The gain was 5.6 points for TN, 5.3 for PHN, 5 for LBP, 4.2 for tension headache and 3.2 for PDN. Migraine attacks decreased from 4.1 to 1.2 per month with a gain of 1.4 points on VNS.

Conclusions:: It is evident that BTX has an analgesic effect which has been demonstrated with several clinical studies. Future research should include expanding domains of treatable diseases, doses, injection intervals and complications.
CLINICAL CHARACTERISTICS OF LOW BACK PAIN IN PATIENTS WITH HYPERMOBILITY SPECTRUM DISEASES

Dina Khaibullina, Yuri Maksimov, Elvira Ihsanova, Dmitriy Busygin, Elza Rakhmatullina, Olga Kochergina, Lidia Kadirova, Oksana Alekseeva, Rady Esin

Background and Aims:: The diseases of the hypermobility spectrum (DHS) influence the clinical characteristics of Low Back Pain (LBP). The purpose of the study: to identify the clinical features of LBP in patients with DHS.

Methods:: 250 people were examined (147 men and 103 women) with LBP aged 18 to 45 years. External signs of the DHS were detected in 95 (38.0%) people. The control group amounted to 30 patients with LBP without DHS.

Results:: The degree of joints hypermobility in 4 points was revealed in 22.1%, 5-6 points - in 50.5%, 7-8 points - in 16.8% and 9 points - in 10.6% of cases. The character of pain was described as "pulling" in 30 (31.6%), "biting" at 27 (28.4%), "rodent" at 15 (15.8%), "scoring" at 23 (24.2 %) cases. The pain intensity was characterized by patients with DHS as "moderate" - 69.4%, "tolerant" - 30.5%, "unbearable" - 0.08%, in the control group 76.6%, 20% and 3.4%, respectively. The pain severity in the visual analog scale in patients with DHS was 6 +/- 1.3 points, in the control group 5 +/- 0.6 points. In case of LBP on the background of the DHS, static functional deformations of the spine, the functional blockade of sacroiliac joints and vertebral segments were also more common (p≤0.05) compared to the control group.

Conclusions:: Patients with LBP on the background of the DHS have a larger spectrum and the degree of clinical manifestations compared to patients without DHS.

Dilnoza Bobamuratova, Shukhrat Boymuradov, Yokubjon Kurbanov
Tashkent Medical Academy, Otolaringology & Stomatology, Tashkent, Uzbekistan

Background and Aims:: Patients who have undergone Covid-19 with maxillofacial complications suffer from headaches and local pain for a long time. Purpose: monitoring the clinical course of the nature of pain syndrome in the maxillofacial region of patients with Covid-19.

Methods:: Clinical analysis was carried out on 78 patients who applied to the TMA clinic. The average age of patients was 60 ± 9.0 years, including 41 women (54%) and 37 men (46%), with the diagnosis of cavernous sinus thrombosis, maxillar osteomyelitis 1–3 months after the onset of acute Covid-19 disease. During 1 years of rehabilitation, the pain was assessed according to a 10-point criterion (pain load - 0 points, very strong - 10 points) through the questionnaire.

Results:: In addition to inflammation in these patients, include headache, dizziness, n. Facialis paresis in 39 patients, paresthesia of the 3rd corneal nerve in all patients. In the beginning, severe irradiating headaches were observed in 85% of cases, and in some patients, in the absence of taking non-steroidal anti-inflammatory drugs, the need for narcotic analgesics, sedatives, tranquillizers. During observation, severe pain was in 40% of patients (8-10 points), and in 25% of patients, the average simultaneous pain remained within 3.5 ± 0.18 (p≥0.05). In 15% of patients, the headache persisted up to 4-5 (on average) points. The mean pain score was 3.6 ± 0.13 (p ≥ 0.05) in all patients end of the year.

Conclusions:: In patients undergoing COVID 19, thrombosis, facial bone necrosis was very long-term, predominant headaches. In 40% of patients, severe pain persisted for years.
CAUDAL EPIDURAL PULSED RADIOFREQUENCY FOR DISTAL SYMMETRICAL POLYNEUROPATHY

Hussein Mousa
alsdr teaching hospital, Neurosurgery, basra, Iraq

Background and Aims:: Background distal symmetrical polyneuropathy (DSP) present with numbness, tingling, pain, and/or weakness starting in the toes and progressing proximally in a stocking-glove distribution. Still there are no specific treatment Objective: in this study, clinicians use caudal epidural pulsed radiofrequency (CPRF) for the management patients complain from sensory symptom of DSP.

Methods:: CPRF stimulation for twenty four patients with DSP had sensory symptom not response to treatments. Inserted a caudal cannula into the epidural space through the sacral hiatus under fluoroscopy or ultrasound guidance. After Sensory and motor PRF, administered PRF at 5 Hz with a 5-ms pulse width for 600 seconds at 45 V. The effect of stimulation was evaluated using a numeric rating scale (NRS) within first week and monthly for 3 months after the procedure. Successful pain relief was defined as a reduction in the NRS score of ≥ 50% as compared with the score prior to treatment. In addition, at 4 months after treatment, patient satisfaction levels were examined; patients that reported “very good” (score = 7) or “good” (score = 6) results were considered to be satisfied with the procedure.

Results:: Neuropathic pain was significantly reduced in four visit after PRF (P < 0.001, repeated measures one-factor analysis). In addition, at 3 months post-PRF, more than half of the patients achieved a successful response (≥ 60% pain reduction) and were satisfied with treatment results.

Limitations:: limited number of patients and short duration of the study.

Conclusions:: CPRF safer, cheaper and more relieve of symptoms.
ULTRASOUNIC APPROACH CAUDAL EPIDURAL PULSED RADIOFREQUENCY

Hussein Mousa
alsdr teaching hospital, Neurosurgery, basra, Iraq

Background and Aims:: Background: The recently introduced pulsed radiofrequency (PRF) technique is used to provide relief from neuropathic pain had done under C-arm fluoroscopy. Objective: In this study use ultrasounic guided for caudal epidural pulsed radiofrequency (CPRF) for the management of neuropathic pain and central sensitivity syndromes.

Methods:: a prospective study CPRF stimulation for thirty patients with neuropathic pain or central sensitivity syndromes. Linear prope ultrasound (Sonosite) guidance for inserted a 22-gauge cannula into the epidural space through the sacral hiatus. After Sensory and motor PRF, administered PRF at 5 Hz with a 5-ms pulse width for 600 seconds at 45 V. The effect of stimulation was evaluated using a numeric rating scale (NRS) within first week and monthly for 3 months after the procedure. Successful pain relief was defined as a reduction in the NRS score of ≥ 50% as compared with the score prior to treatment. In addition, at 4 months after treatment, patient satisfaction levels were examined; patients that reported “very good” (score = 7) or “good” (score = 6) results were considered to be satisfied with the procedure.

Results:: Neuropathic pain and central sensitivity syndromes was significantly reduced at each visit follow up after PRF (P < 0.001, repeated measures one-factor analysis). In addition, at 3 months post-PRF, more than half of the patients achieved a successful response (≥ 60% pain reduction) and were satisfied with treatment results.

Conclusions:: CPRF stimulation under ultrasonic guided more safe for patients and clinicians. And can do in outpatients.
POST AUTHORIZATION SAFETY STUDY ON PITOLISANT (PASS-PITOLISANT) IN NARCOLEPSY: RESPONSE TO TREATMENT FROM THE ITALIAN MULTICENTER COHORT.

Michela Figorilli¹, Carlotta Mutti², Valerio Brunetti³, Paola Proserpio⁴, Claudio Liguori⁵,⁶, Isabelle Lecomte⁷, Nora Blanchard⁸, Tommaso Sacco⁹, Giuseppe Plazzi¹⁰,¹¹
¹Università di Cagliari, Centro Di Medicina Del Sonno, Dipartimento Di Scienze Mediche E Sanità Pubblica, Cagliari, Italy, ²Azienda-Ospedaliero-Universitaria (AOU) di Parma, Centro Di Medicina Del Sonno, Dipartimento Di Medicina E Chirurgia, Parma, Italy, ³IRCCS Fondazione Policlinico Universitario A. Gemelli, Neurology Unit, Rome, Italy, ⁴ASST Grande Ospedale Metropolitano Niguarda, Centro Di Medicina Del Sonno. Dipartimento Di Neuroscienze, Milano, Italy, ⁵Università degli Studi di Roma Tor Vergata, Centro Di Medicina Del Sonno, Dipartimento Di Medicina Dei Sistemi, Roma, Italy, ⁶Policlinico Tor Vergata, Uoc Neurologia, Roma, Italy, ⁷Bioprojet, Medical Department, Paris, France, ⁸Bioprojet, Pharmacovigilance Department, Paris, France, ⁹Bioprojet Italia, Direzione Medica, Milano, Italy, ¹⁰Università di Modena e Reggio-Emilia, Dipartimento Di Scienze Biomediche, Metaboliche E Neuroscienze, Modena, Italy, ¹¹IRCCS Istituto Scienze Neurologiche di Bologna, Università di Bologna, Dipartimento Di Scienze Biomediche E Neuromotorie, Bologna, Italy

Background and Aims:: 14 Italian Centers enrolled 191 narcoleptic patients in the observational PASS-pitolisant. Besides drug’s safety, the study analyzed variations of narcolepsy symptoms, depression, quality of life and disease burden.

Methods:: from PASS-Pitolisant’s 3rd Interim report we extracted detailed clinical data on patients who concluded the 1-year follow-up (FU) visit. Clinical Global Impression (CGI) for Excessive Daytime Sleepiness (EDS) and cataplexy severity were judged by sleep experts. Validated questionnaires were administered to evaluate EDS (Epworth Sleepiness Scale, ESS), depression (Beck Depression Inventory, BDI), quality of life (EQ-5D-5L) and disease burden (Functional Outcome of sleep questionnaire, FOSQ10).

Results:: of the 191 patients (76.4% narcolepsy type I and 23.6% narcolepsy type II) enrolled, 96 completed the 1-year FU visit. ESS decreased from 15.2±4.4 at baseline to 12.4±4.5 and responders (ESS≤10 or ESS decrease≥3) were 57.3%. Other main narcoleptic symptoms including cataplexy, sleep attacks, sleep paralysis and hypnagogic hallucinations ameliorated in 39.7%, 49.4%, 15.6% and 21.5% of patients, respectively. According to CGI, 87.5% of patients had improvement of EDS and 64.5% of cataplexy. Moreover, at FU visit an increase of EQ-5D-5L score (baseline: 64.7; FU:15.6±3.4), an increase of FOSQ-10 score (baseline: 13.7±3.8; FU:15.6±3.4), and no worsening of BDI score for 96.3% of patients were observed.

Conclusions:: According to PASS-Pitolisant interim report, patients recruited from the Italian centers reported improvement of narcolepsy symptoms at 1-year FU. Treatment favorably impacted on quality of life and on depressive symptoms, mitigating the burden of disease.
Background and Aims:: To investigate sleep disorders in patients with Chronic kidney disease.

Methods:: Neurological Examination and the Pittsburgh Sleep Quality Assessment Scale

Results:: The study involved 42 patients undergoing routine hemodialysis (15 women (35.7%), 27 men (64.2%)) the average age was 41.6±2.8 years. 35 patients after kidney transplantation (15 women (43%), 20 men (57%), the average age was 40.6±2.3 years. For control, 40 completely healthy people, the average age of which was 37.6±3.2 years. In the group of patients undergoing routine hemodialysis, the main complaints were: insomnia (36%), daytime sleepiness (19%), restless legs syndrome (23.8%), frequent awakenings (21.4%). In the group of patients after the transplant, complaints of difficulty in falling asleep prevailed 45.7%; 17.1% of patients complained of insomnia, and 37.1% had no problems with sleep. In the control group, only 25% of patients had problems with sleep, and this was manifested in difficulty in falling asleep. The Pittsburgh Sleep Quality Assessment Scale shows the total value for all components of the PSQI scale in the group receiving hemodialysis was 8.90±1.32 points, in the group of patients after transplantation 5.34±1.54; in the control group – 3.06±0.98 points

Conclusions:: According to the Pittsburgh Scale, sleep problems are less common in transplanted patients than in patients receiving routine hemodialysis. The transplanted patients had significantly better overall sleep quality than the patients on maintenance hemodialysis, but at the same time, their sleep was worse than that of the healthy control group.
IMPACT ON THE SLEEP OF PATIENTS WITH COVID 19 IN SELF-ISOLATION: A SYSTEMATIC REVIEW

Amanda Lira
Santa Casa Hospital/Maceió/Alagoas, Ent Department, Maceió, Brazil

Background and Aims:: COVID-19 challenges medicine in numerous aspects, including the triggering and / or worsening of sleep disorders, which can both hinder the treatment of this disease and may imply the emergence of other morbidities, especially mental and cardiovascular diseases. For this reason, this systematic review was carried out with the objective of verifying the sleep behavior in self-isolated individuals as well as identifying which preventive and therapeutic measures can be used to decrease sleep disturbances.

Methods:: The author performed the data extraction in 4 different databases (PUBMED, COCHRANE, MEDLINE, SCIELO) using the terms "sleep disorders" and "COVID-19 disease" as descriptors. A total of 12 articles were found from which the titles and abstracts were read, but only 5 articles were considered in accordance with the research objectives. These were then carefully analyzed and the main considerations were compiled.

Results:: The articles alert to the importance and care with the prevention, recognition and treatment of sleep-related diseases, given that social confinement and concerns about the pandemic generate negative emotions that can predispose sleep diseases and / or mental disorders that can cause considerable damage to health.

Conclusions:: Alternatives treatment as relaxation techniques, implementation of social capital and even the use of melatonin must be established to reduce the impact of sleep disorders in the COVID-19 population.
ARTIFICIAL NEURAL NETWORKS ANALYSIS OF SLEEP FEATURES AND COGNITIVE-BEHAVIORAL PROFILE IN SLEEP-RELATED HYPERMOTOR EPILEPSY AND DISORDERS OF AROUSAL

Elisa Casaglia, Michela Figorilli, Antonella Gagliano, Ludovica Tamburrino, Roberta Coa, Maria Giuseppina Mascia, Davide Fonti, Rosamaria Lecca, Patrizia Congiu, Enzo Grossi, Monica Puligheddu

1University of Cagliari, Department Of Medical Sciences And Public Health, Cagliari, Italy, 2University of Cagliari, Sleep Disorder Center, Department Of Medical Sciences And Public Health, Cagliari, Italy, 3University of Cagliari, Unità Di Neuropsichiatria Dell'infanzia E Dell'adolescenza-dipartimento Di Scienze Biomediche, Cagliari, Italy, 4ATS Cagliari, Neurologia Riabilitativa Po Ss Trinità, Cagliari, Italy, 5Villa Santa Maria Foundation, Autism Research Unit, Tavernerio, Italy

Background and Aims:: Increased sleep instability and reduced sleep quality are both features and promoting factors for sleep-related hypermotor epilepsy (SHE) and disorders of arousal (DOA). We aimed to compare subjective sleep quality, objective sleep features and cognitive-behavioral profile in patients with SHE and DOA.

Methods:: A total of 11 subjects with DOA (3 males mean age 32.3±10.9 years) and 12 subjects with SHE (6 males 33.5±15.2 years) were enrolled at the Sleep and Epilepsy Center of the University of Cagliari. All subjects were not taking any medications and they underwent a full-night video-polysomnography together with a broad cognitive and behavioral assessment. Subjective sleep quality was evaluated by Pittsburgh Sleep Quality Index. A data mining approach with fourth-generation Artificial Neural Networks has been used in order to discover subtle trends and associations among variables.

Results:: SHE patients reported significantly more depressive symptoms (p=0.01) and they performed significantly worse in short-term verbal memory (p=0.003) and verbal learning (p=0.002), moreover, they showed worse subjective sleep quality and objective sleep efficiency (p=0.001; p=0.004) compared to DOA patients. The artificial neural network methodology and the self-contracting map exploited the links of variables that reveal the complexity of a specific phenotype allowing to group SHE and DOA respectively.

Conclusions:: SHE is associated with decreased subjective and objective sleep quality, worse cognitive profile and depressive symptoms compared to DOA patients. These results suggest a severer sleep disruption that might be associated with heavier burden of diseases in terms of sleep-based health consequences, compared to DOA.
TWENTY-FOUR HOURS BLOOD PRESSURE PROFILE IN IDIOPATHIC REM SLEEP BEHAVIOR DISORDER

Laura Pilati¹, Michele Terzaghi², Natascia Ghiotto³, Dario Arnaldi⁴, Maurizio Versino⁵, Valter Rustioni⁶, Ivana Sartori⁷, Raffaele Manni⁸
¹University of Palermo, Department Of Biomedicine, Neuroscience And Advanced Diagnostics, Palermo, Italy, ²IRCCS Mondino Foundation, Unit Of Sleep Medicine And Epilepsy, pavia, Italy, ³Interinstitutional Center of Neurological Medicine, Irccs Mondino Foundation, Pavia, Italy, ⁴University of Genova, Dipartimento Di Neuroscienze (dinogmi), Genova, Italy, ⁵Università dell’ Insubria, U.o. Neurologia, Ospedale Di Varese, Varese, Italy, ⁶University of Pavia, Department Of Brain And Behavioral Sciences, pavia, Italy, ⁷Niguarda Hospital, C.munari Center Of Epilepsy Surgery, Milano, Italy, ⁸IRCCS Mondino Foundation, Unit Of Sleep Medicine And Epilepsy, Pavia, Italy

Background and Aims:: The aim of this study is to determine whether autonomic dysfunction in idiopathic REM sleep behavior disorder (iRBD) subjects affects circadian blood pressure (BP) profile.

Methods:: We performed a cross sectional study including 22 iRBD (19 males; mean age 68.1±6.1, mean age at onset 61.7±9.2), 22 de novo drug-free subjects with Parkinson’s Disease (PD) and 22 control subjects (HC) comparable for age and sex undergoing 24-hour ambulatory BP monitoring. Prospective follow-up study evaluated the occurrence of neurodegenerative disorders in iRBD cohort.

Results:: Mean BP decrease at night was lower in iRBD (4.6±8.9% for systolic and 9.1±8.1% for diastolic BP; p=.001 and p=.003 respectively) than HC. The non-dipping status was more frequent in iRBD subjects (72.7% for systolic and 54.5% for diastolic BP; p=.001 and p=.01 respectively) than HC. Inverted dipping was found in 22.7% for systolic (p=.048) and 4.5% for diastolic BP in iRBD. Non dipping status was not associated with differences in gender, age, disease duration, age at onset, UPDRS score, presence of antihypertensive therapy and polysomnographic measures. Patients with de novo PD showed comparable daytime and nighttime BP profile compared to iRBD. Sub-analysis considering only subjects without antihypertensive therapy (13 iRBD, 12 PD) showed the same results(Table1). At follow up (mean 5.2±1.9 years) no differences in BP profile at baseline were found between converters (n=7) and non-converters(table2).

Abbreviation: UPDRS: Unified Parkinson's Disease Rating Scale; MMSE: Mini mental Status Examination; AHI: Apnea hypopnea Index; ODI: oxygen desaturation index
Conclusions:: 24-hour BP control was impaired in iRBD with reduced amplitude of nocturnal dipping and increased frequency of non-dipping status, similarly to de novo PD. This could affect cardiovascular morbidity and mortality in iRBD.
PREVALENCE OF SLEEP AND ANXIETY DISORDERS ON BATIK WORKERS WITH LOW BACK PAIN IN YOGYAKARTA, INDONESIA

Cempaka Thursina¹, Abdul Gofir¹, Keisha Lyubiana², Kusumastuti Dewi², Giga Alkarani¹
¹Universitas Gadjah Mada, Neurology, Yogyakarta, Indonesia, ²Universitas Gadjah Mada, Faculty Of Medicine, Public Health, And Nursing, Yogyakarta, Indonesia

Background and Aims:: Yogyakarta is one of Indonesia’s batik producer regions, one of which is located in Lendah, Kulon Progo where the batik industry is the main source of income. Throughout the process of batik production, batik workers have to do repetitive movements with non-ergonomic posture for the long-hour shifts. This puts them at risk of getting any neuromuscular and psychological problems. In Lendah, 70.4% of its batik workers suffer low back pain. This condition may affect their productivity at work, their economics, and their quality of life. The purpose of this research is to know the prevalence of sleep and anxiety disorders on batik workers with low back pain in Kulon Progo, Yogyakarta, Indonesia.

Methods:: This research is using a cross-sectional method and it takes place in batik-producing centers in Kulon Progo, Yogyakarta. The number of subjects in this research is 26 people. This research uses the Indonesian version of the Insomnia Severity Index and Hamilton Rating Anxiety Scale (HARS) questionnaire to determine sleep disorders and anxiety disorders.

Results:: The result shows that 5 out of 26 subjects (19.2%) suffer sleep disorders and 4 out of 26 subjects (15.4%) suffer anxiety disorders. The majority of subjects who suffer from sleep and anxiety disorders are workers with a range of age 25-34 years old, worked for less than 6 years, work in the stamping section, and work for less than 8 hours a day.

Conclusions:: The prevalence of sleep and anxiety disorder in batik workers with low back pain in Kulon Progo, Yogyakarta is 19.2% and 15.4%
Background and Aims:: Hypersomnolence is a risk factor of ischemic stroke (IS), as well as one of its complications. We analyzed literature sources to study existing methods and neurotransmitters for diagnosing hypersomnolence in acute IS, and to assess the possibility and necessity of their use in this group of patients.

Methods:: We reviewed 64 publications taken out from the databases PubMed, Embase, Frontiers, ResearchGate.

Results:: Currently, for the clinical and instrumental assessment of hypersomnolence disorders, questionnaires (ESS, SSS, PSQI), sleep diary, MSLT, PSG, actigraphy are used. Each method has its own pros and cons. They all complement each other, making it possible to compose the most complete picture. The main criteria for choosing a method – the ability to perform a specific study in a hospital, and the patient's ability to postpone the study / fill out questionnaires. GABA, adenosine, glutamate, norepinephrine, serotonin, acetylcholine were mentioned as laboratory biomarkers. In the context of our search for hypersomnia biomarkers in IS, glutamate, GABA, and acetylcholine seem to be the most promising. The influence of most neurotransmitters on the regulation of sleep and wakefulness has been studied only experimentally. The gradual accumulation of deeper knowledge about the neurochemistry of the sleep-wake cycle will lead to the development of new laboratory tests, as well as new treatments for patients with post-stroke hypersomnolence.

Conclusions:: To determine the optimal diagnostic algorithm for hypersomnolence in patients in the acute period of stroke, it is necessary to study with the rational use of the considered methods.
Background and Aims:: autoimmune encephalitis (AE) is frequently associated with manifold sleep disturbances, but limited information on sleep structure is available. Polysomnographic (PSG) features were analyzed in a 32-year-old woman with AE manifesting with subacute behavioral anomalies, confusion, aphasia and focal left temporal seizures. Anti-thyreoperoxidase antibodies were detected on cerebrospinal fluid.

Methods:: overnight PSG was recorded 10 days after admission. Standardized sleep scoring (macrostructure), enriched by cyclic alternating pattern (CAP) analysis (microstructure) was performed and compared to age-matched healthy sleepers (HS).

Results:: PSG showed sleep fragmentation (30 awakenings), reduction of sleep efficiency (81%), curtailment of REM sleep (16%). The most relevant deviations were noticed at the microstructural level, with reduction of sleep instability (CAP rate 16.5% vs 33% in HS), flat nocturnal distribution and reduced length of CAP cycles, shorter A phases and prevalence of CAP subtypes A2. Diffused paroxysmal discharges were observed during NREM and REM sleep. Notably most CAP cycles were triggered by epileptiform discharges, however they rarely structured into CAP sequences.

Conclusions:: to the best of our knowledge this is the first PSG analysis of an AE in the subacute phase evaluating microstructural data. Reduction of CAP oscillations and anomalies in their duration and ultradian distribution were the main findings, in contrast with the commonly observed increase of CAP rate in epileptic patients during sleep. Recent evidences described impairment of CAP parameters in various neurodegenerative disorders. The role of sleep in the entanglement between epilepsy, inflammation and evolving neurodegeneration in AE is discussed.
UNDERESTIMATED SLEEP BREATHING DISORDERS IN A COHORT OF PATIENTS ADMITTED TO POST-COVID19 FOLLOW-UP PROGRAM: A SINGLE CENTER EXPERIENCE

Marco Cesare Angeli¹, Francesco Rausa¹, Elia Satta², Marcello Luigi Salvatelli¹, Irene Pollara¹, Clara Rapina¹, Marina Aiello², Pier Anselmo Mori², Raffaele D'Ippolito³, Emanuela Burlone³, Veronica Alfieri³, Maria Majori⁴, Carlotta Mutti¹, Liborio Parrino¹
¹University Hospital of Parma, Neurology Unit, Sleep Disorder Center, Department Of Medicine And Surgery, Parma, Italy, ²University Hospital of Parma, Occupational Medicine Unit, Department Of Medicine And Surgery, Parma, Italy, ³University Hospital of Parma, Respiratory Disease And Lung Function Unit, Department Of Medicine And Surgery, Parma, Italy, ⁴University Hospital of Parma, Unit Of Pulmonology And Thoracic Endoscopy, Department Of Medicine And Surgery, Parma, Italy

Background and Aims:: Sleep Breathing Disorders (SBD) have been suggested as potential risk factors for critical Covid19. We explored the prevalence of undiagnosed SBD in a cohort of > 200 adult patients admitted to the multidisciplinary follow-up program for Covid19 at Parma Hospital. Functional outcomes and prognosis will be compared between obstructive sleep apnea (OSA) versus non-OSA patients.

Methods:: In the follow-up program patients considered at high risk for SBD, measured through validated questionnaires (STOP-BANG, Epworth Sleepiness Scale) supported by the physician’s evaluation, are sent to our Sleep Disorders Centre for nocturnal cardiorespiratory recording.

Results:: So far 94/150 patients (mean age 59.3 +/- 11.5, 59.6% male, mean BMI 32.6 +/-6.95) have been admitted to our Sleep Disorders Center. Overall 68.1% (64/94) were affected by OSA divided in: 38/94 (40.4%) mild (apnea hypopnea index - AHI 5-15/h), 9 (9.6%) moderate (AHI 15-30/h) and 18 (19.1%) severe (AHI>30/h). 9/94 obese patients (9.6%) presented sleep-related hypoxemia suspected for obesity hypoventilation syndrome. 22/94 (23.4%) showed a periodic limb movements disorder.

Conclusions:: Our preliminary results identified a high rate of undiagnosed sleep-related breathing and movement disorders in a large adult cohort of patients with recent Covid19. Disease severity and clinical outcomes between undiagnosed OSA versus non-OSA patients will be detailed. Sleep evaluation enriches post-Covid19 follow-up investigation, providing highly informative in patients complaining of excessive daytime sleepiness.
PREDICTORS ASSOCIATED WITH VERY SEVERE OBSTRUCTIVE SLEEP APNEA [AHI>60 EVENTS PER HOUR] AMONG SLEEP CENTER PATIENTS IN MONGOLIA

Shuren Dashzeveg1, Otgonbayar L2
1General hospital for state special servants, Sleep Center, Ulaanbaatar, Mongolia, 2Mongolian National University of Medical Sciences, Neurology, Ulaanbaatar, Mongolia

Background and Aims:: Obstructive sleep apnea (OSA) is a common condition characterized by repetitive obstruction of the upper airway during sleep with resultant episodic hypoxia and arousal. The presence of OSA is determined from Apnea-Hypopnea Index (AHI). Our goal is to characterize the demographics, clinical and sleep characteristics of very severe OSA (vsOSA). Moreover, we aimed to analyze predictive factors for OSA.

Methods:: In this cross-sectional, prospective, hospital-based study patients were divided of AHI < 60, and AHI >60. Demographic, anthropometric, clinical and polysomnographic (PSG) variables included for the analysis were: age, weight, BMI, neck and abdominal circumference, Malanpatti’s score, Tonsil grade, blood pressure (BP), oxygen saturation (SpO2) and selected PSG indicators. Data analyses were conducted with SPSS version 26.0.

Results:: Male (105) were slightly more than women (102) out of remaining 207. Mean age was 48.7±12.7. 70% of had higher education and live in the Ulaanbaatar. Patients divided into 2 groups of AHI<60 (157) and AHI>60 (50). Meantime women tend to have AHI<60 (62%), while man have severe (90%) (p<0.0001). Most of anthropometric; vital measurements were significantly increased in AHI>60 group (p<0.0001). All sleep questionnaires showed decreased sleep quality and day time sleepiness in AHI>60. PSG variables showed decreased sleep efficiency. (p<0.0001). Between possible risk factors and the AHI were gender, SpO2 min, neck circumference, and PSQI questionnaire showed high correlation.

Conclusions:: In Mongolia 90% of male OSA patients have AHI>60, younger obese men. Increased abdominal and neck circumference, lower level of minimal and maximum SpO2 had significant risk factor for vsOSA.
OBSTRUCTIVE SLEEP APNEA (OSA) DETECTION SYSTEM BASED ON FAST FOURIER TRANSFORM (FFT) ALGORITHM ON ELECTROCARDIOGRAM

Rifaldy Fajar, Prihantini Jupri, Sahnaz Putri
Yogyakarta State University, Computational Biology And Medicine Laboratory, Sleman, Indonesia

Background and Aims:: In this study, an Obstructive Sleep Apnea (OSA) disease detection system was created using the RR interval parameter. The design of this detection system uses backpropagation Artificial Neural Network (ANN) which is implemented using MATLAB software as a method in the classification of OSA determination.

Methods:: The steps taken to design an OSA disease detection system in this study include data collection, feature extraction, ANN training, ANN testing, and performance determination. The feature extraction stage is performed using the Fast Fourier Transform (FFT) mathematical algorithm process. The result of feature extraction is then carried out ANN training using 10% of the entire data and ANN testing using 90% of the total data. To get the best performance results, variations in segment length features, variations in OSA definition features, and variations in frequency composition features are performed.

Results:: The best performance results in this OSA disease detection system design are features that use a combination of frequency components 2, 5, and 6 with an OSA definition of 5% in the 90-segment length. This is shown from the results of ANN performance in the form of specialization, sensitivity, and best accuracy, with successive values of 79.3%, 84.6%, and 81.6%.

Conclusions:: A system design has been made to detect OSA. The feature used in this detection system is the RR interval feature that has been transformed using the Fast Fourier Transform operation. Based on the results of performance calculations, all values indicate a number exceeding 75% so that a system that can be said to be good in detecting is obtained.
PHASE AND AMPLITUDE CORRELATIONS CHANGE WITH DISEASE PROGRESSION IN IDIOPATHIC RAPID EYE-MOVEMENT SLEEP BEHAVIOR DISORDER PATIENTS

Dario Arnaldi¹, Monica Roascio², Pietro Mattioli¹, Andrea Donniagio¹, Francesco Famà¹, Laura Giorgetti¹, Nicola Girtler¹, Beatrice Orso¹, Andrea Brugnolo¹, Matteo Pardini¹, Silvia Morbelli², Flavio Nobili³, Gabriele Arnulfo²

¹University of Genoa, Department Of Neuroscience (dinogmi), Genoa, Italy, ²UNIGE, Department Of Informatics, Bioengineering, Robotics And System Engineering (dibris), Genoa, Italy, ³University of Genoa and IRCCS Ospedale Policlinico San Martino, Department Of Health Science (dissal), Genoa, Italy

Background and Aims:: Increased phase synchronization in EEG bands is thought to reflect the activation of compensatory mechanisms of cognitive decline in people with neurodegenerative diseases. Here we investigated whether altered large-scale couplings of brain oscillations could be linked to the balancing of cognitive decline in a longitudinal cohort of people with Idiopathic Rapid eye-movement sleep Behavior Disorder (iRBD).

Methods:: High-density EEG (HD-EEG), presynaptic dopaminergic imaging, clinical and neuropsychological data have been acquired in 18 patients (17 males, 70.6.8 years) with iRBD at two time-points (time interval 24.2 ± 5.9 months). HD-EEG power distribution, orthogonalized amplitude correlation and weighted phase lag index have been quantified at both time-points and correlated with clinical, neuropsychological and imaging data.

Results:: Four patients phenoconverted at follow-up (three parkinsonism and one dementia). At group level, neuropsychological scores decreased over time, without reaching statistical significance. However, alpha phase synchronization increased, and delta amplitude correlations decreased significantly at follow-up compared to baseline. Both large-scale network modulation significantly correlated with neuropsychological scores but not with sleep quality indices or presynaptic dopaminergic imaging data.

Conclusions:: These results suggest that increased alpha phase-synchronization and reduced delta amplitude correlation may be considered as electrophysiological signs of an active compensatory mechanism of the cognitive impairment in people with iRBD. Large-scale functional modifications may be helpful biomarker in the characterization of prodromal stages of alpha-synucleinopathies.
SLEEP DISORDERS AS A PREDICTOR OF PARKINSON'S DISEASE IN UZBEK NATIONALITY.

Bakhrom Amonov, Rustambek Matmurodov, Eldor Abdukodirov, Khanifa Khalimova
Tashkent medical academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: One of the earliest and most significant non-motor disorders in Parkinson's disease (PD) is sleep disturbance. To study sleep disturbance in PD in persons of Uzbek nationality.

Methods:: We examined 106 patients with PD (56 men and 51 women aged 56.09±10.9 years) and 10 healthy individuals matched by sex and age. The duration of the disease was 5.35±5.5 years, the stage of the disease according to the Hoehn-Yahr scale was 2.7±0.9.

Results:: The obtained results show that in 92 patients (86.75%) sleep disorders of the type of hyposmia and hypersomnia were observed. After 4–5 years, these patients developed a triad of symptoms such as bradykinesia, muscle rigidity and resting tremor. In 13 patients (12.2%), the disease began with movement disorders. Of 106 patients, 54 patients began to have sleep disturbances and changes in human character after a year, and motor disturbances developed very slowly. The long-term stage of the disease in these patients was 2.6 ± 0.6 years. In 52 patients, after 1/2 year, bradykinesia and an increase in the tone of the plastic type were observed, and the treatment of diseases was rapidly aggravated. The long-term stage of the disease in these patients was 1.5 ± 0.7 years.

Conclusions:: It should be noted above that the clinic and course of Parkinson's disease non-moving disorders, such as sleep disturbances, the characteristics and characteristics of the disease, depend on the duration and stage of the disease. Disorders are the main preclinical predictor of PD development, which requires timely diagnosis and treatment.
INFLUENCE OF COVID 19 IN MEDICAL STUDENTS’ SLEEPING CIRCLE

Francinny Kelly¹, Vhirginea Helena De Oliveira Staut Federle¹, Monaí Oliveira², Fernanda Garcia Passos³, Marcelo Hettwer⁴
¹Sao Caetano do Sul University, Sao Paulo, Neurology, São Paulo, Brazil, ²Sao Caetano do Sul University, Neurology, São Paulo, Brazil, ³Sao Caetano do Sul University, Sao Paulo, Neurology, Sao Paulo, Brazil, ⁴Municipal University of São Caetano do Sul, Medical School, São Paulo, Brazil

Background and Aims:: The correlation between COVID 19 and its impact in the people's lifestyle are still very new. However it is already possible to notice that it have been affecting human behavior and their way of living. The aim of this study is to evaluate the correlation of the COVID pandemic and how it affected medical students’ sleep quality.

Methods:: One hundred-fifty-three medical students from first to fifth year, volunteered to participate through an online questionnaire. Written approval was granted. The students answered a question (Q1) about the quality of their sleep. Q1: “During the pandemic, did you have any change on your sleep?”

Results:: Sleeping more but with lower quality: 34,6%; Sleeping more and with better quality: 22,2%; Sleeping less and lower quality: 20,3%; Sleeping less but with the same quality: 11,1%; No changing on the sleep: 11,8%

Conclusions:: The changes in lifestyle during the pandemic were significant, especially for medical students that have had all their schedules changed and in some cases, have been even fighting against COVID-19. As a result of these changes, it’s possible to notice that the amount and the quality of sleep have both been impacted during the COVID-19 pandemic. It could have been caused by a multitude of causes, ranging from emotional disorders to changes in the of the students’ quality of life.
A DATA DRIVEN APPROACH TO NEUROPSYCHOLOGICAL FEATURES IN ISOLATED REM BEHAVIOR DISORDER: A FOLLOW-UP INVESTIGATION.

Samantha Mombelli1, Caterina Leitner1,2, Marco Sforza1,2, Andrea Galbiati1,2, Giada D’Este1,2, Sara Marelli1,2, Marco Zucconi3, Francesca Casoni3, Luigi Ferini-Strambi3

1Vita-Salute San Raffaele University, Milan, Italy, Neurology, Sleep Disorder Center, Milan, Italy, 2“Vita-Salute” San Raffaele University, Milan, Italy, Psychology, Milan, Italy, 3San Raffaele Hospital, Milan, Italy, Neurology, Sleep Disorder Center, Milan, Italy

Background and Aims:: Isolated REM Behavior Disorder (iRBD) predates the insurgence of neurodegeneration by many years. Therefore, the neuropsychological evaluation in this condition is crucial. This study has two main goals: (1) to provide a neuropsychological profiling of a large cohort of iRBD subjects based on a data driven approach using Latent Class Analysis (LCA); (2) to evaluate neuropsychological trajectories from baseline to follow-up for each latent class.

Methods:: 289 iRBD patients at baseline (85.5% males, mean age: 67.58±7.69 years) underwent neuropsychological assessment. A subsample of 66 patients (86.4% males, mean age: 69.53±7.60 years) underwent a neuropsychological evaluation at follow-up (36.15±30.24 months). LCA was carried out to identify iRBD subtypes according to baseline neuropsychological scores, categorized into the following cognitive domains: global cognition, language, short-term memory, long-term memory (LTM), executive function (EF), and visuospatial abilities.

Results:: The most parsimonious model identified 3 latent classes. Groups were labeled as follows: class 1, moderately impaired (n=44); class 2, severely impaired (n=83); class 3, slightly impaired (n=162). EF and LTM significantly worsen (p<0.01) for all 3 classes over time. Considering EF, class 1 exhibited the greatest decrease in this cognitive domain compared to the other classes. Accordingly, class 1 showed the greatest increase in Mild Cognitive Impairment (MCI) frequencies from baseline (50.0%) to follow-up (58.3%).

Conclusions:: Our study identified 3 different cognitive phenotypes of iRBD. This identification might help in predicting different trajectories of neuropsychological performances and MCI diagnosis.
COGNITIVE-BEHAVIORAL INTERVENTIONS FOR THE ADHERENCE TO POSITIVE AIRWAY PRESSURE THERAPY: A META-ANALYSIS.

Marco Sforza¹,², Andrea Salibba¹,², Alessandro Scarpellino¹,², Andrea Galbiati¹,², Vincenza Castronovo³, Luigi Ferini-Strambi²,⁴
¹Vita-Salute San Raffaele University, Milan, Italy, Neurology, Sleep Disorder Center, Milan, Italy, ²“Vita-Salute” San Raffaele University, Milan, Italy, Psychology, Milan, Italy, ³Vita-Salute San Raffaele Hospital, Neurology, Sleep Disorder Center, Milan, Italy, ⁴San Raffaele Hospital, Milan, Italy, Neurology, Sleep Disorder Center, Milan, Italy

Background and Aims:: The first-line treatment of obstructive sleep apnea (OSA) is positive airway pressure therapy (PAP). In this context, adherence is widely recognized as problematic with mean adherence rates ranging between 46% to 89% limiting the effectiveness. Cognitive and behavioral interventions (CB) are promising for promoting adherence to PAP therapy. Our aim is to quantify the efficacy of CB interventions (Cognitive-Behavioral Therapy for Insomnia, Motivational Enhancement Therapy, Motivational Interview Nurse Therapy, Stage Matched Care and SCIP-PA Tailored Intervention) on PAP adherence in OSA patients through a meta-analysis.

Methods:: A systematic search of the relevant literature was performed by two independent researchers in Pubmed, Psychinfo, Cinhal, Embase, Scopus, and Medline up to December 2020. Including Randomized Controlled Trial (RCT) with CB interventions and PAP adherence as principal outcome, we implement a classical meta-analysis design with follow-up duration as covariate.

Results:: 10 RCT were selected (N intervention=466; N controls=471). The results suggest that the CB interventions’ effects on PAP adherence is medium (RE model d=0.44, CI 0.13-0.75). The mean usage for the control group was 3.46±2.15 hours, and 4.21±2.15 hours for the intervention group. No effect of follow-up duration was found (p=0.96).

Conclusions:: This meta-analysis provides evidence of a medium positive effect of CB intervention compared to the control group, on PAP adherence. These findings suggest that OSA patients with PAP therapy might receive beneficial effects from CB intervention, however there is a need for further investigation in this field.
SYMPTOMS AND RISK OF OBSTRUCTIVE SLEEP APNEA IN THE MONGOLIAN POPULATION: A NATION-WIDE ANALYSIS FROM THE MON-TIMELINE STUDY

Puntsagdulam Byambajav¹, Misheel Munkhtsetseg², Oyuntugs Byambasukh³, Batbayar Badral⁴, Tsolmon Jadamba², Byambasuren Dagvajantsan¹
¹Mongolian National University of Medical Sciences, School of Medicine, Department Of Neurology, Ulaanbaatar, Mongolia, ²Mongolian National University of Medical Sciences, School of Dentistry, Department Of Oral And Maxillofacial Surgery, Ulaanbaatar, Mongolia, ³Mongolian National University of Medical Sciences, School of Medicine, Department Of Endocrinology, Ulaanbaatar, Mongolia, ⁴Mongolian National University of Medical Sciences, School of Dentistry, 5department Of Orthodontics, Ulaanbaatar, Mongolia

Background and Aims:: The prevalence of obesity is dramatically increasing in Mongolia. Obese people have a higher risk for non-communicable diseases and Obstructive Sleep Apnea (OSA) syndrome. There is no data on the prevalence of OSA in the Mongolian population.

Methods:: We evaluated the risk of OSA using data from the population-based Mon-Timeline cohort (18 - 65 years of age). The risk of OSA syndrome was evaluated using the Berlin questionnaire, which consists of three categories (category 1: snoring and witnessed apneas; category 2: daytime sleepiness; and category 3: high blood pressure/obesity). Those who met any two of the three categories were considered at high risk for OSA syndrome.

Results:: In this cross-sectional study, a total of 1405 people - with a mean age of 42 ± 14.3, of which 42.5% were males - completed the questionnaire. Among them, 24.4% was classified as being at higher risk for OSA syndrome. Furthermore, 41.7% of the participants reported snoring, of which 39.3% responded that their snoring bothers other people. The prevalence of people with a higher risk for OSA syndrome was found to increase with age: notably 6.7%, 28.3% and 39.4% for age groups <30, 30 - 50, and >50 years, respectively. There were no differences between gender and education throughout the OSA risk categories.

Conclusions:: Based on a representative sample population, we conclude that OSA is prevalent and common among the Mongolian population.
RESTLESS LEGS SYNDROME AS A PREDICTOR OF SLEEP, FATIGUE, AND MENTAL HEALTH IN PATIENTS WITH CARDIOVASCULAR DISEASE

Nudra Malik
Lahore College Women University, Applied Psychology, Lahore, Pakistan

Background and Aims:: Restless legs syndrome (RLS) is a neurological disorder which is associated with sleep disruption and poor quality of life. It is often found to be a comorbid condition in individuals having cardiovascular diseases (CVD). The purpose of the current study was to find out the frequency of RLS among CVD patients and to examine sleep, fatigue, and mental health in patients with and without RLS.

Methods:: It was a cross-sectional study. A convenience sample of 200 CVD patients with age range between 35-65 years (55.49±7.67) was selected from different hospitals of Lahore, Pakistan. The patients completed the fatigue severity scale (FSS), general health questionnaire12 (GHQ-12), sleep problems scale and restless legs syndrome scale.

Results:: The results indicated that 14% of the CVD patients had RLS. Fatigue, sleep, and mental health was worse in patients having comorbid RLS as compared to the ones without RLS. General linear model showed RLS, BMI, and CVD duration as significant predictors (p<.05) of poor sleep, fatigue, and deteriorated mental health in patients. Being female, increasing age and obesity were associated with an increased likelihood of RLS.

Conclusions:: RLS may affect patients having CVD affecting their treatment outcomes negatively. Screening the CVD patients for RLS could prove to be beneficial by reducing complications. The awareness of the associations indicated in this study among these variables might help health care providers in treating patients with CVD, sleep disorders or psychological problems to recognize potential contributing factors and to address those causes accordingly.
ASSOCIATION BETWEEN SUBJECTIVE–OBJECTIVE DISCREPANCY OF SLEEPING TIME AND HEALTH-RELATED QUALITY OF LIFE: A COMMUNITY-BASED POLYSOMNOGRAPHIC STUDY

Jae Myeong Kang¹, Seo-Eun Cho¹, Kwang Pil Ko², Seung-Gul Kang¹
¹Gachon University Gil Medical Center, Psychiatry, beon-gil, Namdong-daero, Namdong-gu, Incheon, Korea, Republic of, ²Gachon University College of Medicine, Preventive Medicine, Incheon, Korea, Republic of

Background and Aims:: This study aims to investigate the existence of a difference in QOL between individuals with and without significant subjective–objective discrepancy (SOD) of total sleep time (TST).

Methods:: From the Sleep Heart Health Study (SHHS) 2, a total of 2,540 individuals who had completed polysomnography, a morning sleep survey, and the 36-item Short-Form Health Survey (SF-36) were included in the analyses. The participants were classified as normoestimators (estimation of TST < ± 60 min), underestimators (underestimation of TST ≥ 60 min), or overestimators (overestimation of TST ≥ 60 min). The standardized SF-36 QOL scores were compared between the 3 groups. An adjusted partial correlation analysis was conducted between SOD and QOL.

Results:: Of the 2540 participants, 1617 (63.7%), 433 (17.0%), and 490 (19.3%) were assigned to the normo-, under-, and overestimator groups, respectively. The bodily pain and social functioning components of the SF-36 score were significantly lower in the underestimators than in the normoestimators, whereas the physical functioning component was significantly lower in the overestimators than in the normoestimators. The absolute value of SOD in TST showed a significant negative correlation with physical and mental components of the SF-36.

Conclusions:: QOL was significantly better in the normoestimator than in the other groups, and linearly correlated with the absolute value of SOD. This study suggests that highly prevalent positive and negative sleep misperception in a community population can be a potential marker for poor QOL and potential co-morbidities.
SEX RELATED DIFFERENCES IN INFLAMMATION MARKERS IN ADULT PATIENTS WITH OBSTRUCTIVE SLEEP APNEA.

Chiara Rocchi¹, Valentina Conti², Viviana Totaro¹, Serena Broggi¹, Simona Lattanzi¹, Giovanna Viticchi¹, Lorenzo Falsetti³, Mauro Silvestrini¹, Laura Buratti³
¹Marche Polytechnic University, Neurological Clinic, Ancona, Italy, ²San Marino Hospital, Respiratory Medicine, San Marino, San Marino, ³Ospedali Riuniti Ancona, Internal And Subintensive Medicine, Ancona, Italy

Background and Aims:: Obstructive Sleep Apnea (OSA) is the highest prevalent sleep-related breathing disorder. Its link to inflammation and metabolic derangement is well known, as is its role as vascular risk factor. Men and women may show different symptom presentation and response to therapy. In this study we aimed to valuate sex-related differences in inflammatory status and their relationship with OSA severity.

Methods:: 110 consecutive subjects referred to the outpatient Sleep Disorder Service of the Respiratory Medicine Department, San Marino Hospital, were considered. Inclusion criteria were a diagnosis of moderate or severe OSAS and age range 45-80 years. Subjects with inflammatory conditions were excluded. All subjects underwent a polygraphic study and a blood draw for inflammatory markers.

Results:: Fifty-one of our subjects were females and 72 were affected by severe OSA. We created a 4-level categorical variable (moderate OSA, males; severe OSA, males; moderate OSA, females; severe OSA, females), where significant differences for interleukin-6 (IL-6) and C-reactive protein (CRP) emerged. The pairwise comparison for estimated marginal means of IL-6 and CRP showed a significant difference in IL-6 levels with a significant ascending trend (p=0.045) from females with moderate OSAS to males with severe OSAS. Similarly, we observed a significant trend (p=0.0001) for CRP levels from males with moderate OSAS to females with severe OSAS.

Conclusions:: OSA and inflammation are strongly related and both conditions are associated with vascular morbidity. Men and women may differ in OSA presentation and in inflammatory status, suggesting a personalized clinical approach.
Background and Aims:: Solriamfetol, a dopamine/norepinephrine reuptake inhibitor, is approved (EU/US) to treat excessive daytime sleepiness (EDS) in adults with narcolepsy (75-150 mg/day) or obstructive sleep apnoea (OSA) (37.5-150 mg/day). This study characterised patients with narcolepsy starting solriamfetol and prescribers’ rationales for initiating treatment.

Methods:: This retrospective chart review enrolled US-based physicians prescribing solriamfetol. Solriamfetol initiation was de novo (no prior EDS medication), transition (switched/switching from existing EDS medications), or add-on (adding to current EDS medication).

Results:: Twenty-three physicians entered data from 70 patients with narcolepsy (type 1, n=24; type 2, n=46; mean±SD age, 40±11 years; 57% female; 31% obese [BMI≥30]; 6 also had OSA). EDS was primarily moderate (59%) or severe (36%). Common comorbidities were migraines (17%), depression (14%), and cardiovascular disorders (14%). Solriamfetol initiation was de novo (n=19, 27%), transition (n=31, 44%), or add-on (n=20, 29%). Most transitioning (29/31, 94%) patients were taking 1 EDS medication, typically wake-promoting agents (22/31, 71%). Add-on patients were primarily taking 1 EDS medication (16/20, 80%), most frequently sodium oxybate (11/20, 55%). Solriamfetol’s efficacy was the primary reason prompting discussions to prescribe de novo (12/19, 63%); need for improved efficacy/augmenting effects of other medications was the primary reason for transitioning (18/31, 58%) and add-on (19/20, 95%). At data collection, 63 (90%) patients were on a stable solriamfetol dose. The most common reasons for discontinuing solriamfetol were lack of efficacy (n=3) and side effects (n=3).

Conclusions:: Efficacy and need for improved efficacy over existing medication(s) were key considerations for physicians prescribing solriamfetol to patients with narcolepsy.
Background and Aims:: Solriamfetol is a dopamine/norepinephrine reuptake inhibitor approved (EU/US) to treat excessive daytime sleepiness (EDS) in adults with narcolepsy (75-150 mg/day) or obstructive sleep apnoea (OSA) (37.5-150 mg/day). Given its clinical availability, this study characterised real-world dosing and titration with solriamfetol.

Methods:: This descriptive study included a quantitative retrospective patient chart review among US-based physicians prescribing solriamfetol for patients with EDS associated with narcolepsy or OSA. Initiation strategies were classified as de novo (no prior EDS medication), transition (switched/switching from existing EDS medications to solriamfetol), or add-on (adding solriamfetol to current EDS medication).

Results:: Physicians (n=23) entered data from 70 patients with narcolepsy (24/70 type 1; 46/70 type 2; mean±SD age, 40±11 years; 57% female; 6 also had OSA). EDS was mainly moderate (59%) or severe (36%). Nineteen patients (27%) initiated de novo, 31 (44%) transitioned, and 20 (29%) were add-on. Most patients (86%) started solriamfetol at 75 mg and were stable at 150 mg (76%). Most (67%) had 1 dose adjustment; median (range) time to a stable dose was 14 (1-60) days. EDS severity (44% of patients) was frequently considered when titrating. Fourteen of 22 (64%) transitioning from a wake-promoting agent (WPA) stopped it abruptly while 5/9 (56%) using stimulants tapered off. Physicians were likely (n=33, 47%) or very likely (n=30, 43%) to recommend their approach for similar patients.

Conclusions:: In a real-world study, most physicians prescribing solriamfetol to patients with narcolepsy started at 75 mg, tapered stimulants, abruptly discontinued WPAs, and made 1 dose adjustment.
SLEEP AND PREGNANCY

Laura Buratti¹, Antonio Pupillo¹, Chiara Rocchi¹, Serena Broggi¹, Simona Lattanzi¹, Giovanna Viticchi², Lorenzo Falsetti², Mauro Silvestrini¹
¹Marche Polytechnic University, Neurological Clinic, Ancona, Italy, ²Ospedali Riuniti, Internal And Subintensivemedicine, Ancona, Italy

Background and Aims:: The occurrence of anatomical, physiological, hormonal and psychological changes during pregnancy can be responsible for sleep alterations that can affect maternal and fetal health state of the pregnant woman and the well-being of the fetus. In this respect, an increased prevalence of obstructive sleep apnea syndrome (OSAS), restless legs syndrome (RLS) and insomnia have been demonstrated.

Methods:: Fifty consecutive pregnant women aged 28.47±3.75 were selected and evaluated during the three trimesters. Validated approaches for the diagnosis of OSAS, RLS and insomnia were used. In the presence of one of these conditions, their severity was determined also by using specific scales.

Results:: During the study period, a high prevalence of OSAS, RLS and insomnia was evidenced. Furthermore, in subjects who complained of disorders in the early periods of pregnancy, there was a progressive increase in the severity of symptoms.

Conclusions:: OSAS and RLS are associated with an increased prevalence of pre-eclampsia and diabetes. In particular, the risk of hypertension in pregnancy, negatively influences intrauterine growth and increases the risk of caesarean delivery. Insomnia in pregnancy greatly increases the risk of postpartum depression. Despite the well-documented complications resulting from the presence of sleep disorders in particular OSAS, RLS and insomnia during pregnancy, to date sleep alterations in this particular condition are not adequately taken into account. Common sleep disorders such as OSAS, RLS, insomnia have a high prevalence in pregnancy, particularly during the third trimester with important effects on the outcome of pregnancy itself and the puerperium. Hence, the importance of promoting adequate screening aimed at an early identification.
THE PSYCHOLOGICAL IMPACT OF SLEEP QUALITY ON HEALTH CARE WORKERS DURING COVID-19 IN JORDAN

Hamza Wadi¹, Rabab Shannaq², Tareq Abu-Libdeh¹, Rama Hailat², Sajeda Albustanji³, Radi Tofaha Alhusseini¹, Amer Rawajfeh⁴, Zidan Alsaleh⁵, Ghina Zaidan⁶, Anas Hassouneh¹, Salsabeel Abughanmi¹ ¹Al-bashir hospital, Medicine, Amman, Jordan, ²princess Basma teaching hospital, Medicine, Amman, Jordan, ³assalt governmental hospital, Medicine, Amman, Jordan, ⁴mutah university, Psychiatry, Amman, Jordan, ⁵mutah university, Faculty Of Medicine, Amman, Jordan, ⁶prince rashid ben al-hasan military hospital, Medicine, Amman, Jordan

Background and Aims:: Sleep quality is a key aspect of the overall psychological health. Sleep quality can affect mental health in many aspects, causing major psychological disorders, such as: depression and anxiety. Objectives: to assess the overall psychological impact of sleep quality on health care providers in Jordan during COVID-19 pandemic.

Methods:: This is a descriptive cross-sectional multicenter hospital-based study conducted in Jordan from the period of 2/7/2021 to 12/7/2021. 418 participants were included in the study. Data collection was done online via Google form. A questionnaire was used containing 4 validated scales, the insomnia severity index (ISI), Epworth sleepiness scale (EPS), generalized anxiety disorder-7 (GAD-7), patient health questionnaire-9 (PHQ-9).

Results:: (56.7%) were males, (43.3%) were females. (28.8%) were residents, followed by (20.3%) were nurses, (19.7%) were general practitioners, and (16.8%) were specialists. About (44.8%) of the participants were diagnosed with COVID-19 and (75.4%) managed patients with COVID-19. (32%) suffered from moderate difficulty falling asleep, and (30%) have moderate difficulty staying asleep. About (21.2%) said that there sleep problems much interfere with their daily functioning. (34.4%) feel nervous and anxious more than half of the days, while (26%) had the same problem nearly every day. (34.5%) feel tired more than half of the days, while (26%) suffered from the same issue nearly every day.

Conclusions:: The results of this study support the view that poor sleep quality can affect the overall mental health dramatically. Poor sleep quality can cause a psychological problems, such as: depression, and anxiety.
ROLE OF SLEEP DURATION IN THE RELATIONSHIP BETWEEN EDUCATION AND MORTALITY

Sri Banerjee\textsuperscript{1,2}, Gary Szirony\textsuperscript{2}
\textsuperscript{1}Walden University, College Of Health Professions, Leola, United States of America, \textsuperscript{2}Walden University, College Of Health Professions, Baltimore, United States Minor Outlying Islands

\textbf{Background and Aims::} Growing evidence suggests an association between both short and long duration of habitual sleep and adverse health outcomes. In order to determine whether the population longitudinal evidence supports the presence of a relationship between duration of sleep and all-cause mortality, and how education plays a role in mortality outcomes.

\textbf{Methods::} This is a population-based cohort study of the 2005-2010 National Health and Nutrition Examination Survey with mortality data obtained through 2015. Adults aged 20 years or older with sleep duration information were categorized into Low(\leq 6), Medium(7-8), and High(\geq 9) hours. Stratified outcomes of all-cause mortality were evaluated using Cox regression.

\textbf{Results::} Percentage of deaths from low-sleep duration among the population (N=15,586) were higher among individuals without High School (HS) Diploma (12.8\%) versus at least some college education (5.7\%). The mean follow-up was 7.7 years. For all-cause mortality, the overall unadjusted hazard ratio (HR) of individuals without HS Diploma to college-educated individuals was 2.36 (95\% confidence interval [CI], 2.00-2.79, \(p < 0.001\)). Adjusted HR was elevated, 1.59 (CI 1.01-2.52, \(p = .04\)), among those with low-sleep duration but closer to 1.0 (0.89 CI 0.51-1.55, \(p < 0.25\)) among high-sleep duration, after controlling for physical, mental, and demographic risk factors.

\textbf{Conclusions::} Our study shows an unambiguous and consistent pattern of increased risk of dying among individuals with low education. However, this relationship is especially pronounced among individuals who have low sleep duration making it an important determinant of health. Screening for sleep disorders is especially important in the consideration of other neurological disorders.
SLEEP DISRUPTION, AS A CAUSAL AGENT FOR FIBROMYALGIA.

Isaac Mosquera
Instituto de Neurologia y Neurociencias Aplicadas, Neurología, Caracas, Venezuela

Background and Aims:: Sleep has an important role in neuronal plasticity and brain cellular signaling and its deprivation can lead different negative effects in brain and cognitive functions. FM is a chronic pain condition with abnormal pain processing and central sensitization. Reports show that sleep deprivation in healthy individuals can induce FM symptoms.

Methods:: A descriptive, cross-sectional study was conducted in 190 FM patients evaluated at the INNAP, Caracas, Venezuela. The ACR criteria for Fibromyalgia, Impact Questionnaire (FIQ), Generalized Pain Index (WPI), Symptom Severity Index (SS), Beck Depression Inventory, State-Trait Anxiety (STAI) were followed. Sleep interruption or fragmentation was evaluated by polysomnography.

Results:: According to the American Academy of Sleep Medicine, we found that all FM patients (48.39 + 13.75 years) had sleep disturbances, 31.38% related to their medical condition, 23.19% moderate to severe apnea, and 45.43% restless legs syndrome. We found a correlation (p = 0.069) between the effectiveness of sleep and the number of awakenings and an association with pain and depression. It is important to note that 100% of FM patients had non-restorative sleep and sleep disturbances as symptoms associated with their FM.

Conclusions:: Our data confirm that sleep disturbances can exacerbate the characteristic symptoms of FM and the importance of the sleep study as a routine diagnosis in patients with FM.
ASSOCIATION OF TRIGLYCERIDE-GLUCOSE INDEX WITH CLINICAL OUTCOMES IN PATIENTS WITH ACUTE ISCHEMIC STROKE RECEIVING INTRAVENOUS THROMBOLYSIS

Emma Toh¹, Amanda Lim², Leonard Yeo³, Ching-Hui Sia⁴, Jamie Ho⁵, Bryce Tan⁶, Aloysius Leow², Bernard Chan³, Vijay Sharma¹,³, Benjamin Tan¹,³
¹National University of Singapore, Yong Loo Lin School Of Medicine, Singapore, Singapore, ²National University Health System, Division Of Endocrinology, Department Of Medicine, Singapore, Singapore, ³National University Health System, Division Of Neurology, Department Of Medicine, Singapore, Singapore, ⁴National University Heart Centre, Department Of Cardiology, Singapore, Singapore, ⁵Cambridge University, School Of Clinical Medicine, Cambridge, United Kingdom, ⁶National University of Singapore, Department Of Physiology, Yong Loo Lin School Of Medicine, Singapore, Singapore

Background and Aims:: The Triglyceride-Glucose (TyG) Index is a novel marker of insulin resistance which has been shown to predict poor outcomes in acute coronary syndrome. However, this marker has not been evaluated in acute ischemic stroke (AIS) patients who have received intravenous tissue plasminogen activator (tPA).

Methods:: Consecutive AIS patients who received tPA in a comprehensive stroke centre were studied. TyG Index was calculated using the formula ln[fasting triglycerides(mg/dL) × fasting glucose(mg/dL)/2]. The primary outcome measured was 90-day mortality. Secondary outcomes included early neurological improvement (ENI), poor functional outcome (90-day modified Rankin Scale 3-6) and symptomatic intracranial hemorrhage (SICH). Adjusted logistic regression evaluated associations of TyG index with outcomes.

Results::
Of 698 AIS patients, TyG index was significantly lower in patients that survived at 90-days than those who died (8.61 [IQR: 8.27-8.99] vs 8.76 [IQR: 8.39-9.40], p=0.007). After adjustment for hypertension, age, NIHSS and presence of large vessel occlusion (LVO), TyG index remained significantly associated with 90-day mortality (adjOR: 1.97, 95% CI:1.34–2.90, p<0.001). Lower TyG index was found among those who achieved ENI (8.56 [IQR: 8.26-8.92] vs 8.69 [IQR: 8.31-9.08], p=0.006). On ordinal shift analysis, having 'high TyG' (TyG Index ≥ 9.28) was associated with an unfavorable shift in mRS outcomes (adjOR: 2.45, 95% CI: 1.67–3.60, p<0.001).

**Conclusions:** In AIS patients who received tPA, a higher TyG index or degree of insulin resistance was significantly associated with increased 90-day mortality and poorer outcomes.
ENDOTHELIAL NITRIC OXIDE SYNTHASE (GLU298ASP) POLYMORPHISM IS ASSOCIATED SIGNIFICANTLY WITH ISCHEMIC STROKE PRESENTING WITH SEIZURES AND ALTERED SENSORIUM

Alvee Saluja1, Kallur Saraswathy2, Shubhalaxmi Margekar2, Ankit Goyal3, Rajinder Dhamija1
1Lady Hardinge Medical College, New Delhi-110001, Neurology, New Delhi, India, 2Delhi University, Genetic Anthropology, New Delhi, India, 3Lady Hardinge Medical College, New Delhi-110001, Medicine, New Delhi, India

Background and Aims:: Endothelial nitric oxide synthase (eNOS) is an enzymatic marker whose genetic polymorphism might predispose to acute ischemic stroke (AIS) via vascular endothelial dysfunction. It has potential role in atherosclerosis, making it a plausible risk factor for stroke. Prior studies have failed to prove a conclusive relationship between eNOS polymorphism and AIS. The aim of this study is to find an association between the presence of eNOS polymorphism (Glu298Asp) and the risk of developing AIS.

Methods:: Materials and Methods: We recruited 307 subjects including 153 AIS cases and 154 healthy controls. The eNOS (Glu298Asp) polymorphism was identified in EDTA blood by PCR amplification of the target region followed by restriction enzyme digestion, and genotyping on Agarose gel. GG, GT and TT genotypes were obtained. Statistical analysis was done using SPSS software version 20.

Results:: A significant association was found between the presence of TT genotype and the risk of AIS (Odd’s ratio (OR): 2.43, P-value = 0.038). There was no significant association between the TT genotype and the traditional stroke risk factors. However, the TT genotype was significantly associated with the presence of altered consciousness (OR: 5.27, 95% CI: 1.59–17.04, P-value = 0.003) and with the occurrence of seizures at presentation (OR: 7.98, 95% CI: 1.99–32.09, P-value = 0.007).

Conclusions:: There is a significant association between the presence of eNOS polymorphism (Glu298Asp) and the risk of AIS, and the TT genotype may predispose to a more severe initial presentation of ischemic stroke.
ROLE OF ACE POLYMORPHISM IN ACUTE ISCHEMIC STROKE

Ankit Goyal¹, Alvee Saluja², Kallur Saraswathy³, Priya Bansal¹, Rajinder Dhamija²
¹Lady Hardinge Medical College, New Delhi-110001, Medicine, New Delhi, India, ²Lady Hardinge Medical College, New Delhi-110001, Neurology, New Delhi, India, ³Delhi University, Genetic Anthropology, New Delhi, India

Background and Aims:: Stroke is one of the leading causes of death and disability in India. Angiotensin-converting enzyme (ACE) is involved in the development of hypertension, atherosclerosis, cardio, and cerebrovascular disease and is a plausible genetic candidate for stroke. The role of ACE polymorphism is still uncertain and requires further investigation. The aim of this study was to study the role of ACE insertion/deletion polymorphism in acute ischemic stroke (AIS).

Methods:: Materials and Methods: One hundred thirty AIS cases and 130 age and sex matched healthy controls were recruited. Ten milliliters venous blood was drawn and 6 mL of blood was used for routine hematological, biochemical tests. Remaining 4 mL of EDTA blood was used for DNA extraction, PCR amplification, and restriction digestion. Three genotypes (II, ID, and DD) were visualized on 3% agarose gel. Association between genotypes among stroke case was done by Chi-square test with P-value <0.05 taken as significant.

Results:: DD genotype was significantly associated with the risk of stroke with P-value of 0.0001. Both the dominant and recessive models showed that the DD genotype was independently associated with an increased risk of ischemic stroke (OR= 20.732; 95% CI: 2.7241–157.7864; P-value= 0.003 for the recessive model and OR= 2.848; 95% CI: 1.5127–5.3649; P-value= 0.001 for dominant model).

Conclusions:: Our study showed a strong association between ACE polymorphism and the risk of AIS. This study paves the way for further studies to confirm the role of ACE polymorphism as genetic risk factors for AIS.
MASSIVE HEMORRHAGIC TRANSFORMATION IN PATIENT PREVIOUSLY TREATED WITH TICAGRELOR WITH ACUTE ISCHEMIC STROKE TREATED WITH ALTEPLASE

Lina Carazo Barrios, Alejandro Gallardo-Tur, Agustin Rodriguez Belli, Carlos De La Cruz Cosme
University Hospital Virgen de la Victoria, Neurology, Málaga, Spain

Background and Aims:: Patients with acute ischemic stroke treated with intravenous thrombolysis are often under previous treatment with antiplatelet drugs. The safety of Ticagrelor in this clinical scenario is unknown.

Methods:: We present a case report of a patient attended, admitted and treated in Neurology and Critical Care Unit of our hospital.

Results:: 88 year old male, previously under treatment with Acetylsalicylic Acid (100 mg) and Ticagrelor (90 mg) as dual antiplatelet therapy following acute myocardial infarction five months before, was admitted to the emergency room with acute hemiparesis and aphasia. The diagnosis was acute ischemic stroke (NIHSS 7) and the patient was treated with intravenous thrombolysis with Alteplase 90 minutes after the onset of symptoms. Despite being transferred to the Intensive Care Unit and being under treatment with Labetalol in order to strictly control blood pressure, the patient's condition worsened in the following days and a massive intracranial hemorrhagic transformation was found. A comfort care based approach was adopted and the patient died within the next 3 days.

Conclusions:: Antiplatelet therapy is widely used in patients with minor stroke, but Ticagrelor is currently not recommended for stroke or high risk transient ischemic stroke prevention. The evidence about safety of Ticagrelor pretreatment in patients suffering from acute ischemic stroke treated with intravenous thrombolysis is scarce, and further studies must be performed to determine the safety of Ticagrelor in this particular clinical scenario.
NEUTROPHIL TO LYMPHOCYTE RATIO AS A PREDICTOR OF ATRIAL FIBRILLATION IN ISCHEMIC STROKE

Marco Burattini¹, Eleonora Potente¹, Sergio Salvemini¹, Silvia Paolucci¹, Lorenzo Falsetti², Marco Bartolini¹, Mauro Silvestrini¹, Giovanna Viticchi¹
¹Marche Polytechnic University, Neurological Clinic, Ancona, Italy, ²Ospedali Riuniti Ancona, Internal And Subintensive Medicine, Ancona, Italy

Background and Aims:: Neuroinflammation is one of the main determinants of the final damage in ischemic stroke. Neutrophil to Lymphocyte Ratio (NLR) is a systemic inflammation biomarker, which has been related to poor outcome in ischemic stroke and to a higher risk of Atrial Fibrillation (AF). However, little is known about the association between NLR and AF in ischemic stroke patients.

Methods:: We enrolled patients admitted for acute ischemic stroke to the Stroke Unit of the Ospedali Riuniti Ancona from January 2019 to December 2019. For each patient we collected sex, age, stroke’s features, white blood cells count and subtypes on admission. We evaluated the occurrence of new-onset AF, the presence of pre-existing AF and the presence of any type of AF.

Results:: We evaluated 153 subjects (mean age 70,7 ± 11,8 years; 53% males) of whom 23 (15,0%) had pre-existing AF and 21 (13,7%) had new-onset AF. Patients affected by any form of AF had a significantly higher NLR than patients without AF (p=0,001). Patients with new-onset AF had a mean NLR of 8,0 ± 7,1, significantly higher than the cohort without, which was 4,7 ± 4,1 (p=0,003).

Figure 1: Neutrophil to Lymphocyte ratio (NLR) differences between patients with Atrial Fibrillation (AF) and patients without AF
Conclusions:: Inflammation plays a key role on AF development and maintenance. Therefore, NLR could reflect a higher systemic inflammation which can favor AF insurgence. Future larger studies are needed to clarify the relationship between AF and NLR as a biomarker of suspected cardioembolic stroke.

Figure 2: Neutrophil to Lymphocyte ratio (NLR) differences between patients with new-onset Atrial Fibrillation (AF) and patients without new-onset AF.
AMAUROSIS FUGAX DUE TO RADIATION INDUCED CAROTID STENOSIS TREATED BY CAROTID ARTERY STENTING

Shashank Nagendra, Avinash Gutte, Abhijit Gaikwad, Kamlesh Jagiasi
JJ Hospital, Neurology, Mumbai, India

Background and Aims:: Amaurosis fugax can be a presentation of a patient presenting with radiation induced carotid artery stenosis and such patients can be safely managed by carotid angioplasty and stenting.

Methods:: A 59 year old male, presented with four episodes of transient, painless loss of vision in the right eye since past 20 days which resolved spontaneously and completely. The patient had a history of oropharyngeal squamous cell carcinoma three years ago, for which he had received 6 cycles chemotherapy along with radiotherapy. MRI brain with angiogram was suggestive of diffuse long segment wall thickening with luminal narrowing of Right Internal Carotid Artery without any acute infarct or hemorrhage; which was confirmed by 4 vessel digital subtraction angiogram.

Results:: He underwent Right Carotid Artery angioplasty using a cutting balloon using a distal protection device, followed by stenting. Patient had no further episodes and did well on follow-up.

Conclusions:: Thus, amaurosis fugax can be a presentation of a patient with carotid artery stenosis after radiotherapy and such patients can be safely managed by carotid angioplasty and stenting.
UNUSUAL CAUSE OF STROKE IN YOUNG, A CASE OF BOW HUNTER SYNDROME

Shashank Nagendra, Avinash Gutte, Vinayak Sawardekar, Kamlesh Jagiasi, Pawan Ojha
JJ Hospital, Neurology, Mumbai, India

Background and Aims:: Bow hunter's syndrome is a rare vascular phenomenon characterized by dynamic insufficiency of the posterior cerebral circulation induced by rotation of the head within normal physiologic range and may lead to transient ischemic symptoms.

Methods:: We report a case of an 18-year-old male with vertebro-basilar stroke. On dynamic imaging with neck rotated to right, there was complete cessation of flow through left vertebral artery which was suggestive of Bow hunter syndrome. The right vertebral artery was normal even after dynamic imaging. There was a single PICA originating from the left vertebral artery that was supplying both the sides. There was a dysplastic left arch of atlas and bony spur and c7 vertebral anomaly with single posterior inferior cerebellar artery.

Results:: In view of the single stroke episode, patient was advised conservative management on antiplatelets, cervical collar and was advised to avoid turning neck to the right. On follow up after 3 months, he had no further such episodes.

Conclusions:: In this case, the most likely cause was significant narrowing of left foramen transversarium at C7 vertebra and the cause of vertebral artery dissection was the small superior bony projection at left arch of atlas. It is a rare presentation of congenital cranio vertebral junction anomaly with vertebro-basilar insufficiency. In regards to our patient, since symptoms were mild, conservative treatment and continued stroke prophylaxis by antiplatelets was pursued at this time with no surgical intervention.
INTRAVENOUS ADMINISTRATION OF DANTROLENE AND NIMODIPINE IN COMBINATION SIGNIFICANTLY IMPROVES CEREBRAL BLOOD FLOW PERFUSION IN A RAT MODEL OF CEREBRAL-INDUCED VASOSPASM

Maria J. Crespo¹, Marie Roman¹, Javier Morales², Henrique Martins³, Yancy Ferrer⁴
¹University of Puerto Rico-School of Medicine, Physiology, San Juan, Puerto Rico, ²University of Puerto Rico-School of Medicine, Anesthesiology, San Juan, Puerto Rico, ³University of Puerto Rico-School of Medicine, Pharmacology, San Juan, Puerto Rico, ⁴Universidad Central del Caribe, Neurosciences, Bayamon, Puerto Rico

Background and Aims:: Experimental evidence shows that concomitant administration of dantrolene and nimodipine has synergistic effects in reducing vasospasms in aortic rings from Sprague Dawley rats. To determine if this effect extends to the cerebral circulation, we investigated the effect of intravenous administration of dantrolene (2.5 mg/kg) and nimodipine (1 mg/kg and 2 mg/kg) on MCA blood flow velocity (BFV) in Sprague Dawley rats.

Methods:: BFV was evaluated with a Laser Doppler System seven days after induction of cerebral vasospasms. Mean blood pressure (MBP) and heart rate (HR) were also measured.

Results:: Individual administration of these drugs resulted in similar reductions in BFV (34% with dantrolene, n=6, p<0.05; 32% with nimodipine 2 mg/kg, n=6, p<0.05). Moreover, dantrolene combined with 1mg/kg of nimodipine decreased BFV by 48% (from 435.70 ± 21.50 to 284.30 ± 26.10 perfusion units, n=6, p<0.05). Similarly, dantrolene combined with 2 mg/kg of nimodipine, reduced BFV by 54% (from 536.00 ± 32.60 to 367.80 ± 40.90 perfusion units, n=6, p<0.05).

Conclusions:: The combination of dantrolene and 1mg/kg of nimodipine, did not alter MBP or HR. Thus, concurrent administration of 2.5 mg/kg dantrolene and 1 mg/kg nimodipine significantly reduces BFV in the MCA without altering hemodynamic parameters. Therefore, adding dantrolene to current standard pharmacological therapies may allow a dosage reduction of CCB and minimize the systemic secondary effects of these drugs. Furthermore, if our findings with rats are applicable to humans, the combined use of dantrolene and nimodipine at optimal doses may be effective in reducing CVSPs. Supported by NIH-MBRS-RISE Grant R25GM061838, and NIMHD-CCRHD-RCMI (U54-MD007600).
FUNCTIONAL OUTCOME AFTER RECANALIZATION THERAPY FOR BASILAR ARTERY OCCLUSION: A SINGLE CENTER EXPERIENCE

Ivona Šamle, Svjetlana Šupe, Josip Ljevak, Marko Radoš, Danilo Gardijan, David Ozretić, Ivan Jovanović, Ivan Perić, Nikola Blažević, Zdravka Poljaković

1School of Medicine, University of Zagreb, Neurological Intensive Care Unit, Zagreb, Croatia, 2University Hospital Center Zagreb, Neurological Intensive Care Unit, Zagreb, Croatia, 3Medical School of Zagreb, University Hospital Center Zagreb, Dept. Of Interventional Neuroradiology, Zagreb, Croatia, 4University Hospital Center Zagreb, Dept. Of Interventional Neuroradiology, Zagreb, Croatia, 5Medical School of Zagreb, University Hospital Center Zagreb, Neurological Intensive Care Unit, Zagreb, Croatia

Background and Aims: Acute ischemic stroke due to basilar artery occlusion (BAO) is a life-threatening condition with a mortality up to 90% if left untreated. The current practice of recanalization therapy consists of pharmacological thrombolysis and endovascular mechanical thrombectomy. This study aimed to determine predictors of functional outcome in those patients.

Methods: We conducted a retrospective data analysis of 57 patients with verified BAO in whom recanalization therapy was performed in the period from February 2016 to October 2019. Good functional outcome was defined as mRS 0-2, while successful recanalization as mTICI 2b-3. Futile recanalization was defined as mRS 6 despite successful recanalization.

Results: Mechanical thrombectomy was performed in 53 out of 57 (93%) patients included in our study preceded by intravenous thrombolysis in 21 (36.8%) patients. Successful recanalization was achieved in 64.9% (n= 37) of cases. Overall, 28.1% (n= 16) of patients achieved good functional outcome. Mortality was 52.6% (n= 30). In a multivariate analysis, atrial fibrilation was shown to be a statistically significant predictor of mortality in patients (p= 0.016), but also a significant predictor for futile recanalization (p=0.040) which occured in 35.1% of patients. Initial NIHSS was the only statistically significant predictor of good functional outcome (p= 0.006).

Conclusions: This study suggested that functional outcome after recanalization therapy for BAO may be influenced by the initial stroke severity and the presence of atrial fibrilation. Futile recanalization might be the reason for unfavourable functional outcome in patients with successful recanalization.
Background and Aims:: Anatomical cerebral arteries variations are relatively common. Their knowledge has become essential with the development of stroke treatments.

Methods:: Case report.

Results:: A 70-year-old man with a history of hypertension, smoking, and diabetes was found comatose. Brain CT was normal. CT-angiography showed an ulcerated atherosclerotic plaque in the right internal carotid artery (ICA, panel A) and full fetal origin of the right-sided posterior cerebral artery (PCA, panel B; panel C: schematic representation of the intracranial circulation). Brain MRI demonstrated bilateral thalamic infarction (right>left) consistent with acute ischemic stroke (panel D-F). Echocardiography and prolonged EKG monitoring resulted normal. The patient was diagnosed with artery of Percheron (AOP) territory stroke, likely due to artery-to-artery embolism originating from the right ICA.

Conclusions:: When PCA arises directly from the ipsilateral ICA, it’s defined “fetal”. AOP is a rare anatomical variant consisting of a single perforating artery arising from one of the PCAs and supplying both thalami. The diagnosis of an occluded AOP is inferred from the peculiar ischemic pattern, since AOP cannot be displayed by conventional angiography. In most cases, thalamic involvement is asymmetrical being greater on the side of AOP origin. Signs and symptoms include decrease consciousness, memory deficit, impaired eye movements. Given the lack of “classic” stroke signs, the majority of these strokes go overlooked in the emergency setting leading to delay of time-sensitive treatments. Keeping AOP infarcts
in the differential diagnosis of stupor and coma, and being aware of vascular variations, is critical to avoid misdiagnosis of potentially treatable syndromes.
CLEVELAND CLINIC ABU DHABI: STROKE PATIENTS JOURNEY FROM REFERRING HOSPITAL TO DISCHARGE, METHODOLOGY

Ahmed Tamimi, Terrence St John, Najla Touma, Victoria Mifsud, Prince Thakkar, Seby John, Syed Hussain, Bartlomiej Piechowski-Jozwiak
Cleveland Clinic Abu Dhabi, Research Office, Abu Dhabi, United Arab Emirates

Background and Aims:: Healthcare organizations in the United Arab Emirates (UAE), are looking for ways to improve the quality of services and to increase productivity. In the UAE stroke patients receive healthcare services from acute hospitals, dedicated stroke centers, rehabilitation and home care facilities. Cleveland Clinic Abu Dhabi (CCAD) is a stroke referral centre that operates as a 24/7 comprehensive neurovascular service providing thrombolysis and thrombectomy. Objectives: We aimed to map the journey of the stroke patients admitted to CCAD from the referring provider to post-acute care.

Methods:: Data was collected from March 2015 till the end of February 2019. The patients' pathways were mapped for both origins of admission to CCAD and discharge destination. We assessed patients' demographics, details of stroke and treatment, and health outcomes. The mapping was constructed using Bayesian Network analyses.

Results:: 1,550 patients (Mean age= 56 +/-15.76 years, Male (67%)) were tracked from five distinct routes: home (57%), CCAD (0.6%), other public/private hospitals or rehabilitation stroke centres (42%), and overseas point of entry; the final overlapping pathways account for 97.5% of the patients. These are direct local home discharges (72%), local rehabilitation centers (5%), local inpatient transfers (5%), deceased (6.5%), or repatriated to their home countries (9.5%).

Conclusions:: This study delineates the journeys of stroke patients receiving stroke services in the emirate of Abu Dhabi through the CCAD’s system. Mapping the journey of these patients advances our understanding of their interactions with other local healthcare organizations, and allows us to determine areas for service development at the country level.
A CASE SERIES: ARTERY OF PERCHERON SYNDROME

Muhammad Hassan¹, Omojowolo Olubunmi², Ahmad Shrourou¹, Nuno Lobatoribeiro²,³
¹Worcester Royal Hospital, Stroke Unit, KEIGHLEY, BRADFORD, United Kingdom, ²Worcester Royal Hospital, Stroke Unit, WORCESTER, United Kingdom, ³Worcestershire Acute Hospital NHS Trust, Stroke Medicine, Worcester, United Kingdom

Background and Aims:: Thalamus and midbrain share a complex blood supply from perforators arising from posterior cerebral artery (PCA) and posterior communicating artery. Artery of Percheron (AOP) is a rare anatomic variant arising from a PCA supplying paramedian thalami bilaterally and rostral midbrain. Occlusion of AOP infarcts with characteristic symptoms of vertical gaze palsy, memory impairment and coma called AOP Syndrome. It accounts for 0.3% of ischemic strokes. We share experience of managing four case of AOP strokes.
Methods:: All four of our patients presented with sudden collapse followed by loss of consciousness or fluctuating conscious level. Encephalitis and seizure were suspected and treated accordingly. Speech was dysarthric and cranial nerve abnormalities i.e. oculomotor and facial nerve palsy were noted. Patients had no recall of their presentation. Standard management was done in Hyperacute Stroke Unit. One of the patients received IV thrombolysis therapy. Another patient was complicated by pneumonia and pulmonary embolism (PE) and was treated with antibiotics and anticoagulation. Complete stroke diagnostic workup was requested. Initial CT head was unremarkable in all. Subsequently, MRI Brain showed acute bithalamic infarcts.
Unfortunately, the patient who had chest infection and PE succumbed to death. However, other three patients were discharged home after inpatient MDT rehabilitation with minor residual neurology.

**Conclusions:** Occlusion of AOP causes a rare ischemic infarct syndrome. Symptom complex of AOP syndrome may vary according to location of stroke. Having a Low threshold for clinical suspicion of AOP involvement makes early diagnosis possible. Prompt diagnosis allows earlier initiation of standard treatment. This has positive effects on prognosis.
THE ROLE OF PLATELET AGGREGATION IN HYPERTENSIVE INTRACEREBRAL HEMORRHAGE

Ivan Koltsov, Mikhail Martynov, Albina Yasamanova, Mikhail Fidler, Ivan Shchukin
Pirogov Russian National Research Medical University, Neurology, Neurosurgery, And Medical Genetics Department, Moscow, Russian Federation

Background and Aims:: Small penetrating vessels are a major source of bleeding in acute hypertensive intracerebral hemorrhage (ICH). The goal of this study was to evaluate the role of platelet aggregation in hematoma formation and evolution.

Methods:: Fifty patients with acute hypertensive ICH were included in the study. At admission, platelet aggregation tests were performed using a Biola LA230-2 aggregometer. Adenosine diphosphate, collagen, ristocetin, epinephrine, and arachidonic acid were used as aggregation inducers. A baseline computed tomography was obtained in every case. A partial least squares structural equation model was constructed in order to evaluate the relationship between platelet aggregation and intracerebral hemorrhage. The study was approved by the Local Ethics Committee.

Results:: A "Platelet Aggregation" latent variable (composite reliability = 0.719) was inferred from aggregate sizes measured during induced platelet aggregation tests with all inducers. A "Hematoma" latent variable (composite reliability = 0.811) was inferred from hematoma volume, midline shift, and the presence of an intraventricular extension of hemorrhage at admission. The total effect of the "Platelet Aggregation" latent variable on the "Hematoma" latent variable was -0.410 [95% CI from -0.665 to -0.296, T = 2.716, p = 0.007], indicating that low platelet aggregation was a poor prognostic factor in acute hypertensive ICH.
Conclusions: Platelet aggregation plays a major role in hematoma formation and evolution in acute intracerebral hemorrhage.
INTERLEUKIN-6 AND INTERLEUKIN-8 CONCENTRATIONS ARE PREDICTORS OF POOR OUTCOME IN ACUTE HYPERTENSIVE INTRACEREBRAL HEMORRHAGE

Ivan Shchukin, Mikhail Martynov, Ivan Koltskov, Mikhail Fidler
Pirogov Russian National Research Medical University, Neurology, Neurosurgery, And Medical Genetics Department, Moscow, Russian Federation

Background and Aims:: Interleukin-6 (IL-6) and interleukin-8 (IL-8), produced by macrophages, are major inflammatory cytokines. It is known that M1 macrophage activity (indicated by IL-6 upregulation) plays a major role in ischemic stroke. However, this subject is less studied in intracerebral hemorrhage (ICH). The goal of this pilot study was to investigate the role of IL-6, IL-8, and M1 macrophage activity in acute hypertensive ICH.

Methods:: In 24 acute ICH patients, blood plasma samples were collected and stored at minus 80 degrees Celsius. IL-6 and IL-8 concentration analysis was performed using a multiplex immunoassay. 21-day MRS score was obtained from medical records. The study was approved by the Local Ethics Committee.

Results:: There was a strong positive correlation between IL-6 and IL-8 concentrations ($r_s = 0.651, p = 0.001$) indicative of macrophage transition to M1 phenotype. In univariate models, IL-6 and IL-8 concentrations were predictive of in-hospital death [OR = 1.088 per 1 pg/mL of IL-6, 95% CI 1.009 - 1.174, $p = 0.029$ and OR = 1.124 per 10 pg/mL of IL-8, 95% CI 1.004 - 1.260, $p = 0.043$]. Additionally, in univariate models, IL-6 and IL-8 concentrations were predictive of higher 21-day MRS score [OR = 1.138 per 1 pg/mL of IL-6, 95% CI 1.063 - 1.263, $p = 0.002$ and OR = 3.646 per 10 pg/mL of IL-8, 95% CI 1.840 - 8.930, $p = 0.001$].

Conclusions:: A combination of IL-6 and IL-8 is an important marker of M1 macrophage activity in ICH and a predictor of 21-day disability and in-hospital death.
ROLE OF SOCIO-ECONOMIC STATUS IN CHOOSING THROMBOLYTIC AGENT AND ITS OUTCOME IN ACUTE ISCHEMIC STROKE: DATA FROM A TERTIARY CARE CENTER IN NORTH INDIA

Alex Rebello, Manoj Goyal, Vivek Lal, Manish Modi, Sarath Aleti, Saravana Sukriya
Postgraduate Institute of Medical Education and Research (PGIMER), Neurology, Chandigarh, India

Background and Aims:: Alteplase, a recombinant tissue-type plasminogen activator(rtPA) is the only FDA-approved thrombolytic drug in acute ischemic stroke(AIS). Tenecteplase is a modified rtPA which is cheaper. Cost is a major concern in stroke thrombolysis. We aimed to study role of Socio-economic status(SES) in patients' preference of thrombolytic agent and its outcome.

Methods:: This prospective observational study conducted in PGIMER, a tertiary care center in India, recruited AIS patients thrombolysed between July 2017 and September 2018. We studied variables including SES based on modified Kuppuswamy scale, thrombolytic agent chosen and outcome in terms of modified Rankin Scale(mRS) after 3months.

Results:: 39 patients received tenecteplase and 39 patients received alteplase. 7 patients belonged to upper class, all of whom(100%) chose alteplase. 30 patients belonged to upper middle class, of whom 25(83.3%) and 5(16.7%) patients chose alteplase and tenecteplase respectively. 25 patients belonged to lower middle class in which 7(28%) and 15(72%) chose alteplase and tenecteplase respectively. 20 patients were in upper lower class, of whom 4(20%) and 16(80%) chose alteplase and tenecteplase respectively. The between group difference in distribution of SES in tenecteplase and alteplase groups was statistically significant(p=0.000). Median mRS scores at 3months were 3.5 and 3 in tenecteplase and alteplase groups respectively, the difference being statistically insignificant(p=0.608). There was no correlation between SES and 3month-mRS score in tenecteplase (Spearman’s rho= 0.101, p=0.398) and alteplase groups (Spearman’s rho= -0.035, p=0.834).

Conclusions:: Majority of patients in upper and lower SES chose alteplase and tenecteplase respectively. However, there was no correlation between outcome and SES in both the groups.
FREQUENCY OF CEREBRAL INFARCTION AND INTRA-EXTRACRANIAL ARTERY STENOSIS IN MONGOLIAN YOUNG ADULTS

Delgermaa Tsagaankhuu¹, Baigalmaa Gongor², Tsagaankhuu Guntev¹
¹Mongolian National University of Medical Sciences, Neurology, Ulaanbaatar, Mongolia, ²Third central hospital, Stroke Unit, Ulaanbaatar, Mongolia

Background and Aims: The frequency of cerebral infarction and stenosis of intra- and extracranial arteries may vary with age-group and gender. This study was conducted to clarify the risk factors and characteristics of cerebral infarction and stenosis of vessels in Mongolian young adults.

Methods: This was a prospective study, from October 2015 to July 2020, of 100 patients below 50 years diagnosed with acute cerebral infarction. Patient characteristics were compared according to sex (61 males and 39 females) and age group (29 patients were below 34 years and 71 patients were 35–49 years). Characteristics of acute cerebral infarction were studied by DWI-diffusion weighted MRI imaging. Stenosis of intra- and extracranial arteries was diagnosed by duplex sonography, head and cervical magnetic resonance angiography (MRA).

Results: Leading causes for cerebral infarction in the young patients were hypertension (71%), smoking (57%), dyslipidemia (45%), diabetes (33%), and migraine with aura (25%). Lacunar Infarction was most common in our patients (33%). Partial anterior circulation infarction was predominant in males (45.9% vs 38.5%; P < 0.05) and posterior circulation infarction in females (23.1% vs 11.5%; P < 0.05). Small artery atherosclerosis was found in 33% of cases, with higher prevalence in patients of the 35–50 years age-group. Intracranial stenosis was more common than extracranial stenosis, and middle cerebral artery stenosis was most prevalent (38.9%). Stenosis in the anterior circulation was more frequent than in the posterior circulation (P < 0.001).

Conclusions: In these young patients, hypertension, smoking, dyslipidemia, diabetes, and migraine with aura were common risk factors. Intracranial stenosis was most common, particularly in the middle cerebral artery.
PREVALENCE AND PATTERN OF ADVERSE EVENTS IN PATIENTS RECEIVING INTRAVENOUS THROMBOLYSIS FOR ACUTE ISCHAEMIC STROKE

Olubunmi Omojowolo, Nuno Lobatoribeiro
Worcestershire Acute Hospital NHS Trust, Stroke Medicine, Worcester, United Kingdom

Background and Aims:: BACKGROUND Thrombolysis should be offered to all patients with Ischemic stroke who meets the selection criteria. It involves the intravenous infusion of tissue plasminogen activator tPA, which in our Trust is Alteplase. The rationale is to break down the clot in the blood vessel and restore blood flow to save the area of penumbra
AIMS •To determine the prevalence of adverse events •To highlight the different types of adverse events •To find out if there is aggregation of these adverse events to certain period of the day or months

Methods:: •This was a retrospective and prospective audit spanning between January and December 2020. The data was obtained from SSNAP and patients record, study conducted in the Acute Stroke Unit of Worcester Royal Hospita, United Kingdom All patients with acute Ischemic stroke who received thrombolysis were included in the study

Results:: •A sizeable numbers of patients who were administered Intravenous thrombolysis 42% developed various types of adverse reactions. •Bleeding complication both intracerebral and extracranial were the commonest encountered adverse events making up 46% •Out of hour thrombolysis resulted in more proportion of adverse events 46% as compared to 37% during normal working hours.

Conclusions:: •The NICE and RCP guidelines emphasizes offering thrombolysis to all patient with acute ischemic stoke who meets the selection criteria. •The percentage of compliance of 12.7% thrombolysis in this audit though similar to the national average is an indication that many factors are responsible for the relatively low level of thrombolysis in ischemic stoke.
Background and Aims:: Cervical artery dissections (CAD) are responsible for 10-25% of stroke in young adults, prior mild trauma is identified in up to 40% of cases. However, triggering or risk factors are absent in many patients so we should always include CAD in the etiological study of undetermined stroke.

Methods:: We present a case of CAD with recurrent stroke and difficult diagnosis due to its atypical presentation.

Results:: A 36 year old healthy man is brought to the emergency room after a mild car accident caused by sudden onset blurry vision and dizziness while driving. The previous days he had experienced spontaneous self-limited cervical pain and vomits. Physical examination reveals bradypsychia without focal neurological deficits. Urgent computed tomography (CT) scan shows capsulothalamic hypodensity suggestive of previous stroke. Rapidly onset dysphagia, dysarthria and dyspnea appear the following day; vocal cord paralysis is detected and the patient is intubated. After cerebrospinal fluid (CSF) analysis reveals 15 leukocytes, and given epidemiological context of gastroenteritis, Lysteria monocytogenes rhomboencephalitis is suspected. However, after 24 hours of antiobiotherapy, CSF is normalized and magnetic resonance (MRI) shows lesions compatible with cerebellar, hemimedullary and capsulothalamic infarction as well as right vertebral threadlike flow suggestive of dissection. The patient starts anticoagulation therapy and evolves favourably without recurrences.
Conclusions:: Diagnosis of CAD is made by angio-CT or angio-MRI; arteriography is limited to cases with high level of suspicion despite normal non-invasive neuroimaging. As for treatment, antiplatelet therapy is preferred in intracranial CAD; in extracranial CAD anticoagulation and antiplatelet therapy are both equally effective and safe.
THE INVOLVEMENT OF THE FACTOR V G1691A GENE ON RECURRENT ISCHEMIC STROKE IN YOUNG ADULTS

Lamia Mbarek¹, Salma Sakka¹, Fatma Megdich², Khadija Sonda Moalla³, Nadia Bouattour², Sawsan Daoud³, Olfa Hdiji³, Choumous Kalle³, Mariem Damak³, Chokri Mhiri⁴

¹UNIVERSITY HOSPITAL CENTER HABIB BOURGUIBA, Neurology, SFAX, Tunisia, ²UNIVERSITY HOSPITAL CENTER HABIB BOURGUIBA, Laboratory Of Hematology, SFAX, Tunisia, ³Universal Hospital Habib Bourguiba, Neurology, SFAX, Tunisia, ⁴Habib Bourguiba university hospital, Neurology, Sfax, Tunisia

Background and Aims:: Although the association between traditional risk factors and ischemic stroke (IS) recurrence has been widely studied, the involvement of inherited thrombophilia such as the factor V G1691A gene (FV) in stroke recurrence has not been clearly defined. This study aims to determine the involvement of the FV in recurrent ischemic stroke in young Tunisians.

Methods:: We included retrospectively all young adults of age 18–50 years with first-ever ischemic stroke who were treated in the neurology department during a period of 5 years. The predictive effect of all demographic characteristics, traditional risk factors and clinical data were collected, a complete etiological assessment, and genetic test was screened.

Results:: The diagnosis of ischemic stroke was confirmed in 200 patients. Among them, 93 had a second stroke within two years following the first attack. The heterozygous form of FV polymorphism present in 32 patients, 66% for the recurrent stroke population. Statistical analysis found a significant association between recurrent stroke and heterozygous factor V variant (p: 0.018).

Conclusions:: The study emphasizes the important role of factor V G1691A genetic screening in patients with stroke in this region. In order, to optimize secondary prevention of stroke to keep safe lifetime events, to improve survival, and to have more successful aging.
TWO CASES OF WATERSHED-PATTERN REVERSIBLE ENCEPHALOPATHY SYNDROME

Valerio Melas¹, Valeria Piras², Giovanni Cossu², Maurizio Melis²
¹University of Cagliari, Department Of Medical Science And Public Health, Neurology Unit, Cagliari, Italy, ²Hospital "G. Brotzu", Department Of Neurology And Stroke Unit, Cagliari, Italy

Background and Aims:: Posterior reversible encephalopathy syndrome (PRES) is a clinicoradiological syndrome characterized by several features, including headache, impaired consciousness, visual disturbances, seizures and vasogenic edema on brain MRI scans. Despite the typical parietal and occipital lobe localization, many reports showed involvement of other brain areas. We describe two cases of reversible encephalopathy syndrome involving brain watershed zones.

Methods:: Two women (51 y.o. and 77 y.o.) were admitted to our Neurology Department; the first patient was admitted for confusion, gait ataxia, speech and visual disturbances occurred after abdominal pain, vomiting and fever; the second one came to our hospital for impaired awareness with right upper limb clonic movements, after recurrent vomiting with severe hypomagnesemia. Both patients showed high blood pressure values. In both cases the Brain MRI showed FLAIR DWI signal abnormalities with a bilateral watershed distribution. The management of blood pressure and metabolic disorders in these patients led to clinical remission of symptoms.

Results:: Considering the clinicoradiological features, a diagnosis of reversible encephalopathy syndrome was made.

Conclusions:: PRES may be caused by the loss of vascular autoregulation with blood-brain barrier disruption and vasogenic edema which might be triggered by increased systolic blood pressure or endothelial dysfunction. Since there are no specific diagnostic criteria for PRES and considering the role of brain MRI in the diagnosis, the knowledge of imaging patterns other than the original parieto-occipital ones (including hemispheric watershed distribution), along with the evaluation of suggestive neurological features in appropriate clinical settings could help the neurologist to a correct diagnosis and management.
HYPERHOMOCYSTEINEMIA FOLATE AND VITAMIN B12 IN YOUNG ISCHEMIC STROKE

Lamia Mbarek¹, Salma Sakka², Khadija Sonda Moalla², Nadia Bouattour³, Sawsan Daoud², Olfa Hdiji², Manel Naeifer⁴, Nouha Farhat², Fatma Ayadi⁴, Mariem Damak², Chokri Mhiri⁵

¹UNIVERSITY HOSPITAL CENTER HABIB BOURGUIBA, Neurology, SFAX, Tunisia, ²Universal Hospital Habib Bourguiba, Neurology, SFAX, Tunisia, ³UNIVERSITY HOSPITAL CENTER HABIB BOURGUIBA, Laboratory Of Hematology, SFAX, Tunisia, ⁴UNIVERSITY HOSPITAL CENTER HABIB BOURGUIBA, Biochemistry Laboratory, SFAX, Tunisia, ⁵Habib Bourguiba university hospital, Neurology, Sfax, Tunisia

Background and Aims:: Hyperhomocysteinemia (Hhcy) is associated with cerebrovascular disease, including ischemic stroke. Homocysteine level is influenced by folate and vitamin B 12 (VB 12), the substrate and cofactor of its metabolism.

Methods:: This is a cross-sectional study of patients under 50 years of age followed for stroke over a 2-year period. All patients received a comprehensive etiologic evaluation that included cardiac and arterial vascular axis assessment. an assay Hcys, folate and VB12 was performed.

Results:: We collected 109 patients with a mean age of 39.6± 6.5 years and a sex ratio of 1. A rise in homocysteine levels was noted in 46.6% of cases (18.8 ± 7.5 µmol/l; p≥ 0.05). In fact, 50 patients had a folate deficiency (2.08 ± 0.7 µmol/l; p≥ 0.05), 16 cases had a VB 12 deficiency (189.5 ± 232.2; p:0.52). A significant correlation between folate deficiency and moderate homocysteine level (21.1± 9.2; p:0.03).

Conclusions:: Hhcy appears to play a role in the genesis of stroke, is mainly associated with a decrease in folate, systematic testing in patients with ischemic stroke would be important for the eventual administration of vitamin therapy.
A RARE CASE OF A NINE SYNDROME WITH A DWI-NEGATIVE IMAGING IN A FILIPINO ADULT

Rodelia Pascua
Baguio General Hospital and Medical Center, Neurology, Baguio City, Philippines

Background and Aims:: The brainstem contains important structures that give an array of clinical manifestations in pathologic process. Here, we report a case of “Nine Syndrome” in an adult Filipino male with no acute findings on DWI imaging. The exact prevalence of Nine Syndrome has been accounted to only less than ten cases reported in the literature noted to be due to a pontine tegmentum lesion.

Methods:: A Case Report

Results:: This is a case of a sixty-five year old male, who had a five-hour history of sudden onset of dizziness. Pertinent neurologic findings revealed an exotropic left eye confirmed by an assymetrical Hirschberg test, with no adduction and corrective saccades upon abduction, with frozen horizontal gaze; right-sided peripheral facial palsy and left-sided weakness of 4/5 and sensory loss of 30%. Using a 1.5T MR cranial scanner with time-of-flight (MRA), there was no evidence of acute territorial infarct but an old lacunar infarct in the right pontine tegmentum with normal course and caliber of both the anterior and posterior circulations. Patient was started on dual anti-platelet, high dose statin, and started on anti-hypertensives on the fourth hospital day. He was then sent home improved.

Conclusions:: Nine syndrome is a rare case and this is the first case of Nine Syndrome in a Filipino patient based on literature. Its diagnosis rely on its clinical manifestations, neuroanatomy, and imaging that may yield a negative finding. This should not impede the clinicians in its early recognition and management.
EMERGENCY STROKE MANAGEMENT DURING COVID-19 PANDEMIC: EXPERIENCE FROM TRIVENETO AREA

Ilario Scali, Marcello Naccarato, Paola Caruso, Carlo Lugnan, Giovanni Furlanis, Alex Buoite Stella, Miloš Ajčević, Paolo Manganotti
University of Trieste, Clinical Unit Of Neurology, Department Of Medicine, Surgery And Health Sciences, University Hospital And Health Services Of Trieste – Asugi, University Of Trieste, Strada Di Fiume, 447, 34149 Trieste, Italy, Trieste, Italy

Background and Aims:: COVID-19 pandemic is a major problem for global healthcare. There are many challenges for stroke emergency chain to maintain high medical care levels: many European Countries showed changes in neurological admissions and treatments. Our aim was to investigate the amount of admissions and treatment of stroke patients Friuli-Venezia-Giulia, Veneto and Trentino-Alto-Adige during the first wave of COVID-19.

Methods:: We retrospectively collected patients admitted to most Triveneto Stroke Units, eventually treated with thrombolysis or thrombectomy, from January to May 2020 (the first Italian pandemic wave). Primary endpoint was the number of patients arriving to these Stroke Units; secondary endpoints were number of thrombolysis and/or thrombectomies. Chi-square analysis was used on all patients; furthermore patients were divided into two cohorts (pre-lockdown and lockdown) and Kruskal-Wallis test was used.

Results:: 2536 patients were admitted in 22 centres. There was a significant decrease (p=0.016) of admissions in April (464) compared to January (570); significant decrease (p=0.032) of thrombectomies in April (32) compared to January (64); thrombolysis rate was unaffected. Analysing non-COVID-19 period - January and February - and COVID-19 period - March and April - there was a significant decrease of admissions (11%) with a collapse of thrombectomies (42%), while thrombolysis rate remained unchanged.

Conclusions:: We found a decrease of stroke patients admissions in North-East-Italy during first wave period, with no impact on thrombolysis rate, confirming a great response of emergency care system to pandemic; instead the significant decrease in thrombectomy rate addresses some considerations on Triveneto stroke networks organization.
DRAMATIC DECREASE OF STROKE ADMISSIONS DURING THE FIRST WAVE OF COVID PANDEMIC IN ITALIAN-SLOVENIAN CROSS-BORDER AREA: A CLINICAL AND RADIOLOGICAL STUDY

Ilario Scali¹, Marcello Naccarato¹, Giovanni Furlanis¹, Miloš Ajčević¹, Sasha Olivo¹, Carlo Lugnan¹, Paola Caruso¹, Roberta Pozzi Mucelli², Maria Cova², Paolo Manganotti¹

¹University of Trieste, Clinical Unit Of Neurology, Department Of Medicine, Surgery And Health Sciences, University Hospital And Health Services Of Trieste – Asugi, University Of Trieste, Strada Di Fiume, 447, 34149 Trieste, Italy, Trieste, Italy, ²University of Trieste, C. Radiology Unit, Department Of Medicine, Surgery And Health Sciences, University Hospital And Health Services Of Trieste – Asugi, University Of Trieste, Strada Di Fiume, 447, 34149 Trieste, Italy, Trieste, Italy

Background and Aims:: The fear of COVID-19 infection may discourage patients from going to the hospital even in case of sudden onset of disabling symptoms. We aimed to evaluate the effects of the COVID-19 pandemics on stroke management during the first month of Italian lockdown in 2020 in the cross-border Italy-Slovenia area.

Methods:: We analyzed admitted patients' clinical features, outcomes and presenting brain CT perfusion (CTP) patterns between 9th March 2020 and 9th April 2020 (first month of lockdown), and compared them with patients admitted during the same period in 2019.

Results:: Total admissions were reduced by 45% during the lockdown compared to the same period in 2019 (16 vs 29, respectively), and a higher prevalence of severe stroke (NIHSS > 10) on admission (n = 8, 50% vs n = 8, 28%) was noted. During lockdown, worse functional and independence outcomes were found, despite the similar proportion of reperfused patients. Similar 'symptoms alert-to-admission' and 'door-to-treatment' times were observed. Moreover significantly higher total CTP hypoperfused volume (83.3 vs 18.5 ml, p = 0.003), core volume (27.8 vs 1.0 ml, p <0.001), and higher infarct volume on follow-up CT during COVID-19 (35.5 vs 3.0 ml, p < 0.001) vs non-COVID-period was noted.

Conclusions:: During the first wave of COVID-19 pandemic there was a dramatic decrease of stroke admissions in our stroke unit. We noted a higher prevalence of severe stroke with higher NIHSS and CTP core volume, suggesting that minor stroke or TIAs generally preferred to stay home.
Background and Aims:: Although « young ischemic stroke » has been considered a relatively rare event, there is evidence that it is increasing. Despite improvements in diagnosis and treatment, ischemic stroke in young adults can cause a long-lasting disability. There is wanting data regarding young ischemic stroke in developing countries, especially in Tunisia. The purpose of this study was to investigate risk factors and etiologies of young ischemic stroke.

Methods:: A total of 70 young ischemic stroke patients (18-45 years old) were admitted, between 2009 and 2019. Stroke etiologies were classified according the Trial of ORG 10172 in acute stroke treatment (TOAST).

Results:: A total of 70 patients were included, out of which 66% were men. The most frequent traditional risk factors were smoking history (50%), history of high blood pressure (27%), diabetes (24%) and hypercholesterolemia (13%). By TOAST, 37% of patients' stroke etiology was classified as undetermined etiology (TOAST V), 34% as other causes (TOAST IV), 20% as cardioembolic (TOAST II), 6% as large artery atherosclerosis (TOAST I), 3% as small vessel occlusion (TOAST III).

Conclusions:: In our study, traditional risk factors were not-so-uncommon in young adults with ischemic stroke suggesting that prevention can go through controlling these factors. A broad and detailed diagnostic workup is crucial to puzzle out the etiology for more and better stroke prevention.
EMBOLIC STROKES OF UNDETERMINED SOURCE IN YOUNG ADULTS: INCIDENCE, RISK FACTORS AND LONG-TERM OUTCOME

Manel Akkari, Mariem Messelmani, Hajer Derbali, Malek Mansour, Jamel Zaouali, Ridha Mrissa
Military Hospital of Tunis, Neurology, Monfleury, Tunisia

Background and Aims:: Embolic stroke of undetermined source (ESUS) is a new clinical entity, not yet thoroughly investigated in young stroke patients. In this population-based study, we aimed to compare the clinical characteristics, risk factors as well as outcomes in young adults with ESUS and other aetiological subgroups of strokes.

Methods:: We included 70 patients aged between 18 and 45 years old with first-ever ischemic stroke (IS). Stroke etiologies were classified according to the Trial of Org 10172 in Acute Stroke Treatment (TOAST), and ESUS patients were identified according to the criteria of Cryptogenic Stroke/ESUS International Working Group.

Results:: Among 70 patients, 19 (27%) were classified as ESUS. They were younger (median age was 35 years vs. 39 Years). Male sex was less common in ESUS (59.2% vs 63.6%). ESUS were of moderate severity (median NIHSS score was 5). They had fewer cardiovascular risk factors than other TOAST groups (less hypertension (24.6% vs. 32.7%, p<0.01), diabetes (16.9% vs. 32.7 ; p<0·01), hypercholesterolaemia (15.3% vs. 25.4% ; p<0-01), and history of smoking (31.5 % vs. 43.2 % ; p=0·01). All patients with ESUS were treated with antiplatelet therapy. A low risk of recurrence stroke was noted in ESUS population (4% vs 13.7%). Patients with ESUS had more favorable functional outcomes.

Conclusions:: In our cohort, ESUS patients were younger and had milder cardiovascular risk factor burden and generally better long-term outcome compared to other causes of young ischemic stroke. Anti-platelet agents remain the first-line treatment for ESUS patients.
MORBIDITY FACTORS OF INTRACEREBRAL HEMORRHAGE

Mariem Elfekih, Ines Bedoui, Zeineb Brahem, Bissene Douma, Hajer Derbali, Mariem Messelmani, Malek Mansour, Anis Riahi, Jamel Zaouali, Ridha Mrissa
CHU, Military Hospital Of Tunis, tunis, Tunisia

Background and Aims:: Intracerebral hemorrhage (ICH) is the most disabling and deadly form of stroke. Although morbidities remains high, new data suggest that outcomes can be improved with standardized medical care. The aims of this study is to describe the mobility factors of intracerebral hemorrhage.

Methods:: A retrospective study including 253 patients diagnosed with intracerebral hemorrhage was conducted in the department of neurology of the Military Hospital of Tunis from 2016 to 2020.

Results:: The mean age was 58 years old. By far the most common complication was infectious lung disease (ILD)(39.1%). The mean time to onset of ILD was 5.5 ± 4.6 days with extremes of 1 to 21 days. More than half of the patients (82.9%) with swallowing disorders had developed infectious ILD. Septic shock was the second complication in our series (17.39%) but remains the most serious. Urinary tract infections were noted in 15.8% of cases. Meningitis and thromboembolic complications were more rarely described (8.3% and 12.2%).

Conclusions:: The identification of mobility factors for the ICH makes it possible to optimize the therapeutic procedures and to better organize the care channels.
THROMBOLYSIS IN ACUTE ISCHEMIC STROKE: EXPERIENCE IN TERTIARY CARE CENTER IN DEVELOPING COUNTRY

Rahil Ansari, Gajanan Panandikar, Karan Desai, Sangeeta Ravat, Neeraj Jain, Priyanka Walzade, Piyush Anshu
Seth GSMC and KEM hospital Mumbai, Neurology, Mumbai, India

Background and Aims:: Stroke is one of the leading cause of death and disability. Rate of IV thrombolysis is much less in India. Stroke units are predominantly available in urban areas that too in private hospitals in India as it’s an expensive treatment. Our hospital caters to lower socio-economic class of patients, so we had to make special provision. We have made drug available free for immediate use & patient has to replace in 48 hrs of thrombolysis. To explore the association between Door to needle time (DTNT) and outcome & assess factors influencing in-hospital delay & DTNT

Methods:: All patients treated with IV tissue plasminogen activator (tPa) between June 2015 and April 2017 were enrolled & studied. Multivariate logistic regression model was used to evaluate outcomes.

Results:: 100 patients were treated with IV tPa within 4.5 hours of symptom onset. 48 had favourable outcome & 6 good outcome (MRS 0-2). 54 had DTNT <60 min. Patients with DTNT <60min significantly associated with post-thrombolysis MRS 0-1 (p<0.005). DTNT significantly affected by time to obtain consent(p<0.005),onset to door time(p<0.005) & NIHSS. Major contribution to in-hospital delay is due to delay in obtaining consent(P<0.005) delay in CT room, while pre-hospital delay was mainly due to unawareness of symptoms.

Comparison of DTPT, DTIT, DTNT with AHA guideline
Conclusions: Major hurdle in acute stroke thrombolysis are poor awareness about golden hours of stroke & treatment, delay in reaching to hospital and finance. First two hurdles should be addressed on mass scale to get the impact. To alleviate the financial issue we made drug available for immediate use.

COMPARISON OF FOUR SCORE, GCS AND GCS-P IN PREDICTING OUTCOME AT DISCHARGE IN PATIENTS WITH ACUTE STROKE:

Sadaf Majid¹, Umaira Rafiq¹, Asfandyar Khan Niazi¹, Hina Yusuf¹, Qamar Zaman¹, Maimoona Siddiqui²
¹Shifa International Hospital, Neurology, Islamabad, Pakistan, ²Shifa International Hospital, Shifa Tameer-e-millat university, Neurology, Islamabad, Pakistan

Background and Aims:: Stroke is the second most common cause of death and adult disability. The Glasgow Coma Scale (GCS) is the most commonly used scale, and full Outline of Unresponsiveness (FOUR) score is new validated coma scale as an alternative to GCS. Our aim is to evaluate FOUR scores, GCS-P and GCS in predicting outcomes in patients with acute stroke.

Methods:: We prospectively studied consecutive adult patients with acute ischemic and hemorrhagic stroke (less than 48 h after onset) admitted to our stroke unit. FOUR scores, GCS, GCS-P and demographic profiles were documented at admission and discharge.

Results:: We included 120 patients with a mean age of 61.87±14.46. Most of the participants were males 68 (56.7%). Diabetes was seen in 57 (47.5%) patients, hypertension in 86 (71.7%), ischemic heart disease in 22 (18.3%), end stage renal disease in 7 (5.8%), and atrial fibrillation in 8 (6.7%) patients. Mean GCS was 12.32± 2.86, mean GCS-P was 12.13±2.95 and mean mRS at 3 months was 3.18±1.59. There was a significant correlation between mRS at 3 months and GCS (correlation coefficient -.46; p value <0.01), GCS-P (correlation coefficient -.45; p value <0.01) and FOUR scores (correlation coefficient -.56; p value <0.01).

Conclusions:: Our study showed that mRS at 3 months after stroke significantly correlated with GCS, GCS-P and FOUR scores. However, the strongest correlation was with FOUR scores followed by GCS. GCS-P, on the other hand, did not have a stronger correlation with mRS than GCS.
Background and Aims:: Stroke is a leading cause of death worldwide consisting mostly of ischemic strokes, which are most effectively treated with thrombolysis. A high neutrophil to lymphocyte ratio (NLR) is associated with poor functional outcome at 3 months, higher mortality and a higher hemorrhagic transformation. Our aim is to assess the role of NLR as a predictor of functional outcome in patients with acute ischemic stroke after thrombolysis.

Methods:: A retrospective chart review of 98 patients who presented with acute ischemic stroke who received thrombolysis between 2015 and 2019 at a tertiary care setup in a developing country was done. A ratio between neutrophils and lymphocytes for all patients at admission and the mean values with standard deviation were calculated. Patients with an mRS of 0–2 were classified as a good functional outcome and with the mRS of 3–6 as a bad functional outcome. The mean NLC was compared using an independent student's t-test.

Results:: In our study most of our participants were male 60(61.2%) with mean age 58±6.4. At 3 months, a good functional outcome was seen in only 31 patients (31.6%). Of the patients with a good functional outcome, 19 (61.3%) were in group 1 and 12 (38.7%) were in group 2. Patients in Group 2 have a bad functional outcome (OR 2.7; 95% CI 1.11 to 6.39; p < 0.02).

Conclusions:: Our study revealed that patients who present with acute ischemic stroke who has a raised NLR at the time of administration of thrombolysis may have a poor functional outcome (mRS 3-6) at 3 months.
Background and Aims:: DAVF is an abnormal connection between arteries and veins, where blood is supplied to DAVFs mainly through branches arising from the external carotid artery. Common symptoms are headache, orbital bruit, pulsatile tinnitus, and ophthalmoplegia and acute intracranial hemorrhage. There are only a few reports of DAVFs presenting with dementia syndrome, and a decline in neurocognitive function.

Methods:: We present 2 patients presenting with history of multiple episodes of seizures and progressive behavioral and cognitive changes. The first patient presented with ptosis and ophthalmoplegia in the right eye, while the second patient presented with altered sensorium. Both had severe cognitive impairment, inattention and disorientation to time, place and person. In both, Digital subtraction angiography provided a definitive diagnosis of hypervascular Dural AV fistula at the right transverse sigmoid junction with arterial feeders from the right ECA and meningohypophyseal trunk of the ICA, with significant cortical venous hypertension noted.

Results:: Through a femoral access, both underwent transarterial embolization through the Middle Meningeal branch of the right External Carotid Artery using Onyx, resulting in complete occlusion of fistula and resolution of venous hypertension. Post embolisation, Cognitive function assessment revealed increased attention span and improved orientation with time, place and person.

Conclusions:: DAVF can be one of the rare but reversible causes of dementia. Early diagnosis and treatment may help to dramatically improve patients’ clinical condition and minimize long-term disability.
USEFULNESS OF MULTIMODAL CT PC-ASPECT CALCULATION IN INFRATENTORIAL STROKE

\textsuperscript{1}University of Trieste, Clinical Unit Of Neurology, Department Of Medicine, Surgery And Health Sciences, University Hospital And Health Services Of Trieste – Asugi, University Of Trieste, Strada Di Fiume, 447, 34149 Trieste, Italy, Trieste, Italy, \textsuperscript{2}Cattinara University Hospital, ASUGI, University of Trieste, Trieste, Italy, Neurology Unit, Department Of Medical, Surgical And Health Sciences, Trieste, Italy, \textsuperscript{3}Radiology Unit, Radiology Unit, Department Of Medicine, Surgery And Health Sciences, University Hospital And Health Services Of Trieste – Asugi, University Of Trieste, Trieste, Italy

\textbf{Background and Aims::} Routine examinations for the diagnosis of posterior circulation stroke include clinical assessment using the National Institutes of Health Stroke Scale (NIHSS) and brain imaging, generally, non-contrast brain CT; both of them proved to be unreliable on detection of infratentorial strokes. We tested the validity and the prognostic value of posterior circulation Alberta Stroke Program Early CT Score (pc-ASPECTS) in patients with posterior circulation stroke calculated on noncontrat CT (NCCT), CT-angiography source images (CTA) and CT-perfusion (CTP) images.

\textbf{Methods::} Routine examinations for the diagnosis of posterior circulation stroke include clinical assessment using the National Institutes of Health Stroke Scale (NIHSS) and brain imaging, generally, non-contrast brain CT; both of them proved to be unreliable on detection of infratentorial strokes. We tested the validity and the prognostic value of posterior circulation Alberta Stroke Program Early CT Score (pc-ASPECTS) in patients with posterior circulation stroke calculated on noncontrast CT (NCCT), CT-angiography source images (CTA) and CT-perfusion (CTP) images.

\textbf{Results::} 50 patients with posterior cerebral stroke were enrolled. CTP showed abnormalities in 34 cases (68%), mainly involving cerebellum or occipital regions. The pc-ASPECT score calculated on NCCT, CTA and CTP had a sensibility of 72%. Pc-ASPECT calculated on MTT maps had the best correlation with NIHSS score at discharge, mRS at discharge and at 3 months ($p$=0.001, $p$=0.00, $p$=0.003).

\textbf{Conclusions::} we evaluated the usefulness of newly developed pc-ASPECTS on CTP in predicting functional outcome in acute posterior circulation ischemic stroke, and found that this appears be a powerful marker for predicting functional outcome.
Background and Aims:: Hyperglycemia is a known predictor of hemorrhagic transformation (HT) after ischemic stroke. However, it is unclear whether the association is due to diabetic hyperglycemia or stress hyperglycemia. We aimed to use the stress hyperglycemia ratio (SHR) to better determine the role of stress hyperglycemia in HT.

Methods:: Consecutive patients with ischemic stroke within 24 h of onset evaluated from January 2016 to September 2018 were included. SHR was calculated by admission random glucose divided by estimated average glucose derived from glycosylated hemoglobin. HT was rated on follow-up brain imaging and classified as hemorrhagic infarction (HI) and parenchymal hematoma (PH). Multivariable logistic regression was performed to evaluate the association between SHR and HT as well as its subtypes.

Results:: Among the 865 patients, 122 (14.1%) developed HT with 79 HI and 43 PH. Compared with the bottom tertile, patients in the top tertile of SHR were associated with an increased risk of HT after adjustment for confounders (OR 1.84, 95% CI 1.05–3.25, $P_{\text{trend}} = 0.036$). A multiple-adjusted spline regression model showed a dose-response relationship between SHR and HT. Subgroup analyses further confirmed the association. In multinomial regression analysis, SHR was significantly associated with PH rather than HI. The addition of SHR to conventional risk factors improved the prediction of HT (net reclassification improvement index = 22.48%, $P = 0.013$; integrated discrimination improvement = 0.61%, $P = 0.026$).

Conclusions:: Elevated SHR was related to HT after ischemic stroke. This may improve the stratification of HT risk in clinical practice or future trials targeting HT.
SHIFT FROM DRIP-AND-SHIP TOWARDS MOTHERSHIP MODEL FOR MECHANICAL THROMBECTOMY DURING COVID-19 PANDEMIC: A RETROSPECTIVE ANALYSIS OF A STROKE NETWORK PERFORMANCES.

Matteo Paolucci¹, Maria Ruggiero², Vanni Agnoletti³, Maurizio Menarini⁴, Raffaella Francesconi⁵, Tiziana Perin⁶, Andrea Fabbri⁷, Sara Biguzzi¹, Francesco Cordici⁸, Marco Longoni⁹
¹“M. Bufalini” hospital, Neurology, Cesena, Italy, ²“M. Bufalini” hospital, Neuroradiology, Cesena, Italy, ³“M. Bufalini” hospital, Intensive Care Unit, Cesena, Italy, ⁴AUSL Romagna, 118, Cesena, Italy, ⁵“M. Bufalini” hospital, Emergency Department, Cesena, Italy, ⁶“Infermi” Hospital, Emergency Department, Rimini, Italy, ⁷“Morgagni-Pierantoni” Hospital, Emergency Department, Forlì, Italy

Background and Aims:: The choice between transport of acute ischemic stroke patients to the nearest Primary Stroke Centers (drip-and-ship model) versus direct transport to the Comprehensive Stroke Center (mothership model) is still a matter of debate. We shifted from a drip-and-ship towards a mothership model during the first wave of COVID-19 pandemic in spring 2020. We retrospectively analyzed stroke network performances comparing the two models.

Methods:: All spoke-district patients treated with endovascular thrombectomy (EVT) between 15th March – 15th June 2019 (drip-and-ship) and 2020 (mothership) were included in the study. We compared call-to-door time (CDT), door-to-CT time (DCT), door-to-needle time (DNT), door-to-groin time (DGT), call-to-needle time (CNT) and call-to-groin time (CGT) between the two periods. We also compared functional independence (modified Rankin Scale, mRS) at 3 months.

Results:: 24 spoke-district patients in 2019 (drip-and-ship) and 26 in 2020 (mothership) underwent EVT. In 2020 a higher number of patients received IV thrombolysis in combination with EVT (p=.030). The groups did not differ for age, sex, risk factors, pre-stroke mRS 0-1, NIHSS and ASPECTS distribution. In 2020 we found longer CDT (+23 minutes, p<.005), but shorter DCT (-11.5 minutes, p=.017), DNT (-20.5 minutes, p=.001), and DGT (-78 minutes, p<.005). Overall, in 2020 we found a significant decrease in CGT time (-55.5 minutes, p<.005) without significant differences in CNT (p=.324). We found no effects of the stroke network model on the 3-month mRS (shift analysis, p=.241; mRS categories 0-1 vs 2-6, p=.706).

Conclusions:: The mothership model guaranteed quicker EVT without significantly delaying IVT.
IMPLANTABLE LOOP RECORDER TO DETECT ATRIAL FIBRILLATION IN CRYPTOGENIC STROKE: A REAL-WORLD EXPERIENCE

Arianna Manini, Giuseppe Scopelliti, Francesco Mele, Ilaria Cova, Pierluigi Bertora, Silvia Rosa, Marco Schiavone, Maurizio Viecca, Giovanni Forleo, Leonardo Pantoni

1Stroke and Dementia Lab, "luigi Sacco" Department Of Biomedical And Clinical Sciences, University Of Milan, Milan, Italy, 2Neurology Unit, "luigi Sacco" University Hospital, Milan, Italy, 3ASST-Fatebenefratelli Sacco, Luigi Sacco University Hospital, Department Of Cardiology, Milan, Italy

Background and Aims: Paroxysmal atrial fibrillation (AF) represents one of the main mechanisms underlying cryptogenic stroke (CS). Trials have shown that prolonged cardiac monitoring through Implantable Loop Recorders (ILR) allows higher AF detection frequency after CS compared with routine follow-up and 24-hour Holter monitoring, reaching 30% rate at 3 years. We aimed at assessing whether these data are reproducible in clinical practice.

Methods: From July 03, 2018 to March 10, 2021, CS patients were implanted with ILR after that extensive testing (24-hour ECG monitoring, echocardiography, head and neck computed tomography angiography) had not revealed a definite stroke etiology. Exclusion criteria were anticoagulant therapy contraindication, scarce compliance, and short-term poor prognosis. ILR online transmissions were regularly checked by neurologists; arrhythmias alarms were reviewed by cardiologists.

Results: Out of 114 hospitalized CS patients, 86 (75.4%) (mean age 72.2 years, range 49–88) were subjected to ILR. Median follow-up time from implantation is currently 457 days (range 19–1000). AF was detected in 24/86 (27.9%) patients after a median time of 99.5 days (range 1–520). Three patients had ischemic stroke recurrence. In one case, AF was not detected; one had ischemic stroke recurrence caused by internal carotid artery plaque after five months from AF diagnosis and anticoagulation start; the third was waiting for anticoagulants starting after AF diagnosis.

Conclusions: ILR is feasible and effective to detect occult AF after CS in clinical practice, with higher sensitivity compared to short-term monitoring. Our results suggest that up to 30% of CS patients may have AF as underlying stroke etiology.
MULTIPLE VASCULAR EVENTS REVEALING VARICELLA-ZOSTER VIRUS VASCULOPATHY, THE IMPORTANCE OF THE MEDICAL HISTORY: CASE REPORT

Roukya Benkhadra, Biljana Djurisic, Kosta Vassilev, Sophie Dupont
Pitié Salpêtrière Hospital, Neurological Rehabilitation, PARIS, France

Background and Aims:: Varicella-zoster virus (VZV) usually causes localized zoster in adults. However, in immunocompromised patients, it can cause systemic manifestations. Early diagnosis and therapy are crucial for the prognosis of the patients. To raise awareness of the diagnosis of VZV vasculopathy and the importance of looking for signs of previous infection up to 12 months.

Methods:: We report the case of an 85 year old lady, with a history of ophthalmic zoster who presented numerous vascular events with a progressive neurological worsening.

Results:: An 85 year old women presented in December 2018, an ischemic stroke of the right middle cerebral artery which was thrombolysed. An intracranial stent was also placed with a favorable evolution. An atheromatous cause was retained. Additionally, a pulmonary and mediastinal tuberculosis was diagnosed. Her neurologic condition was continuously worsening with cognitive impairment. In April 2019, she presented a right post traumatic subdural hematoma. But the evolution was marked by the occurrence of a contralateral subdural hematoma. Three days later she developed an ischemia of the right lower limb and died shortly. Looking back to her medical history we found a right ophthalmic Herpes Zoster in May 2018. The keypoint of this case is that this immunocompromised patient had ipsilateral ophthalmic herpes zoster 6 months before the stroke, a progressive neurological worsening despite all the treatment. The most likely hypothesis is a VZV vasculopathy, after the exclusion of any other etiology.

Conclusions:: Systemic VZV vasculopathy, can cause serious complications, with diverse clinical manifestations. Early detection and proper treatment is crucial.
RECURRENT SUBCORTICAL INFARCTS, INTRACRANIAL HYPERTENSION AND ASEPTIC MENINGITIS: POSSIBLE NEUROSARCOIDOSIS? A CASE REPORT

Pietro Anceschi, Alessia Fiore, Stefania Lazzari, Elisabetta Chierici, Lucia Zinno, Irene Florindo
Neurosciences Unit, Department Of Medicine And Surgery, University Of Parma, Parma, Italy

Background and Aims:: Neurosarcoidosis (NS) is a rare etiology of small-vessel-vasculitis of CNS. Even if the majority of cases shows systemic extraneural inflammation, a small percentage of patients (10-19%) manifests a disease isolated to CNS, making histological confirmation difficult to obtain. Various disease presentation and lack of relevant diagnostic tests contribute to diagnostic challenge.

Methods:: We describe the case of a 47-years-old African man with subacute onset of headache, fatigue, serotine low-grade fever, asymmetric spastic paraparesis and intention tremor.

Results:: Inflammation rates (ESR, C-reactive protein) were increased. Subsequent brain MRI showed recurrent subcortical infarcts suggesting a small-vessel-vasculitis. Angio-MRI didn’t reveal any vascular pathology. CSF opening pressure was elevated with mononuclear pleocytosis, hyperproteinorrachia, hypoglycorrhachia and oligoclonal bands (mirror pattern) on chemical examination. CSF cytological and microbiological analysis including PCR-based assay for Mycobacterium were negative. Chest HRCT and total-body FDG-PET didn’t find any signs of extra-CNS involvement apart from diffuse mild lymphadenopathy, not typical for lymphoma and too small for biopsy. Ocular evaluation was normal. TE Echocardiography revealed a hypertrophic cardiomyopathy. Enzymatic assay for Fabry disease is ongoing. Assuming NS as a probable cause, the patient underwent a high dose steroid treatment with immediate disappearance of headache and fatigue. Clinical and radiological follow-up are in progress.
Conclusions: The case highlights sarcoidosis as a possible etiology of isolated small-vessel-vasculitis of CNS, given the absence of clear-cut extraneural involvement. If contraindications are excluded, therapeutical attempt can be considered even when a validation biopsy is unfeasible.
POSTSTROKE DEPRESSION INCIDENCE AND CORRELATED FACTORS IN A DEVELOPING COUNTRY POPULATION: A PROSPECTIVE STUDY

Majdi Al-Qawasmeh¹, Zahra Alalwani², Haneen Qasim¹, Jumana Alseidi¹, Ahmed Alhusban³, Haneen Al Refa’¹, Khalid El-Salem¹
¹Jordan University of Science and Technology, Department Of Neurology/faculty Of Medicine, Ar Ramtha, Jordan, ²University of Oxford, Department For Continuing Education, Oxford, United Kingdom, ³Jordan University of Science and Technology, Clinical Pharmacy, Irbid, Jordan

Background and Aims:: Poststroke Depression (PSD) is a well-recognized psychological disorder affecting patients after suffering from either a hemorrhagic or ischemic stroke. PSD have serious repercussions on stroke survivors rehabilitation and recovery process. This study objective is to assess the incidence rate and the factors associated with developing PSD among Jordanian stroke patients.

Methods:: A 151 acute stroke patients were recruited for follow-up after their admission to the neurology ward at a tertiary teaching hospital. The sociodemographic characteristics, clinical features and other related variables were collected upon admission. Stroke outcome was identified by one-month modified Rankin score (mRS) and Barthel Index (BI) scores. PHQ-9 Scale was used to establish the diagnosis of PSD for those scoring five or more. Furthermore, a logistic regression analysis was conducted to assess for significant predictors.

Results:: The incidence rate of PSD was found to be 15% (on admission), 24.83% (on one month), and 17.39% (on 3 months). Severity was noted to correlate increasingly with time, as the incidence of severe PSD was 1% (on admission), 2.13% (on one month), and 6.52% (on 3 months). PSD was correlated significantly with coexisting chronic kidney disease (P= 0.007), current smoking status (P=0.002), moderate or severe disability (mRS score) at stroke onset (P=0.014), and severe dependency (BI) after one month (P= 0.031).

Conclusions:: In Jordanian stroke survivors the highest incidence of PSD (24.8%) was noted after one month, while sever PSD was highest after three months.
COGNITIVE IMPAIRMENT AT 30 DAYS IN FIRST-EVER STROKE SURVIVORS

Khadija Sonda Moalla¹, Mariem Damak¹, Olfa Chakroun², Olfa Hdiji¹, Salma Sakka¹, Sawsan Daoud¹, Nadia Bouattour¹, Nouha Farhat¹, Noureddine Rekik², Chokri Mhiri¹
¹Universal Hospital Habib Bourguiba, Neurology, SFAX, Tunisia, ²Universal Hospital Habib Bourguiba, Emergency, SFAX, Tunisia

Background and Aims:: Functional assessment in stroke survivors is mostly limited to motor abilities, with cognitive assessment largely omitted. We sought to analyze the frequency of cognitive impairment (CI) in stroke survivors and its prognostic relationship at 1 month after the initial event.

Methods:: We assessed first-ever stroke survivors 30 days after the event by the mini-mental state examination (MMSE). Patients with a stroke recurrence during the follow-up were not included. The distribution of MMSE scoring was analyzed according to functional categories as determined by the Modified Rankin Scale (mRS).

Results:: A total of 161 stroke survivors (57.8% men, median age 67.7 years, interquartile range: 24–96 years) received cognitive assessment by MMSE [mean: 20.65 points, standard deviation (SD): 7.3 points]. The mean MMSE score was progressively lower in patients with mRS 0–1 (23.4, SD: 6.9 points), mRS 2–3 (19.7, SD: 6.6 points) and mRS 4–5 (15.45, SD: 6.3 points) (p < 0.001). Moreover, the frequency of cases with MMSE <22 was significantly higher as motor disability increased, but remarkably, patients with a very good functional status (mRS 0–1) also had a high frequency of suboptimal performance (<22 points) on the MMSE (mRS 0–1: 32.4%, mRS 2–3: 38.2%, mRS 4–5: 29.4%, p < 0.001). A similar situation was observed with MMSE <16 points (mRS 0–1: 30%, mRS 2–3: 30%, mRS 4–5: 40%, p=0.004).

Conclusions:: Despite the limitations of MMSE as screening tool of the mental function in patients with cerebrovascular injury, it is clear that CI occurs after a first-ever stroke, even in subjects without significant motor disability.
DETECTION OF CEREBRAL MICROEMBOLISM BY A MODERN TECHNIQUE OF ACUTE ISCHEMIC STROKE WITH CONFIRMED CORONAVIRUS DISEASE (COVID-19)

Aziz Umirov
Tashkent Medical Academy, Treatment, Tashkent, Uzbekistan

Background and Aims:: The aim of this study was to examine the detection of cerebral microembolism by a modern technique of acute ischemic stroke with confirmed coronavirus disease (COVID-19).

Methods:: We studied 10 people who had an acute ischemic stroke in the Department of Neurology at the TMA. All patients with confirmed COVID-19 who underwent clinical TCD ultrasound to detect microembolism were included.

Results:: A total of ten TCD studies were conducted in eight COVID-19 patients (5 men and 3 women, mean age 65 ± 5 years), five with confirmed ischemic stroke and three with refractory encephalopathy. Microembolism were found in four male patients, three patients had a confirmed ischemic stroke, and two developed long-term encephalopathy. Microemboli of varying severity were detected in multiple vascular areas in four patients, and in the second patient, microemboli persisted despite therapeutic anticoagulation. Of five patients without signs of microembolism on ultrasound of TSD, two patients had a confirmed ischemic stroke, and three remained refractory encephalopathy.

Conclusions:: Ultrasonography (TCD) to detect microemboli identified five confirmed COVID-19 patients with signs of cerebral arterial microembolism, including two who received therapeutic anticoagulants. TCD ultrasonography is a non-invasive method for assessing cerebral microembolism in patients with COVID-19 and may be useful to assess the response to treatment in cases of suspected and impaired hypercoagulability. Further studies investigating the prevalence of cerebral microembolism and associated risk factors to characterize their pathogenetic mechanism and guide therapeutic interventions in hospitalized COVID-19 patients.
MULTIPLE EMBOLIC INFARCTIONS IN A CASE OF A PARANEOPlastic SYNDROME CAUSED BY HEPATOCELLULAR CARCINOMA

Si Baek Lee, Sung-Hoon Kim, Yun Jeong Hong, Yong Bang Kim, Jeong Wook Park
College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea, Department Of Neurology, Uijeongbu-Si Gyeonggi-Do, Korea, Republic of

Background and Aims:: Patients with polycythemia are at high risk for ischemic events including ischemic stroke. Secondary polycythemia is one of the manifestations of paraneoplastic syndrome of hepatocellular carcinoma. Increased red blood cells can elevate blood viscosity causing individuals susceptible to ischemic events.

Methods:: We present a case of a patient who visited the Emergency Department with right leg weakness suggestive of the left anterior cerebral artery infarction.

Results:: MRI showed multiple small nodular and fragmented acute embolic infarctions at the both internal border zone and corpus callosum. On admission, he was found to have elevated hemoglobin, hematocrit, and total cholesterol. Serum erythropoietin was also elevated. An abdominal CT scan revealed heterogeneous enhanced 2 masses in the right liver, compressing the main portal vein, about 12cm, and 1.5cm respectively with several prominent lymph nodes in the gastrohepatic ligament, suggestive of malignant masses. There was a marked elevation of tumor markers for hepatocellular carcinoma such as α-fetoprotein (AFP) and protein induced by vitamin K absence II (PIVKA-II). Needle biopsy of the hepatic lesion showed moderately differentiated hepatocellular carcinoma with a trabecular pattern. The patient was treated with antiplatelet agents during the acute stage and regained right leg motor function only with right foot drop.

Conclusions:: Elevated blood viscosity is associated with vaso-occlusive events including ischemic stroke. This case suggests that acute ischemic stroke could be an initial symptom of a paraneoplastic syndrome caused by hepatocellular carcinoma. It is needed to check erythropoietin level for the evaluation of ischemic stroke patients with polycythemia for detecting underlying cause.
THYROID DYSFUNCTION – AN INDEPENDENT RISK FACTOR FOR ISCHEMIC STROKE IN YOUNG ADULTS?

Raluca Ivan¹, Corina Posirca¹, Marian Mitrica², Anca Sirbu³, Florentina Plesa⁴, Carmen Sirbu⁴
¹“Dr. Carol Davila” Central Military Emergency University Hospital, Neurology, Bucharest, Romania, ²Central Military Emergency University Hospital –Neurosurgery Clinic, Carol Davila University of Medicine and Pharmacy, Neurosurgery, Bucharest, Romania, ³National Institute of Endocrinology Cl Parhon, Endocrinology, Bucharest, Romania, ⁴Central Military Emergency University Hospital –Neurology Clinic, Titu Maiorescu University, Neurology, Bucharest, Romania

Background and Aims:: Various studies plead for the association between thyroid dysfunction and cerebrovascular disease, not only as a result of subsequent atrial fibrillation and cardioembolic stroke. Among the mechanisms incriminated are the increased adrenergic activity, the elevated levels of reactive oxygen species, the hemodynamic changes, and the coagulopathies found in hyperthyroidism whereas, in hypothyroidism alterations in lipids metabolism, in the arterial muscle structure, and a greater risk for atherosclerosis are described. The question is if thyroid dysfunction increases the risk of acute ischemic stroke.

Methods:: We analyzed the cases of two patients admitted for acute ischemic stroke, one presenting subclinical hypothyroidism due to autoimmune causes and one overt hyperthyroidism. They were both females, under 55 years old, previously undiagnosed, and untreated for thyroid dysfunction. Clinical, biological, and imaging investigations were made to establish the cause of the stroke, no apparent explanation being found.

Results:: The MRI imaging revealed that the patient with hyperthyroidism presented a left frontotemporal ischemic stroke, while the one with hypothyroidism had a small, left, pontine ischemic lesion. After extensive investigations, finding no causative factor for the onset of the strokes raised the possibility of an association between the underlying thyroid disease and the cerebral infarction.

Conclusions:: Although not many existing studies find the relationship between the dysfunction of the thyroid and the ischemic stroke significant, the clinical findings from our cases lead to the plausibility of this association.
INTRACEREBRAL HAEMORRHAGE (ICH) EVACUATION BY MINIMALLY INVASIVE NEUROSURGERY (MIN) TECHNIQUES

Klaus D M Resch
University of Guadalajara, Neurosurgery Min, Guadalajara, Mexico

Background and Aims:: Evaluation of a minimally invasive ICH-evacuation series. Describing a cheap and fast method, that can be learned everywhere.

Methods:: More than 260 patients underwent this application by the presenting author. A series of the 56 recent cases, 26 female and 29 male, 69.1 y (40 - 83) (1 child excl.), was analyzed This MIN concept combined several key-techniques to assist microsurgery: mouth-tracked high-zoomed Microscope, Neuro-Endoscopy, Neuro-Ultrasound, LASER and Sealing.

Results:: Compared with STICH I, the favorable outcome was pushed from 26.1% to 86.0%. In nearly all cases it was possible to evacuate the complete hematoma within 1 hour, and the hematoma evacuation decreased the ICP always fast to normal levels. Clinical results were excellent in lobar bleedings with isochoric before surgery. Large and deep-seated hemorrhages needed longer recovery time, but in all cases postop CT showed fast reduction of perifocal edema and ICP -levels.

Conclusions:: Combination of ultrasound, mouth tracking, endoscopy, LASER and sealing technique enabled evacuation of all type of hematoma minimal invasively and very effectively within one hour. Ultrasound real-time control detected all types and locations of bleeding causes (aneurysms, angiomas, cavernomas, tumors and origin of bleeding). The evacuation amount and the reaction of the brain were under visual real-time control. Mouth tracking enables maximal-zoomed, and free hands fast acting for safe operative control. The method is cheap, fast, and can be learned during regular training. Ref.: KDM Resch, Key Concepts in MIN Vol. 1, 2020; Vol. 2, 2021 (in press)/ Springer, Heidelberg
MECHANICAL THROMBECTOMY IN STROKE AND THE AVAILABILITY OF THE ENDOVASCULAR TEAM DURING INSTITUTIONAL EMERGENCY SERVICE - THEORY VERSUS REALITY

David Černík¹, Ľudmila Kmečová², Filip Cihlář³, Kateřina Bělinová⁴, Petra Janousová⁴
¹Masaryk Hospital, KZ a.s., Comprehensive Stroke Center, Department Of Neurology, Ústí nad Labem, Czech Republic, ²Slovak Medical University Children's faculty hospital Banská Bystrica, 2nd Pediatrics Clinic, Banská Bystrica, Slovak Republic, ³Masaryk Hospital, KZ a.s., Faculty of Health Studies, J.E. Purkynje University, Ústí nad Labem, Department Of Radiology, Ústí nad Labem, Czech Republic, ⁴Masaryk Hospital, KZ a.s., Comprehensive Stroke Center, Department Of Emergency, Ústí nad Labem, Czech Republic

Background and Aims:: Mechanical thrombectomy (MT) is the standard treatment for stroke in occlusion of a large endovascularly accessible artery. The topic discussed is the permanent presence of the endovascular team in the center 24/7 to reduce delays until the beginning of MT.

Methods:: 355 patients who underwent MT for large artery occlusion in 2018-2019 from Comprehensive stroke center (CSC) were analyzed retrospectively. The data were confronted with theoretical assumptions according to the calendar share of working hours and the total annual time fund.

Results:: The period of institutional emergency service according to calendar data in the Czech Republic is approximately 76% of the time of the year. This value was chosen as the most pessimistic value of the number of patients potentially admitted in the absence of the endovascular team (with a concomitant 100% admission of patients by primary transport to the CSC). 355 patients treated with MT in CSC (171 in 2018 and 184 in 2019) were analyzed. At the time of institutional emergency service, 227 patients (63.9 %) were admitted. However, in the absence of the endovascular team at the time of institutional emergency service, there were only 58 patients (16.3 %). In the next steps, this number could be reduced below 5%.

Conclusions:: Even with the impossibility of establishing the presence of an endovascular team in the center in the 24/7 mode, it is possible to reduce the number of patients admitted during the absence of the team below 5%.
Background and Aims:: We present a case of acute ischemic stroke (AIS) in a pregnant woman treated with recombinant tissue plasminogen activator (rt-PA) and mechanical thrombectomy (MT).

Methods:: A 33-years-old woman at 5 weeks gestation referred to emergency room 1 hour after developing dysarthria, left hemiplegia and anesthesia of the left limbs (NIHSS=14).

Results:: CT angiography revealed a right M1 segment occlusion. The patient underwent IV rTPA and then was subjected to MT with good reperfusion of cerebral blood flow. Extensive diagnostic workup was unremarkable except for evidence of patent foramen ovale. A medical physics evaluation showed an estimated total dose of radiations acquired of 1,26 mGy. Neurological condition improved with residual mild paresis and hypoesthesia of the left arm at dismissal (NIHSS=3). The pregnancy is ongoing, but an extensive gynecologic exam ruled out intrauterine or foetal complications. The effectiveness and safety profile of thrombolytic agents and MT in pregnant women is not known as these patients have been excluded from reperfusion trials. Rt-PA does not cross the placenta, but maternal hemorrhagic complications and abortion have been reported. MT raises concerns regarding radiation exposure and the use of iodinated contrast agents during the procedure. Few cases of pregnant women treated with MT ± IV rt-PA have been reported with positive outcomes for both mother and fetus.

Conclusions:: IV rt-PA and MT may be effective and safe treatments for pregnant patients. Precautions need to be taken to reduce the foetal radiation exposure and the dose of iodinated contrast agents.
Liver fibrosis indices associated with hematoma expansion in patients with intracranial hemorrhage

Huan Wang, Jiongxing Wu, Xue Yang, Junfeng Liu, Bo Wu, Ming Liu, Shihong Zhang, Deren Wang
West China Hospital, Sichuan University, Neurology, Chengdu, China

Background and Aims:: Liver fibrosis may cause subclinical coagulopathy and endothelial dysfunction, which link to hematoma expansion (HE) after intracerebral hemorrhage (ICH). We evaluated the association between liver fibrosis indices and HE in a Chinese population with primary ICH.

Methods:: We performed a retrospective review of data from 438 consecutive patients with primary ICH who had admission laboratory data and neuroimaging data to calculate HE (>33% or >6 mL). Selected liver fibrosis indices include aspartate aminotransferase (AST)-platelet ratio index (APRI), (AST/alanine aminotransferase ratio [ALT])/platelet ratio index (AARPRI), Fibrosis-4 (FIB 4), modified Fibrosis-4 (mFIB 4), fibrosis quotient (FibroQ) and Forns Index. The association of fibrosis indices with HE was assessed using multivariable logistic regression analyses. The patients with HBV infection were performed in a sensitivity analysis.

Results:: Of 438 patients with primary ICH, 117 (26%) had HE. After adjusting baseline hematoma volume, APRI (odds ratio [OR], 1.62 [95% CI, 1.01-2.59]), AARPRI (OR, 1.26 [95% CI, 1.00-1.57]) and FIB 4 (OR, 1.15 [95% CI, 1.02-1.30]) were independently associated with HE after ICH. Also, in patients with ICH complicated with HBV infection, AARPRI (OR, 1.39 [95% CI, 1.06-1.81]), FIB 4 (OR, 1.19 [95% CI, 1.03-1.39]), mFIB 4 (OR, 1.07 [95% CI, 1.00-1.13]) and FibroQ (OR, 1.06 [95% CI, 1.00-1.11]) were associated with HE.

Conclusions:: Therefore, two liver fibrosis indices (AARPRI and FIB 4) were independently related to HE after ICH, regardless of whether HBV infection is present. This finding may represent a potential therapeutic target. Future prospective larger studies are needed to confirm our findings.
CT PERFUSION ASPECTS PREDICTS FINAL ISCHEMIA EXTENT IN PATIENTS WITH STROKE BEYOND 6 HOURS AFTER SYMPTOMS ONSET.

Giulia Sajeva¹, Cecilia Zivelonghi¹, Nicola Micheletti¹, Giampaolo Tomelleri¹, Bruno Bonetti¹, Raffaele Augelli², Niccolò Mandruzzato², Mauro Plebani², Giuseppe Kenneth Ricciardi², Piergiuseppe Zampieri², Manuel Cappellari¹
¹Azienda Ospedaliera Universitaria Integrata, Stroke Unit, Department Of Neurosciences, Biomedicine And Movement Sciences, Verona, Italy, ²Azienda Ospedaliera Universitaria Integrata, Neuroradiology Department, Verona, Italy

Background and Aims:: The Alberta Stroke Program Early Computed Tomography Score (ASPECTS) has been previously applied to perfusion CT (CTP). We investigated the capability of CTP-ASPECTS to predict final ischemia extent in patients with stroke beyond 6 hours after symptoms onset.

Methods:: We reviewed prospectively collected data from stroke patients with internal carotid artery and/or M1-segment middle cerebral artery occlusion who performed CTP between 6 to 12 hours after symptoms onset. We identified patients with complete recanalization after thrombectomy and patients who have not received revascularization treatment. Using ordinal regression, we estimated the predictive effect of cerebral blood volume (CBV)-ASPECT and mean transit time (MTT)-ASPECTS on 24-hour ASPECTS (0 to 10) by calculating the odds ratios (ORs) with two-sided 95% confidence intervals (CI) after adjustment for baseline ASPECTS and onset-to-imaging time.

Results:: Of the 12 patients with complete recanalization after thrombectomy, median value was 9 (IQR 9-10) for baseline ASPECTS, 10 (IQR 9-10) for CBV-ASPECTS, 8 (IQR 5-9) for MTT-ASPECTS, and 8 (IQR 5-10) for 24-hour ASPECTS. Of the 18 patients who have not received revascularization treatment, median value was 9 (IQR 8-10) for baseline ASPECTS, 10 (IQR 9-10) for CBV-ASPECTS, 8 (IQR 5-9) for MTT-ASPECTS, and 8 (IQR 7-9) for 24-hour ASPECTS. CBV-ASPECTS predicted 24-hour ASPECTS in patients with complete recanalization (OR 4.590, 95% CI 1.038-20.292), while MTT-ASPECTS predicted 24-hour ASPECTS in patients who have not received revascularization treatment (OR 1.799, 95% CI 1.042-3.106).

Conclusions:: CTP-ASPECTS predicts final ischemia extent in patients with stroke beyond 6 hours after symptoms onset.
A NOVEL HOME PATIENT TELEMONITORING SYSTEM FOR POST-ACUTE TIA/MINOR STROKE: AN EXPERIENCE DURING COVID-19 PANDEMIC

Giovanni Furlanis\(^1\), Miloš Ajčević\(^1\), Marcello Naccarato\(^1\), Paola Caruso\(^1\), Alex Buote Stella\(^1\), Carlo Lugnan\(^1\), Ilario Scali\(^1\), Paola Polverino\(^1\), Alessandro Marsich\(^2\), Agostino Accardo\(^3\), Paolo Manganotti\(^1\)

\(^1\)University Hospital and Health Services of Trieste - ASUGI, Clinical Unit Of Neurology, Department Of Medicine, Surgery And Health Sciences, Trieste, Italy, \(^2\)Televita, Televita, Trieste, Italy, \(^3\)University of Trieste, Department Of Engineering And Architecture, Trieste, Italy

**Background and Aims:** Telemonitoring solutions may assure patients' safety in the TIA/stroke post-acute phase outside the hospital. Currently there is a lack of a multi-parametric telemonitoring system for early post-acute TIA/stroke patients, in particular potentially useful in COVID-19 emergency period. We aimed to design and test a comprehensive e-Health system based on a multiparametric telemonitoring solution in this fragile group.

**Methods:** We proposed a novel e-Health system and performed a preliminary evaluation of a 14-day telemonitoring protocol for TIA/minor stroke during COVID-19 emergency. The proposed system involves the use of portable devices for BP/HR/SpO2/temperature sensing, panic-button and a dedicated informatic platform.

**Results:** Eight consecutive TIA/minor stroke patients were included in the proof-of-concept validation test. A mean of 32 exceeding threshold events for each patient was observed. 52% of alarms were related to BP, 34% to HR, 9% to lower SpO2 and 5% to higher body-temperature. In 7 out of 8 patients the clinician changed the prescribed therapy, in particular the neurologist modulated the antihypertensive therapy. 6 out of 8 patients had a normalization of all parameters in the last two days of study period. We observed a significant improvement of quality of life, as well as a significant reduction of anxiety and depression status. The 3-month follow-up showed total adherence of prescribed therapy and no stroke/TIA recurrence or other emergency department admissions.

**Conclusions:** The proposed telemonitoring solution allowed to promptly and remotely identify vital sign alterations at home during the early post-acute phase, allowing therapy and behavioral intervention adjustments.
EEG SPECTRAL PARAMETERS CORRELATE WITH THE EXTENT OF BRAIN ISCHEMIA IN HYPER-ACUTE ISCHEMIC STROKE

Miloš Ajčević¹, Giovanni Furlanis², Aleksandar Miladinović¹, Alex Buote Stella², Paola Caruso², Maja Ukmar³, Maria Cova³, Marcello Naccarato², Agostino Accardo¹, Paolo Manganotti²
¹University of Trieste, Department Of Engineering And Architecture, Trieste, Italy, ²University of Trieste, Clinical Unit Of Neurology, Department Of Medicine, Surgery And Health Sciences, University Hospital And Health Services Of Trieste – Asugi, Trieste, Italy, ³University of Trieste, Radiology Unit, Department Of Medicine, Surgery And Health Sciences, University Hospital And Health Services Of Trieste – Asugi, Trieste, Italy

Background and Aims:: Brain electrical activity alterations in acute ischemic stroke are related to neurophysiological changes during hypoperfusion as manifestation of neurovascular coupling. EEG could be applicable for bedside functional monitoring in the hyper-acute phase of ischemic stroke. This study aimed to investigate the relation between EEG changes and ischemic core-penumbra CT Perfusion (CTP) volumes, and their association with neurological deficit in the hyper-acute phase of ischemic stroke.

Methods:: CT Perfusion imaging and EEG recordings, measured with bedside wireless-EEG, were performed at admission in thirty-one ischemic stroke patients within 4.5 h from symptom onset. Ischemic core and total hypoperfused volumes were estimated from calculated CTP maps. Spectral parameters were extracted from EEG recordings. Correlation between ischemic volumes and EEG spectral parameters were investigated. In addition, we investigated the association of EEG and CTP parameters with neurological deficit measured by NIHSS.

Results:: The significant positive correlations were observed between ischemic volumes (core volume and total ischemic volume) and EEG spectral parameters: delta/alpha ratio (DAR), (delta + theta)/(alpha + beta) ratio (DTABR) and relative delta power, while the relative alpha power correlated inversely both with core volume and total ischemic volume. The identified EEG parameters, as well as CTP volumes, showed significant relation with NIHSS.

Conclusions:: The results showed that quantitative EEG can be a possible complementary tool in the evaluation of stroke severity and monitoring of the brain ischemia evolution in hyper-acute phase.
LIVER FIBROSIS-4 SCORE PREDICTS HAEMORRHAGIC TRANSFORMATION IN ISCHEMIC STROKE UNDERGOING MECHANICAL THROMBECTOMY.

Davide Norata, Serena Broggi, Chiara Rocchi, Mauro Silvestrini, Simona Lattanzi
Marche Polytechnic University, Neurological Clinic, Ancona, Italy

Background and Aims:: Haemorrhagic transformation (HT) of brain infarct is a complication of acute ischemic stroke, and may be induced or favoured by reperfusion therapy. The Fibrosis-4 (FIB-4) score is one validated index to assess the extent of liver fibrosis. The aim of this study was to assess the validity and accuracy of the FIB-4 score as a predictor of HT in patients with ischemic stroke treated with mechanical thrombectomy.

Methods:: We retrospectively identified consecutive acute ischemic stroke patients hospitalized at the Stroke Unit of the Marche Polytechnic University, Ancona, Italy, who underwent mechanical thrombectomy, with or without intravenous thrombolysis. The FIB-4 score was computed for every patient, as follows: FIB-4 = (Age × AST) / (PLT × \sqrt{ALT}) The study endpoint was the occurrence of HT as detected by routine brain CT or MRI performed within 72 hours. Predictive performance of the FIB-4 index was investigated through logistic regression and discrimination test.

Results:: Out of the 162 included patients, HT occurred in 72 (43.64%) patients. The median FIB-4 score was significantly higher among patients who developed HT than those without HT. The FIB-4 score was an independent predictor of HT [adjustedOR = 2.877, 95% confidence interval 1.006-8.224, P = 0.049] after the adjustment for potential confounders. It showed good discriminatory power with an area under the ROC curve of 0.910 and yielded a sensitivity of 73.3% and a specificity of 91.2%).

Conclusions:: The FIB-4 score was a significant predictor of HT and showed high predictive accuracy in patients with acute ischemic stroke undergoing mechanical thrombectomy.
ASSESSMENT OF CEREBRAL VASOMOTOR REACTIVITY IN PATIENTS WITH ACUTE STROKE AND TRANSIENT ISCHEMIC ATTACK (TIA) WITH DIFFERENT ETIOPATHOGENESIS: PRELIMINARY RESULTS

Nicoletta Brunelli, Claudia Altamura, Carlemima Maria Costa, Adriana Fallacara, Carlo Vico, Fabrizio Vernieri
Headache and Neurosonology Unit, Neurology Unit, Campus Bio-medico University Of Rome, Rome, Italy

**Background and Aims:** An impaired vasomotor reactivity (VMR) represents a negative prognostic factor for vascular and degenerative cognitive deterioration. Only few studies have addressed VMR in acute phase of stroke. We aim to investigate if VMR, calculated through the breath holding index (BHI), is a prognostic marker of clinical outcome in stroke/TIA patients.

**Methods:** In this longitudinal observational study (January 2020-2023) we enroll patients with acute mild stroke or TIA of anterior circulation with NIHSS < 8. The study observation period of 12 months includes 4 assessments: T1 (48-72h from stroke onset), T2 (1 month follow up (FU)), T3 (6 months FU) and T4 (12 months FU). Clinical scales and cognitive tests are performed every time. VMR is evaluated at T1 and T3.

**Results:** From January 2020 to March 2021, 48 patients (63% men) with a median age of 69 (53.8-73.3) years were enrolled. 75% had a stroke. The median NIHSS was 2 (1-4) at onset. The median pre-mRS was 0 (0) while the median mRS was 1 (0-1) at baseline. We found an inverse correlation between the adjusted mean MMSE and Pulsatility Index (PI) of Middle Cerebral Artery (MCA) (p=0.039) and PI of Posterior Cerebral Artery (PCA) (0.037) and between the mean MOCA and PI of MCA (p=0.020) and PI of PCA (p=0.004) at baseline. 39 patients performed T2 evaluation, 25 T3 evaluation and 6 of them were evaluated at T4.

**Conclusions:** These are the preliminary results of our ongoing 3-year clinical observation and VMR evaluation of stroke/TIA patients admitted at our Neurology Unit.
INCIDENCE AND MORTALITY OF STROKE IN ULAANBAATAR, MONGOLIA: EARLY RESULTS OF A POPULATION-BASED STROKE REGISTRY

Chimegilkhham Banzrai¹, Oyungerel Bosookhuu¹, Bolormaa Dambasuren¹, Sarantsetseg Turbat⁶, Erdenechimeg Yadamsuren¹, Khansuren Baatar¹, Tuguldur Erdenedalai¹, Mandakhnar Myagmarsuren¹, Uuriintuya Munkhtur¹, Xia Wang², Craig Anderson²

¹Institute of Medical Sciences of Mongolia, Department Of Neurology, Ulaanbaatar, Mongolia, ²The George Institute for Global Health, Department Of Neurology, Camperdown, Australia

Background and Aims:: Mongolia has one of the highest stroke rates in the world but there have not been any population-based registry data since 1999. We aimed to provide current stroke epidemiological data from a prospective registry among adult residents of the capital Ulaanbaatar (UB), Mongolia.

Methods:: All first-ever strokes in adults (≥18 years) from 3 suburbs of UB from 1 January 2019 to 31 December 2019 were registered. Surveillance according to WHO STEP methods to include all hospitals including state, district, private and family, forensic medicine center, general authority for state registration, and emergency medical services. According to CT/MRI/autopsy findings, strokes were categorized as ischemic stroke (AIS), intracerebral hemorrhage (ICH), subarachnoid hemorrhage (SAH), and stroke of undetermined type (UND).

Results:: A total of 878 first-ever stroke cases have been documented. After excluding duplicate cases and patients, 764 cases were included. Crude incidence and mortality rates are 132 and 65 per 100 000 person-years, respectively. Among all cases, AIS constituted 45.3%, ICH 42.5%, SAH 8.5%, and UND 3.7%, respectively. AIS:ICH ratio was 1.06. Age-specific rates in men (129/100000) aged ≥40 years was significantly greater than in women (81/100000) (P<0.001).

Conclusions:: Our study has established a comprehensive stroke surveillance system, which will expand to all of UB and include 12-months follow-up of a broad range of health outcomes to provide a contemporaneous assessment of stroke burden in Mongolia.
NEUROPROTECTIVE POTENTIAL OF HESPERETIN PHARMACOLOGICAL POSTCONDITIONING AGAINST CEREBRAL ISCHEMIC REPERFUSION INJURY IN MICE

Gurfateh Singh, Anshumala Anshumala
UNIVERSITY SCHOOL OF PHARMACEUTICAL SCIENCES, RAYAT-BAHRA UNIVERSITY, SAS NAGAR, PUNAB, INDIA 140104, Pharmacology, KHARAR-SAS NAGAR (MOHALI), India

Background and Aims: Cerebral ischemic reperfusion injury results in neuronal destruction during the period of ischemia due to the deprivation of oxygen and energy. Pharmacological post conditioning is playing road map for neuroprotection. The present study has been designed to investigate the neuroprotective potential of Hesperetin-pharmacological post-conditioning against cerebral ischemic reperfusion injury in mice.

Methods: There was five group in the present study and each group having seven mice. The protocol no. is USPS/IAEC/CPCSEA/2020/Protocol No. 45. Bilateral carotid artery occlusion (BCAO) for 12 min followed by reperfusion for 24 hours was given to induced cerebral injury in Lacca mice. Hesperetin (50mg/kg and 100mg/kg i.p) was administered 30 min prior to global cerebral ischemia and ischemic post-conditioning (IPost). Memory were assessed using morris water maze test, degree of motor incoordination was evaluated using rota-rod and actophotometer employed to evaluate the locomotor activity of experimental animals. In addition, oxidative parameters were also estimated.

Results: BCAO followed by 24 hours’ reperfusion produced a significant loss of memory, motor dysfunction along with impairment of locomotor activity. I/R injury significantly increased thiobarbituric acid reactive substances level and decreased the glutathione level as well superoxide dismutase level. Ischemic & Pharmacological post-conditioning with Hesperetin significantly restored the memory impairment, motor dysfunction, locomotor activity and altered biochemical levels which were assessed by behavior, oxidative stress parameters (TBARS, SOD & reduced form of Glutathione) and histopathological examinations.

Conclusions: The neuroprotective effect of pharmacological post-conditioning in the current study may be via activation of eNOS followed by activation of cGMP and down regulation of MPTP.
EXPRESSIVE APHASIA AND HORIZONTAL GAZE Palsy FOLLOWING A RIGHT INTERNAL CAPSULAR AND GLOBUS PALLIDAL ISCHAEMIC STROKE: A CASE REPORT

Pramith Ruwanpathirana, Bimsara Senanayake, Vithoosan Sahathevan, Sudath Ravindra
National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

Background and Aims: Expressive (non-fluent) aphasia is commonly attributed lesions involving the dominant posterior inferior frontal cortex which includes the Broca’s area. Horizontal gaze palsies are mainly due to lesions either in the contralateral frontal cortex or the ipsilateral pons. A gaze palsy with ipsilateral paraparesis is usually due to a lesion in the frontal eye field. Gaze palsies are not described in subcortical infarcts whereas subcortical aphasia is a field under evaluation. We describe a case of acute ischaemic stroke involving the right internal capsule and the globus pallidum which resulted in left hemiparesis, left gaze palsy and expressive aphasia.

Methods: A 65-year-old left-handed male presented with acute onset left sided face, arm, leg weakness, left sided gaze palsy (involving saccadic movement) and expressive aphasia for 1 hour duration. After excluding an intra-cerebral haemorrhage, he was medically thrombolysed with poor clinical resolution.

Results: The diffusion weighted MRI brain done within 24 hours of stroke onset revealed an acute infarction with diffusion restriction in the right internal capsule and the globus pallidus region. There was no evidence of cerebral oedema or haemorrhagic transformation. The clinical deficits were the same by the end of one week.
Conclusions: Gaze palsies and aphasias can be seen in internal capsular infarcts in some patients. Gaze palsy could be due to the involvement of fronto-mesencephalic fibres traversing through the genu and the posterior limb of the internal capsule. Speech is a complex neurological process involving many cortical and subcortical structures. Subcortical strokes can lead to expressive aphasias as seen in this patient.
FASTING AND NON-FASTING TRIGLYCERIDES PROFILES IN ACUTE ISCHEMIC STROKE PATIENTS

Jun Yup Kim, Keon-Joo Lee, Jihoon Kang, Beom Joon Kim, Hee-Joon Bae
Seoul National University Bundang Hospital, Department Of Neurology, Seongnam, Korea, Republic of

Background and Aims:: The prevalence and clinical implications of elevated fasting triglycerides (FTG) and non-fasting triglycerides (NFTG) in acute ischemic stroke (AIS) patients remain unknown. We aimed to elucidate the correlation of FTG and NFTG levels in AIS patients, and the clinical significance of elevated FTG and NFTG.

Methods:: Based on a multicenter prospective stroke registry, we identified AIS patients hospitalized within 24 h of onset with available NFTG results. The primary outcome measure was a composite of stroke recurrence, myocardial infarction, and all-cause mortality up to one year after stroke onset.

Results:: This study analyzed 2,176 patients. The differences between non-fasting and fasting lipid profiles according to intervals between the last mealtime and sampling time were significant only for TG. The prevalence of fasting and non-fasting hypertriglyceridemia was 11.5% and 24.6%, respectively. Multivariate analysis revealed that younger age, diabetes, and higher body mass index and initial systolic blood pressure were independently associated with both fasting and non-fasting hypertriglyceridemia (all p<0.05). Patients with higher quartiles of NFTG were more likely to be male, younger, ever-smokers, and diabetic, and have a family history of premature coronary heart disease and stroke (all p<0.05). Similar tendencies were observed for FTG. The composite outcome was not associated with FTG or NFTG quartiles.

Conclusions:: Our study showed that fasting and non-fasting hypertriglyceridemia are prevalent in AIS patients and show similar clinical characteristics and outcomes. High FTG and NFTG levels were not associated with occurrence of subsequent clinical events up to one year.
FIBRINOGEN DEPLETION AND INTRACEREBRAL HEMORRHAGE AFTER THROMBOLYSIS FOR ISCHEMIC STROKE: A META-ANALYSIS

Michele Romoli¹, David Giannandrea², Andrea Zini¹
¹IRCCS Istituto delle Scienze Neuroligiche di Bologna, Neurologia E Rete Stroke Metropolitana, Bologna, Italy, ²USL Umbria 1, Neurology, Gubbio, Italy

Background and Aims:: Intracerebral hemorrhage (ICH) can be a fatal complication of intravenous thrombolysis (IVT) for acute ischemic stroke. An early coagulopathy can develop after IVT, in relation to a significant fibrinogen depletion, increasing the risk of ICH. This systematic review and meta-analysis aimed at defining the role of fibrinogen depletion after IVT on the risk of ICH after IVT.

Methods:: Protocol was registered with PROSPERO (CRD42020124241) and followed PRISMA and MOOSE guidelines. We systematically searched English studies reporting rates of post-IVT ICH depending on fibrinogen depletion until 7/1/2021. Primary outcome was symptomatic ICH (sICH). Meta-analysis followed random-effect model to account for heterogeneity in design and timing of ascertainment. Bias were assessed via Newcastle-Ottawa Scale.

Results:: Overall, among 352 records identified, 5 observational studies were eligible for quantitative synthesis (n=2142), all of fair quality. Considering sICH within 24-36 h post-IVT, pooling data from 4 studies (n=1753) fibrinogen depletion consistently increased the risk of sICH (OR 3.67, 95%CI 2.28-5.90, p heterogeneity=0.55). Pooling adjusted estimates for age, gender and NIHSS from 3 studies (n=723), fibrinogen depletion was confirmed to significantly increase the risk of ICH after IVT (OR 5.41, 95%CI 2.96-9.89).

Conclusions:: Fibrinogen depletion significantly increases the risk of ICH after IVT for acute ischemic stroke. Routine fibrinogen assessment might be considered to identify people at higher risk of ICH. As fibrinogen repletion is feasible, trials should investigate its efficacy in preventing ICH, potentially increasing the net benefit profile of IVT in acute ischemic stroke.
PSEUDOXANTHOMA ELASTICUM AND STROKE: A RARE ENTITY

Emna Smaoui1, Khadija Sonda Moalla2, Salma Sakka3, Nadia Bouattour1, Olfa Hdiji1, Sawsan Daoud1, Mariem Damak1, Nouha Farhat1, Chokri Mhiri1
1CHU habib bourguiba Sfax, Neurology, sfax, Tunisia, 2Universal Hospital Habib Bourguiba, Neurology, SFX, Tunisia, 3UNIVERSITY HOSPITAL CENTER HABIB BOURGUIBA, Neurology, SFX, Tunisia

Background and Aims:: Introduction: Pseudoxanthoma elasticum (PXE) is a rare autosomal recessive connective tissue disease caused by mutations of ABCC6. The deterioration of elastic fibers leads to dermatologic, ophthalmologic, and vascular dysfunction.

Methods:: A woman had 2 episodes of regressive ischemic stroke at the age of 48 and 62 years old respectively. Previously she was a healthy woman, but she had family history of dermatosis and young stroke in first-degree relatives. She developed hypertension by the second ischemic attack. Initial stroke diagnostic protocol, including laboratory studies and cardiac evaluation, was negative. On general examination, she had yellow plaque-like skin lesions on the lateral neck. Ophthalmological exam revealed retinal angioid streaks complicated by neovascularization. Brain MRI and MR angiography revealed multiple lacunar infarcts, with slight focal narrowing of cervical segments of the internal carotid arteries.

Results:: Patients with PXE have higher incidence of ischemic strokes than the general population. Cerebrovascular manifestations include ischemic strokes, transient ischemic attacks and intracranial aneurysms with hemorrhagic strokes. Main mechanisms are early arteriosclerosis and arterial hypertension. Ocular manifestations are retinal pigmentation, angioid streaks and retinal hemorrhages which can lead to blindness. Skin biopsy reveals fragmentation and calcification of elastic fibers. Diagnosis is definite if characteristic skin signs, ophthalmologic and histological features are present.

Conclusions:: PXE must be considered when confronted with ischemic attacks of undetermined origin in young patients. Family history can be useful to suspect PXE. Aspirin should be used with precaution to prevent ocular and neurological thromboembolic events.
RATIONALE FOR INITIATING FEASIBILITY STUDY OF TRIIODOTHYRONINE SUPPLEMENTATION FOR STROKE PATIENTS TO IMPROVE OUTCOMES

Dmytro Filimonov¹, Anna Fedorova², Alexander Yeresko³, Margarita Belotserkovskaya², Nadezgda Trubnikova²
¹V.K. Gusac Institute of Urgent and Reparative Surgery, Experimental Surgery Department, Donetsk, Ukraine, ²V.K. Gusac Institute of Urgent and Reparative Surgery, Experimental Surgery Department, Donetsk, Ukraine, ³L.M. Litvinenko Institute of Physical Organic and Coal Chemistry, Department Of Biologically Active Substances, Donetsk, Ukraine

Background and Aims:: According to numerous studies low triiodothyronine (T3) syndrome is associated with poor stroke outcome but possible neuroprotective effects of thyroid hormones are underestimated in human studies. Aim of this study was to determine endogenous thyroid hormones levels effect on stroke outcome.

Methods:: In this study 121 adult patients with first-ever acute ischemic stroke were enrolled. Concentrations of free T3, free T4, TSH and basic stroke risk factors were assessed during 24h from symptoms onset. Neurological deficit was assessed by Scandinavian Stroke Scale (SSS). Patients were dichotomized for mRs 0-2 and 3-6 at 6 months after stroke.

Results:: Patients with fT3 level in 4th quartile (≥5.35 pmol/l) had a less severe deficit (SSS median 48 in Q4 vs. 37 in Q2-3, p=0.0481), especially in compare with Q1 (≤3.4050 pmol/l, SSS median 48 vs. 30, p=0.0018). Patients with free-T3 level in Q4 had a more favorable outcome in comperison with Q2-3 (mRs median 3 (95% CI 2-4 ) vs 4 (95% CI 3-5), overall difference p=0.0175).
Free-T3 level above 8.67 pmol/L was associated with 75% probability of favorable outcome. There was a correlation between fT4 and atrial fibrillation (R=0.297; p=0.0071) but no relationship between thyroid hormones in Q3-4 and increased risk of any cause death or recurrent events.

**Conclusions:** Dose-dependent effects of fT3 on stroke outcome, absence of negative events in high-T3 group and results of previous studies made the rationale of conducting a feasibility trial of T3 supplementation in stroke patients to improve outcomes.
PREDICTION OF EARLY FUNCTIONAL OUTCOMES OF HEMORRHAGIC STROKE

Background and Aims:: A common limitation of studies on hemorrhagic stroke (HS) outcomes is that authors concentrate exceptionally on clinical data and do not consider environmental factors. There is a rising body of evidence for highly informative value of weather in the forecast. We aimed to predict unfavorable outcomes in patients with HS at the time of discharge from in-patient service in hot dry climate.

Methods:: We studied 160 consequent HS cases admitted over the course of four years. Supervised ML models were built for two classes: mRS ≤ 3 and mRS > 3. To build the models we first performed feature selection. Risk factors were ranked in importance according to their impurity-based predictive potential. To evaluate classifier output quality, we trained models in a stratified 10-fold cross-validation technique.

Results:: The most valuable clinicodemographic factors were BMI, NIHSS at admission and age. The list of significant features predictive of outcome changed pronouncedly when meteorological data was incorporated into the model, in which case NIHSS at admission was the most predictive clinical factor, followed by the changes in air masses during two days preceding the stroke. The inclusion of weather estimates increases the predictive metrics of the classifying model (F1 score of 0.900 vs. 0.667; AUC of 0.896 vs. 0.685).

Conclusions:: Outcomes of HS may be predicted precisely with ML models trained on a combination of the full range of meteorological and clinicodemographic data. Hospitals may improve stroke management practice with the employment of predictive models. Climatic factors should be included in stroke prediction applications.
ATRIAL FIBRILLATION DETECTION IN POST-STROKE PATIENTS: A CLINICAL AUDIT AT PORTIUNCULA HOSPITAL BALLINASLOE.

Aisling Egan
University Hospital Limerick, Elderly Medicine/geriatrics, Dooradoyle, Limerick, Ireland

Background and Aims: Stroke is a leading cause of death and disability worldwide and approximately 10,000 people have a stroke related event every year in Ireland (1). Atrial fibrillation (AF) is one of the most common sustained arrhythmias and is a major risk factor for stroke (2). However, a substantial number of patients with stroke have asymptomatic AF (3). Thus, the NICE guidelines, recommend that a 24-hour Holter monitor/24-hour ECG monitor be used to detect AF (1). Aims: Identify the number of patients with a background history of AF prior to stroke. In reference to the RCP NICE Stroke guidelines (1), audit if a Holter monitor was performed on all stroke patients without a background of AF.

Methods: A search for all patients who had a stroke between January 2018 and December 2018 in Portiuncula hospital was conducted. Of these 17 patients, 4 patients had a background history of AF prior to their stroke. Abiding by the RCP NICE accredited guidelines 2016, the 13 remaining patients with no background history of AF, should have had Holter monitors performed to assess for undiagnosed AF. The incidence of ischemic stroke increases with age (2). Thus, patients’ ages were also investigated.

Results: 41% of the patients were above the ages of 71 years. 24% of all stroke patients had a background history of AF prior to their stroke.

Conclusions: Stroke patients who have no background of AF and no known cause for their stroke, should have a Holter monitor performed (1).
Background and Aims:: Frailty is an important short and long term predictor of disability in the elderly and might influence the clinical outcome of acute treatment of stroke. Aim of the study was to evaluate whether frailty predicts short- and long term all-cause mortality and neurological recovery in old patients who underwent reperfusion acute treatment of stroke.

Methods:: Consecutive patients older than 65 years who underwent thrombectomy or thrombolysis in a single stroke Unit from 2015 to 2018. Predictors of stroke outcomes were assessed including demographics, baseline NIHSS, time to needle, treatment and medical complications. Premorbid Frailty was assessed with a comprehensive geriatric assessment (CGA). At 3 and 12 months, all-cause death and clinical recovery were evaluated.

Results:: 102 patients, of whom 31 underwent mechanical thrombectomy and 71 venous thrombolysis (mean age 77.5, 65-94 years) entered the study. Frailty was diagnosed in 32 out of 70 patients and associated with older age (p=0.001) but no differences in Baseline NIHSS score or treatment strategies. At follow-up, frail patients showed higher incidence of death at 3 (25% vs 3%, p=0.008) and 12 (38% vs 7%, p=0.001) months. Frailty was the best predictor of worse neurological recovery at 3 month (mRS 3.4 + 1.8 vs 1.9 + 1.9, p=0.005) and one year follow-up (mRS 3.2 + 1.9 vs 1.9 + 1.9) for free survival patients.

Conclusions:: Frailty is an important predictor of efficacy of acute treatment of stroke. Larger longitudinal studies are warranted in order to evaluate the risk-benefit of reperfusion treatment in the growing elderly frail population.
EMBOLIC STROKE COMPLICATION FOLLOWING HEMOPTYSIS EMBOLIZATION: A CASE REPORT

Eko Arisetijono1, Riskiyan Riskiyana1, Achmad Bayhaqi2, Susanthy Djajalaksana3
1Medical Faculty of Universitas Brawijaya - Saiful Anwar General Hospital, Neurology, Malang, Indonesia, 2Medical Faculty of Universitas Brawijaya - Saiful Anwar General Hospital, Intervention Radiology, Malang, Indonesia, 3Medical Faculty of Universitas Brawijaya - Saiful Anwar General Hospital, Pulmonology, Malang, Indonesia

Background and Aims:: Bronchial and non-bronchial systemic arterial embolization (BAE/ NBSAE) is a safe and effective non-surgical intervention for patients with massive hemoptysis. Stroke is a rare complication of BAE/ NBSAE. We reported a case of cerebellum infarction as a one of complication of BAE/ NBSAE

Methods::

Case: A 33-year-old woman had experienced productive hemoptysis for 3 years. She had a history of completely treated lung tuberculosis, yet she had productive hemoptysis due to cavity with isodens lesion with crescent sign. Both, bronchial and non-bronchial systemic arterial embolization (BAE/NBSAE), had been performed to reduce hemoptysis. The transarterial approach was done accessing right intercostal and intercostobronchial artery. Decannulation of catheter was hard to perform due to tortuous vessels. Unfortunately, the catheter inadvertently engaged to origin of right vertebral artery. It made the suddenly symptoms of vertigo and nystagmus response. The emergency brain non-contrast computed tomography (CT) scan revealed a suspicion of acute infarction of left cerebellum. It was confirmed as an acute infarction of right cerebellum by brain magnetic resonance imaging (MRI) and magnetic resonance angiography (MRA). She then was administered heparin and had completely
neurological recovery for ten days
hospitalization
Results: BAE and NBSAE are effective methods for the control of moderate-massive hemoptysis due to bronchiectasis and pulmonary tuberculosis or aspergilloma. The worldwide prevalence of transient ischemia/stroke and cortical blindness complication following BAE is 0.6-2%. It is mostly attributed to subclavian arteries maneuvers or embolizing agents crossing bronchopulmonary arterial anastomoses. Conclusions: Early detection of neurological dysfunctions following BAE/NBSAE could improve the clinical outcome of neurological complications.
Background and Aims:: Ischemic stroke (IS) in young adults is a serious medical problem due to its potential socio-economic consequences. The risk of recurrence is highest 22% in the first year and 53% in the following five years. Moreover, recurrent stroke is the leading cause of disability and death. Data on long-term survival and recurrence after stroke are missing. We studied temporal trends in 5-year ischemic stroke case fatality and recurrence rates stratified by etiological subtype according to the ORG 10172 trial classification in acute stroke treatment (TOAST).

Methods:: A total of 270 consecutive patients younger than 50 years with a diagnosis of ischemic stroke were included for 5 years in the neurology department. The clinical evaluation consisted of a complete neurological examination and the National Institutes of Health Stroke Scale. Diagnostic workup included vascular axis exploration, extensive laboratory, radiological, and cardiological examination. Etiology-specific time trends for recurrence were estimated by Cox regression.

Results:: The mean age of the patients was 41 ± 7 years and the sex ratio was 1. Recurrence of IS was noted in 98 patients. According to TOAST classification, atherosclerosis and cardio-embolism were associated with stroke recurrence in our study. Moreover, the hazard ratio (HR) of determinate causes of stroke was 3.658 (95% CI 1.837-7.284) dominated by hypercoagulability state. Thrombophilia was associated with recurrence vascular accident (p:0.001), the HR was 2.293 (95%CI 1.405-3.741).

Conclusions:: Thrombophilia increases the risk of early recurrent IS in young adults. They require special secondary prevention efforts.
SPEECH AND NEUROPSYCHOLOGICAL STATUS IN A RUSSIAN-LANGUAGE PATIENT WITH CROSSED APHASIA: A CASE STUDY

Elena Gorobets¹, Elvira Mukhametova², Victor Gorobets¹, Yulia Laykova¹, Yulia Volskaya¹, Ilyas Fattakhov¹, Rimma Gamirova³
¹Kazan Federal University, Laboratory Of Clinical Linguistics, Kazan, Russian Federation, ²Kazan Federal University, Department Of Neurorehabilitation At The Scientific And Clinical Center For Precision And Regenerative Medicine, Kazan, Russian Federation, ³Kazan Federal University, Laboratory Of Clinical Linguistics, Department Of Fundamental Basis Of Clinical Medicine, Kazan, Russian Federation

Background and Aims:: Clinical cases of crossed aphasia in Russian-speaking patients, especially in ambidextrous, have not yet been adequately described. In the current study, we report a patient (male, 49 years old, Russian monolingual, ambidextrous: right-handed in writing, left-handed in everyday activities) with aphasia and neuropsychological deficits after right hemisphere (RH) hemorrhagic stroke.

Methods:: MRI of the brain; EEG-monitoring; neurological examination; neuropsychological (A.R.Luria's methodology) and speech (methodology of T.V.Akhutina, L.S.Tsvetkova, N.M.Pylaeva) assessment.

Results:: In September, 2020, a patient had a stroke – putamenal hemorrhage in RH with the development of left-sided hemiparesis to plegia in the arm, left-sided hemihypesthesia, left-sided homonymous hemianopsia. MRI: acute hemorrhage in the RH of the brain, putamenal region. EEG-monitoring: interhemispheric asymmetry, continued deceleration of background activity to the theta range in RH with regional deceleration to the delta range in the temporo-central parietal area. The patient passed through endoscopic removal of hypertensive right-sided putamenal hematoma using neuronavigation. Speech and neuropsychological assessment: complex cross aphasia (efferent motor and semantic according to A.R.Luria’s classification, severe prosodic violations); severe acalculia, dysgraphia, moderate dyslexia; premotor apraxia followed by a moderate deficit in the executive functions; left-sided neglect due to hemianopsia.

Conclusions:: The current study represented symptoms of speech disorders in ambidextrous patient with aphasia which are typical for the dominant left hemisphere damage in right-handed patients and a range of deficits (severe prosodic violations) which are typical for the dominant RH damage in right-handed patients. This work was supported by the Program of Strategic Academic Leadership of Kazan Federal University.
NEURON-SPECIFIC ENOLASE AS A BIOMARKER OF ISCHEMIC STROKE

Ivan Ternovykh1, Alexandra Chaykovskaya1, Maria Topuzova1, Pavel Kovzelev1, Albina Makhanova1, Daria Korotkova1, Alina Kipkeeva1, Anna Zatey1, Anna Mikheeva1, Tatiana Vavilova2, Elena Vasilieva3, Kaium Simakov4, Tatiana Sergeeva5, Tatiana Alekseeva1

Background and Aims:: Early detection and evaluation of ischemic stroke (IS) can have a positive impact on its outcomes. One of the most promising ways is to use neuron-specific enolase (NSE). The goal of this study was to clarify the serum levels of NSE in the acute period of the IS and define their relationships with severity of neurologic deficit and short-term outcomes.

Methods:: 63 patients with IS and 20 controls were included in this study. Blood samples were drawn in the first 72 hours (point 1, p1) and 10-14 days (point 2, p2) since the IS, once in controls. Severity of neurological deficit, short-term outcome and functional outcome were evaluated with NIHSS, Rankin (mRs), Rivermead and Barthel scales twice at p1 and p2.

Results:: NSE levels were elevated in 66.6% of patients with IS at p1, which was significantly different from controls (29.3±3.9 and 15.5±1.4, p=0.002), lowering significantly by p2 (17.5±0.9; p = 0.003). In patients with the higher severity at p1 NSE at p1 was higher (p=0.03), and with higher severity in p2 NSE were higher at p1 (p=0.04) and p2 (p=0.005). Correlations were found between NSE at p1 and Barthel at p2 (r=0.3) and Rivermead at p2 (r=0.27); NSE at p2 and NIHSS at p1 (r=0.31) and p2 (r=0.28), mRs at p1 (r=0.34) and p2 (0.26), Barthel at p1 (r=-0.3) and p2 (r=-0.34), Rivermead at p1 (r=-0.35) and p2 (r=-0.33).

Conclusions:: NSE can be useful for stroke diagnostics, prognosis, monitoring and estimating rehabilitation potential in the acute period of the ischemic stroke.
SUCCESS AND PITFALL OF ANTICLOTTING THERAPY

Patrizia Fiori¹, Lia Allegorico¹, Guglielmo Capaldo¹, Antonio Corbo¹, Marco Massarelli¹, Chiara Pelosi², Patrizia Savino², Annamaria Bellizzi², Filomena Botticella², Angela Di Gianni³, Carmela Dragonetti³, Carmela Lo Conte³, Gianvito Manganelli³, Alessandro Morella³, Vincenzo Pellecchia³, Gennaro Bellizzi³, Carminantonio Tammaro⁴, Antonio Monaco¹

Ottone Frangipane Hospital, Cardiology, Ariano Irpino (Avellino), Italy, ⁴S. Ottone Frangipane Hospital, Laboratory, Ariano Irpino (Avellino), Italy

Background and Aims:: In Italy, prescription of novel therapeutical agents is under strict control. Nonetheless, efficacy and safety of NOACs (Novel Anti-Clotting drugs) fostered their off-label prescription.

Methods:: We recruited the following patients affected with atrial fibrillation (AF): 7 Chronic Cerebrovascular Disease (CCVD), 58 Acute Stroke (AS), treated with NOAC; 13 CCVD and 98 AS, under Vitamin K Anticoagulants (VKA). INR of the latter at emergency department was < 2 in 40 (52%), > 3 in 15 (19%), 2-3 in 22 (29%) AS patients.

Results:: Rivaroxaban, apixaban, edoxaban and dabigatran were prescribed in 30 (45%), 18 (27%), 10 (15%) and 8 (12%) patients, respectively. According to pharmaceutical recommendations, under dose or upper dose were reported in a minority of patients. However, the prescription resulted to be “inappropriate” considering valvular cardiopathy at echocardiography. No NOAC treated patients had haemorrhagic infarction. Among VKA treated AS patients, aortic and mitralic prosthesis, moderate-severe mitral, aortic and tricuspidal failure, septal aneurisms, dilatative chronic ischaemic cardiomyopathy were present. Haemorrhagic infarctions occurred in 10/77 (13%) AS patients (4 in INR < 2, 3 in INR 2-3, 3 in INR > 3).

Conclusions:: Our results confirm the safety of NOAC. Their efficacy may be lessened in moderate-severe valvulopathies. Further studies are needed in order to validate the probable reduction in mortality. The paradox of no differences in the rate of haemorrhagic infarction related to the entity of anticlotting effect of VKA, in the absence of traumatic events, highlight the increased risk related to underlying cardiological dysfunction and late recanalization.
PREVALENCE OF ASYMPTOMATIC UNRUPTURED INTRACRANIAL ANEURYSM IN THE ELDERLY THAI POPULATION

Naruchorn Kijpaisalratana¹, Pongpat Vorasayan², Wasan Akarathanawat², Aurauma Chutinet¹, Supparat Charnwut², Tikumporn Kanchong², Pakawan Vongvasinkul², Supaporn Krittanupong³, Nijasri Suwanwela¹

Background and Aims:: Subarachnoid hemorrhage is one of the devastating cerebrovascular event. Ruptured intracranial aneurysm is the leading cause of subarachnoid hemorrhage. Early detection of unruptured intracranial aneurysm (UIA) may help prevent subarachnoid hemorrhage. This study aimed to identify the prevalence of asymptomatic UIA among elderly Thai population.

Methods:: Participants age ≥ 55 years old who had no previous history of ischemic or hemorrhagic stroke were enrolled in the study. Magnetic Resonance Imaging with MR angiography were performed in all participants. Aneurysms types, sizes, and locations were evaluated. Baseline characteristics among participants with and without saccular aneurysms were compared.

Results:: Two hundred participants were enrolled in the study, 136 (68%) were female. Twenty-six aneurysms were detected in 22 participants. Among these, 20 participants (90%) and 2 participants (10%) had saccular and fusiform aneurysm respectively. Prevalence of unruptured intracranial saccular aneurysm was 10%. Mean (SD) size of saccular aneurysms was 3.05 (1.71) mm. (max 10 mm., min 1.2 mm.). Cavernous part of internal carotid artery (ICA) was the most common location of saccular UIA (33%) followed by supracinoid (25%) and paracintoid (25%) ICA. There was non-significant trend towards higher female and smoking participants with saccular UIA. Other risk factors including age, smoking, diabetes mellitus, hypertension, dyslipidemia, and peripheral arterial disease were similar between 2 groups. None of the participants had subarachnoid hemorrhage during 6 months follow-up period.

Conclusions:: This is the first study to demonstrate the prevalence of UIA among elderly Thai population without previous history of stroke.
EPISODES OF PULSELESS, NON-PERFUSING RHYTHM: A SUBTLE KILLER

**Background and Aims:** Cardiovascular reactivity (CR) may be defined by beat indices (ratio or difference) between higher maximal or minimal heart rate (HR) on higher maximal or minimal pulse rate (PR) (Fiori P. et al., 2020). Episodes of negative CR (NCR) may subtly occur and impair cerebrovascular and cardiovascular function. The aim of our study was to examine the correlation between haematological parameters (HP), Holter Arterial Pressure Measurements (HAP) and burden of vascular encephalopathy (VE) in acute ischaemic cerebrovascular events, chronic cerebrovascular diseases (CCVD), other neuropsychiatric disorders (OND).

**Methods:** VE was calculated by scoring the presence of: - enlarged liquoral space (1); - white matter hyperintensities (1); - lacunar Acute Stroke (AS) (1); - AS > 0.5 cm diameter (2); - enlarged perivascular space (1); - cerebral microbleeds (1).

**Results:** Significant differences and correlations were found concerning HP, HAP and outcomes in AS, CCVD compared to OND. VE was found in 29% OND, 100% CCVD, 84% AS. Patients with NCR have a higher probability of AS and/or CCVD (AS OR 4, CCVD OR 6).

**Conclusions:** CR correlates with VE. Anti-hypertensive therapies may account for discrepancies in CR in CCVD. Three stages of ischaemic lesional burden may be conceived: I - Preserved ejection fraction (prEF), high CR / low VE risk; II - PrEF, low CR / intermediate VE risk; III - Reduced EF, low CR / high VE risk (no-perfusion, core, no-collateral compensation). The relation of HR, PR with age and VE may be represented by U and reversed U curves, respectively.
FOCUSING ON SINGLE CT PERFUSION QUANTITATIVE MAPS: PERCHERON’S ARTERY STROKE DETECTION IN AN EMERGENCY SETTING

Tommaso Cillotto, Giovanni Furlanis, Alex Buoite Stella, Carlo Lugnan, Paola Caruso, Roberta Pozzi Mucelli, Marcello Naccarato, Paolo Manganotti
University of Trieste, Clinical Unit Of Neurology, Department Of Medicine, Surgery And Health Sciences, University Hospital And Health Services Of Trieste – Asugi, University Of Trieste, Strada Di Fiume, 447, 34149 Trieste, Italy, Trieste, Italy

Background and Aims:: Occlusion of Percheron Artery may be challenging due to its rare occurrence, confounding clinical presentation and neuroimaging assessment.

Methods:: Here we report the case of a 58-years-old man admitted to the Stroke Unit after awakening with drowsiness, global aphasia, right hemiplegia symptoms (NIHSS=19), a Total Anterior Circulation Syndrome mimicking an infarct in the territory of the middle cerebral artery.

Results:: Non-Enhanced Computed Tomography (NECT), CT angiography and CT Perfusion (CTP) core/penumbra summary map did not show abnormalities. Follow-up NECT at 24 h showed bilateral thalamic hypodensity. Because of the late presentation the patient was not treated with thrombolysis and died six days later. Despite the initial CTP core/penumbra summary map was negative, the careful re-evaluation of single parametric CTP maps (MTT/TTP/CBF/CBV) revealed bilateral symmetrical thalamic hypoperfusion in TTP, CBF and MTT, but no CBV alteration, a suggestive pattern of penumbra in the Percheron’s artery territory(Figure 1). This symmetrical alteration of parametric maps yields a negative core/penumbra summary map if the software criteria is based only on the asymmetry-based thresholds, so the median vascular territories are not visualized on the summary map.

Conclusions:: In conclusion, this case highlights the opportunity of early diagnosis of Percheron’s artery occlusion through complete CTP analysis, which require both the acknowledgment of the automatic core/penumbra summary maps’ pitfalls and the evaluation of all parametric maps.

Figure 1. (A) NECT at admission; (B) CTP core/penumbra summary map; (C), (D), (E), (F) Quantitative CTP parameters maps - MTT, CBV, TTP, CBF, respectively. Single CTP quantitative maps revealed bilateral symmetrical thalamic marked hypoperfusion in TTP, CBF and MTT; (G) follow-up NECT.
Background and Aims: To analyze modern approaches to the treatment of speech disorders in patients with acute ischemic stroke.

Methods: A total of 115 people with ischemic stroke was examined. Patients were divided into three groups: 35 with aphasia, 42 with dysarthria and 38 patients without speech disorders. Rivermid mobility index, the MMSE, the Hamilton scale and the aphasic test were applied.

Results: In the first group the average on the Hamilton scale was 10.2 points, 16.4 points on the MMSE, and the Rivermid index was 4.6. A strong correlation of $r = 0.67$ was found between the motor disorders and depressive manifestations. Applying the Hamilton scale was difficult for this group, but indirect signs of depression were common - 83%. In a group of patients with dysarthria: the mean value on the Hamilton scale of 9.7 and the index of motor disorders of 4.3; also indirect signs of depressive manifestations (36%) were found. In this group, there was a strong correlation ($r = 0.78$) between the indicators of mobility index and the presence of depression on the Hamilton scale. In the group without speech disorders, the medium value for the depression scale was 9.1 points, the cognitive impairment on the MMSE was 20.2 points, and the Rivermid index - 4.8 points. Indirect signs of depression - 20%.

Conclusions: The high prevalence of clinically significant depressive manifestations among the patients with speech disorders was found.
WRONG OR RIGHT DECISION MAKING?

Ottone Frangipane Hospital, First Aid, Ariano Irpino (AV), Italy, ¹³Criscuoli Hospital, Laboratory, S. Angelo dei Lombardi, Italy

Background and Aims:: High density of population, lack of birth control in developing countries with subsequent emigration, extreme social and economic differences, poor environmental resources, conflicts are emerging challenges to political and economic assets all over the world

Methods:: A 28 years-old, Nigerian, male patient was transferred to our Neurological Unit from First Aid for subacute, ischaemic stroke caused by a large occlusion of right, middle cerebral artery. He came to observation because of cephalalgia, agitation, left facio-brachio-crural hemiparesis with hypoesthesis, sphincterial release, tachycardia, pulmonary crackling.

Results:: Assay for psychotropic substances showed tetrahydrocannabinoid positivity. A wide, right fronto-parieto-temporal ischaemia, pleural effusion, dilatative cardiomyopathy were present at Computerized Tomography. Thoracic Echocardiography detected a thromboembolic formation in left ventricle and an ejection fraction of 20%. At admission, the following parameters were revealed: arterial pressure 122/85 mmHg, heart rate 56 b/min, respiratory rate 22, body temperature 36.3°C, SaO2 70%, NIHSS 23. Haematological examinations showed monocytosis, increased Erythrosedimentation Rate, C-Reactive Protein, hsTroponin, Brain Natriuretic Peptide, d-dimer, a1, a2 proteins, decreased albuminemia, g globulins, presence of albuminuria, anti-HCV, anti-rubeola, anti-EBNA, anti-cytomegalovirus IgG positivity. Titer of anti-Lupus Anticoagulant antibodies was high. Asymptomatic stenosis of left internal carotid artery was revealed by EchoDoppler Ultrasonography. A diagnosis of cardioembolic ischaemic stroke, dilatative cardiomyopathy, suspected post-infectious vasculitis was posed. Because of incipient heart failure, a defibrillator was implanted. The patient was transferred to rehabilitation for further diagnostic analyses and physio-kinesis-therapy.

Conclusions:: A concerted action is needed in order to establish a common strategy for ensuring humanitarian, medical assistance, safeguarding shared rules and public health care.
Background and Aims:: Hypereosinophilic syndrome (HES) is a rare cause of recurrent ischemic stroke and the underlying pathogenesis is heterogeneous. Herein, we describe a gentleman presenting with recurrent strokes due to idiopathic HES for 3 years, with a dramatic response to Imatinib.

Methods:: A 56-year-old gentleman with dyslipidemia, hypertension and past history of multiple strokes involving different vascular territories presented with acute onset slurring of speech and left sided weakness. Neurological evaluation showed dysarthria and left hemiparesis. He also complained of dry cough for 6 months and non-specific symptoms like fatigue, myalgia. His investigations (Figure 1 and Table 1) confirmed the HES and Hydroxyurea and Prednisolone was started. Imatinib was started after 6 months due to poor response and the eosinophil count normalized within 3 months.

Figure 1: (A) sagittal, (B, C) axial T1 flare and (D) DWI brain images showing multiple acute infarcts in right side with bilateral multiple chronic lacunar infarcts and evidence of small vessel disease.
Results: HES is diagnosed based on persistent eosinophilia (≥ 1500 eosinophils/mm³) for at least 6 months, organ involvement including cardiac, brain, bone marrow and exclusion of other conditions. The treatment goal is to reduce the eosinophil level in blood and tissues to prevent tissue damage. Treatment includes glucocorticoids, hydroxyurea, Chlorambucil and Vincristine. Tyrosine kinase inhibitors such as Imatinib indicated for patients with positive FIP1L1-PDGFRA fusion. Mepolizumab (antiIL-5) has received FDA approval recently for negative FIP1L1-PDGFRA. Our patient was treated with Imatinib even though his mutation was negative and he responded excellently.

Conclusions: HES is a treatable cause of recurrent stroke and need to consider particularly when involving different vascular territories. HES can be fatal, hence early diagnosis and prompt treatment to mitigate disability and mortality is essential.

PROTEIN S DEFICIENCY AND MTHFR MUTATION: AN UNCOMMON CAUSE OF SPINAL CORD INFARCTION: A CASE REPORT

Nesrine Charfi1, Ines Bedoui2, Bissene Douma2, Hajer Derbali3, Malek Mansour4, Ridha Mrissa4
1Primary Military Hospital of Tunis, Neurology, Tunis, Tunisia, 2CHU, Tunis Military Hospital, tunisia, Tunisia, 3Military Hospital of Instruction of Tunis, Department Of Neurology, tunis, Tunisia, 4Military Hospital of Instruction of Tunis, Department Of Neurology, sousse, Tunisia

Background and Aims:: Ischemia of the spinal cord represents only 5 to 8 % of acute myelopathies and < 1% of all strokes. The clinical and radiological presentation are varied. Protein S deficiency and MTHFR mutation are an uncommon cause of spinal cord infarction and often misdiagnosed. Aim : To recommend an exhaustive etiological assessment in front of any spine ischemia in young adult.

Methods:: This is a case about a patient who was diagnosed with spinal cord infarction due to protein S deficiency at the primary military hospital of Tunis.

Results:: A 27-year-old pregnant women, presented with acute onset of flaccid quadriplegia associated with bladder incontinence. On initial examination she was afebrile. Muscle strength was 0 out of 5 in bilateral upper and lower extremities, with generalized loss of tone. Muscle stretch reflexes were absent. Sensory evaluation revealed absent sensation to all modalities with a C4 sensory level. Repeat spine Magnetic resonance imaging (MRI) showed central cord T2 hyper intensity C4-T2, with prominent owl sign on transverse views. An exhaustive etiological assessment including cérebro spinal fluid analysis, cardiac exploration, and laboratory panels found a protein S deficiency and MTHFR mutation. Patient was treated with aspirine and outcome was favorable.

Conclusions:: Unlike the classical etiologies of spinal cord ischemia, haematological cause, in particular the protein S deficiency and MTHFR mutation must be researched in young adults.
CEREBRAL AIR EMBOLISM: A HIDDEN CAUSE OF ACUTE ISCHEMIC STROKE.

Cecilia Zivelonghi¹, Carlo Alberto De Pasqual², Nicola Micheletti¹, Giampaolo Tomelleri¹, Bruno Bonetti¹, Manuel Cappellari¹
¹Azienda Ospedaliera Universitaria Integrata, Stroke Unit, Department Of Neurosciences, Biomedicine And Movement Sciences, Verona, Italy, ²AOUI Verona, Gastrointestinal Surgery, Verona, Italy

Background and Aims:: Cerebral air embolism (CAE) is a rare but well-documented complication of endoscopic procedures. The precise mechanism is still debatable since no right-to-left shunts are found in most cases.

Methods:: Case-report

Results:: A 46-year-old male with a history of eosinophilic oesophagitis presented to the Emergency Department because of food bolus impaction. Under general anesthesia, an emergent EGD was performed and the bolus was successfully pushed into the stomach. Three hours later the patient complained of drowsiness and left-sided weakness. Brain CT-scan was unremarkable. Neurologic examination revealed left-sided sensory-motor impairment and hemianopia. Intravenous thrombolysis was started and the patient was referred to our tertiary center for stroke treatment. CT-angiography failed to prove large vessel occlusions but revealed a pneumo-mediastinum (FigureA). A second EGD confirmed a small oesophageal laceration without signs of perforation or bleeding (FigureB). Follow-up brain MRI revealed two ischemic lesions in the right hemisphere, in both anterior and posterior territories (FigureC-D). Echocardiography and prolonged cardiac monitoring resulted normal. Transcranial doppler with bubble test was unremarkable. A presumptive diagnosis of CAE was made. A definite diagnosis must be supported by a brain CT-scan positive for air detection. However, air dissolves quickly in the blood and in most reported cases no evidence of air embolisms can be demonstrated with CT-scan already after few hours from the acute event.
Conclusions:: Despite its rarity, cerebral air embolism should be considered when neurologic impairment occurs soon after endoscopic procedures, in order to promptly implement the correct treatment (e.g. hyperbaric chamber) and to avoid potentially catastrophic consequences from misdiagnosis.
THROMBECTOMY FOR ISCHEMIC STROKE WITH LARGE VESSEL OCCLUSION AND CONCOMITANT SUBARACHNOID HEMORRHAGE

Cecilia Zivelonghi¹, Andrea Emilianii², Nicola Micheletti¹, Giampaolo Tomelleri¹, Bruno Bonetti¹, Manuel Cappellari¹
¹Azienda Ospedaliera Universitaria Integrata, Stroke Unit, Department Of Neurosciences, Biomedicine And Movement Sciences, Verona, Italy, ²AOU Verona, Neurology, Verona, Italy

Background and Aims:: Nontraumatic subarachnoid hemorrhage (SAH) can rarely occur in the acute phase of ischemic stroke (AIS), especially if due to large vessels occlusion (LVO). Such intracranial bleeding hinders AIS management and the choice of revascularization approach.

Methods:: Case report.

Results:: A 52 year-old man presented with acute right hemiparesis and aphasia. Brain CT showed a SAH in the left central sulcus (Fig. 1A). CT-angiography revealed sub-occlusive stenosis of the left internal carotid artery (ICA, Fig. 1B) and the occlusion of the left middle cerebral artery (MCA, Fig. 1C). The patient underwent an emergent angiographic procedure with successful recanalization (TICI score of 3). Follow-up CT, 24 hours later, demonstrated an ischemic lesion in the striatal-lenticular region (Fig. 2B) without SAH progression.
While the absolute contraindication to IVT during intracranial bleeding remains unquestionable, the potential injury/benefit from MT is still debatable. Thus, cases like ours constitute a blind spot in the guidelines where physicians face the dilemma of choosing between an acute endovascular treatment with the risks of hemorrhage progression and conservative treatment with the associated poor clinical outcome. We decided to treat our patient invasively, considering the relatively young age and the expected poor clinical outcome following untreated tandem occlusion, also given the absence of prognostic factors that generally predict post-procedural reperfusion injury (hyperglycemia, low ASPECTS, hypertension, older age, delayed onset-to-treatment time, high NIHSS etc.).

**Conclusions:** We believe that, in similar cases, MT should be considered – despite not free of risks and drawbacks – to avoid the detrimental consequences of untreated AIS from LVO.
MIMICS AND CHAMELEONS IN THE REPERFUSION ERA: TWO CASE REPORTS

Sabrina Gasverde, Federica Masuzzo, Davide Quartana, Chiara Baima, Diego Maria Papurello
ASL TO 4 Cirié Hospital, Neurology, Cirié, Italy

Background and Aims:: Stroke mimics and chamaleons cannot always be ruled out in emergency and we have to manage the risk of misdiagnosis to properly treat our patients.

Methods:: We describe two cases occurred in our emergency department (ED).

Results:: A 84 years old woman presented to ED at 2 p.m. because of acute nonfluent aphasia, last time seen well at 9 a.m. TC scan was normal and ischemic stroke was suspected. Neither thrombolysis (onset>4,5 hours) nor thrombectomy (no artery occlusion demonstrated) were performed. She recovered spontaneously in 24 hours. An EEG documented lateralized periodic discharges on left hemisphere and MRI revealed left mesial temporal and pulvinar hyperintensity on T2 and DWI; CSF examination excluded encephalitis and aphas； Status epilepticus was diagnosed. A 86 years old man, on DOACs for atrial fibrillation and previous stroke, referred to ED because of sudden loss of consciousness with diffuse rigidity. On examination one hour after onset, the patient was alert with speech impairment and right paresis. TC scan demonstrated old ischemic lesions and seizure due to remote stroke with post ictal deficits was suspected. 24 hours later symptoms were persistent with a left medial talamic ischemic lesion on TC scan according to top of basilar syndrome.

Conclusions:: In ED we need to go fast and accept the risk of treating a few mimics; the problem with chamaleons is more serious because unrecognized stroke means a patient not properly treated.
ISCHAEMIC STROKE AFTER SNAKEBITE: A CHALLENGING DIAGNOSIS AND TREATMENT

Irene Berto¹, Luca Petraglia², Emilia Sbardella², Alina Diaczenko³, Oscar Gaetano Schiavo¹, Paolo Boldrini⁴, Danilo Toni¹², Manuela De Michele²
¹Sapienza University of Rome, Department Of Human Neurosciences, Rome, Italy, ²Sapienza University of Rome, Emergency Department, Stroke Unit, Rome, Italy, ³Sapienza University of Rome, Emergency Department, Rome, Italy, ⁴Sapienza University of Rome, Poison Control Centre, Rome, Italy

Background and Aims:: Introduction: Snakebite envenoming represents a common cause of morbidity and mortality in developing countries, whereas it is a more unusual event in Europe, affecting 0.4 to 1.1 people per 100,000 population per year and causing approximately 1000 severe envenoming cases and less than 5 deaths per year. Post-snake envenomation stroke (both ischaemic and hemorrhagic) pathogenesis is multifactorial, depending on several mechanisms such as vascular endothelial damage and blood coagulation impairment. To our knowledge, only one case of hemorrhagic stroke has been described in Europe, while no cases of ischaemic stroke have been reported so far.

Methods:: Not available

Results:: Case presentation: A 66-year old man was admitted to our Emergency Department complaining diplopia and postural instability 24 hours after a viper bite on his left foot. Magnetic Resonance Imaging showed multiple bilateral ischaemic lesions involving anterior and posterior circulation, without arterial stenosis or occlusion. Muscle and cardiac venom damage was also present.

Conclusions:: We present the case of a patient who suffered from an ischaemic stroke with an embolic pattern after viper bite in Rome surrounding. Although the low frequency of snake bites at our latitudes, viper envenomation can cause severe complications and must be recognized and promptly treated. Neurologists need to be aware that viper envenomming can also be a possible rare cause of stroke and antivenom should be promptly administered to avoid this complication. Indeed, the high risk of serious events in symptomatic victims is much greater than the low risk of anaphylaxis associated with high quality modern antivenoms.
CEREBRAL VENOUS THROMBOSIS POST LOBAR PUNCTURE

Hassane Zobiri
CHU Sétif service neurologie, Neurology, SETIF, Algeria

**Background and Aims::** Cerebral venous thrombosis (CVT) is a multifactorial disease which can result from the association of several risk factors. Lumbar puncture (LP) and epidural anesthesia could be the cause of TVC but no study formally shows their involvement in the occurrence of this pathology.

**Methods::** Observation We report 03 cases (02 women and 01 man). During a lumbar puncture in the context of exploring cerebral demyelinating pathology, the 2 patients aged 27 and 32 respectively presented abnormally intense headaches, not responding to the usual analgesics and the patient aged 39 years of age presented with complex focal motor epileptic seizures. The performance of angio-MRI confirmed the presence of TVC in these patients.

**Results::** Lumbar puncture is frequently performed as part of the exploration of neurological pathologies. Post-lumbar puncture syndrome is common, found in 12 to 38% of cases depending on the series. A link between PL followed by intravenous steroid treatment is suspected to be the cause of the occurrence of CVT, with or without risk factors such as thrombophilia. It is difficult to assess the part of the responsibility of LP in the occurrence of CVT because it is often carried out during the exploration of pathologies themselves at risk of thrombosis.

**Conclusions::** It appears that in the course of LP, the presence of post-LP syndrome prolonged beyond the usual times with or without epileptic seizure, should suggest a CVT. The precocity of diagnosis thanks to cerebral angio-MRI and the speed of initiation of an anticoagulation condition the prognosis.
Safflower yellow (SY) inhibits the ischemia and hypoxia-induced inflammatory signaling transduction in both rats and BV2 cell lines

Li-Juan Song1,2, Xing-Wang Yang1, Zhi-Bin Ding1,3, Guang-Yuan Han1, Zhu-Yue Miao1, Qing Wang1, Zhi Chai1, Ce Zhang2, Jie-Zhong Yu1,4, Yu-Qing Yan4, Jian-Jun Huang5, Cun-Gen Ma1,2,3,4
1Shanxi University of Chinese Medicine, Research Center Of Neurobiology / The Key Research Laboratory Of Benfiting Qi For Acting Blood Circulation Method To Treat Multiple Sclerosis Of State Administration Of Traditional Chinese Medicine, Jinzhong, China, 2Shanxi Medical University, The Key Laboratory Of Cellular Physiology Of Ministry Of Education, Taiyuan, China, 3Shanxi Medical University, Neurology, Taiyuan, China, 4Shanxi Datong University, Institute Of Brain Science / Shanxi Key Laboratory Of Inflammatory Neurodegenerative Diseases, Datong, China, 5General Hospital of National Medicine and Datong Coalmine, Neurosurgery, Datong, China

Background and Aims:: Ischemia and hypoxia may induce inflammation in CNS. Our aim was to investigate the effects of Safflower Yellow (SY), the main active component in the traditional Chinese medicine safflower, on the ischemia and hypoxia-induced inflammatory signal transduction in both rats and BV2 cell lines.

Methods:: SD rats were randomly divided into 3 groups: control, tMCAO model and SY-treated group. The neurological deficits of rats were evaluated. The rats were sacrificed for the following assessments, including TTC staining, HE staining and RT-PCR and Western Blot. BV2 cells were divided into 3 groups: control, OGD/R and SY-treated group and assessed by RT–PCR, Western Blot and ELISA.

Results:: Compared with the control group, the behavioral function in tMCAO group was declined, while the SY application could ameliorate the changes. SY treatment significantly decreased the brain infarct volume and alleviated the pathological impairment. Compared with the control group, cell viability in OGD/R BV2 group was decreased, while SY treatment obviously improved the viability. SY suppressed the elevation of both mRNA and protein of TLR-4, TNF-α and IL-6 in tMCAO rats and OGD/R BV2 cells. Meanwhile, we found SY treatment decreased NF-κB p65 in tMCAO rats and OGD/R BV2 cells.

Conclusions:: SY effectively inhibits the ischemia and hypoxia-induced inflammatory signaling transduction in rats and BV2 cell lines. (NSF of China, 82004028; Fellowship of China Postdoctoral Science Foundation, 2020M680912; Shanxi Applied Basic Research Project, 201901D211538; Young Scientists Cultivation Project of Shanxi University of TCM,2021PY-QN-09,Ma and Huang are corresponding authors.)
Background and Aims: In recent decades, a detailed picture of language lateralization (LL) has emerged: LL can differ across the sub-processes (speech production, speech perception, and reading) and individuals (Haegen & Cai, 2019). The present study seeks to find lesion data to reflect on the gradient notion of LL.

Results: SE, a 69-year-old female had a sudden onset of aphasia and left hemiplegia. Neuroimaging studies of her brain revealed a hemorrhagic lesion in the right head of the caudate and putamen (See Figure 1.). Her language was categorized as global aphasia in the first week after onset. Seven weeks post-onset, her aphasia syndrome evolved into agrammatic Broca’s aphasia. At this stage, symptoms of speech apraxia and limb apraxia have persisted. Her LVF neglect also persisted. TS, a 76-year-old female suffered a stroke that had resulted in global aphasia and left-sided weakness. Brain imaging revealed large lesions in the areas of right temporal, parietal and frontal areas (See Figure 2.). Severe impairment of all language sub-processes persisted at 19 months post-onset. A systematic review of crossed aphasia in 38 published articles revealed the occurrence of all syndromes of aphasia that are usually reported in left hemisphere damage (See Table 1.).

Conclusions: The findings of the present study appear to offer support for the gradient view of LL.
INTERNETABLE MACHINE LEARNING FOR EARLY NEUROLOGICAL DETERIORATION PREDICTION IN ATRIAL FIBRILLATION-RELATED STROKE

Background and Aims:: We aimed to develop a novel prediction model for early neurological deterioration(END) based on an interpretable machine learning(ML) algorithm for atrial fibrillation(AF)-related stroke and to evaluate the prediction accuracy and feature importance of ML models.

Methods:: Data from multi-center prospective stroke registries in South Korea were collected. After stepwise data preprocessing, We utilized logistic regression, random forest, extreme gradient boosting, support vector machine, light gradient boosting machine (LightGBM), and Multilayer perceptron models. We then used the Shapley additive explanations (SHAP) method to evaluate feature importance.

Matrix plots of top 24 important features. Bar plot (A) and violin plot (B).
Of the 3,623 stroke patients, the 2,363 who had arrived at the hospital within 24 hours of symptom onset and had available information regarding END were included. Of these, 318 (13.5%) had END. The LightGBM model showed the highest area under the curve (0.778, 95% CI, 0.726 - 0.830). The feature importance analysis revealed that the National Institute of Health Stroke Scale score and fasting glucose were the most influential factors.

Conclusions: The LightGBM model was particularly useful for predicting END. The SHAP method can be adjusted to individualize the features’ effects on the predictive power of the model.
INVOLVEMENT OF POLYMORPHISMS OF COMPLEMENT LECTIN PATHWAY SERINE PROTEASES ENCODING GENES IN ETIOPATHOGENESIS OF ISCHEMIC STROKE

Gohar Tsakanova¹,², Elina Arakelova², Violetta Ayvazyan², Arsen Arakelyan²
¹CANDLE Synchrotron Research Institute, Laboratory Of Experimental Biology, Yerevan, Armenia, ²Institute of Molecular Biology NAS RA, Laboratory Of Human Genomics And Immunomics, Yerevan, Armenia

Background and Aims:: Complement is a major part of innate immune system. The complement system is a proteolytic cascade, where serine proteases activate each other by limited proteolysis in a strictly ordered manner. Serine proteases are essential in both the initiation and the amplification of the cascade. The aim of current study was to reveal the possible involvement of complement lectin pathway mannan-binding lectin-associated serine proteases, MASP-1 and MASP-2 in etiopathogenesis of ischemic stroke (IS) by investigating the potential association of single nucleotide polymorphisms (SNPs) in their genes (rs3203210, rs28945070, rs28945073 in MASP1 gene and rs2273343, rs12711521, rs147270785 in MASP2 gene) with IS.

Methods:: 250 IS patients and 300 healthy subjects were genotyped using the method of SSP-PCR. All primers were designed using the genomic reference sequences of studied genes. The presence/absence of allele-specific amplicons in the genotyping products was visualized by ethidium bromide stained 2% agarose gel. The significance of differences in genotype and allele frequencies and minor allele carriage between patients and HS was determined using Pearson's Chi-square test. The odds ratio (OR), 95% confidence interval and Pearson's p-value were calculated to evaluate the effects of any difference.

Results::

![Diagram of MASP1 and MASP2 genes with SNPs](image-url)
The genotype distribution was in correspondence with Hardy-Weinberg equilibrium in both groups. The results of genotyping demonstrated association of two SNPs (rs3203210 in MASP1 gene and rs147270785 in MASP2 gene) with IS.

**Conclusions:** MASP1 rs3203210 and MASP2 rs147270785 SNPs are strongly associated with IS, and their rs3203210*C and rs147270785*A minor alleles may be considered as protective factors for IS at least in the Armenian population.

NEUROAID USE IN INTRACRANIAL HEMORRHAGE (ICH)

Ramesh Kumar¹, Farizal Fadzil², Soon Bee², Palani Kamalanathan², Ainul Jaffar², Sanmugarajah Paramasvaran², Toh Jeng², Jegan Thanabalan², Azizi Bakar², Peh Shawn²  
¹University Kebangsaan Malaysia Medical Centre, Division Of Neurosurgery, Department Of Surgery, Kuala Lumpur, Malaysia, ²University Kebangsaan Malaysia, Division Of Neurosurgery, Department Of Surgery, Kuala Lumpur, Malaysia

Background and Aims: MLC601/MLC901 (NeuroAiD™), a combination of natural products, has been shown to be safe and to aid neurological recovery after brain injuries, particularly ischemic stroke. Few studies explored NeuroAiD use in primary intracerebral hemorrhage (ICH). The NeuroAiD Safe Treatment Registry (NeST) studies NeuroAiD use in the real-world setting. This cohort study aimed to assess its use and safety in ICH.

Methods: The online NeST registry of subjects with ICH given NeuroAiD respectively collected clinical data at baseline and monthly visits (V) 1 to 3. Outcome measures included compliance, side effects, Glasgow Coma Scale (GCS), modified Rankin Scale (mRS), National Institutes of Health Stroke Scale (NIHSS), and Short Orientation-Memory-Concentration Test (SOMCT).

Results: Sixty-six subjects were included. NeuroAiD was well-tolerated with fair compliance over 3 months. Two non-serious side effects were reported. Mean scores significantly improved in all outcome scales. The proportion of subjects with favorable outcomes improved from baseline to V3: GCS 13-15, from 64% to 88% (p=0.007); mRS 0-1, from 9% to 37% (p=0.004); NIHSS 0-4, from 12% to 59% (p<0.0001); and SOMCT score 0-8, from 44% to 68% (p=0.029).

Conclusions: NeuroAiD in the real-world setting was safe and showed potential for a sustained positive result on neurological recovery after ICH.
ASSOCIATION BETWEEN AIR POLLUTION AND POST STROKE DEPRESSION & COGNITIVE DECLINE.

Sakshi Sharma¹, Mv Padma Srivastava², Neha Kuthiala¹
¹ALL INDIA INSTITUTE OF MEDICAL SCIENCE, Neurology, NEW DELHI, India, ²AIIMS, New Delhi, Neurology, Delhi, India

Background and Aims:: Stroke affects the cognitive domain, which includes attention, memory, language, and orientation. Air pollution is one of a variety of man-made environmental disasters that are currently taking place all over the world. To examine the associations of gaseous air pollutants and climate change (humidity& temperature) and depression including cognitive decline.

Methods:: All strokes: acute (within two weeks from onset) & chronic (within one year of event) presenting to the Neurology and Emergency services of AIIMS, were screened & recruited. Gaseous air pollutants and PM 2.5 & PM10 in diameter were measured in me Delhi designated areas using the help of Delhi Pollution Control Board at onset of stroke, 15 days of enrollment & 3 months. Stroke demographics and PHQ-9, GAD-7, SF-36 were correlated with the air pollution and climate change.

Results:: 90 patients were recruited. We found that depression and anxiety levels were high among the stroke patients. PM2.5 & PM10 levels were statistically related to stroke onset, depression & anxiety. The mean PM10 level was high as compared to PM-2.5 at all-time points indicating that higher particulate or coarse particles are better measured than the fine particles and its associated with cognitive decline & anxiety. We observed that the high level of particles effect on cognition and cause of depression. Multivariate regression analysis keeping age, type of stroke as constant with covariables like type of fuel, CO, PM2.5 showed R²= 0.119, F=3.92, p=0.057.

Conclusions:: We found that cognitive decline and depression is common in stroke patients but its also associated with high level of air pollution & climate changes. We need more results for final conclusion.
CORTICAL REORGANIZATION IN STROKE PATIENTS USING UPPER-LIMB ROBOTIC REHABILITATION THERAPY

Megha Saini¹, Neha Singh¹, Nand Kumar², S Kumaran³, Amit Mehndiratta¹, Mv Padma Srivastava⁴
¹Indian Institute of Technology, Centre For Biomedical Engineering, New Delhi, India, ²ALL INDIA INSTITUTE OF MEDICAL SCIENCES, Department Of Psychiatry, New Delhi, India, ³ALL INDIA INSTITUTE OF MEDICAL SCIENCES, Department Of Nmr, New Delhi, India, ⁴All India Institute of Medical Sciences New Delhi, Neurology, New Delhi, India

Background and Aims:: Coexistence of myriad of sensorimotor-impairments in stroke limit patient's functional-capacity. In current-scenario robotic-therapy involving objective strategies enhance motor-restoration. We aimed to analyze cortical-remapping after robotic-therapy in association with clinical-parameters.

Methods:: Low-cost, 3D-printed hand-exoskeleton has been designed in-house at IIT and AIIMS, New-Delhi, India. Six right-handed, left-hemiparetic patients with 3-24 months chronicity were recruited; with three patients(mean-age=37.33±5.03 yrs) in control-group and three patients(mean-age=38.33±16.44 yrs) in robotic-therapy group. All patients underwent 20-sessions of 45-minutes therapy each. Clinical-assessment(MAS, Fugl-Meyer Scale, Barthel-Index, mRS), cortical-excitability measure (RMT), neuroimaging (fMRI) were performed pre and post-intervention. Block-design paradigm of 40-seconds alternate baseline and activation-task were used. Patients performed self-paced wrist-extension repeatedly in full Range-of-Motion with affected-hand. fMRI-data were acquired as 31 slices, TR=2000ms, TE=30ms, FOV=230x230x155mm, Flip angle:90°, voxel-size:1.8x1.8x5 mm.

Results:: All six patients showed clinical-improvement using clinical-scales. Robotic-therapy was effective in reducing spasticity at wrist (1.66±0.28 to 1.33±0.57) compared to control-group (2±0 to 2±0), increase independence in ADL as demonstrated by Barthel-Index(75±13.2 to 93.33±5.77) compared to control-group(66.66±17.55 to 80±13.22). Sensorimotor-control improvement was established in both groups (37.33±6.6 to 46.66±6.5) in robotic-therapy compared to control-group (29.33±7.63 to 42±5.85). Resting Motor Threshold a measure of cortical-excitability demonstrated better improvement with robotic-therapy (87.66±2.51 to 71.33±8.08) versus control-group (87.33±12.50 to 84±16). Ipsilesional-activation pattern(BA4=12,BA1=33) and contralesional-activation(BA4=139,BA6=27,BA1=59 and BA5=13) was observed in robotic-therapy group(Fig1). Activation of contralesional-cerebellum(voxels=272) and ipsilesional-cerebellum(voxels=34) was observed in control-group(Fig1).

Conclusions:: Activation in ipsilesional-cortex indicates improved recovery reorganizational-pattern in stroke as compared to activation of contralesional-cortex or cerebellar-regions. Robotic-therapy is effective post-stroke rehabilitation-paradigm that can enhance recovery by means of use-dependent
plasticity.

**Fig 1:** BOLD activation pattern showing activation volume in functional MRI for affected hand movement at 10 voxel thresholds and FEW corrected at $p=0.05$

MICRO-EMBOLIC SIGNAL (MES) MONITORING IN STROKE SUBTYPES: A SYSTEMATIC REVIEW AND META-ANALYSIS OF 58 STUDIES

Pachipala Sudheer, Shubham Misra, Manabesh Nath, Pradeep Kumar, Deepti Vibha, Mv Padma Srivastava, Manjari Tripathi, Rohit Bhatia, Awadh Pandit, Rajesh Singh
All India Institute of Medical Sciences, Neurology, Delhi, India

Background and Aims:: Micro embolic signals(MES) detected using transcranial doppler(TCD) help in risk stratification in stroke patients. A systematic review and meta-analysis was performed to estimate the prevalence of MES and its association with stroke recurrence, functional outcome and mortality in different stroke subtypes.

Methods:: A comprehensive literature search was conducted before 26th January 2021 in PubMed, Embase, Google scholar, Cochrane library and ClinicalTrials.gov. Studies were identified that used TCD to detect MES in stroke/TIA patients. Pooled prevalence and Odds Ratio (OR) along with 95% Confidence Interval (95%CI) were calculated for different outcome measures. Entire statistical analysis was conducted in R version 3.6.2.

Results:: 58 studies involving 5123 patients (1329 MES +, 3794 MES -) were included in our meta-analysis. The pooled prevalence of MES among all acute stroke/TIA patients was 30% (95%CI 25% to 34%). Prevalence of MES was high among all stroke subtypes except in patients with small vessel disease (SVD). In patients with new onset stroke/TIA, presence of MES was associated with high risk of recurrence of cerebral ischemia (OR 3.71; 95%CI 2.64 to 5.23). Although there was no significant association of presence of MES with increased mortality (OR 1.84; 95%CI 0.91 to 3.70) and poor functional outcome (OR 2.11; 95%CI 0.69 to 6.49) among patients with new onset stroke/TIA, this could only be determined in a smaller sample size of 477 patients.

Conclusions:: Presence of MES increased the chance of recurrence of cerebral ischemia but was not associated with poor functional outcome and mortality in the studied subgroup.
SAFETY AND EFFICACY OF N ACETYLCYSTEINE AS AN ADJUNCT TO STANDARD TREATMENT IN PATIENTS WITH ACUTE ISCHEMIC STROKE - A RANDOMIZED CONTROLLED TRIAL (NACTLYS)

Snigdha Komakula¹, Rohit Bhatia¹, Mv Padma Srivastava¹, Manjari Tripathi¹, Deepti Vibha¹, Mamta Singh¹, Ajay Garg², Leve Joseph², Rajesh Singh¹, Roopa Rajan¹, Anu Gupta¹, Awadh Pandit¹, Vishnu V Y¹

¹AIIMS, Neurology, NEW DELHI, India, ²AIIMS, Neuroradiology And Neurointervention, NEW DELHI, India

Background and Aims:: There is a clinical need for thrombolytic agents that can disaggregate arterial thrombi without significantly increasing the risk of bleeding. We aimed to study if adjunctive therapy of N-acetylcysteine (NAC) along with recombinant tissue plasminogen activator (rtPA) was safe and effective in patients with acute ischemic stroke.

Methods:: IV NAC with IV rtPA or IV rtPA alone was given in a 1:1 ratio in this open label randomized blinded assessor pilot study. Primary or safety outcomes were any intracerebral hemorrhage (ICH) or symptomatic cerebral hemorrhage (SICH), any systemic bleeding and any adverse reactions. Secondary or efficacy outcomes were major neurological improvement at 24 hours, recanalization on first run of angiography or on vascular imaging at 24 hours, mRS and mortality at 3 months of followup.

Results:: Out of 38 patients enrolled, 20 were in control arm and 18 in the intervention arm. Among primary outcomes, no significant difference was noted in the adverse reactions (p=0.99), ICH (p=0.21), SICH (p=0.47) and extracranial bleeding (p=0.21). Among the secondary outcomes, 7 patients (38.8%) in the intervention arm and 3 patients (15%) in the control arm had major neurological improvement at 24 hours (p=0.19). Proportion of patients with good outcome at 3 months (mRS 0-2) (p=0.84) and mortality at 3 months was similar in both the groups (p=0.65).

Conclusions:: NAC as an adjunct to rtPA did not show any significant difference in morbidity and mortality at three months. However, there was a favourable trend towards higher recanalization and early neurological improvement with co-administration of NAC and rtPA. Future larger trials are needed to further conclude on safety and efficacy of N-acetylcysteine as a thrombolytic agent.
**Background and Aims::** Basilar artery occlusion accounts for 11-39% of posterior circulation strokes, being prevalent in elderly population, with a wide-ranging clinical presentation. Consequently, its diagnosis may be particularly challenging and subtle symptoms might lead to misdiagnosis.

**Methods::** A 22 years-old woman referred for episodes of hyperventilation and stiffness at four limbs. She reported the same morning transient right ear tinnitus, paresthesia in right half face and hand. Her family mentioned a story of anxiety disorder with self-harm treated with sertraline, while cardiovascular risk factors, estroprogestinic or drug assumption were excluded. At neurological examination patient appeared mutacic, with dystonic posturing at four limbs, without signs of other functional systems involvement.

**Results::** Urgent brain CT scan was normal. She underwent psychiatric evaluation which ended up for acute anxiety crisis. In the following 48 hours patient reported decline in consciousness, with fever and desaturation. Another CT scan revealed no abnormalities, while electroencephalogramp profile excluded metabolic or irritative etiology. Cerebrospinal spinal fluid examination was unremarkable. Urgent MRI revealed a large subacute infarct involving the width of pons and part of mesencephalus and medulla oblungata, due to basilar artery occlusion extended for 18 mm, further confirmed by angioCT. Vascular studies showed no dissemination or fibromuscular dysplasia, hypercoagulation and cardiac investigation disclosed no significant contributing factor.

**Conclusions::** Although uncommon, this case represents a possible pitfall in clinical practice: neurologists should be aware that subtle clinical presentations, especially in young and low-risk patients, might hide severe conditions as basilar artery occlusion which require a prompt diagnosis in order to prevent following neurological disability.
CLINICAL UTILITY OF INTRAVASCULAR ULTRASOUND (IVUS) IN CAROTID ARTERY INTERVENTIONS - A SYSTEMATIC REVIEW AND META-ANALYSIS.

Biswamohan Mishra¹, Awadh Pandit², Shubham Misra³
¹AIIMS, New Delhi, Neurology, Delhi, India, ²All India Institute of Medical Sciences, Neurology, Delhi, India, ³AIIMS, New Delhi, Neurology, New Delhi, India

Background and Aims:: IVUS and its extension VH (Virtual Histology) IVUS evaluate plaque characteristics in real time and guide decision making during stenting. To date there is no consensus about indications of IVUS and its validated methods. This systematic review and meta-analysis aims to evaluate the clinical utility of IVUS in carotid artery stenting and develop a future consensus for research and practice parameters.

Methods:: A systematic review and meta-analysis was performed of articles published till February 2021. Studies reporting on IVUS parameters and findings and also its performance compared to other imaging modalities were included in study. Pooled prevalence with 95% Confidence Intervals (95%CI) were calculated. The statistical analysis was conducted in R version 3.6.2.

Results:: A total of 1825 patients from 30 studies were included. Meta-analysis performed on 1566 patients from 11 studies. In nine studies, stroke/TIA had a pooled prevalence of 4% (95%CI 3-5%) (Figure 1) while asymptomatic stroke had a pooled prevalence of 46% (95%CI 31-62%) in four studies (Figure 2). Two studies reported that IVUS detected more Plaque protrusion (PP) compared to angiography (n= 33/396 vs. 11/396), with PP group having higher stroke risk. IVUS led to stent type or size change in 8 of 48 cases in three other studies. Concordance between VH IVUS and true histology
was at 80-85% reported in 2 studies.
Conclusions: This study showed though IVUS fared better to CTA/MRA/angiography for better stent selection during CAS, however large scale, preferably randomized controlled studies are needed to predict its role in determining clinical outcome.
POSTERIOR CIRCULATION WAKE-UP STROKE AND CT PERFUSION: EFFECTIVENESS AND SAFETY OF REPERFUSION THERAPY

Radiology Unit, Department Of Medicine, Surgery And Health Sciences, University Hospital And Health Services Of Trieste – Asugi, University Of Trieste, Strada Di Fiume, 447, 34149 Trieste, Italy, Trieste, Italy, ⁶Radiology Unit, Radiology Unit, Department Of Medicine, Surgery And Health Sciences, University Hospital And Health Services Of Trieste – Asugi, University Of Trieste, Trieste, Italy, ⁷University of Trieste, Neurology Unit, Headache Centre, Department Of Medical, Surgical And Health Sciences, Cattinara University Hospital, Asugi, Trieste, Italy

Background and Aims:: Patients waking up with acute ischemic stroke (AIS) represent an underprivileged subgroup of stroke patients. Because in wake-up stroke (WUS) time of symptom onset is unknown, best management is challenging. Patients with WUS involving posterior circulation stroke represent an even more delicate subgroup. Use of multimodal computed tomography (mCT), combination of non-contrast CT, CT angiography and CT perfusion (CTP) is generally used in anterior ischemic strokes to identify candidates for reperfusion therapies; its use in posterior AIS has not been widely accepted. We aimed to describe effectiveness and safety of CTP in evaluation of posterior-WUS patients eligible for reperfusion treatment.

Methods:: We included patients with posterior-WUS who underwent thrombolysis treatment at Trieste Stroke Unit between March 2016 and October 2019. All patients underwent mCT and neurological evaluation. Out of 80 patients with WUS, there were 21 posterior-WUS.

Results:: In all those patients CTP showed abnormalities. All 21 patients underwent thrombolysis, 3 also underwent thrombectomy. Large vessel occlusion was reported in 14 cases (3 basilar artery, 7 vertebral artery, 4 posterior cerebral artery occlusion). Outcome given by NIHSS score at 7 days and mRS score at discharge (1 and 3 months) was favorable in all cases (NIHSS at 7 days: 1(0-42); mRS at 1 months ≤2: 16/21; mRS at 3 months <2: 11/21). Reperfusion therapy was safe in all cases (sICH: 0/21).

Conclusions:: CTP-guided reperfusion therapy was associated with improving outcome and safety profile.
Background and Aims:: Early neurological deterioration (END) in acute ischemic stroke occurs frequently. This phenomenon has a heterogeneous pathomechanism. Immature platelet fraction (IPF) is known as the useful marker of increased platelet production and turnover which could occur in patients with increased platelet activation. We investigated whether the IPF is associated with the prevalence of END in acute ischemic stroke patients.

Methods:: A total 1655 of acute ischemic stroke patients in single tertiary academic center was enrolled from January 2013 to October 2018 via stroke registry. IPF levels were quantified by whole blood flow cytometry with automated assays (Sysmex XE-2100™). High IPF was defined as the IPF level was more than 5%. Early neurological deterioration was defined as an increment change of at least one point in motor power or total National Institute of Health Stroke Scale (NIHSS) score deterioration ≥2 points within the first week after admission.

Results:: A total of 72 patients (4.4%) experienced END. END was more prevalent in the patients with high IPF [13 (11.7%) vs 59 (3.8%), p<0.0001]. Multivariate logistic regression analysis showed high IPF was an independent predictor of the prevalence of END (adjust odds ratio = 1.32; 95% confidence interval = 1.03–1.70).

Conclusions:: A high IPF levels was associated with the prevalence of END in acute ischemic stroke patients.
ESTIMATION OF THE BURDEN OF ATHEROSCLEROSIS IN STROKE DUE TO CRANIOCERVICAL DISSECTION- A CLINICORADIOLOGICAL STUDY

Deependra Singh¹, Vivek Lal², Sucharita Ray², Kamalesh Chakravarty², Chirag Ahuja³
¹POST GRADUATE INSTITUTE, CHANDIGARH, Neurology, CHANDIGARH, India, ²PGIMER,Chandigarh, Neurology, Chandigarh, India, ³Postgraduate Institute of Medical Education and Research (PGIMER), Neuroradiology, Chandigarh, India

Background and Aims:: The etiology of craniovertebral dissection is not fully understood. Atherosclerosis being a pro-inflammatory state might be a predisposing factor. Indians, as well as South Asians, are unique in that, they have a high burden of atherosclerosis. This study was planned to find a consortium between dissection and atherosclerosis by radiological imaging and estimation of vasomotor reactivity by TCD

Methods:: This study was carried out at a tertiary care institute in North India and included dissection (31), stroke (31) and 29 controls. All subjected for a TCD study, vessel wall and neuroimaging for parenchymal evidence of atherosclerosis and infarct pattern

Results::

Prevalence of atherosclerosis and stenosis (>50% ) was higher in Group(B) compared to (Group A) (p=0.05) and (p=0.007) respectively. In (Group A), patients with long-segment atherosclerosis, and higher thickness of plaque are significantly more likely to have infarcts > 5mm in size and long segment arterial dissection (p=0.005)
Conclusions:: Our results suggest that atherosclerosis to play at least some role in the causation of CAD as well as in its consequences such as size of infarcts.
EARLY CHILDHOOD GROWTH AND RISK OF ADULT CEREBROVASCULAR DISEASE DASH THE NORTHERN FINLAND BIRTH COHORT STUDY 1966

Milja Kivelä1,2, Markus Paananen1,2, Eero Kajantie3,4, Marja Ojaniemi2,3, Rozenn Nedelec1, Harri Rusanen5,6, Jouko Miettunen1,2, Ina Rissanen2,5

1University of Oulu, Center For Life Course Health Research, Helsinki, Finland, 2Oulu University Hospital and Oulu University, Medical Research Center Oulu, Oulu, Finland, 3Oulu University Hospital and Oulu University, Pedego Research Unit, Mrc Oulu, Oulu, Finland, 4Finnish Institute for Health and Welfare, Public Health Promotion Unit, Oulu, Finland, 5Oulu University Hospital and Oulu University, Research Unit Of Clinical Neuroscience, Oulu, Finland, 6Oulu University Hospital, Department Of Neurology, Oulu, Finland

Background and Aims:: Low birth weight is associated with increased risk of adulthood cerebrovascular disease. Not much is known about effects of early childhood growth. We studied whether the risk of cerebrovascular disease in adulthood is associated with growth or nutritional factors during early childhood.

Methods:: Within the Northern Finland Birth Cohort 1966, 11,991 persons were followed from birth to 52 years of age. Cerebrovascular disease diagnoses came from national hospital and death registers with diagnostic coding based on the World Health Organization classification. Cox proportional hazard models were used to estimate associations of childhood growth variables, growth trajectories (by Latent Class Growth Modelling) and nutritional factors with adult cerebrovascular disease. The analyzes were adjusted for socioeconomic status and birth weight.

Results:: 453 (3.8%) cerebrovascular diseases were recorded. Among women, the trajectory groups of consistently low weight and length had an increased risk for ischemic strokes, with an adjusted hazard ratio (aHR) of 1.97 (95% confidence interval (CI) 1.21-3.20) and 2.05 (95% CI 1.11-3.81), respectively. In addition, women with BMI over 1 SD at BMI rebound had an increased risk for ischemic stroke (aHR 1.90; 95% CI 1.19-3.04) compared to women with BMI -1 to +1 SD. These associations were not found among men.

Conclusions:: Women who are short and light in early childhood or who have high BMI at BMI rebound have as adults increased rates of ischemic strokes. These findings suggest that timing of weight gain during childhood is of significance for development of cerebrovascular disease risk.
SERUM S100B PROTEIN AND GLASGOW COMA SCALE AS PREDICTIVE MARKERS OF THE SURVIVAL RATE IN ACUTE ISCHEMIC STROKE

Ekaterina Koroleva, Valentina Alifirova, Stanislav Kazakov, Denis Plotnikov, Maria Nikitina
Siberian State Medical University, Neurology And Neurosurgery, Tomsk, Russian Federation

Background and Aims:: Serum S100β is increasing after acute ischemic stroke (AIS), and peaking within 72 hours and correlating with the volume of damage and clinical symptoms. Our postulate is that evaluation of serum S100β after 48-72 hours from onset of AIS and assessment of the patient's level of consciousness on the Glasgow Coma Scale (GCS) is suitable to predict of survival rate and/or life-threatening outcome of early rehabilitation in the first 14 days of AIS.

Methods:: Serum S100β was determined by using DY1820-05 Human S100β DuoSet ELISA-kit (USA) of 105 patients after 48-72 hours from onset of AIS in the middle cerebral artery (middle age=63(57;67) years, NIHSS=16(8;23) points, GCS=13(11;15) points). The predictive model was constructed by logistic regression method. The critical values for categorical variables were identified by ROC-analyses.

Results:: The cut-off points: S100-β=13.3 (sensitivity 95.5%; specificity 72.0%; sum 167.5%); GCS=14 (sensitivity 87.4%; specificity 84.0%; sum 171.4%). The characteristics of logistics regression model: Chi-square=64.7; p<0.001, Nigel-Kirk's coefficient=0.72; 94.9% sensitivity and 72% specificity; percentage of correct decisions 89.3%. Serum S100-β ≥13.3 pg/ml decrease the chances of survival by a factor of 58.1 and prognostically favorable (95% CI[10.0-339.6], p<0.001). The GCS≥14 points increases the chances of survival by a factor of 24.5 and prognostically favorable (95% CI[4.6-130.3], p<0.001).

Conclusions:: Quantitative features of S100β and GCS after 48-72 hours from onset of AIS are allowed stratifying patients into a group with a high risk of lethal outcomes. This predictive model is convenient to use for rapid assessment of survival and solving issues of doses of mobilization on safety outcomes of early rehabilitation.
COMPARISON OF THE NEW CANADIAN SCORE TO ABCD2 FOR TIA RISK STRATIFICATION IN A COMMON CLINICAL SETTING

Lucia Gentili, Silvia Cenciarelli, Tatiana Mazzoli, Antonella Picchioni, Angela Verzina, Antongiulio Gallina, David Giannandrea, Paolo Eusebi, Stefano Ricci
USL Umbria 1, Uo Neurologia, Città di Castello, Italy

Background and Aims: INTRODUCTION Patients who have a TIA are at high risk of subsequent stroke, especially in the short term. The degree of risk is usually determined using clinical scores, most commonly ABCD2. Recently, a new score (Canadian TIA Score) has been proposed, which may be better in terms of prediction, and which includes more variables, both clinical and instrumental (i.e. presence of AF, carotid stenosis, any infarction on CT). We aimed at evaluating whether the two scores were reproducible, using data from our admission registry.

Methods: MATERIAL AND METHODS We retrospectively analysed prospectively collected data from our Stroke Unit registry in 2018 and 2019. We recalculated ABCD2 and de novo calculated CTS for each patient. Then we compared the two scores both with Spearman rank correlation and with Cohen Kappa, using commonly defined cutoff points (4 for both scores, which would have been used to decide whether to admit the patients or not).

Results: RESULTS There were 51 patients. Median ABCD2 was 4 and median CTS was 9. Spearman rank correlation was 0.64 (p<0.001), whereas Kappa statistics gave a value of 0.35 (fair agreement).

Conclusions: CONCLUSION The two scores are only moderately reproducible. However, since the decision to admit the patient is usually based both on scores and on other information (which are included in the Canadian score, but not in ABCD2), it would be useful in the future to compare the common clinical practice (including ABCD2 score use) to the Canadian score, which, however, seems less practical to use in an emergency settings.
CEREBRAL VENOUS THROMBOSIS IN SUB-SAHARAN AFRICA: A SYSTEMATIC REVIEW

Yanina Munira Baduro¹, José Ferro²
¹Maputo Central Hospital, Neurology, Maputo, Mozambique, ²Hospital Santa Maria-CHULN, Neurociência E Saúde Mental, Lisboa, Portugal

Background and Aims: The global clinical epidemiology of cerebral venous thrombosis (CVT) is well described in high-income countries and in some middle-income countries, where hospital-based case series, suggest that the frequency of CVT is probably higher than in high-income countries.

Methods: We followed Meta-Analysis of Observational Studies and observational studies reporting original data on any of demographics, etiology, clinical and neuroimaging features, associated conditions, treatment, functional outcome and mortality in Sub-Saharan Africa.

Results: Notificação de 274 pacientes com TVC Em ambos os relatos de casos e séries de casos, a cefaleia foi o sintoma de apresentação mais comum (92,3% e 71,6% em relatos de casos e séries de casos, respectivamente), seguido por déficits neurológicos focais (38,5% e 23,8%).
Table 1. Summary of 274 patients with cerebral vein thrombosis from Sub-Saharan countries

| Age            | Minimum-maximum | Number | %    | Valid %
|----------------|-----------------|--------|------|--------
| Females        | 8 months-78 years | 153    | 55.8 | 58.6   |

Associated conditions

| Condition                    | Number | %    | Valid %
|------------------------------|--------|------|--------
| Infection                    | 173    | 63.1 |        |

UF = unfractionated LMWH = low molecular weight heparin VKA = vitamin K antagonist.
Conclusions: The low number of reported CVT cases from Sub-Saharan Africa suggests that CVT is either infrequent, not diagnosed or not reported. Infection is the most common risk factor. Most CVT cases were confirmed by CT alone. Almost all patients reported after year 2000 received anticoagulation. Death rate was higher than in high income countries.
Background and Aims:: Diffusion-weighted magnetic resonance imaging (DW-MRI) is considered to be a sensitive tool to detect an acute stroke. However, MRI may not be 100% sensitive in very early stages, especially in posterior circulation strokes.

Methods:: We present the case of a 67-year-old diabetic, hypertensive female who presented with unresponsiveness with right-sided reduced movements and facial deviation of 30 minutes duration. (BP 130/72, RBS 129, INR 1.2). Non-contrast computerized tomography (NCCT) of the brain was unremarkable. (ASPECTS 10), CT angiogram did not show any large vessel occlusion (Figure 1 a and b) and MRI brain (2.5 hours of symptoms) was negative (Figure 2 a).

Figure 1 a Non-Contrast CT showing no infarct. b CT angiogram showing no large vessel occlusion
Results:: Although initial DW-MRI was negative, the repeat MRI brain on day 5 revealed infarcts in the left midbrain and bilateral thalami. (Figure 2b). The patient was thrombolysed (Window Period: 45 minutes) with IV alteplase (door to CT time of 5 minutes and door to needle time of 20 minutes). 24 hours post thrombolysis, NIHSS improved to 6, and alertness improved when she also noticed double vision. Examination showed a left 3rd nerve palsy with pupillary involvement. Diplopia and weakness gradually improved over 2 days (NIHSS 2).

Conclusions:: Artery of Percheron stroke with unremarkable initial MRI-DWI, a repeat MRI after 24 hours of consistent neurological deficit is more demonstrative. Our case serves as a reminder that clinical assessment shall be the priority until a diagnostic modality showing 100% sensitivity and specificity are evident and our report also emphasizes that negative DW-MRI with clinical presentation of stroke should not preclude thrombolysis.
COMPARISON OF CODE STROKE RESPONSE TIMES BETWEEN THE EMERGENCY DEPARTMENT AND INPATIENT SETTING IN A MAJOR METROPOLITAN HOSPITAL

Catarina De Marchi Assuncao¹, Henry Taques Grein², Beth Chauncey Evers³, Kerri Remmel⁴
¹University of Louisville Hospital, Neurology, Louisville, United States of America, ²Universidade Federal do Parana, Medicine, Curitiba, Brazil, ³Jewish Hospital University of Louisville, Stroke Center, Louisville, United States of America, ⁴University of Louisville, Chair Of The Neurology Dept., Louisville, United States of America

Background and Aims:: In stroke care, speed is essential for good outcomes. Opportunities for speed improvements have been extensively documented in the medical literature. This retrospective study is aimed at providing data and insights for the development of a quality improvement project in the same hospital, with the ultimate goal of increasing code stroke speed response times without compromising quality of care.

Methods:: All code stroke cases with a CT scan were included. Data were collected between January and December 2020, from both emergency department and inpatient settings. Emergency room stroke code times were compared with those in the inpatient setting by using a two-tailed t-test and a 95% confidence interval.

Results:: Statistically significant p values were observed for a difference between ED and inpatient code-to-CT start times for both thrombolysed and non thrombolysed events. Code-to-CT read times for events that did not go into t-PA administration also had a p value smaller than 0.05.

Conclusions:: This study highlights the urgent need to improve code-to-CT times in this hospital’s inpatient setting, since ED code stroke times were markedly better from a statistical viewpoint. Improving quality of care will have to address the evident delay in transporting inpatients to the CT scan after a code stroke has been activated. This study calls for the enactment of a CT-first comprehensive new protocol, aimed at helping to mitigate inpatient delays and further enhance the quality of the care provided. The approach discussed may be valuable to the improvement of other services in the region.
Background and Aims:: A clinical audit was undertaken to measure time intervals including door-to-needle time (DNT) and factors affecting major steps of stroke thrombolysis and to develop a protocol to optimize acute stroke care at National Hospital Kandy (NHK).

Methods:: A standards-based clinical audit was conducted among acute ischaemic stroke (AIS) patients presenting to NHK. Data on emergency care, time intervals, pre-hospital data and awareness of stroke and available facilities were collected using an interviewer administered data collection sheet.

Results:: The median DNT in 28 patients thrombolyzed over a period of 7 months was 70 minutes. Being male was associated with a statistically significant likelihood of receiving thrombolysis. Out of the 5 pre-specified audit criteria, initial evaluation and interpreting the CT brain met the targets. Door-to-CT time, informing neurology team and DNT failed to meet the pre-specified targets. In 28 non-thrombolyzed AIS patients, late presentation and intra-hospital delays were the commonest causes for conservative management. Waiting for the official CT brain report to inform neurology was the commonest intra-hospital delay. Only 26.8% were aware of stroke thrombolysis, 80% of whom knew about a time limit. 66.6% knew it was available at NHK. 85.7% were aware of the island-wide free ambulance service, however only 58.3% knew the toll-free telephone number and only 12.5% AIS patients used the service.

Conclusions:: Several factors have contributed to unsatisfactory DNTs at NHK. A 'stroke code' and an 'acute stroke pathway' was introduced to optimize AIS care and re-analysis is currently being conducted to assess outcome.
RELATIONSHIP BETWEEN SLEEP DISTURBANCES AND QUALITY OF LIFE IN THE PATIENTS AFTER ISCHEMIC STROKE.

Charos Rustamova, Marhamat Yakubova
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: To evaluate the interaction between the subjective sleep quality and the quality of life in patients who had an ischemic stroke.

Methods:: We examined 80 patients (men - 44, (55%) women - 36, (45%), aged from 40 to 78 years, average age – 60.37 ± 0.95 years) in post-stroke patients with ischemic type at the Tashkent Medical Academy in neurology department. The Pittsburgh questionnaire was used for determining the quality of sleep index (PSQI). The quality of life (QOL) was assessed with “SF-36 Health Status Survey” taking into considerations two parameters - mental health and physical health.

Results:: On the Pittsburgh scale, various sleep disorders were observed in 70 patients (88%) 100% of cases from 1 to 5 times a week) in relation to the duration of sleep, daytime dysfunction, and subjective sleep quality. Poor sleep quality (higher PSQI components (19–29 points) were observed in patients with ischemic stroke, the average PSQI score was 0-5 points). According to “SF-36 Health Status Survey”, it was established that, in post-stroke patients who had suffered from ischemic stroke, demonstrated decreased parameters in physical sphere of the QOL, whereas mental health was within the control parameters. Concerning sleep quality, the greater sleep scores were the worse QOL would be.

Conclusions:: In addition to physical and mental impairment resulting from stroke itself, the presence of sleep disorders impact negatively QOL in ischemic stroke patients. Therefore, diagnosing and treating sleep disorders is of a great importance in ischemic stroke patients to optimize their functional outcome and improve their QOL.
IMPROVING ACUTE STROKE ASSESSMENT IN NON-ENHANCED CT: AUTOMATED TOOL FOR EARLY ISCHEMIC LESION VOLUME DETECTION

Giovanni Furlanis1, Mara Bernardi2, Alex Rodriguez2, Paola Caruso3, Marcello Naccarato1, Alessandro Laiò2, Daniele Amati2, Paolo Manganotti4

1University Hospital and Health Services of Trieste - ASUGI, Clinical Unit Of Neurology, Department Of Medicine, Surgery And Health Sciences, Trieste, Italy, 2SISSA - International School for Advanced Studies, Molecular And Statistical Biophysics Group, Trieste, Italy, 3University of Trieste, Clinical Unit Of Neurology, Department Of Medicine, Surgery And Health Sciences, University Hospital And Health Services Of Trieste – Asugi, Trieste, Italy, 4University of Trieste, Neurology Unit, Headache Centre, Department Of Medical, Surgical And Health Sciences, Cattinara University Hospital, Asugi, Trieste, Italy

Background and Aims:: The ASPECTs is a widely adopted marker to identify early stroke signs on non-enhanced CT (NECT), but it presents inter-individual variability and it can be hard to use for non-experts. We introduce an algorithm capable of estimating automatically the NECT volumetric extension of early acute ischemic changes in the 3D-space. We compared the power of this marker with ASPECTs evaluated by experienced practitioner in predicting the clinical outcome.

Methods:: We analyzed and processed neuroimaging data of 153 patients admitted with acute ischemic stroke. All patients underwent a NECT at admission and on follow-up. The developed algorithm identifies the early ischemic hypodense region appearing based on an automatic comparison of the gray level of the images of the two hemispheres.

Results:: The volume marker and the ASPECTs agree in 66% of the patients. In the two standard axial slices used to estimate the ASPECTs, the regions identified by the algorithm overlap significantly with those identified by experienced practitioners. However, in many patients the regions identified automatically extend significantly to other slices. In these cases, the volume marker provides supplementary and independent information. Indeed, the clinical outcome of patients with volume marker=0 can be distinguished with higher statistical confidence than the outcome of patients with ASPECTs=10.

Conclusions:: The volumetric extension and the location of acute ischemic region in the 3D-space, identified automatically by our algorithm, provide an information which is mainly consistent with the ASPECTs value decided by expert practitioners, but is often complementary and independent.
Background and Aims:: There is a lot of experimental and clinical evidence that atherosclerosis is a chronic inflammatory disease with an autoimmune component. Endothelial damage causes a cascade of inflammatory reactions involving monocytes, macrophages, T-lymphocytes, and vascular smooth muscle cells. The aim - to study the ability of vascular wall’s smooth muscle cells to change their phenotype and their involvement in immune responses in cerebrovascular atherosclerosis.

Methods:: The total of 50 individuals deceased of cerebral atherosclerosis, 50 - without ischemic stroke and 20 deceased from causes not associated with atherosclerosis (comparison group) were studied. The following markers were used: CD4, CD8, CD20, CD68, Actin Smooth Muscle Ab-1, Desmin, Vimentin.

Results:: Under ischemic strokes and severe atherosclerosis the cerebral vessels endothelium acquires structural changes in form of rupture, desquamation and exfoliation, formation of desquamated endothelial cells clusters. Speaking of endothelial damage, it should not be supposed that changes should occur at the macroscopic level only, endothelial damage at the cellular level shall be sufficient enough. Immunocompetent cells are of key importance in atherosclerosis development; adhesion on the luminal surface of arteries, presence of a large number of these cells under the endothelium and of more mature macrophages in the intima depth indicates the influx of these cells, which actively potentiate atherosclerosis formation, from the blood into the artery wall.

Conclusions:: Disorders of the endothelial lining with changes in endothelial cells morphology contribute to the atherosclerotic plaque development. Lymphocytes and macrophages form the molecular basis of many important processes, including the inflammatory response and the immune response.
THE ASSOCIATION BETWEEN HEMOGRAM PARAMETERS AND POST STROKE DEPRESSION

Emna Jarrar, Salma Naija, Asma Nasr, Nesrine Amara, Anis Hassine, Sana Ben Amor
Service De Neurologie CHU SAHLOUL, Neurology Departement, SOUSSE, Tunisia

Background and Aims:: Post-stroke depression (PSD) is the most common psychological consequence among stroke patients. Currently, patients with PSD has been reported with decreased quality of life, poor functional outcomes and increased mortality. Early recognition and diagnosis of PSD with accurate identification of novel risk factors is essential for clinicians to optimize patient care and management. Our aim was to assess the association between serum platelet to lymphocyte ratio (PLR) and serum neutrophil-to-lymphocyte ratio (NLR) at the admission day and the development of PSD at 3-month post-stroke.

Methods:: This cross-sectional study conducted in the Department of Neurology at the university hospital of Sahloul-Sousse-Tunisia. We included patients suffering from acute stroke between July 2018 and June 2019. Clinical characteristics, PLR and NLR at hospital admission were noted. PSD at 3 months were assessed with The Beck Depression Inventory (BDI).

Results:: A total of 250 stroke patients were included with mean age SD of 64±12.2 years 50.2 % men. Sixty percent of patients suffered from PSD. In the univariate analysis being male (p=0.004), admission National Institutes of Health Stroke Scale (NIHSS)(p<0.001) , presence of cognitive impairment assessed by Montreal Cognitive Assessment(p=0.021) , marital status (p=0.04), and poor functional outcome assessed by Modified Rankin Scale(p=0.001) were associated with PSD. Patients diagnosed with PSD had higher levels of PLR and NLR without significant association 112.93 vs 131.28 (p=0.148) and 2.48 vs 2.88 (p=0.132).

Conclusions:: Our findings suggest that Increased NLRs and PLRs at admission are found in patients suffering with PSD without significant correlation. It need to be validated by a larger trial.
STROKE-RELATED MORTALITY, DISABILITY AND ASSOCIATED FACTORS IN TWO REGIONAL HOSPITALS IN CAMEROON: A PROSPECTIVE COHORT STUDY

Angwafor Anye1, David Ojong1, Nkouonlack Cyrille2, Wepnyu Njamnshi3, Leonard Ngarka4, Alfred Njamnshi3

1Faculty of Health Sciences, University of Bamenda, Clinical Sciences, Bamenda, Cameroon, 2b. Faculty of Health Sciences, University of Buea, Clinical Sciences, Buea, Cameroon, 3c. Neurology Department, Central Hospital Yaoundé/Faculty of Medicine and Biomedical Sciences (FMBS), The University of Yaoundé I, Neurology, Yaoundé, Cameroon, *c. Neurology Department, Central Hospital Yaoundé/Faculty of Medicine and Biomedical Sciences (FMBS), The University of Yaoundé I, Neurology, Yaoundé, Cameroon

Background and Aims:: Stroke is the second leading cause of death worldwide, causing 5.7 million deaths annually. Stroke mortality is seven times higher in low-income than high-income countries. Given the scarcity of data on stroke-related mortality and disability in Cameroon, this study aimed to estimate stroke mortality and disability in 2 Cameroonian hospitals.

Methods:: This was a prospective cohort study from January to July 2020, enrolling neurologist-confirmed stroke patients. Demographic and clinical data of stroke patients were collected using the WHO STEP questionnaire for hospital stroke surveillance. Survival and disability were assessed on the 7th (early mortality) and 30th days (overall mortality) post-stroke. Disability was assessed using the Modified Rankin Scale (mRS) and the Barthel index (BI). Deaths were confirmed from death reports by physicians in patient files and by verbal autopsy for discharged patients. Logistic regression was used to determine factors associated with mortality and disability.

Results:: Stroke mortality at 7 and 30 days were respectively 14.3% and 26.2%. On multivariate analysis, 30-day mortality was associated with altered consciousness (OR=5.462, P=0.008), haemorrhagic stroke (OR=2.980, P=0.027), and aspiration pneumonia (OR=11.677, P=0.004). One month (30 days) after stroke event, there were 62 survivors of whom 38.9%, 17.7%, 16.2%, and 40.3% were completely independent, partially independent, partially dependent, and totally dependent respectively. On multivariate analysis, poor functional outcome (dependence) was associated with severe stroke, NIHSS ≥16 (OR=8.321, P=0.011).

Conclusions:: Mortality and disability of stroke are high in our study population. Haemorrhagic stroke, severe stroke and presence of complications (dysphagia) were associated with worse outcomes.
ACUTE DIZZINESS AND VERTIGO IN CORTICAL STROKE: BIAS OF SUBJECTIVE RECALL

Y Chan¹, Y Wong², N Khalid¹, A Flores-Martin³, L Frank¹, Nehzat Koohi⁴, Qadeer Arshad⁵, I Davanagnam², Patricia Castro⁶,⁷, Diego Kaski⁴
¹University College London, Clicial And Movement Neurosciences, London, United Kingdom, ²National hospital for Neurology and Neurosurgery, Imaging, London, United Kingdom, ³Imperial College London, Neurology, London, United Kingdom, ⁴University College London, Centre For Vestibular And Behavioural Neuroscience, Department Of Clinical And Movement Neurosciences, Institute Of Neurology, London, United Kingdom, ⁵University of Leicester, Neurosciences, Leicester, United Kingdom, ⁶Imperial College London, Brain Sciences, London, United Kingdom, ⁷University College London Hospitals, Adult Diagnostic Audiology, London, United Kingdom

Background and Aims:: Vertigo/dizziness may be early presenting symptoms of posterior circulation stroke. However, single case reports of isolated hemispheric strokes presenting with vertigo are present in the literature. We explored the prevalence of vertigo/dizziness in acute stroke and evaluated the cortical distribution of these lesions in relation to the known vestibular cortical network.

Methods:: We conducted structured interviews in 173 patients admitted to the hyperacute stroke unit in University College London Hospitals. The interview was used to evaluate whether the patient was suffering from dizziness and/or vertigo 1) before the onset of the stroke, 2) at the time of the stroke and 3) since the onset of the stroke.

Results:: In total 173 completed questionnaires were collected. A total of 71 patients had cortical infarcts with appropriate imaging registration for further analysis. Of these, 50 patients did not report any dizziness symptoms, 21 patients reported acute dizziness. Out of the total 71 patients with cortical infarcts, 31 patients had lesions in the vestibular cortical areas distributed within the insular and parietal opercular cortices, but only eight patients had acute dizziness.

Conclusions:: We found a low prevalence of vertigo in acute cortical strokes, with no single locus of lesion overlap. There is growing evidence supporting a lateralised vestibular cortex, with speculation that cortical strokes affecting the right hemisphere, are more likely to cause vestibular symptoms than left-hemispheric strokes. We observed a trend for this association, with the right hemisphere affected in 4 of 5 patients who reported spinning vertigo at the onset of the stroke.
WATERSHED INFARCTION ASSOCIATED WITH CEREBRAL VENOUS THROMBOSIS: BORDER ZONE CONGESTIVE CEREBRAL ISCHEMIA

Alexander Pabon Moreno, Gustavo Gaitan Quintero, Adolfo Castro Beltran, Juan Ovalle Rojas, Edgard Castillo Tamara
universidad del sinú, Bolivar, cartagena, Colombia

Background and Aims:: Cerebral venous thrombosis is a rare form of stroke (< 1%). It generally occurs in younger patients (< 50 years old) with high variability of clinical manifestations ranging from acute or chronic headache to coma. Its diagnosis is often delayed or overlooked, and imaging studies are essential for its identification being magnetic resonance with venography sensitive and specific technique to detect it. We report an unusual case.

Methods:: The methodology is a case report

Results:: 37-years-old male with headache and right focal neurological deficit of subacute evolution initially diagnosed as an acute ischemic stroke without clear etiology after routine evaluation. Due to the worsening of the headache originated 4 months ago with the initial event is retrospectively diagnosed with thrombosis of superior sagittal sinus when reviewing the old resonace (figure 1). It was also noted superficial and deep unilateral ischemic involvement in border zone on new resonance (figure 2). Low level of vitamin b12 was evidenced. The patient improved after starting cyanocobalamin, due to recanalization of the sagittal sinus it was not considered anticoagulation (figure 3). Figure 1.
Conclusions: There are few published data on the patterns of parenchymal damage in the context of venous stroke, and although there is no typical pattern or location, the lesion usually corresponds to the venous drainage territory. This is an unusual case because the pattern found was a unilateral border zone.
WHAT BECOMES OF PEOPLE WITH STROKE IN SUB-SAHARAN AFRICA 2-3 YEARS AFTER THEIR FIRST STROKE?

Leonard Ngarka¹, Jonas Ngah², Samuel Angwafor³,Michel Mengnjo⁵, Leonard Nfor⁶, Wepnyu Yembe Njammshi⁶, Eric Chokote⁵, Godwin Tatah⁵, Alfred Njammshi¹,³

¹c. Neurology Department, Central Hospital Yaoundé/Faculty of Medicine and Biomedical Sciences (FMBS), The University of Yaoundé I, Neurology, Yaounde, Cameroon, ²Akwaya District Hospital, General Medicine, Yaounde, Cameroon, ³d. Brain Research Africa Initiative (BRAIN), Yaoundé, Cameroon/Geneva, Switzerland, Administration, Bamenda, Cameroon, ⁴Faculty of Health Sciences, University of Bamenda, Clinical Sciences, Bamenda, Cameroon, ⁵Brain Research Africa Initiative, Neuroscience Research, Yaoundé, Cameroon, ⁶Brain Research Africa Initiative, Research, Yaounde, Cameroon

Background and Aims:: Stroke is one of the leading causes of acquired disabilities in adults, accounting for increased morbidity and physical dependence. Very little is known about the outcome of stroke in sub-Saharan Africa. We therefore sought to determine the morbidity and mortality of stroke patients.

Methods:: We carried out a multi-center, hospital-based, cross-sectional study enrolling consenting stroke survivors, 2 years after their first stroke episode. Socio demographic and clinical data were collected using pre-established and standard questionnaires; Barthel index, Mini mental scale Examination, Hamilton depression scale, Short form-36 health survey. Information on deceased subjects were either obtained from hospital files or reported by their caregivers.

Results:: We enrolled 102 participants with a mean age was 65.04 ± 13.99 years (range: 22-96 years) out of who 70 (68.63%) died within 2-3 years after a first stroke. Out of 32 survivors, 28 (87.5%) had complications ranging from depression (71.9 %), musculo-skeletal pain (53.1 %), dementia (46.9 %), paresis/paralysis (40.6 %), recurrent stroke (31.3 %), seizures (28.1 %) varus deformity (30.3 %) and joint contracture (24.2 %). Among the survivors, 7 (25 %) were severely dependent and 6 (18.8 %) were moderately dependent. The majority of post-stroke subjects (62.5 %) were unable to work 2-3 years after a first stroke as a result of post-stroke disability (42.9 %) and incomplete recovery (33.3 %).

Conclusions:: Stroke is associated with significant disability, morbidity and mortality in Cameroon. Early diagnosis and a multi-disciplinary approach in the management could curb this trend.
CHARACTERISTICS OF STROKE IN TWO REGIONAL HOSPITALS IN CAMEROON

Samuel Angwafor¹, Nono Steve¹, Nkouonlack Cyrille², Wepnyu Yembe Njamnshi³, Leonard Ngarka⁴, Alfred Njamnshi⁴,⁵
¹Faculty of Health Sciences, University of Bamenda, Clinical Sciences, Bamenda, Cameroon, ²b. Faculty of Health Sciences, University of Buea, Clinical Sciences, Buea, Cameroon, ³Brain Research Africa Initiative, Neuroscience Research, Yaoundé, Cameroon, ⁴c. Neurology Department, Central Hospital Yaoundé/Faculty of Medicine and Biomedical Sciences (FMBS), The University of Yaoundé I, Neurology, Yaoundé, Cameroon, ⁵d. Brain Research Africa Initiative (BRAIN), Yaoundé, Cameroon/Geneva, Switzerland, Administration, Bamenda, Cameroon

Background and Aims:: The burden of stroke and its risk factors is increasing in low- and middle-income countries. Data have on the characteristics and risk factors of stroke in Africa are limited to tertiary hospitals. The aim of this study was to describe the characteristics of stroke in two Regional hospitals in Cameroon.

Methods:: This was a cross-sectional descriptive study among stroke survivors in the Bamenda and Buea Regional Hospitals over 5 months. Socio-demographic, clinical, and paraclinical data were recorded using a modified version of the WHO STEPwise questionnaire for stroke surveillance in hospitals.

Results:: A total of 84 participants were enrolled with a male/female sex ratio of 0.8. The mean age of participants was 64.8 ± 16 years. Ischaemic and haemorrhagic stroke represented 58.3% and 16.7% respectively. About one-quarter of all strokes were unclassified (absence of Brain CT). The main risk factors for stroke were hypertension (84.5%), diabetes mellitus (31%) and dyslipidaemia (31%). The median time from symptoms onset to consultation was 72 hours. The main clinical features on admission were hemiplegia (89.3%) and aphasia (56.0%). The most frequent complications were pressure sores (23.8%), and aspiration pneumonia (17.9%).

Conclusions:: Ischaemic strokes were the most common stroke types; hypertension was the most common risk factor while pressure sores and aspiration pneumonia were frequent complications of stroke in our sample. Urgent public health measures are needed in this population.
ONE AND A HALF SYNDROME AND BILATERAL CEREBELLAR ATAXIA AS A UNCOMMON BRAINSTEM STROKE.

Zahra Abuzaid, Majed Alotaibi, Adnan Alsarawi, Talal Al-Harbi
King Fahad Specialist Hospital-Dammam, Neurology, Ad Dammam, Saudi Arabia

Background and Aims:: One-and-a-half syndrome, a term originally coined by Fisher in 1976 to describe a syndrome with horizontal movement disorder of eyeballs, presents a combination of ipsilateral conjugate horizontal gaze palsy (one) and ipsilateral internuclear ophthalmoplegia (INO) (a half). The diagnoses of one-and-a-half syndrome and its spectrum disorders rely on distinctive clinical symptoms, neuroanatomy, especially imaging technologies. On the other hand, ophthalmoplegia and bilateral cerebellar ataxia are not typical presentations that perplex the clinicians trying to look for a treatable cause such as multiple sclerosis, miller fisher syndrome, and brainstem encephalitis. However, a rare cause like brainstem stroke might be not considered.

Methods:: Case Report and literature review.

Results:: A 61-year-old diabetic and hypertensive lady presented with a history of acute onset dysarthria, dysphagia, double vision, and clumsiness in using her hands. Examination revealed ophthalmoplegia, one and a half syndrome, left facial weakness, and bilateral cerebellar signs. Brain MRI showed multiple bilateral small infarcts at the level of the midbrain and pons. Stroke work up included echocardiography and 24-hour Holter monitor both of which were normal studies. The patient was started clopidogrel and was referred for rehabilitation.

Conclusions:: One and half syndrome and Bilateral ataxia can be signs of multiple ischemic brainstem stroke. Clinicians should consider ischemic brain stroke first when they encounter a patient with such presentation to avoid unnecessary investigations and missing a treatable cause.
CONTRALATERAL DEEP MEDULLARY VEINS IS ASSOCIATED WITH POOR FUNCTIONAL OUTCOMES IN ISCHEMIC STROKE PATIENTS WITH ATRIAL FIBRILLATION AND/OR RHEUMATIC HEART DISEASE

Chen Ye, Junfeng Liu, Chenchen Wei, Yanan Wang, Bo Wu, Ming Liu
West China Hospital, Sichuan University, Center Of Cerebrovascular Disease, Department Of Neurology, Chengdu, China

Background and Aims:: Little is known about the association between deep medullary veins (DMVs) and outcomes of ischemic stroke patients with atrial fibrillation (AF) and/or rheumatic heart disease (RD). Our aim is to investigate the prognostic implications of DMVs in ischemic stroke patients with AF and/or RD.

Methods:: Ischemic stroke patients with AF and/or RD (time from onset to admission ≤ 7 days) admitted to West China Hospital of Sichuan University were consecutively and prospectively enrolled between October 2013 and June 2018. Demographic, clinical and neuroimaging characteristics were collected. A four-grade scales (0: not visible, 1: < 5 conspicuous DMVs, 2: 5-10, 3: > 10; mild: 0-2, severe: 3) were used to assess the severity of DMVs on the contralateral hemisphere based on susceptibility-weighted imaging. Functional outcomes was classified as poor if the modified Rankin Scale (mRs) score was ≥ 3 at 3-month.

Results:: Of 170 patients, 149 presented with mid DMVs grades and 21 with severe DMVs. Those patients who presented with mild and severe DMVs differed significantly in NIHSS score, SBP, infarct lesion > 1/2 MCA territory, mRs scores and poor outcomes at 3-month (all p < 0.05) but not in age, gender, AF and/or RD, heart failure, stroke risk factors, treatments (prior or in hospital) and hemorrhagic transformation (p > 0.05). After adjustment for confounders, patients with severe DMVs were more likely to have higher mRs scores (OR 3.337; 95% CI, 1.351-8.248; p = 0.009) and poor outcome at 3-month (OR 5.830; 95% CI, 1.266-26.856; p = 0.024).

Conclusions:: A severe contralateral DMVs grade was independently associated with poor outcomes, indicating that it needs to be taken into account when assessing the prognosis. Further studies with larger samples are required to validate these findings.
A CASE OF ACUTE ISCHEMIC STROKE DUE TO INNOMINATE ARTERY THROMBOSIS TREATED BY EMERGENCY BRACHIOCEPHALIC ENDARTERECTOMY PERFORMED IMMEDIATELY AFTER IV THROMBOLYSIS

Arianna Braccia¹, Francesca Carta², Domenico Fiorillo³, Renato Simonetti³, Sabrina Rossi⁴, Luca Traina⁵, Onofrio Marcello⁶, Alessandro De Vito⁴, Valeria Tugnoli⁷
¹Clinical Neurology, University Of Ferrara, Ferrara, Italy, ²Azienda ospedaliera universitaria Sant’Anna (Ferrara), Neurologia, Ferrara (FE), Italy, ³University of Ferrara, Sant’Anna Hospital, Clinical Neurology, Ferrara, Italy, ⁴Hospital of Ferrara, Neurology, Ferrara, Italy, ⁵University of Ferrara, Department Of Morphology, Surgery And Experimental Medicine, U, Ferrara, Italy, ⁶Neuroradiology, Neurosciences, Ferrara, Italy, ⁷S. Anna University Hospital, Neuroscience And Rehabilitation, Cona (Ferrara), Italy

Background and Aims:: The timing of endarterectomy after intravenous thrombolysis (IVT) is controversial. Most of literature reports concern IVT and carotid endarterectomy (CEA), while consistent data about IVT followed by other vessels endarterectomy are still lacking; moreover, majority of studies are based on an average interval from IVT to CEA of 48 hours or more.

Methods:: A 32-year old woman, with history of CHT-treated Hodgkin lymphoma, birth control pill assumption, cigarette smoke, was admitted to our ER with sudden left facio-brachial weakness; first examination revealed reduced left arm blood pressure, central facial palsy and distal left arm hypostenia with paresthesias (NIHSS 3). Multimodal CT, including non-contrast CT, angio-CT and penumbral measurement with PCT showed no early ischemic changes involving the MCA territory (ASPECTS 10), signs of hypoperfusion in orbito-frontal and fronto-parietal cortex and brachiocephalic artery stenosis extended to ipsilateral internal carotid artery and right subclavian artery; angio-CT also evidenced left subclavian artery subocclusion.
Results: Immediately after, we administered IV-rTPA, followed by resolution of brachial paresis (NIHSS 2); an echo doppler exam of the epiaortic vessels was performed, showing a floating thrombus in the brachiocephalic trunk. After vascular-surgical evaluation, she underwent brachiocephalic endarterectomy, performed 6 hours after the end of thrombolysis. Post-operative course was uneventful and the patient was discharged with no neurological deficits (NIHSS 0) after 9 days.

Conclusions: This single experience suggests that emergency endarterectomy may be an option in selected patients, to address symptomatic stenosis even immediately after rt-PA therapy (1). NIHSS it’s an
 Brah STROKs in ENVIRONMENTALLY UNFAVORABLE AREAS OF THE ARAL SEA

Ibadulla Kilichev, Murod Matyokubov, Nurmamat Khudaybergenov
Urgench branch of Tashkent Medical Academy, Neurology And Psychiatry, Urgench city, Uzbekistan

Background and Aims:: To study the structure of morbidity and the impact of a set of weather and climate factors on the course and outcome of cerebral strokes in ecologically unfavorable areas of the Aral Sea region.

Methods:: To solve this problem, we analyzed 427 patients with cerebral strokes who were hospitalized in the Khorezm branch of the Republican Scientific Center for Emergency Medical Aid in 2012. Of these, 236 (55.2%) were men, 191 were women (44.8%). The average age of the patients was 57.3 years (56.7 for men and 58.2 for women).

Results:: The study showed that the cause of acute cerebrovascular accident in 58% of cases was hypertension, in 15.2% - atherosclerosis of the cerebral vessels, in 15.8% - a combination of cerebral arteriosclerosis with hypertension. The greatest number of patients was between 60 and 74 years old (43.4%) and from 45 to 59 years (40%), patients with working age (from 20 to 59 years) accounted for 52.6%. Further study showed that hypertension was the cause of brain hemorrhage in 72.3% of cases, subarachnoid hemorrhage of the brain in 64.7%, and cerebral infarction in 55.3%. Atherosclerosis of cerebral vessels mainly caused cerebral infarction in 18.6%, its combination with hypertension was observed with subarachnoid hemorrhage in 23.5%, cerebral hemorrhage in 19.2%, and in cerebral infarction - 14.8%.

Conclusions:: Brain strokes in the Aral Sea region are characterized by a predominance of patients of working age and the main cause of all forms of cerebral strokes is hypertension.
Background and Aims: In acute stroke deterioration of oral function and alteration of consciousness increases the risk of aspiration and pneumonia. Correct oral hygiene and screening for dysphagia is essential to prevent ab ingestis pneumonia that critically increase the days of hospitalization and its long term complications. In our study we compare standardized approach, described in ASA/AHA Guidelines, with a new personalized protocol used in our centre.

Methods: As a first step we carry out a simple swallowing test with a glass of water. If the test is positive, a specialist evaluation is performed which consists of: phoniatric visit, bedside oral exam, flexible endoscopic evaluation of swallowing (FEES) and quantification of the dysphagia degree by 3 clinical scales (Dysphagia Outcome and Severity Scale (DOSS), Penetration Aspiration Scale (PAS), Pooling-score (P-score)); finally, the type of diet and a specific plan of oral hygiene and swallowing rehabilitation are prescribed. In our study we randomized patients into 2 groups: a group treated only with ice chip protocol (ICP) and another group treated with ICP and humidification of secretions with Vapinal. All patients in both groups received basic oral hygiene.

Results: In our study we have demonstrated that an intensive oral hygiene and rehabilitation plan (ICP and Vapinal) guarantees shorter feeding tube durations with faster recovery of oral feeding, improved respiratory function and earlier discharge from the hospital.

Conclusions: In patients with acute stroke and dysphagia an intensive oral hygiene performed by a multidisciplinary approach improve recovery of oral feeding, reduce the days of hospitalization and risk of pneumonia.
RISK FACTORS PROFILE AND CLINICAL OUTCOME OF CARDIOEMBOLIC STROKE PATIENTS ADMITTED IN STROKE CENTER, MONGOLIA

Uurtsaikh Gongor, Lkhamtsoo Natsagdorj
Intermed Hospital, Internal Medicine iii, Ulaanbaatar, Mongolia

Background and Aims:: In Mongolia, data on the etiology, risk factors, clinical profile, and outcome of cardioembolic stroke (CES) is scarce and few clinical studies have been performed to date. The aim of this study was to describe risk factors, clinical characteristics, and outcomes of CES in our setting.

Methods:: The case-control study carried out in the Stroke Center and Cardiovascular Center of the State Third Central Hospital for over 7 month period from July 1 2019 to January 31, 2020.

Results:: The study enrolled a total of 525 subjects. CES was detected in 63 (35.7%) out of 176 (33.5%) ischemic stroke patients with a predominance in the age group of 60-69 and men (33%). The main etiology of CES was atrial fibrillation (AF). AF especially paroxysmal AF increased the risk of CES by 4.6 times (p=<0.0001, OR 4.6, 95% CI 1.4-44.6). The main cerebrovascular risk factor was hypertension.

CES involved large volume infarctions and displayed predominantly cortical syndrome (62.2% and 86.5% respectively), while the main clinical signs at onset were sudden onset of maximal deficit (81%), weakness (36.4%), aphasia (18%), and an altered state of consciousness and visual field deficits (10.5%). Neurological deficits assessed by the NIHSS were more severe in men than in women.

Conclusions:: CES accounted for 1/3 of ischemic stroke with substantial morbidity and mortality. The commonest underlying medical conditions were hypertension and non-valvular AF. Hence, all patients with hypertension and non-valvular AF should be meticulously screened for the prevention of CES.
A KOREAN VERSION OF THE OXFORD COGNITIVE SCREEN: VALIDATION STUDY FOR KOREAN HEALTHY GROUP

Eunyoung Cho¹, Sungwon Choi¹, Seulgi Lim¹, Hyerin Namgoong², Nele Demeyer³
¹Duksung Women’s University, Clinical Psychology, Seoul, Korea, Republic of, ²Duksung Women's university, Psychology, Seoul, Korea, Republic of, ³Oxford University, Clinical Psychology, Oxford, United Kingdom

Background and Aims:: Cognitive impairment occurs frequently after suffering from stroke and it makes both rehabilitation treatment and returning to work very difficult. And has negative effects on quality of life. Neuropsychological assessment could provide useful information that can be used to assess the extent of post stroke cognitive impairment in order to lead to the accurate diagnosis and proper therapeutic intervention for the patients. This study reports normative data of the Korean version of Oxford Cognitive Screen (OCS-K), a stroke-specific cognitive screening tool.

Methods:: A sample of fifty healthy Korean participants aged 35-79 was assessed using the OCS-K and Montreal Cognitive Assessment (MoCA).

Results:: Mean performance and 5th percentile cut offs were calculated for OCS-K. OCS-K results were similar for results from prior studies Positive and significant correlations found between cognitive subtests in the OCS-K and MoCA indicated good concurrent validity and excellent intra-rater reliability.

Conclusions:: OCS-K including semantics, memory, number writing, praxis, visuospatial, executive functions and orientation will be an optimized tool for cognitive evaluation of stroke patients.
HIGH FREQUENCY OF POST-STROKE SEIZURES AMONG WEST AFRICANS

Fred Sarfo¹, Mayowa Owolabi², Bruce Ovbiagele³
¹Kwame Nkrumah University of Science & Technology, Medicine, Kumasi, Ghana, ²University of Ibadan, Medicine, Ibadan, Nigeria, ³University of California, San Francisco, Neurology, San Francisco, United States of America

Background and Aims: Post-stroke seizures (PSS) are associated with significant morbidity and mortality across the globe. There is paucity of data on PSS in Africa. To assess the frequency and factors associated with PSS by stroke types across 15 hospitals in Nigeria and Ghana.

Methods: We analyzed data on all stroke cases recruited into the Stroke Investigative Research and Educational Network (SIREN). We included adults aged ≥18 years with radiologically confirmed ischemic stroke (IS) or intracerebral hemorrhage (ICH). PSS were defined as acute symptomatic seizures and unprovoked seizures occurring after stroke. We used logistic regression to estimate adjusted odds ratios (aOR) with 95% Confidence Interval.

Results: Among 3,344 stroke patients, 499 (14.9%) had PSS (95% CI: 13.7 – 16.2%). There were 294 (14.1%) PSS among 2091 ischemic strokes and 159 (17.7%) among 897 with ICH, p=0.01. The factors associated with PSS occurrence were age <50 years, aOR of 1.59 (1.08-2.33), National Institute of Health Stroke Score (NIHSS), 1.29 (1.16-1.42) for each 5 units rise and white cell count 1.07 (1.01-1.13) for each 10^3 mm^3 rise. Factors associated with PSS in ischemic were NIHSS score, aOR of 1.17 (1.04-1.31) and infarct volume of 10-30 cm³ aOR of 2.17(1.37-3.45). Among ICH, associated factors were alcohol use 5.91 (2.11-16.55) and lobar bleeds 2.22 (1.03-4.82)

Conclusions: The burden of post-stroke seizures among this sample of west Africans is substantial and may contribute to poor outcomes of stroke in this region. Further longitudinal studies are required to understand the impact on morbidity and mortality arising from PSS in Africa.
AN OBSERVATIONAL ANALYTICAL STUDY OF CEREBRAL COLLATERALS ON COMPUTERIZED TOMOGRAPHIC ANGIOGRAPHY (CTA) IN PREDICTING FUNCTIONAL OUTCOME IN PATIENTS WITH ACUTE ISCHEMIC STROKE IN ANTERIOR CIRCULATION.

Sankar Prasad Gorthi¹, Umesh Bonala², K Prakasini³, K Krithyshree³, Arvind Prabhu²
¹Bharati Vidyapeeth (DTU) Medical College & Hospital, Neurology, PUNE, India, ²Kasturba Medical College, Neurology, Manipal, India, ³Kasturba Medical College, Radiology, Manipal, India

Background and Aims:: BACKGROUND: Good cerebral collaterals restrict the volume of cerebral infarction and improve functional outcome. There are various collateral scoring systems in vogue and this study aims to correlate the relative merits of these scoring systems with functional outcome at three months follow up. Aim To study cerebral collaterals on Computerise Tomographic Angiography in patients with ischemic stroke and classify them using collateral scoring systems. To study the functional outcome in acute anterior circulation ischemic stroke at three months follow up with modified Rankin Scale

Methods:: METHODS: In this prospective observational analytical study patients with acute ischemic stroke in anterior circulation cerebral collaterals were assessed on single phase CTA using MITEFF and MASS scoring systems. Collateral scores were correlated with functional outcome after three months follow up.

Results:: RESULTS: One hundred and four subjects were studied and 62% were males. The mean age was 58±14. Median NIHSS at baseline was 9.5. Good collaterals by MASS (Grade 3-5) were seen in 37% and by Miteff (Grade 3) in 36%. Favourable Outcome was seen in 46%. Using Chi-square test good collaterals were compared between two groups. In Good outcome group 54%had good collaterals by Mass system (p<0.001) and 50% by Miteff System (p<0.05).

Conclusions:: CONCLUSION: In acute anterior ischemic stroke patients with good collaterals by Mass and Miteff system will have good outcome at 3 months.
STRUCTURE OF HEMORRHAGIC STROKES IN YOUNG PEOPLE IN NOVOSIBIRSK (RUSSIAN FEDERATION)

Larisa Shchepeankevich¹, Kseniya Rerikh², Elena Taneeva³, Irina Gribacheva¹, Tatyana Popova¹, Ekaterina Petrova¹, Maria Shchepeankevich¹
¹Novosibirsk state medical university, Neurology Department, Novosibirsk, Russian Federation, ²Novosibirsk state medical university, Stroke Unit, Novosibirsk, Russian Federation, ³Novosibirsk State Regional Clinical Hospital, Stroke Unit, Novosibirsk, Russian Federation

Background and Aims:: Morbidity among persons under 44 years old is 10% of the total incidence of ischemic stroke and 15% of the total incidence of hemorrhagic stroke. The aim of our study was to estimate the structure of stroke in persons under 45 years old in Novosibirsk, Russia.

Methods:: We analyzed 222 cases of stroke in young people, aged 15 to 45 (mean age 33±15), admitted in the Stroke Unit at the Regional Clinical Hospital (Novosibirsk, Russian Federation) since 01.01.2018 to 31.12.2020.

Results:: There were 42% patients with ischemic stroke (IS) (94 cases), 40% patients with hemorrhagic stroke (HS) (88 cases), 18% with transient ischemic attack (TIA) (40 cases). There was an approximately equal number of subarachnoid hemorrhage (SAH) and intracerebral hemorrhage (ICH) in the structure of hemorrhagic strokes. The main cause of SAH in 85% of cases was rupture of cerebral artery aneurysms, spontaneous hemorrhage in 10%, and in 5% the cause remained undetected. More often, ICH was caused by hypertension or hypertension syndrome (71%), in the second place were vascular anomalies (aneurysm, cavernous angioma, AVM) - 19%, a rare cause (4%) was cerebral sinus thrombosis, in 6% the cause remained unspecified.

Conclusions:: The data of untypical structure of HS can help using a right diagnostic algorithm in young patients
A QUALITY IMPROVEMENT INITIATIVE LOOKING AT OPTIMISATION OF STATIN DOSE IN SECONDARY ISCHAEMIC STROKE PREVENTION AT A TERTIARY STROKE CENTRE

Manasi Jyothish, Ranvir Cheema, Alice Packham, Sara Shinwari, Kiran Kadara, Shalini Rajcoomar, Don Sims
University Hospitals Birmingham NHS Foundation Trust, Department Of Stroke Medicine, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom

Background and Aims:: NICE recommend high-intensity statin therapy after stroke to reduce non-HDL cholesterol by >40% by 3 months. No recommendation is provided regarding statin choice or dosage. We aimed to assess the effect of statin choice on lipid profile. The results were used to make recommendations for optimal prescribing.

Methods:: The effectiveness of statins in lowering non-HDL cholesterol in all patients admitted to a HASU over a six-month period was analysed. Categorical data was assessed using the Χ² test and non-parametric data via Mann-Whitney or Kruskal-Wallis. Recommendations were added to discharge summaries requesting GPs to evaluate cholesterol at three months and adjust statin dose. Effectiveness of statin prescribing in all stroke patients presenting to the same HASU over a further one-month period was then analysed.

Results:: In the initial six-month period, 277/310 patients suffered non-haemorrhagic stroke. 55% of these were followed up. 33% of patients on statins achieved >40% reduction in non-HDL cholesterol. All of these were on Atorvastatin with 56% reductions seen at 80mg. All patients on simvastatin had a relative increase in non-HDL cholesterol. Neither failure to measure baseline cholesterol (11%) nor failure to prescribe statin (21-22%) altered across cycles. Atorvastatin prescription was significantly increased in the second cycle (p<0.005) Length of stay was significantly decreased in the second cycle (p<0.0001).

Conclusions:: We propose that Atorvastatin 80mg daily is the most effective lipid-lowering medication. We also recommend including lipid profile blood tests in follow up tertiary review and, if over 40% non-HDL cholesterol reduction is not achieved, to increase to 80mg atorvastatin.
Background and Aims:: Intravenous tissue plasminogen activator (tPA) when administered early to eligible patients with acute ischemic stroke reduces long-term disability and reduces the risks for complications. The international guidelines recommend a door-to-needle (DTN) time to be less than 60 minutes. There are no measured data in our center for DTN times for tPA administration for patients presented with Acute Ischemic Stroke. Hence, our aim is to evaluate DTN times for tPA administrations for patients with acute ischemic stroke before and after the initiation of a quality improvement project.

Methods:: An expert working group in our center developed a quality improvement project after performing a systematic review of the published data on improving DTN times for tPA administration in patients with acute ischemic stroke and identifying protocols and strategies associated with better DTN times. We collected retrospectively all patients presented in our center with AIS and treated with tPA before initiation of the quality improvement project (from September 2018 until October 2019) and 1 year after the initiative (from December 2019 – December 2020).

Results:: Preliminary results showed a significant improvement in DTN times after initiation of the quality improvement strategies. The final analysis will be presented at the conference.

Conclusions:: This single-center quality improvement project was started and showed significant improvement in administrating IV tPA DTN times. We recommend further national strategies for further improvement of tPA administration timelines.
CASE REPORT: ACUTE ISCHEMIC STROKE IN A 15 YEARS OLD FEMALE WITH PATENT FORAMEN OVALE

Anita Arsovska
University Clinic of Neurology, Urgent Neurology, Skopje, North Macedonia

Background and Aims:: Patent foramen ovale is a highly prevalent finding in cryptogenic ischaemic stroke, particularly in young adults.

Methods:: We present the case of a 15 year old female patient, previously healthy, with regular sports activity and health check-ups.

Results:: She was admitted due to acute onset of consciousness impairment, left sided hemiplegia, speech impairment, gaze deviation with NIHSS 24 and mRS 5. First brain CT scan performed after 4 hours of the initial treatment was normal. IVT treatment was not provided due to her young age. Laboratory blood and urine analysis, D-dimer, coagulation factors, ECG and extracranial color duplex sonography of the carotid and vertebral arteries were normal. Antiedematous, anticoagulant, antiplatelet, statin and neuroprotective therapy with MLC901 was initiated. Brain MRI 12 hours after initial symptoms showed massive right MCA ischemic stroke in evolution, in nucleus lentiformis, nucleus caudatus and temporal region with surrounding oedema. In the follow-up period, genetic factors for thrombophilia showed heterozygous mutation for F7, F13, ITGA2, PAI-1, MTR, MTHFR 677. TCCS and echocardiography discovered patent foramen ovale, hemodinamically significant, that was treated with percutaneous closure with intracardial prothesis 3 weeks later. Dual antiplatelet therapy with ASA and clopidogrel, as well as statin and neuroprotective therapy with MLC901 was continued. The patient showed dramatic recovery in the follow up period with significantly improved NIHSS, mRS and Short Orientation-Memory-Concentration Test.

Conclusions:: Young patients with stroke should be thoroughly examined for possible risk factors, such as. PFO. MLC901 use was safe and had additional benefit on patients improvement.
Background and Aims:: Acute vestibular syndrome (AVS) features continuous dizziness and may result from a benign inner ear disorder or potentially life-threatening stroke. Misdiagnosis is common and can lead to poor long-term outcome. An oculomotor bedside assessment, the Head Impulse-Nystagmus-Test of Skew (HINTS) is more sensitive than brain Magnetic Resonance Imaging in identifying stroke as the cause of AVS within the first 48 hours, when applied by specialist clinicians. Clinicians’ perspectives of the test in secondary care remains unknown. Here, we explore frontline clinicians’ perspectives of use of the HINTS

Methods:: Clinicians from two large UK hospitals who assess AVS completed a short online survey, newly designed with closed and open questions.

Results:: Almost half of 73 total responders reported limited, or no experience (n=19), reflected in low rates of use (n=31) of HINTS. Whilst the potential utility of HINTS was recognised, many reported concerns about subjectivity, need for specialist skills and poor patient compliance. No clinicians reported high levels of confidence in performing HINTS, with 98% identifying training needs. A lack of formalised training was associated with onward specialist referrals and neuroimaging (p=.044).

Conclusions:: We identified barriers to the application of the HINTS and training needs to improve rapid, cost effective and accurate clinical diagnosis of stroke presenting with vertigo.
ANTITHROMBOTIC PRESCRIPTION AND CLINICAL OUTCOMES AMONG PATIENTS WITH ATRIAL FIBRILLATION IN A RESOURCE LIMITED SETTINGS

Annick Melanie Magnerou¹,², Anastase Dzudie³, Daniel Gams Massi³,⁴, Siddick Mouliom³, Félicité Kamdem³, Yacouba Mapoure⁵
¹Douala Gynaeco-Obstetric and Pediatric Hospital, Internal Medicine, Douala, Cameroon, ²University of Douala, Clinical Science, Douala, Cameroon, ³Douala General Hospital, Internal Medicine, Cardiology, Douala, Cameroon, ⁴Faculty of Health Sciences, University of Buea / Douala General Hospital, Internal Medicine And Paediatrics, Buea, Cameroon, ⁵Douala General Hospital, Internal Medicine, Neurology, Douala, Cameroon

Background and Aims:: Atrial fibrillation (AF) is the most common arrhythmia worldwide and is associated with increased risk of morbidity and mortality. Optimal oral anticoagulation therapy significantly improves the outcomes of patients with AF. We aimed to evaluate the clinical outcomes and their associated factors in patients with AF on antithrombotic therapy in Douala (Cameroon).

Methods:: We prospectively conduct a hospital-based multisite cohort study. Participants enrolled in the Douala Atrial Fibrillation Registry, on antithrombotic treatment were recruited. The composite endpoint of heart failure, stroke, major bleeding, hospitalization and mortality as well as their individual occurrence were assessed 12 months after inclusion in the registry.

Results:: A total of 113 participants were included, and follow-up was completed for 107 of them. The study population was predominantly female (68%), with a mean age of 70 ± 12 years. Antiplatelets were used in 25% of participants and oral anticoagulants in 75% (52% on vitamin K antagonists and 23% on direct oral anticoagulants). At least one outcome occurred in 47.7% (51/107) of cases. Heart failure, stroke, major bleeding, hospitalization and mortality rates were found in 18%, 5%, 3%, 35% and 17% respectively. The mean survival was 11 months. There was no significant difference in the outcomes of patients according to their antithrombotic treatment. Previous heart failure was independently associated with the occurrence of outcomes.

Conclusions:: Three quarter of patients with AF are on oral anticoagulation. About half of the patients with AF will develop an outcome after one year of follow-up, with heart failure being the predicting factor.
EFFECTS OF OUTCOMES (DISABILITY AND APHASIA) OF STROKE ON THE COMMUNITY INTEGRATION OF THE PATIENTS

Adham Yusupov, Feruza Shermuxamedova, Umida Shamsiyeva, Botir Nabiye
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: Stroke commonly results in physical dysfunction and seriously affects the patient’s integration into the community. The aim of this study was to estimate the association of aphasia and disability with the community integration among patients.

Methods:: We investigated the clinical and social aspects of stroke patients. Patients who have undergone ischemic stroke one month ago were assessed with the Modified Rankin Scale (mRS), a severity of aphasia scale and the Community Integration Questionnaire (CIQ). Also, we assayed correlation relationship between these scales.

Results:: Among 141 patients with ischemic stroke, ninety-four patients presented with moderate to severe disability on the Rankin Scale. There was significant negative correlation between CIQ and mRS (p<0.001), and between CIQ and the severity of aphasia scales (p<0.001), indicating lower community integration among people with greater clinical severity of stroke.

Conclusions:: In the present study, the severity of aphasia and disability were inversely correlated with community integration. Improved complex treatment approaches are needed to decrease disability on the social level in these patients.
INTRACRANIAL VERTEBROBASILAR ARTERIAL CALCIFICATION AS A PREDICTOR FOR ISCHEMIC STROKE DUE TO ATHEROSCLEROTIC DISEASE

Eduard Valdes 1, Eytan Raz 1, Adam De Havenon 2, Jose Torres 1, Shadi Yaghi 3
1 NYU Langone Health, Neurology, New York, United States of America, 2 University of Utah, Vascular Neurology, Salt Lake City, United States of America, 3 Rhode Island Hospital, Vascular Neurology, Providence, United States of America

Background and Aims:: Intracranial arterial calcification (IAC) has been identified as an independent risk factor for ischemic stroke. The predictive value of calcification severity for the underlying pathophysiological mechanism of an ischemic stroke remains undetermined. We aimed to assess the degree of intracranial artery calcification in patients with ischemic stroke and evaluate its correlation with intracranial artery atherosclerotic disease as the underlying mechanism.

Methods:: Two hundred and eleven patients with strokes attributed to large vessel atherosclerotic disease from the NYU Ischemic Stroke Database, determined by two independent vascular neurologists, were enrolled. Patients with tandem lesions or competing pathophysiologic mechanisms were excluded. Head CT scans for each patient were reviewed. The degree of calcification of each vertebral and basilar artery was determined by two physicians using the Woodcock Score (interrater reliability score of κ=0.88).

Results:: The highest prevalence of calcification was seen in the left vertebral artery (47%), and less commonly in the basilar artery (15%). There was a trend towards higher prevalence of moderate-severe IAC in patients with stroke due to intracranial atherosclerosis than patients with stroke due to extracranial atherosclerosis (40% vs. 28%, P=0.073). The most common risk factors were hypertension (42 vs. 26%, p=0.890), dyslipidemia (25 vs. 19%, p=0.496), and type 2 diabetes (21 vs. 13%, p=0.415), in patients with stroke due to intracranial atherosclerosis vs extracranial atherosclerosis, respectively.

Conclusions:: There may be a positive correlation between the severity of vertebrobasilar atherosclerotic disease as determined by the Woodcock score and the likelihood that the underlying pathophysiological mechanism of an ischemic stroke is intracranial atherosclerotic disease.
Background and Aims:: Poor management of stroke is associated with higher mortality. The present study assessed risk factors for mortality in stroke patients in Kinshasa, Democratic Republic of Congo (DRC).

Methods:: Cross-sectional interviews and clinical assessments were carried out using on 500 subjects [M/F ratio: 1.56; mean (SD) age: 61.4 (±12.3) years] admitted for stroke between 2013 and 2017 in six hospitals in Kinshasa (DRC). Predictors of mortality were determined using logistic regression at 0.05 significance level (STATA software, version 12.1).

Results:: Forty-eight vs. 24% of subjects were admitted for ischemic vs. hemorrhagic stroke, respectively. Median (IQR) time to admission was 48 (78.25) hours. Only 2% of subjects used medical transportation to reach the hospital. Limited expertise in neurology and psychiatry and lack or resources and adherence to treatment protocols were commonplace. Overall mortality reached 32.6%. Predictors of mortality included lack of neurology expertise [OR (95%IC) : 16.6 (6.6-41.7) ; p=0.000], unconfirmed hemorrhagic stroke [OR (95%IC) : 10.3 (4.94-21.5) ; p=0.000], hyperthermia [OR (95%IC) : 5.39 (3.44-8.46) ; p=0.000], hypoxia [OR (95%IC) : 5.13 (3.10-8.47) ; p=0.000], swallowing difficulties [OR (95%IC) : 2.64(1.46-4.79) ; p=0.001], heart disease [OR (95%IC) : 2.53 (1.03-6.17) ; p=0.042], diabetes [OR (95%IC) : 1.72 (1.08-2.74) ; p=0.0023], confirmed hemorrhagic stroke [OR (95%IC) : 1.70 (1.02-2.82) ; p=0.040].

Conclusions:: Neurology expertise with imaging capabilities and control of cardiovascular risk factors may significantly reduce stroke mortality thereby improving stroke outcomes in DRC.
Background and Aims:: We present a case of acute pseudobulbar palsy.
Methods:: A 57-year-old man presented with acute left facial droop and dysarthria. CT brain and CT angiography were negative and antiplatelet treatment was started. Two days later he suddenly worsened and developed anarthria. On neurological examination he was aphonic, but able to answer the questions with signs and writing. He had bilateral lower face and partial left upper face paralysis, his tongue was mildly deviated on the left side with impaired lateral movements. Moreover examination showed poor velum mobility and difficulty swallowing. Ocular motility was spared, rest was normal. Repeated CT and CTA were negative, CT perfusion showed focal hypoperfusion in frontal cortical regions. Brain MRI revealed multiple acute infarcts involving frontal prerolandic and opercular regions bilaterally. Transthoracic and transesophageal echocardiography demonstrated a marantic endocarditis, a condition probably due to hypercoagulable state associated with a newly-diagnosed lung cancer.

Results:: Foix-Chavany-Marie syndrome (FCMS) or bilateral anterior opercular syndrome is the cortical form of pseudobulbar paralysis. It is described as a facio-labio-glosso-pharyngo-laryngo-brachial paralysis with autonomic-voluntary dissociation. The main etiology is the vascular one, consequence of consecutive, multiple, separates vascular lesions in anterior frontal opercula of both hemispheres. Acute onset without a history of previous stroke is unusual. Our case is a rare example of simultaneous bilateral opercular infarcts presenting with acute cortical type of pseudobulbar syndrome.

Conclusions:: In a patient with acute bilateral bulbar signs, preserved ocular motility and absent cerebellar signs should be an alert for a possible cortical site of the lesion, and stroke should be considered as the most likely etiology.
Background and Aims:: Frailty has been identified as an important factor associated with the recovery of various illness, such as: stroke. Therefore, the purpose of this study was to identify the levels of frailty and associated factors for stroke patients after discharged from acute care.

Methods:: A total of 95 stroke patients were recruited and followed up at 3-month and 6-month. Questionnaires included demographic- and medical-information, stroke self-efficacy, and Edmonton frail scale were selected for data collection. All data was managed by SPSS-22. Inferential statistics (i.e. paired-t-test, Chi-Square, multiple logistic regression) were selected to analyze the expected relationship. P<.05 was selected for all analysis.

Results:: Subjects were characterized as: male, lower educated, married, unemployed, living with family members, older, overweight, moderate dependent, and with first or third stroke (33.7% respectively). Most of the subjects were categorized as severe frailty at 3 months and 6 months (37.9% respectively). Meanwhile, the classification of frailty in each sample was the same between 3 months and 6 months. When total score as an issue, the score at 3 months (8.12+3.52) was significantly higher than that at 6 months (6.60+3.13; paired-t=6.283, p<.001). Different predictors for frailty at 3-month and 6-month were found by multiple logistic regression. Marriage_single, ALD_total dependent, ADL_moderate dependent, and self-efficacy were found in both time points.

Conclusions:: Frailty existed in post-discharge stroke patients and improved at 6 months after discharge. Strategies to help the stroke patients manage their frailty need to be explored.
ROLE OF MAGNETIC RESONANCE IMAGING IN IDENTIFYING ACUTE ISCHEMIC STROKE PRESENTING WITH THUNDERCLAP HEADACHE

Andrea Fortuna¹, Simone Tonello², Silvia Guidoni², Anna Palmieri², Domenico Bonifati²
¹University of Padua, Neurology, Padova, Italy, ²Ca’ Foncello Hospital, Neurocardiovascular, Treviso, Italy

Background and Aims:: Acute ischemic stroke represents the most common cause of new sudden neurological deficit. Rapid diagnosis is imperative due to the time-dependent nature of many acute stroke therapies. Thunderclap headache is a severe headache with sudden onset that is often associated with subarachnoid haemorrhage. Here we present a case of ischemic stroke with thunderclap headache at onset that was treated with thrombolysis after urgent brain MRI.

Methods:: We present the case of a 72-year-old woman admitted to our Stroke Unit with sudden onset of severe right temporal headache and vertigo associated with oscillopsia, nausea and vomiting. Her past medical history included palpitations, for which she was taking propafenone. Head CT and CT angiography were negative for parenchymal lesion and no vessel occlusion was found. An urgent perfusion-MRI was then performed showing a DWI restriction of right cerebellum, with corresponding mild FLAIR hyperintensity, as for an hyperacute ischemic injury. Considering favourable mismatch at 3 hours from onset intravenous thrombolysis was administered with marked improvement. At discharge patient had a mild trunk ataxia and was able to walk unsupported.

Results:: In this case prompt brain MRI led to a diagnosis of ischemic stroke in a patient presenting with sudden severe headache, excluding subarachnoid haemorrhage and permitting on time administration of intravenous thrombolysis.

Conclusions:: Thunderclap headache is frequently associated with subarachnoid haemorrhage and is very rarely the onset of an ischemic stroke. Some mimics and chameleons are absolute contraindications to thrombolysis. Urgent brain MRI is sensitive and specific for the diagnosis of ischaemic stroke allowing reperfusion therapy.
SPINAL CORD ISCHEMIA: A RARE MANIFESTATION OF A FLOATING THROMBUS

Anna Gardin¹, Carmelo Tiberio Currò¹, Paolo La Spina¹, Teresa Brizzi¹, Carmela Casella¹, Masina Cotroneo¹, Cristina Dell'Aera¹, Maria Carolina Fazio¹, Francesco Grillo¹, Antonino Naro¹, Marco Cavallaro², Karol Galletta², Francesca Granata², Antonio Toscano³, Rosa Fortunata Musolino¹

¹Stroke Unit, Clinical And Experimental Medicine Department, University Of Messina, Messina, Italy, ²Neuroradiology Unit Department of Biomedical Sciences and Morphological and Functional Images, University Of Messina, Messina, Italy, ³University of Messina, Unit Of Neurology And Neuromuscular Disorders, Department Of Clinical And Experimental Medicine, Messina, Italy

Background and Aims:: Spinal cord ischemia (SCI) accounts for less than 1% of all strokes and is often caused by aortic pathologies in the elderly. In this group of diseases, the incidence rate of nonaneurysmal aortic mural thrombus is about 0.45% and the ascending aorta (AA) represents the rarest location. We report a singular case of SCI due to a floating thrombus (FT) in the AA.

Methods:: A 75-year-old male presented to our hospital with acute left hemiparesis and hemihypesthesia, NIHSS 3. His medical history was unremarkable, except for former cigarette smoking. He underwent brain CT and MRI, spinal cord MRI and CT angiography.

Results:: Brain CT and MRI excluded cerebral involvement, while spinal cord MRI showed a C4-C6 ischemic lesion, involving the left anterior and posterior horns of the grey matter and the left lateral cord. A CT angiography demonstrated a 6 millimeter-FT in the AA. According to cardiovascular surgeons, a dual antiplatelet therapy and atorvastatin 80 mg were started. On the 7th day, the patient was discharged with an improvement of his motor deficit, NIHSS 2.

Conclusions:: Although the main symptoms of SCI are often bilateral, the reported clinical features at the onset are exceptionally unilateral. The ischemic lesion may be correlated with an anterior arterial branch occlusion, involving the left spinal sulcal artery territory. Even if the presence of a FT severely increases the risk rate of recurrent embolism (about 73%, compared to 12% of a sessile thrombus), conservative medication is generally preferred.
DOUBLE RISK : STROKE IN A PATIENT AFTER IN VITRO FERTILISATION (IVF) PROCEDURE AND FORAMEN OVALE APERTUM

Malbora Xhelili, Sokrat Xhaxho, Eti Muharremi, Jera Kruja
Neurology service, Neurology, Tirana, Albania

Background and Aims:: A major complication of IVF intervention is ovarian hyperstimulation syndrome (OHSS) which can lead to significant arterial and venous thrombosis.

Methods:: We report the case of M.B. a 32 year-old female patient who presented in the Emergency Room in 28 August 2019. She referred that in the morning after the shower she had headache, nausea, vomiting, difficulty speaking and dizziness. She also reported difficulty walking and problems with balance. The situation was aggravated with persisting vomiting and altered consciousness. A head scan was performed and a left cerebellar ischemic lesion was detected. The patient 3.5 years ago consulted an obstetrician and resulted infertile. Then she began a series of more basic hormonal treatments. Has completed a total of 3 FIV cycles within a 2.5 year time frame. (last session April 2019). A complete blood count, coagulation tests, anticardiolipin levels resulted normal. In transesophageal ultrasound was found a foramen ovale apertum. Brain MRI reconfirmed the left cerebellar ischemic lesion, PICA territory. She was given double antiplatelets therapy.

Results:: Ovarian hyperstimulation syndrome (OHSS) remains a serious complication of hormonal treatment among gynecology departments. Haemoconcentration owing to the large fluid shift from the intravascular to the peritoneal cavity results in increased blood viscosity that can lead to arterial and venous occlusion. Thromboembolic stroke, cerebral venous thrombosis and systemic arteriovenous thrombosis have been reported in OHSS.

Conclusions:: Acute ischemic stroke, although much more rare than venous complications, must be considered in a young patient with acute neurological dysfunction and recent ovarian stimulation.
REPERFUSION TREATMENT IN PEDIATRIC ACUTE ISCHEMIC STROKE: A SINGLE-CENTRE EXPERIENCE.

Cristina Motto\textsuperscript{1}, Mariangela Piano\textsuperscript{2}, Monica Brioschi\textsuperscript{1}, Paola Doneda\textsuperscript{3}, Elisabetta Stacul\textsuperscript{4}, Stefania Bergamoni\textsuperscript{5}, Federica Teutonico\textsuperscript{6}, Costantino De Giacomo\textsuperscript{6}, Elio Clemente Agostoni\textsuperscript{1}

\textsuperscript{1}Grande Ospedale Metropolitano Niguarda, Stroke Unit & Neurology, Milano, Italy, \textsuperscript{2}Grande Ospedale Metropolitano Niguarda, Interventional Neuroradiology, Milano, Italy, \textsuperscript{3}Grande Ospedale Metropolitano Niguarda, Neuroradiology, Milano, Italy, \textsuperscript{4}Grande Ospedale Metropolitano Niguarda, Pediatry, Milano, Italy, \textsuperscript{5}Grande Ospedale Metropolitano Niguarda, Child Neuropsychiatry, Milano, Italy, \textsuperscript{6}Grande Ospedale Metropolitano Niguarda, Pediatry, Milano, Italy

Background and Aims:: Reperfusion therapy using intravenous thrombolysis with t-PA and / or endovascular treatment significantly improves clinical outcomes in adults with acute ischemic stroke. In pediatric population evidence from randomised controlled trial is lacking, and only case series are available. We describe our experience in pediatric acute ischemic stroke.

Methods:: Single-centre case series of pediatric acute arterial ischemic stroke aged from 2 to 16 years old since 2016 has been examined. Stroke severity was measured with Ped NIHSS (Pediatric National Institutes of Health Stroke Scale). Favorable outcome was defined as 3-month modified Rankin Scale (mRS) less than 2, when applied. Safety measures were intracranial hemorrhage and procedure complications.

Results:: Four cases out of 10 pediatric acute ischemic stroke performed thrombectomy. Nobody received intravenous t-PA. Age was four, nine, ten, and twelve-year-old. Three were female. Two had Down syndrome. Ped NIHSS at onset was 17, 15, 13, and 10. Three intracranial internal carotid artery and one middle cerebral artery occlusion were observed. Complete recanalisation (TICI 3) was obtained in all cases. No intracerebral hemorrhages, neither other procedural complications were observed. Three-month outcome was favorable in all cases (mRS 2, 1, 1, 1, respectively). Extensive diagnostic work-up was carried out to identify stroke etiology. Two had inflammatory arteriopathy, two cryptogenic stroke.

Conclusions:: Although acute treatment of pediatric ischemic stroke is not supported by data from randomised controlled trial, thrombectomy seems effective and safe in pediatric patients, and it could be taken into account in selected cases and in experienced centre irrespective of ischemic stroke etiology.
"LOGOS" IN THE REHABILITATION OF POST-STROKE APHASIA

Munisa Rasulova, Dilbar Rasulova, Fakhmitdin Muratov, Bahrom Nasrullaev
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

**Background and Aims:** According to the national stroke register of 2019 and 2020, more than 60,000 residents in Uzbekistan are diagnosed with strokes every year, and 1/3 of patients have speech disorders-aphasia. The aim is to study the dynamics of aphasia in the acute period of hemispheric strokes and to apply the prototype of the first mobile application in the Uzbek language "LOGOS".

**Methods:** We examined 60 patients with hemispheric strokes from 2018 to 2019. The state of speech functions was studied three times on day 1-3, from day 3 to 21, and in the early recovery period. Group 1 included 28 patients with motor aphasia; group 2 - 12 patients with dynamic aphasia; group 3 - 20 patients with total aphasia. The male sex prevailed, the average age was 64.0 + 1.3.

**Results:** In group 1, speech recovery after 1 day was observed in 7% of patients, within 3-5 days in 7.1%, within 1 week in 14.3%, by the end of the month in 57% and without dynamics in 7.1% of patients. In group 2, dysarthria was mainly detected, speech recovery during the day was noted in 16.7%, within 3 days in 50%, within 5 days in 8.3% and within 1 week in 16.7% of patients. In group 3, speech recovery was noted only in 1 patient.

**Conclusions:** Speech disorders are restored of in the dynamics. The worst recovery is observed in patients with total aphasia. Speech recovery should start with the most acute period of a stroke using the LOGOS mobile speech recovery apps.
GENDER CHARACTERISTICS OF THE MAIN ARTERIES OF THE HEAD

Azamatjon Umarov, Nargiza Vakhobova, Maksud Asadullaev
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: Among the numerous factors, the focus of researchers is on gender differences in both the frequency and clinical features of cerebrovascular diseases. Purpose of the work was an assessment of gender differences in the risk of ischemic cerebral stroke based on the results of a comprehensive ultrasound examination of the main head arteries.

Methods:: The study involved 110 patients aged from 45 to 78 years, divided into two groups: Group I - patients who had an ischemic cerebral stroke in the recovery period (30 men and 22 women), Group II - patients with essential hypertension but no stroke in anamnesis (20 men and 38 women).

Results:: It was found that the average IMT values in the common carotid arteries in men are expected and significantly higher than in women, as in the first (1.10±0.05 mm versus 0.97±0.04 mm, respectively, p<0.05) and in the second (0.87±0.03 mm versus 0.79±0.02 mm, respectively, p<0.05) groups, while significant differences between men and women according to the results of assessing the stiffness of the walls of common carotid arteries were observed in the first group - 8.33±0.22 m/s and 9.16±0.40 m/s, in the second group. Both men and women with uncomplicated hypertension (group II) showed almost the same increase in arterial wall stiffness with an increase in IMT.

Conclusions:: The revealed trend is evidence of qualitative differences in the vessels affected by atherosclerosis in individuals of different sexes and can be used to assess the risk of ischemic cerebral stroke.
THE GENDER FEATURES AND SEASON RELATED ISCHEMIC STROKE AND ITS FREQUENCY

Azamatjon Umarov, Nargiza Vakhobova, Gulnora Rakhimbaeva, Maksud Asadullaev
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

**Background and Aims::** The aim of the study was to study the seasonal prevalence of ischemic stroke, taking into account its type, gender and deaths.

**Methods::** The analysis included 3112 case histories of patients who are admitted to the TMA clinic. Among them, 1411 are men and 1701 are women.

**Results::** Depending on the month of the year, the maximum prevalence of IS in men was noted in April, and in women - in January (10.9 and 9.9%, respectively). The minimum prevalence of IS was found in men in January, and in women in November (6.3 and 7.0%, respectively). Depending on the season, the prevalence of CS had certain patterns and characteristics. In men, the maximum number of IS cases was noted in summer, and the minimum in winter (28.4 and 21.7%, respectively). In women, if AI is evenly distributed across all seasons of the year. Depending on the type of stroke and gender, certain patterns in the prevalence of deaths at different times of the year were also identified. In men with IS, the maximum number of deaths was noted in the spring, and the minimum - in the summer (32.2 and 16.9%, respectively). In women with IS, the maximum number of deaths was observed in the fall, and the minimum in the summer (30.1 and 20.5%, respectively).

**Conclusions::** AI in men was most often recorded in summer, while in women, its distribution was even throughout the year. The maximum number of deaths with IS was found in spring and fall among men and women respectively.
MINOR STROKE CAN CAUSE MAJOR DISABILITY: IDENTIFICATION OF POOR PROGNOSIS FACTORS IN PATIENTS WITH MINOR STROKE.

Carlos Catedra Carame, Laura Amaya Pascasio, Andres Garcia Pastor, Ana María Iglesias Mohedano, Fernando Díaz Otero, Pilar Vazquez Alen, Marta Vales Montero, Yolanda Fernandez Bullido, Sofia Portela Sanchez, Miguel Mas Serrano, Antonio Carmelo Gil Nuñez

1Hospital Can Misses, Neurology, Ibiza, Spain, 2Hospital Universitario Torrecárdenas, Neurology, Almeria, Spain, 3Hospital General Universitario Gregorio Marañon, Neurology, Madrid, Spain, 4Hospital Universitario de Guadalajara, Neurology, Guadalajara, Spain

Background and Aims:: Previous studies warn about potential poor functional outcome at three months in minor stroke (MS) patients. Our study aims to ascertain the proportion of patients with poor functional outcome or death at 3 months in this subgroup and to identify factors related to it.

Methods:: A prospective cohort of patients with MS (defined as score in the National Institute of Health Stroke Scale (NIHSS) ≤4), admitted in an acute stroke unit from January 2015 to April 2019 was analyzed. Descriptive and uni-multivariate analyses were performed to identify predictive factors of poor functional outcome or death (defined as a score on modified Rankin Modified Scale (mRS) of 3-6).

Results:: 1048 patients were included, 59% males, mean age 69 years (SD 14.54), median baseline NIHSS 2 (IQR 1-3). 126 (12%) large vessel occlusion (LVO) were identified, acute reperfusion treatment was used in 43 patients (36 intravenous thrombolysis, 11 mechanical thrombectomies). 130 (12.4%) scored mRS>2 at 3 months. Age: OR (1.04 [CI 95% 1.02 - 1.06]), baseline NIHSS: OR (1.4 [1.16 - 1.67]), baseline glycemia >155mg/dl: 1.36 (1.03 - 1.86), LVO: 2.18 (1.26 - 3.76), aterothrombotic etiology: 3.07 (1.55 - 6.09), hemorrhagic transformation: 14.28 (2.31 - 88.28), early recurrence: 15.70 (3.04 - 81.08) and pneumonia: 5.94 (1.82 - 19.40) were identified as predictors of poor outcome in the multivariate analysis (adjusted for age, baseline NIHSS and baseline mRS)

Conclusions:: 12% of MS had poor functional outcome at 3 months. Identifying predictors of poor prognosis could have implications in the initial therapeutic management of these patients.
Background and Aims:: Routine examinations for patients with stroke include clinical assessment using the National Institute of Health Stroke Scale (NIHSS). Although this score accurately predicts the outcome of stroke, the NIHSS is weighted for anterior circulation. No reliable clinical assessment tool has been established for predicting the functional outcome of posterior circulation ischemic stroke. We aimed to develop a stroke scale based on clinical assessment that can increase the yield of detection of posterior circulation ischemic strokes in acute settings, the Langone Augmented Posterior-fossa Stroke Scale (LAPSS).

Methods:: A retrospective, dual campus, single center record review of patients that have been diagnosed with posterior fossa circulation strokes between 12/2018-11/2019 will be conducted. We will catalog the presenting symptoms, calculate their prevalence, and use this information to adjust the current proposed LAPSS. The validity of the LAPSS will then be tested by retrospectively applying it to all patients that presented with symptoms of posterior fossa ischemic strokes.

Results:: We project 120 patients will fit the inclusion criteria. The sensitivity, specificity, positive predictive value, and negative predictive value of LAPSS will be calculated. Inter-rater reliability will be assessed using ANOVA to define an intraclass correlation coefficient. Primary clinical outcome in patients with suspected posterior fossa stroke will be independent functional outcome (mRS 2).

Conclusions:: The NIHSS has been shown to detect <60% of posterior circulation strokes in previous studies. We anticipate that the LAPSS will increase the sensitivity of the NIHSS to increase the overall yield of detection of posterior circulation strokes.
Background and Aims:: A gender gap has been frequently described in stroke care in various settings. We reviewed the issue using data from the admission registries of two our "Stroke Units", located in two distinct Italian regions. Our common policy is to admit every suspected case of acute stroke or TIA to our Stroke Unit, without any specific age or severity-based exclusion criteria.

Methods:: From the two registries, we retrieved data on 2020 admissions. We then analysed possible differences based on gender in age, "wrong diagnosis" (i.e. stroke mimics), stroke severity and thrombolytic treatment. We used chi square test for categorical variables and t-test and Mann Whitney test for continuous variables.

Results:: There were 181 available records. Females were 77 (43%) and males 104 (57%). No difference was found between genders in wrong admissions (p=0.8). Females were significantly older than males (mean age 80 vs 76, p=0.025). Stroke severity (measured by NIHSS) was not different between the two groups (p=0.5) Thrombolysis was given to 15 males and 14 females (p=0.5). Only 3 males and 4 females died while in hospital (p=0.4).

Conclusions:: In the daily practice of two different "Stroke Unit" in central Italy (first level emergency hospitals), no gender differences were found in various parameters of care. When the policy is to admit every suspected stroke to the "Stroke Unit" (as recommended by ESO), male and female patients have the same level and type of care.
ECHOCARDIOGRAPHIC FINDINGS AND DIAGNOSTIC ACCURACY OF ECHOCARDIOGRAPHY IN PATIENTS WITH ISCHAEMIC STROKE OR TIA: A SYSTEMATIC REVIEW PROTOCOL

Radim Licenik¹,², Muhammad Khaled Hasan¹,², Ondrej Volny¹,³, Anna Zimovjanova¹, Santhosh Subramonian², Mmua Ngwako⁴, Salman Hussain¹, Miloslav Klugar¹, Jitka Klugarova¹, Andrea Pokorna¹, Simona Slezakova¹, Martin Huncovsky¹,², Felipe Montellano⁶
¹Faculty of Medicine, Masaryk University, Czech National Centre For Evidence-based Healthcare And Knowledge Translation (cochrane Czech Republic, Czech Ebhc: Jbi Centre Of Excellence, Masaryk University Grade Centre), Brno, Czech Republic, ²North West Anglia Foundation NHS Trust, Peterborough City Hospital, Department Of Neurology And Stroke Medicine, Peterborough, United Kingdom, ³University Hospital Ostrava, Department Of Neurology, Ostrava, Czech Republic, ⁴London North West University Healthcare NHS Trust, Northwick Park Hospital, Stroke Unit, London, United Kingdom, ⁵University of Bristol, Bristol Medical School, Bristol, United Kingdom, ⁶University Hospital Würzburg, Department Of Neurology, Würzburg, Germany

Background and Aims:: Stroke is a major cause of mortality and disability worldwide. Approximately 20-30 % of ischaemic strokes are consider to be cardioembolic. Cardioembolic strokes are severe, disabling with high rate of early and long-term recurrence. Both transthoracic and transoesophageal echocardiography are crucial tools in evaluation, diagnosis and management of patients with cardioembolic strokes and TIA’s.

Methods:: A systematic review and meta-analysis has been undertaking to identify studies involving patients with ischaemic stroke and TIA undergoing transthoracic or transoesophageal echocardiogram to detect cardiac source of emboli and to determine the diagnostic accuracy of echocardiography.

Results:: Study question: What are the echocardiographic findings and diagnostic accuracy of echocardiography in patients with ischaemic stroke or TIA? Searches: Electronic databases: MEDLINE (Ovid), EMBASE (Ovid), The Cochrane Library, Scopus. Other resources: the reference lists of included studies, citation tracking, hand searching, grey literature indexed in trials registers ClinicalTrials.gov and the WHO International Clinical Trials Registry Platform (ICTRP). From 01. 01. 2000 to the date of the search with no limitations of languages. Types of study to be included: Cross-sectional diagnostic analytical studies will be considered for inclusion. Condition or domain being studied Ischaemic stroke or transient ischaemic attack. Population: Patients of all ages diagnosed with ischaemic stroke or TIA. Index test: Transthoracic and/or transoesophageal echocardiogram. Diagnosis of interest: Echocardiographic detection of source of emboli.

Conclusions:: The systematic review protocol will be published in Prospero register and results of the systematic review will be presented at the conference.
MLC901 IN SUBACUTE POST-STROKE RECOVERY IN THE EASTERN EUROPEAN POPULATION: PRELIMINARY RESULTS OF A MULTICENTRE STUDY.

Anita Anisovska¹, Mariusz Janta², Anna Tomašová³, Slavomír Guťan⁴, Barbora Garajová⁵, Iveta Nikolová⁶
¹Ss. Cyril and Methodius University of Skopje, University Clinic Of Neurology, Skopje, North Macedonia, ²City Hospital, Department Of Neurology, Częstochowa, Poland, ³Hospital with Polyclinic, Department Of Neurology, Levoča, Slovak Republic, ⁴Hospital with Polyclinic, Department Of Neurology, Považská Bystrica, Slovak Republic, ⁵F.D. Roosevelt Teaching Hospital with Policlinic, Department Of Neurology, Banská Bystrica, Slovak Republic, ⁶Agel Clinic, Center of Movement Medicine, Department Of Neurology, Bratislava, Slovak Republic

Background and Aims:: BACKGROUND: A challenge in the field of Stroke Recovery Research is determining the optimal timing to implement interventions. Acute and subacute (<3 months) is a critical time for neural plasticity, hence should be a target for recovery trials. MLC901, a combination of herbal ingredients, has been used to improve recovery after ischemic stroke. AIM: This study aims to assess the safety and potential efficacy of MLC901 in the subacute to chronic phase after Ischemic Stroke in the Eastern European population

Methods:: MATERIAL AND METHODS: The online NeST registry of subjects with Ischemic Stroke given MLC901 prospectively collected clinical data at baseline and month (M) 1 to M3. Outcome measures included for this analysis is the National Institutes of Health Stroke Scale (NIHSS) and side-effects.

Results:: RESULTS: There were one hundred sixty subjects from Slovakia, Macedonia and Poland, with the mean age was 46.7±27.69 years, with 69 (43%) women, 81% have hypertension and started with MLC901 at 71.13±201 days since the time of stroke onset. Mean NIHSS was 12.5 at baseline, 8.5 at M1, 6.7 at M2 and 5.1 at M3. At M3, 61.01% subjects had minor to no stroke compared to 82.51% with moderate to severe at baseline (Figure 1). During the 3 months follow-up, 1 subject (2.5%) reported at least one adverse event. Figure 1. Proportion of Subjects per scoring levels of NIHSS at baseline, Month 1, M2, M3

Conclusions:: CONCLUSIONS: MLC901 in the real-world setting was safe and showed therapeutic potential for post-stroke recovery at subacute and chronic stages in the Eastern European.
REAL-WORLD EFFECTIVENESS OF MLC901 IN SUBJECTS AFTER BRAIN INJURIES IN THE EASTERN EUROPEAN POPULATION: A PRELIMINARY RESULT OF NEUROAID SAFE TREATMENT (NEST) REGISTRY.

Anita Anisovska1, Mariusz Janta2, Anna Tomašová3, Slavomír Guťan4, Barbora Garajová5, Iveta Nikolová6
1Ss. Cyril and Methodius University of Skopje, University Clinic Of Neurology, Skopje, North Macedonia, 2City Hospital, Department Of Neurology, Częstochowa, Poland, 3Hospital with Polyclinic, Department Of Neurology, Levoča, Slovak Republic, 4Hospital with Polyclinic, Department Of Neurology, Považská Bystrica, Slovak Republic, 5F.D. Roosevelt Teaching Hospital with Policlinic, Department Of Neurology, Banská Bystrica, Slovak Republic, 6Agel Clinic, Center of Movement Medicine, Department Of Neurology, Bratislava, Slovak Republic

Background and Aims:: BACKGROUND: Neurological disorders account for a large and increasing health burden worldwide. MLC901 is a combination of natural products that has demonstrated its clinical efficacy and safety in improving functional and neurological outcomes in stroke, traumatic brain injury, and other neurological conditions. AIM: This study aims to assess the real-world effectiveness of MLC901 in relevant neurological disorders included on the NeST Registry amongst the Eastern European population

Methods:: MATERIAL AND METHODS: Thirty-six physicians from Poland, Macedonia and Slovakia had to enrolled subjects having suffered a brain injury and who were given MLC901 for 3 months. Clinical data were prospectively collected at baseline and month (M) 1 to M3. Outcome measures included National Institutes of Health Stroke Scale (NIHSS), Glasgow Coma Scale (GCS), modified Rankin Scale (mRS) and Short Orientation-Memory-Concentration Test (SOMCT).

Results:: RESULTS: Two hundred six patients were included on this analysis. The mean age was 58.4±14.6 years, 55% are male, and majority have hypertension (76%). Ischemic Stroke accounted for 78% (160/206), Intracranial Hemorrhage (9%), Global Ischemia (6%), and Traumatic Brain Injury (5%). At month 3 (Table 1), mean scores were: 5.87±6.87 (NIHSS), 1.9±1.5 (mRS), 14.13±2.01 (GCS), 14.40±11.24 (SOMCT); with greater proportion of patients improving their mean scores from baseline (Figure 1). Table 1. Baseline characteristics and evolution of scores on neurological scales
Figure 1. Proportions of subjects per scoring levels of four neurological scales at baseline, month (M) 1, M2 and M3.

Conclusions: CONCLUSIONS: MLC901 in the real-world setting showed therapeutic potential for neurological disease in the Eastern European population.
FEATURES OF THE CLINICAL COURSE OF ISCHEMIC STROKE IN POSTCOVID PATIENTS

Shokhida Gazieva, Gulnora Rakhimbaeva
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: The study of the course of the disease in patients previously ill with COVID-19 infection would contribute to adjusting approaches to the treatment of such patients in order to improve the efficiency of the cure.

Methods:: We observed 45 patients previously ill with COVID-19 and admitted with a diagnosis of ischemic stroke and apply the SF-36, MOCA, HADS, Rivermide, Rankin and NIHSS scales. Of these, 44.4% (20) were women, and 55.6% (25) were men. The average age of patients was 61.2 (52-74) years. The control group of patients, also with ischemic stroke, but without Covid-19 disease in anamnesis, also consisted of 45 people, 48.9% (22) were women and 51.1% (23) were men. The average age of patients was 62.8 (53-78) years.

Results:: In 42 patients previously ill with COVID-19, significant results of the studied indicators indicating a more severe course of the disease were observed compared to those in the control group. At the same time, no significant differences were observed among men and women. In the group of patients who had not previously suffered from COVID-19, only 6 patients (13.3%) also suffered from the disease. The majority of these patients were men aged 63 and above.

Conclusions:: The results of the studies indicate a strong influence of the fact of the previously suffered infection COVID-19 on the nature and duration of the course of ischemic stroke. A history of COVID-19 should contribute to the revision of treatment tactics and the intensity of interventions and be prepared for a longer process of rehabilitation procedures.
ASSOCIATION OF MAJOR ADVERSE CARDIOVASCULAR EVENTS IN STROKE PATIENTS WITH CARDIAC WALL MOTION ABNORMALITIES

Saadat Kamran¹, Naveed Akhtar², Rajvir Singh³, Jon Perkins²
¹Hamad General Hospital, Neuroscience, Doha, Qatar, ²HMC, Neuroscience, Doha, Qatar, ³Heart Hospital, Cardiology, doha, Qatar

Background and Aims:: The association of cardiac wall motion abnormalities (CWMAs) in stroke patients with major adverse cardiovascular events (MACE) remains unclear. The purpose of this study was to estimate the 50-month risk of MACE, including stroke recurrence, acute coronary events and vascular death in stroke patients with CWMA.

Methods:: We performed a retrospective analysis of prospectively collected stroke data over a 50-month period by electronic medical records. Data included demographic, clinical, vascular imaging and echocardiography data including CWMA and MACE.

Results:: Out of a total of 2653 acute stroke patients, CWMA was observed in 355 (13.4%). In CWMA, embolic stroke of undetermined source (ESUS) (50.7%) was the most frequent index stroke subtype and stroke recurrences (p=0.001). In multivariate cox regression after adjustment for demographics, traditional risk and confounding factors CWMA was independently associated with higher risk of MACE (aHR 1.74(95% CI 1.37-2.21), p=0.001). Similarly, CWMA independently conferred an increased risk for ischemic stroke recurrence (aHR 1.50(95% CI 1.01-2.17), p=0.04), risk of acute coronary events 2.50(1.83-3.40), p=0.001) and vascular death (aHR1.57(95% CI 1.04-2.40), p=0.03), in comparison to the stroke patients without CWMA.

Conclusions:: In a multiethnic cohort of ischemic stroke with CWMA, CWMA are associated with 1.7-fold higher risks of MACE independent of established risk factors. ESUS was the most common stroke association with CWMA. Stroke patients should be screened for CWMA to identify patients at higher risk of MACE.
INCREASED CEREBRAL VENOUS SINUS THROMBOSIS DURING COVID-19 LOCKDOWN

Saadat Kamran¹, Naveed Akhtar², Fatma Ben Abid², Muna Almaslaman², Jon Perkins²
¹Hamad General Hospital, Neuroscience, Doha, Qatar, ²HMC, Neuroscience, Doha, Qatar

Background and Aims:: During the Coronavirus Disease-2019 (COVID-19) pandemic, reports of increased cerebral venous thrombosis (CVST) have appeared. Few studies have compared the rate of CVST admissions during the outbreak to previous years. It is not known if preventative measures such as lockdowns affect the rate of CVST presentation.

Methods:: A retrospective analysis of CVST admissions from January 1st, 2019 to December 31st, 2020 was carried out by reviewing the electronic database. All CVST with radiological confirmation were included.

Results:: There was a 13.2% increase in CVST in 2020 compared to 2019 (43.4% vs. 56.6%). CVST was higher during the lockdown period (March to September) compared to the rest of 2020 (p<0.001). This finding could not be replicated in 2019. CVST cases during lockdown remained statistically higher than cases in the rest of 2020 even after removing all COVID-19 cases (34.2% vs. 65.8%, p<0.006). During the lockdown period, the incidence of CVST was 4.0 per 100,000 COVID-19 cases.

Conclusions:: There were more CVST during the lockdown in 2020 compared to the same period in 2019. Lifestyle modifications resulting from lockdown may harmfully impact CVST independent of COVID infection.
ASSOCIATION BETWEEN PLASMA OSMOLALITY AND CASE FATALITY WITHIN ONE YEAR FOLLOWING SEVERE ACUTE ISCHEMIC STROKE

Meng Liu¹, Lun Deng¹, Yajun Cheng¹, Simiao Wu², Long Hao¹, Ming Liu²
¹Sichuan University, West China Hospital, Department Of Neurology, sichuan province, China, ²West China Hospital, Sichuan University, Neurology, Chengdu, China

Background and Aims:: Plasma osmolality, one of the markers of dehydration, is associated with cardiovascular mortality. We aimed to investigate whether elevated plasma osmolality is associated with case fatality within one year following severe acute ischemic stroke.

Methods:: We included severe ischemic stroke patients (defined as National Institutes of Health Stroke Scale ≥15 score) within 24 hours from symptom onset admitted to the Department of Neurology, West China Hospital between January 2017 and June 2019. Admission plasma osmolality was calculated using the equation 1.86*(sodium + potassium) + 1.15*glucose + urea +14. Elevated plasma osmolality refers to plasma osmolality >296mOsm/kg, which indicates a status of dehydration. The outcomes included 3-month and 1-year case fatalities. Multivariable logistic regression was performed to determine the independent association between plasma osmolality and case fatalities at different time points.

Results:: A total of 265 patients with severe acute ischemic stroke were included. The mean age was 71.2±13.1 years old with 51.3% being males. Among the included patients, case fatalities were 31.7% (84/265) at 3 months and 39.6% (105/265) at 1 year, respectively. Elevated plasma osmolality (dehydration) was associated with 3-month case fatality (1.98, 95% CI 1.07-3.66, P=0.029) but not 1-year case fatality (OR 1.51, 95% CI 0.84-2.72, P=0.165) after fully adjustment for confounding factors.

Conclusions:: Elevated plasma osmolality was independently associated with 3-month case fatality but not 1-year case fatality for severe acute ischemic stroke.
REVISITING THE CLASSICS: MIDBRAIN STROKE PRESENTING AS A WEBER SYNDROME

Rafaela Evangelista1, Ana Gomes2, Pedro Ribeiro2, Ilídia Carmezim2, Lénea Porto2, Aline Osuna2, Filipe Blanco3, Rui André2, Vera Ermida1, Bruno Lopes1, David Coutinho1, Elisa Moreira1, Andreia Silva1, Pedro Teixeira1, Jorge Caldas1, Ana Lemos2
1Tondela-Viseu Hospital Center, Physical Medicine And Rehabilitation Department, Viseu, Portugal, 2Tondela-Viseu Hospital Center, Medicine Department, Viseu, Portugal, 3Tondela-Viseu Hospital Center, Neurology Department, Viseu, Portugal

Background and Aims:: Pure midbrain infarcts are rare. Knowledge of the complex neuroanatomy of this region is key to understanding the varied spectrum of disease. We report a patient with well-recognizable Weber syndrome and remarkable imaging correlation.

Methods:: A case report and review of the literature.

Results:: A 73-year-old woman with hypertension, dyslipidemia and class II obesity, presented to the emergency department with a pupil-sparing III right cranial nerve palsy and grade 2 (Medical Research Council (MRC) scale) contralateral hemiparesis. The remaining neurological examination was normal. Thrombolysis was not performed, since it was a wake-up stroke. Initial head CT scan was negative for acute intracranial hemorrhage or ischemia. Head CT angiography excluded large vessel occlusion or relevant focal stenosis. A head MRI revealed a right anterior paramedian mesencephalic hyperintense T2 lesion, with restricted diffusion, suggesting a recent ischemic lesion (Figure 1). Transthoracic echocardiogram excluded structural pathology or intracardiac thrombi. Telemetry monitoring excluded dysrhythmias. After participating in a six-week rehabilitation program, she progressed to grade 4 (MRC scale) left hemiparesis (able to walk), maintaining III right cranial nerve palsy (Figure 2).
Conclusions: Distinguishing between classic midbrain syndromes can prove to be a diagnostic challenge even for skilled physicians. It is our belief that this report is of interest, showing the importance of a guided neurological examination, thorough understanding of neuroanatomy and advanced neurovascular imaging for lesion localization. Although significant improvement of the hemiparesis has occurred, recovery from a nuclear/fascicular palsy of the third cranial nerve is limited and has worse functional prognosis.
SEVERE REFRACTORY REVERSIBLE CEREBRAL VASOCONSTRICTION SYNDROME: THE OPTION OF INTRA-ARTERIAL VASODILATORS

Sean Freeman¹, Nicolas Bricout², Nelly Dequatre-Ponchelle¹, Charlotte Cordonnier³, Laurent Puy¹
¹University of Lille, Inserm, CHU Lille, U1172 - Lilncog - Lille Neuroscience & Cognition, Lille, France, ²CHRU de Lille, Interventional Neuroradiology, Lille, France, ³Lille university hospital, Neurology & Stroke Centre, Lille, France

Background and Aims:: Reversible cerebral vasoconstriction syndrome (RCVS) is a cerebrovascular disorder associated with multifocal arterial constriction and dilation. Given the lack of data, the management of RCVS is challenging especially for medically refractory forms. We report the case of a 59-year-old woman with severe RVCS complicated by ischemic stroke and diffuse cerebral hypoperfusion despite optimal medical treatment. Combined endovascular infusion of nimodipine and milrinone was beneficial for the patient's radiological and clinical outcomes, suggesting that dual chemical angioplasty is an interesting option in medically refractory RCVS.

Methods:: Following clinical deterioration after optimal medical treatment, we opted for intra-arterial vasodilatory treatment. DSA revealed severe bilateral multifocal vasoconstrictions of the intracranial arteries. A 50 mL syringe containing 6 mg of nimodipine (0.2 mg/mL) and 8 mg of milrinone (1 mg/mL) diluted in isotonic saline solution was prepared for chemical angioplasty. Endovascular application of nimodipine and milrinone was equally distributed in each internal carotid artery by an infusion pump for 15 minutes at an infusion rate of 100 mL/hour. Mean arterial pressure was maintained with adjunct administration of noradrenaline.

Results:: The patient presented gradual neurological improvement in our stroke unit by recovering normal mentation and demonstrated only right-sided brachiofacial hemiplegia and minimal aphasia. CT angiography before discharge showed no irregularities of the intracranial arteries.

Conclusions:: The patient reported a reduction in headache severity and the neurological deficit improved dramatically after therapeutic IADSA. Although the efficacy of endovascular treatments will require further investigation, the use of intra-arterial therapy could be considered in severe and medical refractory RCVS cases.
Background and Aims: Reversible Cerebral Vasoconstriction Syndrome (RCVS) associated with drug treatment has rarely been reported in aplastic anemia. We report a case of drug naive aplastic anemia patient presenting with RCVS.

Methods: Case report of a 50 year old lady with pancytopenia and RCVS who on subsequent evaluation was diagnosed to have aplastic anemia.

Results: A 50 year old lady presented with three day history of headache followed by bilateral dimness of vision and right hemiplegia. She had fatigue, tiredness and dyspnea on exertion for past 2 months. She was detected to have pancytopenia with a hemoglobin of 3g/dL. She had received four packed cell transfusions, the last one three weeks back. On admission, she had cortical blindess and right hemiplegia. Hemoglobin was 7g/dL, total leucocyte count was 3000/mm3 and platelet count was 15000/mm3. MRI Brain showed multiple bilateral infarcts involving frontal, occipital areas and external watershed territories of ACA-MCA and MCA-PCA. Hemorrhage was noted in the left parietal area. MRA showed vasospasm involving distal basilar, bilateral middle cerebral and posterior cerebral arteries. A diagnosis of RCVS was made and she was treated with oral nimodpine and magnesium sulphate injection. Bone marrow biopsy was suggestive of aplastic anemia. She was started on antithymocyte globulin and cyclosporine (caution regarding worsening with cyclosporine was explained). Bone marrow transplantation was suggested however due to financial constraints she cannot afford it. A repeat MRA done 3 weeks later showed reversal of vasospasm of basilar artery.

Conclusions: A rare case of RCVS in drug naive aplastic anemia is reported. Multiple transfusions might have been the trigger for RCVS. Fact that steroids and cyclosporine may worsen RCVS is a management challenge.
AI IMPROVES STROKE DIAGNOSIS AND CARE AT A LOW RESOURCE HOSPITAL IN INDIA

Ujjwal Upadhyay¹, Jemin Webster², Swetha Tanamala¹, Sasank Chilamkurthy¹, Satish Golla¹, Justy Antony Chiramal¹
¹Qure.ai, Research And Development, Mumbai, India, ²Baptist Christian Hospital, Medicine, Tezpur, India

Background and Aims:: Delay in patient arrival and diagnosis due to limited resources and high patient burden is a key challenge in management of stroke cases. A study was conducted at Baptist Christian Hospital (BCH), India which suffers from a well-known lack of resources and specialists. The study tested the effectiveness of AI solutions to assist low-resource hospitals in LMICs with time-sensitive stroke cases. This abstract suggests AI as a means to improve quality and outcomes to enhance the delivery of healthcare.

Methods:: AI solution (qER) was developed to report abnormalities given a non-contrast CT (NCCT). qER compiles findings into a detailed report highlighting abnormalities, indicating affected brain region along with estimated volume for bleeds. These findings coupled with clinical symptoms helps identify stroke. qER was made accessible by integrating with messaging app enabling notification to be sent about critical diagnosis. This platform further helps in administering medication for the patient in a short time.

Results:: Starting from February 2021 until May 2021, 588 patients were treated with the novel AI based workflow described above. We analyzed 104 consecutively selected patients in the month of February. On average, patients presented 4.5 hrs after the onset of symptoms. Compared to before, novel workflow experienced a reduction of 15-60minutes in the diagnosis phase.

Conclusions:: In stroke cases, qER can help reduce diagnosis time and can guide the treating doctors. qER aims to reduce Door-to-Needle time with intervention via instant reports and phone alerts.
Background and Aims:: Recent studies reported the efficacy of mechanical thrombectomy (MT) alone compared to bridging therapy with intravenous thrombolysis in acute ischemic stroke (AIS) with large vessel occlusion (LVO). This investigation focuses on thrombi composition to gain more insights into the issue.

Methods:: Thirty-seven LVO AIS patients (pts.) who were given either bridging therapy or MT, were studied.

Results:: Twenty-three pts. underwent combined treatment and 14 isolated treatment (MT). Recanalization was achieved in all but two pts., with a good outcome in 29 pts. A slight prevalence of white thrombi, with a greater fibrin load and a lower red blood cell (RBC) component was observed, but with an almost overlapping distribution in both procedures. vWF expression was higher in pts. treated with combined treatment, in line with fibrin load. Statistics: both procedures led to a favourable outcome: P<0.001; no association between fibrin load, RBC load and type of treatment, either isolated or combined, was found: P > 0.05 (MWT). A correlation was observed between collateralization and MT: P = 0.037 (χ²T).

Conclusions:: The study reveals the low thrombolytic efficacy of r-tPA and highlights a more pronounced collateralization in the isolated treatment, probably ascribable to lower thrombus porosity. Given the unproven superiority of TM, the results obtained suggest that further studies are required on thrombi as well as additional research on successful thrombolytic treatments also using adjuvant factors such as antiplatelet or anticoagulants agents, at different doses, antibodies neutralizing pro-thrombotic factors, Adamts-13 enzymes and Nets, nanobodies and novel ultrasound.
KNOWLEDGE OF STROKE RISK FACTORS AMONG THE PATIENTS WITH PREVIOUS STROKE OR TRANSIENT ISCHEMIC ATTACK IN A TERTIARY CARE HOSPITAL OF BANGLADESH

Md Rashedul Islam¹, Tanbin Rahman², Mohammad Sakhawat Hossen Khan¹
¹BIRDEM General Hospital, Neurology, Dhaka, Bangladesh, ²Dhaka Medical College, Hematology, Dhaka, Bangladesh

Background and Aims:: Patients of stroke or transient ischaemic attacks (TIA) are at risk of further stroke. Our objective was to study patients admitted with stroke/TIA regarding their knowledge about risk factors for having a new event of stroke/TIA, possible associations between patient characteristics and patients’ knowledge about risk factors, patients’ knowledge about their preventive treatment for stroke/TIA.

Methods:: A questionnaire was used for 200 patients with stroke/TIA diagnoses. We asked 13 questions about diseases/conditions and lifestyle factors known to be risk factors and four questions regarding other diseases/conditions (“distractors”).

Results:: The risk factors that were most often identified by the patients were Diabetes(75.9%), hypertension(83.3%), previous stroke or TIA(81.5%), smoking(85.2%), regular exercise(75.9%), older age(83.3%), overweight(75.9%) and patients with ischemic heart disease (70.4%). Atrial fibrillation and carotid stenosis were identified by less than 50% of the patients. 44.5% of the patients could identify 10 or more stroke/TIA risk factors. We observed that higher age, having a diagnosis of cerebral infarction/TIA, patients residing in urban area, high income group, businessman/retired service holder, family history of cardiovascular disease, past history of stroke / TIA were related to better knowledge of stroke/TIA risk factors. Only 20(9.3%) of the patients who reported anticoagulants and 76(35.2%) of the patients taking antiplatelets marked them as intended for prevention.

Conclusions:: Knowledge about diabetes, hypertension and smoking as risk factors was good, and patients who suffered from atrial fibrillation or carotid stenosis seemed to be less informed about these conditions as risk factors. Individuals with less knowledge should be given special consideration when developing strategies.
THE EFFICACY OF NEWER NEUROPROTECTIVE AGENT EDARAVONE DEXBORNEOL COMBINED WITH ALTEPLASE ON ACUTE ISCHEMIC STROKE

L.B. Zhang¹, D.H. Wang¹, W. Zhang¹, Y.Q. Dong¹, R.S. Chen¹, F.Y. Hu², J.Z. Yu¹, J. Hu¹, L.X. Zuo¹, Y.S. Sun³
¹The NO.1 Affiliated hospital of Shanxi Datong University, Neurology, Datong, China, ²Affiliated People's Hospital of Shanxi Medical University, Neurology, Taiyuan, China, ³School of Medicine, Datong University, Neurology, Datong, China

Background and Aims:: Edaravone Dexborneol, as a newer multi-target neuroprotective agent, was approved to treat patients with acute ischemic stroke (AIS). The study that efficacy of Edaravone Dexborneol combined with thrombolytic agent alteplase on AIS is less at present. Aims: To observe the clinical efficacy and safety of Edaravone Dexborneol combined with alteplase in the treatment of AIS.

Methods:: 80 patients with AIS were divided into control group (n=40, edaravone combined with alteplase treatment) and study group (n=40, Edaravone Dexborneol combined with alteplase treatment), according to random number table method. The National Institutes of Health Stroke Scale (NIHSS) scores, modified RANKIN Scale (mRS) scores, serum tumor necrosis factor-α (TNF-α) and interleukin-1β (IL-1β) levels before and after treatment, hemorrhagic transformation and adverse reactions during the treatment were compared between two groups.

Results:: The total effective rate of the study group was 87.50% (35/40), which was higher than 67.50% (27/40) of the control group (P<0.05). The NIHSS scores, mRS scores, serum TNF-α and IL-1β levels in two groups were significantly reduced after treatment, and those in the study group were lower than those in the control group (P<0.05). The incidence of hemorrhagic transformation of the study group was 2.50%, which was lower than 15.00% of the control group (P<0.05).

Conclusions:: Edaravone Dexborneol combined with alteplase on AIS has definite effect. It can effectively improve the neurological function, inhibit hemorrhagic transformation, and reduce the level of cytokines.
COMBINATION OF BLOOD BIOMARKERS AND STROKE SCALES IMPROVES IDENTIFICATION OF LARGE VESSEL OCCLUSIONS

Edoardo Gaude
Pockit diagnostics Ltd, Clinical Science, Cambridge, United Kingdom

Background and Aims:: Acute ischemic stroke caused by large vessel occlusions (LVO) is the main contributor to stroke deaths and disabilities; however, a tool for triaging LVO patients with confidence is yet to be implemented. In this study we combined the measurement of blood biomarkers with stroke severity scales with the aim of evaluating their diagnostic accuracy for LVO identification.

Methods:: 151 patients with suspected stroke, including stroke mimics, TIAs, haemorrhagic, and ischemic strokes were recruited retrospectively. We analysed the plasma levels of a panel of selected biomarkers in LVO vs non-LVO. Diagnostic performance for LVO identification was estimated by using blood biomarkers alone or in combination with NIHSS-derived stroke severity scales.

Results:: Among 151 patients, 31 (20%) were stroke mimics, 16 (11%) had transient ischemic attack, 16 (11%) had hemorrhagic stroke, 23 (15%) had LVO ischemic stroke, 42 (28%) had non-LVO ischemic stroke, and 23 (15%) had ischemic stroke of unknown origin. Multivariable analysis found that combining two blood biomarkers with stroke scales significantly improved LVO prediction, compared to the stroke scales alone (p-value<0.001). The combination of biomarkers with FAST-ED or EMSA scales resulted in the highest diagnostic performance for LVO identification, achieving an AUC of 95% (95% CI 91-100%) or 93% (CI 95% 89-97%), a sensitivity of 91% (95% CI 71-98%) or 86 (95% CI 66-97%), and a specificity of 95% (95% CI 89-98%) or 94% (95% CI 88-98%), respectively.

Conclusions:: The combination of blood biomarkers and stroke scales can provide a simple and highly accurate tool for identifying LVO patients.
OUTCOME OF THROMBOLYSIS WITH TENECTEPLASE IN STROKE: PRELIMINARY EXPERIENCE IN A TERTIARY CARE CENTRE IN NORTH INDIA

Alex Rebello¹, Manoj Goyal¹, Vivek Lal¹, Chirag Ahuja², Manish Modi¹
¹Postgraduate Institute of Medical Education and Research (PGIMER), Neurology, Chandigarh, India, ²Postgraduate Institute of Medical Education and Research (PGIMER), Neuroradiology, Chandigarh, India

Background and Aims:: Recombinant tissue-type plasminogen activator (rtPA) is the only FDA approved treatment for thrombolysis in acute ischemic stroke. Tenecteplase, a modified form of rtPA has advantages of lesser cost, ease of administration, longer half-life, and greater fibrin specificity.

Methods:: This was a prospective observational study conducted in PGIMER, a tertiary care centre in India, in acute ischemic stroke patients treated with tenecteplase and alteplase from July 2017 to September 2018. The primary outcomes were improvement in NIHSS scores at 24hours and 1week post thrombolysis or at discharge and functional outcome in terms of mRS at 3months. The safety outcomes were symptomatic intracerebral hemorrhage(SICH) and mortality at 3months.

Results:: There were 39 patients who received tenecteplase and 39 patients who received alteplase. 33.3% patients in tenecteplase group and 41% patients in alteplase group had improvement in NIHSS score by ≥4 or improvement to NIHSS 0 or 1 at 7 days after thrombolysis, or at discharge whichever was earlier(OR: 0.72;CI= 0.29-1.81;p=0.320). Excellent outcome (mRS score of 0-1) at 3-month follow-up was seen in 15.8% patients in tenecteplase group and 38.2%patients in alteplase group(OR: 0.30;CI= 0.10-0.92;p=0.03). Functional independence (mRS 0-2) at 3-month follow-up was seen in 31.6% patients with tenecteplase and 44.1% patients with alteplase(OR: 0.58;CI=0.22-1.53;p=0.27). SICH was significantly higher with alteplase than tenecteplase. Mortality at 3months was 31.6% in tenecteplase and 17.6% in alteplase groups(HR:2.15;CI=0.71-6.58;p=0.27), however, the difference was not statistically significant.

Conclusions:: Tenecteplase was almost as effective as alteplase and safer. It stands as a potential solution for many barriers in thrombolysis especially in resource-limited settings.
EVALUATION OF THE "PARTNERSHIP CARE MODEL" ON QUALITY OF LIFE AND ACTIVITY OF DAILY LIVING IN PATIENTS WITH A CEREBROVASCULAR ACCIDENT

Fateme Hasandoost¹, Eesa Mohammadi¹, Hossein Mozhdehipanah²
¹Tarbiat Modares University, Nursing, Tehran, Iran, ²Bouali Hospital -Qazvin University of Medical Science, Clinical Research Development Unit, Tehran, Iran

Background and Aims:: Stroke is a chronic disease with high incidence nowadays, constituting a major public health problem. Annually, 15 million people suffer a stroke worldwide. Stroke rehabilitation requires a sustained and coordinated effort from a large team, including the patient, family and friends, physicians, nurses, and etc. Partnership Care Model, increases involvement, motivation and responsibility of people. The purpose of this study was to evaluate the effect of Long-Term Care Program based on the Partnership Care Model on quality of life in patients with Stroke.

Methods:: This study was randomized clinical trial conducted in Bouali hospital at Qazvin University of Medical Sciences, Iran. The sample size for each group was 40. After assessment and recording basic information (demographic variables, care requirements and problems highlighted in the first step of PCM), the program had two phases: (i) an educational partnership meeting; (ii) a follow-up partnership meeting. SS-QOL instrument was used. Data was analyzed using SPSS 17.

Results:: An increasing trend was observed in the mean scores of quality of life of patients in the intervention group (P-value < 0.05). Before the intervention, the difference between the means in the two groups was small and was not statistically significant, but 3 and 6 months after the intervention. A significant difference between drug use and quality of life three months after the intervention (P = 0.012).

Conclusions:: PCM-based programs may increase patients' quality of life, motivation for life, and participation in treatment and care processes. Since health care requires theoretical knowledge and a prescriptive model, the PCM based on partnership care theory is more effective for chronically ill patients.
ANALYSIS OF FACTORS AFFECTING STROKE-ASSOCIATED PNEUMONIA AT MOHAMMAD HOESIN GENERAL HOSPITAL PALEMBANG

Achmad Junaidi¹, Andika Okparasta¹, Erial Bahar², Rizki Amelia¹
¹Dr. Moh. Hoesin General Hospital Palembang, Neurology, Palembang, Indonesia, ²Faculty of Medicine Sriwijaya University, Metodology, Palembang, Indonesia

Background and Aims:: Background: Pneumonia is one of the complications that frequently occurs in stroke patients. The incident in stroke patients happens after the first week of stroke and specifically within the first 3 days of hospitalization in 10% of patients and had a highest risk in the prevalence of dysphagia, immobility, loss of consciousness, and severe stroke. Pneumonia in stroke could prolong the hospitalization period, increase the mortality, and increase the cost for medical treatment. Aim: to find out about the risk factor that affects the occurrence of pneumonia in stroke patients.

Methods:: This study is analytic observational with the prospective cohort approach from June - August 2020. The sample consists of ischemic and hemorrhage stroke that fulfill the inclusion and exclusion criteria. This research will observe the occurrence of pneumonia in hospitalized stroke patients from the onset of the third day until the seventh day.

Results:: From a total of 50 subjects, 10 subjects suffered pneumonia. The onset of pneumonia occurred the most are day three until day five with a total of 8 subjects. There are risk factors found to be related to pneumonia are dysphagia (p= 0.003) with OR= 18.6 and A2DS2 score (p= 0.005) with OR= 13.5. In multivariate analysis, dysphagia is the only risk factor that caused the occurrence of pneumonia (p= 0.061) with OR= 9.143 and the probability of 53%.

Conclusions:: Dysphagia is the main risk factor for the occurrence of stroke-associated pneumonia.
ASSOCIATION OF CHANGED SERUM BRAIN BIOMARKERS WITH PERIHEMATOMAL EDEMA AND EARLY CLINICAL OUTCOME IN PRIMARY ICH PATIENTS

Mahtab Ramezani¹, Leila Simani², Ehsan Karimalavijeh³, Ehsan Mohammadi²
¹Shahid Beheshti University of Medical Sciences, Loghman Hakim Hospital, Neurology, Tehran, Iran, ²Shahid Beheshti University of Medical Sciences, Skull Base Research Center, Tehran, Iran, ³Tehran University of Medical Sciences, Emergency Medicine, Tehran, Iran

Background and Aims: Perihematomal edema (PHE) following primary intracranial hemorrhages (ICH) affects the patient outcome. Also, serum biomarkers such as S100 calcium-binding protein B (S100B) and glial fibrillary acidic protein (GFAP) have been associated with ICHs outcome. We aimed to investigate the association between these biomarkers and PHE in ICH patients.

Methods: In this cross-sectional study, patients with primary ICH between January 2020 and August 2020 were evaluated. All participants underwent spiral brain CT scans upon admission, and 48 to 72 hours later and quantification of initial hematoma volume was performed. Serum level of Matrix metalloproteinase-9 (MMP-9), vascular endothelial growth factor (VEGF), GFAP, and S100B on admission were measured by enzyme-linked immunosorbent assays. Acute clinical outcome was assessed by the modified Rankin Scale (MRS), national institute of health stroke scale (NIHSS), and ICH score.

Results: Thirty-seven ICH patients (21 patients with a favorable outcome and 16 unfavorable) were studied. Compared with survival patients, non-survivor patients showed a higher serum level of MMP-9, VEGF, GFAP, and S100B (p<0.05). Scores of absolute PHE, edema expansion distance, and PHE growth rate in the non-survivor group were higher than the survivors (p<0.001). The regression model revealed that MMP-9, VEGF, ICH score, and hematoma volume were associated with the PHE growth rate. S100B and ICH score were associated with edema expansion distance.

Conclusions: Our data showed that the serum level of molecular biomarkers was associated with higher PHE volume and PHE scores were higher in non-survival patients, suggesting it may have a pathogenic role in developing PHE after ICH.
FACTORS AFFECTING THE OUTCOME OF DELAYED INTRAVENOUS THROMBOLYSIS (>4.5 HOURS)

Nada Elsaid1,2, Guido Bigliardi1, Maria Luisa Dell’Acqua1, Laura Vandelli1, Ludovico Ciolli1, Livio Picchetto1, Giuseppe Borzi1, Riccardo Ricceri2, Roberta Pentore1, Stefano Vallone1, Stefano Meletti1, Ahmed Saied1,2
1Ospedale Civile di Baggiovara, AOU di Modena, Stroke Unit – Neurology Clinic, Department Of Neuroscience, Modena, Italy, 2Mansoura University, Neurology Department, Mansoura, Egypt

Background and Aims:: Evidence of the intravenous tissue plasminogen activator (tPA) efficacy beyond the 4.5 hours window is emerging. We aim to study the factors affecting the outcome of delayed thrombolysis in patients of acute ischemic stroke (AIS).

Methods:: Data of patients with AIS who received intravenous thrombolytic after 4.5 hours were reviewed including demographics, risk factors, clinical and laboratory data, stroke classification, vascular distribution, evidence of mismatch, treatment type and onset, National Institutes of Health Stroke Scale (NIHSS) score at baseline, 24 hours, 7 days after thrombolysis and before discharge, modified Rankin Scale (mRS) 3 months after discharge & hemorrhagic transformation (HT).

Results:: We report 136 patients treated by intravenous tPA between 4.53 and 19.75 hours of onset with average duration of 5.7 h. Early neurological improvement after 24 hours occurred in 114(83.8%) patients. After intravenous tPA, the average NIHSS significantly decreased from 6 at admission to 3 after 24 hours, 2 after 7 days, and 1 at discharge (p < .00001). Twenty patients (14.7%) had HT. At 90 days, 91 (67%) achieved good outcome (mRS0–2), while 45 patients (33%) had bad outcome (mRS3-6). Age, endovascular treatment, NIHSS, AF, and HT were significantly higher in the bad outcome group. Age (P=0.001, OR:1.099, 95%CI:1.042-1.160) and baseline NIHSS were predictive of the poor outcome (P=0.002, OR:1.151, 95%CI:1.055-1.256).

Conclusions:: Increased age and admission NIHSS may adversely affect the outcome of delayed thrombolysis and narrow the eligibility criteria. Age and baseline NIHSS based stratification of the patients may provide further evidence as regards the efficacy of the delayed thrombolysis.
RECOVERY OF SPEECH AFTER SUFFERING A STROKE

Aziz Umirov
Tashkent Medical Academy, Treatment, Tashkent, Uzbekistan

Background and Aims:: The aim of this study was to examine the recovery of speech after suffering a stroke.

Methods:: Materials and methods. We studied 28 people who had suffered a stroke in the neurology department at the TMA. After suffering a stroke, the patients were followed up for 6 months, they were divided into 2 groups. Of 28 (100%) patients, 16 (65%) patients underwent individual speech therapy according to the Pimsler method. The remaining 12 (35%) patients underwent rhythmic transcranial magnetic stimulation.

Results:: As a result of speech therapy according to the Pimsler method and rhythmic transcranial magnetic stimulation, an improvement in speech recovery was noted in the first three months, subsequently the effectiveness of the measures carried out for rhythmic transcranial magnetic stimulation significantly improved than with speech therapy. Current results indicate that 16 patients who received rhythmic transcranial magnetic stimulation were more effective. Their speech recovered within 6 months. In 11 of these patients, speech recovered by 88%, in one it recovered by 60%, and in the remaining 2 patients, speech recovered by 76%.

Conclusions:: It was found that in the recovery period of a stroke, aphasia regresses both due to the activation of the zones immediately surrounding the infarction zone or remote areas of the speech dominant left hemisphere of the brain, and due to the compensatory reorganization of symmetrical structures of the right hemisphere (homologues of the speech zones).
PREVALENCE, SEVERITY AND PREDICTORS OF POST-STROKE DEPRESSION IN A PROSPECTIVE COHORT OF JORDANIAN PATIENTS

Majdi Al Qawasmeh1, Belal Aldabbour1, Samah Elamassie2, Amal Abuabada1, Khalid Abdelrahman1, Mohammad Zahran1, Mays Khweileh1, Ahmed Alhusban3, Haneen Qasim4, Mohammad Nofal4, Khalid El-Salem1

1Jordan University of Science and Technology Faculty of Medicine, Neuroscience, Irbid, Jordan, 2United Nations Relief and Works Agency (UNRWA), Health Services, Gaza, Palestinian Territory, Occupied, 3Jordan University of Science and Technology, Clinical Pharmacy, Irbid, Jordan, 4Jordan University of Science and Technology, Faculty Of Medicine, irbid, Jordan

Background and Aims:: Post-stroke depression (PSD) is the most frequent neuropsychiatric complication of stroke, and it is a significant risk factor for poor functional outcomes and lower quality of life. This study aims to assess the prevalence and severity of PSD and its predictors in Jordanian stroke survivors.

Methods:: A prospective study that enrolled 151 patients with ischemic or hemorrhagic stroke, who were admitted to a tertiary teaching hospital. Demographic data, clinical characteristics on admission, and other relevant study variables were collected. Additionally, stroke outcome was represented by one-month modified Rankin score (mRS) and Barthel Index (BI) scores. Depression screening was performed on admission and after one and three months using the PHQ-9 questionnaire. Prevalence of PSD after one and three months was reported. Logistic regression analysis was conducted to evaluate for significant predictors.

Results:: Depression was reported by 15%, 24.83%, and 17.39% of respondents on admission and after one and three months respectively. Severity increased with time as severe depression was found in 0.71%, 2.13%, and 6.52% of respondents on admission and after one and three months respectively. The second and third questions of PHQ-9 questionnaire were most likely to receive high scores. Significant predictors of PSD were having chronic kidney disease, current smoking status, moderate or severe disability (mRS score) at stroke onset, and severe dependency (BI) after one month (p values 0.007, 0.002, 0.014, and 0.031 respectively).

Conclusions:: One in four Jordanian stroke survivors experienced PSD after one month, while PSD severity increased with time up to three months after stroke.
LEFT ATRIAL ENLARGEMENT AND LONG-TERM RISK OF THROMBOEMBOLIC STROKE AFTER ST-SEGMENT ELEVATION MYOCARDIAL INFARCTION

Surenjav Chimed\textsuperscript{1}, Nandin-Erdene Enkhbaatar\textsuperscript{2}
\textsuperscript{1}Sor Clinic, Department Of Cardiology, Ulaanbaatar, Mongolia, \textsuperscript{2}Mongolian National University of Medical Sciences, Department Of Radiology, Ulaanbaatar, Mongolia

Background and Aims:: ST-segment elevation myocardial infarction (STEMI) causes adverse cardiac remodeling, such as left ventricular (LV) and atrial (LA) chamber dilation, which can induce thrombus formation and subsequent ischemic stroke in this patient population. In this study, we evaluated the association between LA enlargement and long-term risk of having ischemic stroke in patients with STEMI.

Methods:: We chose patients with STEMI who have been treated with primary percutaneous coronary intervention. Two-dimensional (2D) echocardiography was used to evaluate LA volume during admission and indexed to body surface area (LAVi). First thromboembolic stroke after index STEMI was chosen for study endpoint. Spline curve estimation was used to evaluate association between LAVi and risk of having thromboembolic stroke.

Results:: A total of 525 patients were chosen (mean age 60±13, male gender 84.8%). Occurrence of thromboembolic stroke was 1.1\% (n=6) during median follow-up of 27 months (IQR 13; 41). Spline curve estimation showed that LAVi more than 35ml/m\textsuperscript{2} is associated with increased risk of having thromboembolic stroke after index STEMI (Figure 1A). Based on this threshold value, patients were divided into 2 groups. Kaplan-Meier estimation revealed that patients who had LAVi more than 35 ml/m\textsuperscript{2} were had significantly lower event free survival rate compared to patients with LAVi less than 35
ml/m^2 (Figure 1B).

Conclusions: The LA enlargement after STEMI is a strong predictor of long-term thromboembolic stroke and patients with LAVi more than 35 ml/m^2 have significantly event free survival rate.
CLINICAL AND ETIOLOGICAL PROFILE OF PATIENTS WITH CEREBRAL VENOUS THROMBOSIS IN A TERTIARY CARE CENTRE

Siddhesh Rajadhyax¹, Vikram Huded²
¹Nirmal Hospital, Neurology, Surat, India, ²Narayana Health City, Neurology, Bangalore, India

Background and Aims:: Aim: To study clinico-etiological factors associated with Cerebral Venous Thrombosis (CVT) in adults and to study factors that influence outcomes in our tertiary care centre.

Methods:: Sample size and technique: 1619 patients with symptoms consistent with CVT evaluated for presence of CVT. 90 cases with a confirmed diagnosis of CVT were included after written and informed consent. Inclusion criteria were age > 18 years and confirmed diagnosis CVT. Exclusion criteria were age < 18 years, those who refused consent for enrolment and arterial strokes. Data collection technique and analysis: A predefined proforma was used to collect data which included demographic profile, clinical profile, imaging findings, routine investigations, investigations specific for etiology of CVT. Outcome was assessed at discharge and at 3 months using the modified Rankin Scale (mRS). Descriptive analyses and comparisons were done for various sub-groups. Significance was assessed at 5 % level of significance.

Results:: 1. The percentage of patients with CVT was 5.55%. CVT was more common in males and average age of 69.9% patients was 36 years. 2. The most common clinical features were headache and seizures. Most common risk factors found were Thrombophilia, Hematological disorders, Idiopathic causes. 3. Endovascular treatment was associated with non-inferior outcomes as compared to medical management. 4. 92.2% patients had a good outcome at discharge and 96.7% at 3 months.

VALUE OF GLASGOW COMA SCALE AS A PREDICTOR OF SURVIVAL AFTER DECOMPRESSIVE CRANIECTOMY FOR MIDDLE CEREBRAL INFARCTION

Dewa Lal, Depal Attanayake
National Hospital of Sri Lanka, Neurosurgery, Colombo, Sri Lanka

Background and Aims: Infarctions of the middle cerebral artery territory increases intracranial pressure rapidly due to ischaemic oedema, often requiring surgical decompression. This study evaluates the value of Glasgow Coma Scale as a predictor of the survival following decompressive craniectomy for Infarctions of the middle cerebral artery territory.

Methods: 21 patients who underwent decompressive craniectomy for Infarctions of the middle cerebral artery territory within 24 hours of the incident were included in the study. Patients with age above 60 years, with severe co-morbidities and with GCS of 15 were not subjected to surgery as a unit policy. Survival and disability based on modified Rankin scale (mRS) were analyzed.

Results: Patients were 08 females and 13 males of 32 to 56 years of age. They were stratified into three groups based on the preoperative GCS. None of the 09 patients with GCS 3 – 8 were survived. 04/08 patients with GCS 9 – 12 and 03/04 patients with GCS 13 – 14 were survived. All survivors of GCS 9 – 12 categories had unfavorable outcome (mRS > 4). 03 survivors of the GCS 13 – 14 categories had favorable outcome (mRS < 3).

Conclusions: GCS 9 is the predictive cut off value for survival in our study group. Therefore, considering the poor survival and unfavorable prognosis, cost of care and clinical work load, decompressive craniectomy for the middle cerebral infarction with GCS less than 09 can’t be rationalized.
A COST-BENEFIT ANALYSIS OF MECHANICAL THROMBECTOMY GENERATED VIA A "BRAIN ATTACK" PROTOCOL

John Rothrock, Allison Koutsandreas
George Washington University, Neurology, Washington, United States of America

Background and Aims:: The advent of mechanical thrombectomy for acute ischemic stroke has produced a paradigm shift in our management of stroke. While mechanical thrombectomy per se appears to represent a cost-effective treatment intervention, the cost-benefit associated with implementation of a thrombectomy-relevant "brain attack" protocol is not as well documented. Purpose of research: To examine selected direct costs and clinical outcome associated with routine use of a thrombectomy-relevant brain attack protocol

Methods:: For a period of 1 year (2020) we prospectively evaluated a consecutive series of patients treated according to our institution’s brain attack protocol. We recorded the frequencies with which RAPID CT perfusion, CT angiography (CTA), catheter-based cerebral arteriography and mechanical thrombectomy were performed and calculated the direct costs associated with those procedures. Assuming a number needed to treat (NNT) of 4 to achieve a positive clinical outcome (i.e., functional independence) from mechanical thrombectomy, we calculated the mean direct cost required to achieve a thrombectomy-related positive clinical outcome.

Results:: We evaluated 412 brain attack patients. RAPID CT perfusion and CTA were performed in 189 cases (46%), catheter-based cerebral arteriography in 41 (10%) and mechanical thrombectomy in 23 (5.6%). The associated direct cost totaled $1.027 million. Applying an NNT of 4 to the 23 patients undergoing mechanical thrombectomy, the mean cost of achieving a positive outcome was approximately $170,000.

Conclusions:: By ICER criteria, these findings suggest that aggressive use of a thrombectomy-relevant brain attack protocol may represent a borderline cost-effective intervention for acute ischemic stroke.
CEREBRAL ISCHEMIC EVENTS IN PATIENTS WITH ATRIAL FIBRILLATION TREATED WITH ORAL ANTICOAGULANTS

Yasuhiro Manabe, Yumiko Nakano, Motonori Takamiya, Hisashi Narai
National Hospital Organization Okayama Medical Center, Neurology, Okayama, Japan

Background and Aims:: This study aimed to evaluate the cerebral ischemic events in patients with atrial fibrillation treated with oral anticoagulants.

Methods:: We studied 92 consecutive patients with atrial fibrillation (AF) who had acute cerebral ischemic events during oral anticoagulants admitted from January 2015 to July 2019 in our hospital. Corresponding controls (n=13) were selected based on AF patients without cerebral ischemic events more than five years during oral anticoagulants. We examined the age, gender, risk factors (current smoker, hypertension, diabetes mellitus, hyperlipidemia, myocardial infarction, history of stroke, congestive heart failure, renal failure, CHA2DS2-VASc score), and oral anticoagulants.

Results:: 46% cases of acute cerebral ischemic events were treated with non-vitamin K antagonist oral anticoagulants (NOACs). Other cases were treated with warfarin. The percentages of female, history of stroke, congestive heart failure, CHA2DS2-VASc score more than 4, and CHA2DS2-VASc score were significantly higher in cases of acute cerebral ischemic events.

Conclusions:: The percentages of female, history of stroke, congestive heart failure, and high CHA2DS2-VASc score might be associated with acute cerebral ischemic events during oral anticoagulants.
PROGNOSTIC VALUE OF NEUTROPHIL LYMPHOCYTE RATIO IN ACUTE ISCHEMIC STROKE PATIENTS EITHER RECEIVED REPERFUSION THERAPY OR NOT

Amira Mohieyeldeen
faculty of medicine, Neuro-emergency, quesna, Egypt

Background and Aims:: Very few studies have investigated the specific relationship between (NLR) and the short-term prognosis of patients with (AIS) and receiving intravenous thrombolysis. This study aimed to investigate whether a high NLR is associated with a poor outcome in patients with AIS and after receiving r-tPA.

Methods:: This study was prospective and included 50 patients admitted with clinical picture and C.T finding of AIS in the ED at Menoufia University hospital. clinical data for all patient were recorded,CBC test was taken on admission NLR was calculated,Neuroimaging like C.T brain and MRI if available was done.Initial stroke severity was evaluated by (GCS), (NIHSS) score and (mRS) then was re-evaluated later after 24 hours of admission and after one month.

Results:: Among the 56 patients enrolled, the mean age of the study population was 62 (35–90) years,40 patients did not receive rt-PA ,37.5 % of them (15 patients) had a good prognosis . their NLR on admission was 2.9±0.7. And 55% of these patients (22 patients) had abad prognosis . their NLR on admission was 10.1±2.7 on the other side the 16 patients who received r-tPA ,68.7% of them (11 patient) had agood prognosis their NLR on admission was 3.3±1.7 and 31% of these patients (5 patients) had abad prognosis their NLR on admission was7.04±1.1.

Conclusions:: Our results confirm that elevated NLR on the hospital admission is an easy and strong predictor of poor outcomes in AIS patients either receiving reperfusion therapy or not.
DOES GENDER DIFFERENCE MATTER IN CEREBRAL VENOUS THROMBOSIS?

Jayantee Kalita, Usha Misra, Varun Singh

1SANJAY GANDHI POST GRADUATE INSTITUTE OF MEDICAL SCIENCES, Neurology, LUCKNOW, India, 2Vivekananda Polyclinic and Institute of Medical Sciences, Neurology, LUCKNOW, India, 3Institute of Medical Science, Banaras Hindu University, Neurology, Varanasi, India

Background and Aims:: There may be gender difference in clinical, imaging findings and outcome of cerebral venous thrombosis (CVT) because of female specific risk factor (FRSFs). We compare the non-FRSF, clinicoradiological severity and outcome in CVT in males and females, and also compare these parameters in female patients with and without FSRFs.

Methods:: 172 patients were included from a prospectively maintained CVT registry. The diagnosis was based on magnetic resonance venography (MRV). Clinical details, risk factors, MRI and MRV findings were noted. The risk factors in the females were categorized as FRSF only, FSRF in addition to other risk factor, non FSRF only and no risk factor groups. Outcome was defined at 6 months using modified Rankin Scale (mRS) as death, poor (mRS > 2) and good (mRS < 2).

Results:: 80 (46.5%) patients were females; 24 (30%) had FSRFs and 18 (75%) of whom also had other risk factors leaving only 6(25%) females with isolated FSRF. The frequency of other prothrombotic risk factors, clinical and imaging findings were similar in males and females except more frequent hyperhomocysteinemia in males (59% vs 41%; P = 0.036) and altered sensorium in females (66% vs 40%; P = 0.001). 17(9.9%) patients died, 12(7%) had poor and 143(83.1%) had good outcome. The outcomes were similar in both the gender, and in the females with and without FSRF.

Conclusions:: Isolated FRSF is rare in CVT, and there is no gender difference in terms of non FRSFs, clinicoradiological severity and outcome.
MEDIATION EFFECTS OF MEAN HOUNSFIELD UNIT ON RELATIONSHIP BETWEEN HEMOGLOBIN AND EXPANSION OF INTRACEREBRAL HEMORRHAGE

Yong Soo Kim¹, Han-Gil Jeong², Hee-Yun Chae³, Moon-Ku Han¹
¹Seoul National University Bundang Hospital, Neurology, Bundang-gu, Seongnam-si, Korea, Republic of, ²Seoul National University Bundang Hospital, Neurology, Neurosurgery, Bundang-gu, Seongnam-si, Korea, Republic of, ³Chungbuk National University Hospital, Neurology, Cheongju-si, Korea, Republic of

Background and Aims:: Low hemoglobin levels are known to be associated with hematoma expansion (HE) of intracerebral hemorrhage (ICH). However, it is not yet known whether low hemoglobin itself causes HE or is merely a confounder. Thus, we investigated the mediation effect of the mean Hounsfield unit (HU) of hematoma on the relationship between low hemoglobin and HE.

Methods:: Overall, 232 consecutive patients with ICH who underwent non-contrast computed tomography (NCCT) within 12 hours since onset were included. The mean HU and hematoma volume on NCCT were investigated using semi-automated planimetry. The respective associations among the hemoglobin level, mean HU, and HE were analyzed using multivariable regression analysis. Mediation analysis was performed to examine the potential causal association among the three.

Results:: HE occurred in 34.5% of patients; hemoglobin levels were inversely associated with HE (adjusted odds ratio, 0.89; p=0.02). The mean HU of the hematoma was lower in patients with HE than in patients without HE (58.5±3.3 vs. 56.8±3.0; p<0.01). Hemoglobin levels on admission were linearly related to the mean HU (adjusted β, 0.35; p<0.01) after adjusting for known HE predictors. Causal mediation analysis showed a significant mediation effect of the mean HU on the association between hemoglobin levels and HE (p<0.01). The proportion of indirect effect through the mean HU among the total effect was 37% (p=0.04).

Conclusions:: The mean HU of the hematoma fully mediated the association between hemoglobin levels and HE. The mean HU of the hematoma may be a robust marker of impaired hemostasis in patients with ICH.
REVERSIBLE CEREBRAL VASOCONTRACTION SYNDROME IN AMPHETAMINE ABUSE

Karthik Mahesh¹, Chirag Ahuja², Abeer Goel¹, Sukriya Saravanan¹
¹PGIMER, Neurology, Chandigarh, India, ²Postgraduate Institute of Medical Education and Research (PGIMER), Neuroradiology, Chandigarh, India

Background and Aims:: Background & Aims: Substance abuse and overdose are a common cause for morbidity and mortality in young healthy individuals. We describe a patient who presented with acute onset loss of consciousness, following IV amphetamine injection. He was diagnosed as RCVS (Reversible cerebral vasoconstriction syndrome) based on angiogram. He was treated with a course of IV steroids followed by complete recovery over 2 weeks.

Methods:: Methods: We present a case of young male with history IV amphetamine abuse followed by sudden loss of consciousness and seizures. On examination he was comatose GCS of E1M1Vt. The NCCT head revealed multiple intraparenchymal bleed and SAH. The CT angiogram revealed vasospasm of B/L MCA (Middle cerebral artery), VA (Vertebral artery) and Basilar artery. His urine toxicology for Amphetamine was positive. He was given Antiepileptics (Levetracitam 1gm/day) and was given 5 days of IV methylprednisolone 1 gm. The patient gradually improved over a period 1-2 weeks and was weaned of the ventilator and discharged.

Results:: The management of Amphetamine induced RCVS is still challenging. The role of steroids is limited to case reports and series.

Conclusions:: RCVS due to any cause especially amphetamine can be steroid responsive and may alleviate morbidity.
WAKE-UP STROKE (WUS) VERSUS STROKE WITH KNOWN ONSET TIME: CLINICAL AND BRAIN IMAGING CHARACTERISTICS AND TREATMENT OPTIONS

Erum Shariff, Danah Aljaafari, Aishah Albakr, Sari Subaihani, Saeed Aljubran, Noman Ishaque, Reem Alomar, Fahad Alkhamis, Abdulaziz Al-Sharydah, Mohammad Alshurem, Majed Alabdali

1King Fahd Hospital, Imam AbdulRahman Bin Faisal University, Neurology, Alkhobar, Saudi Arabia, 2King Fahd Hospital, Imam AbdulRahman Bin Faisal University, Radiology, Alkhobar, Saudi Arabia, 3King Fahd Hospital, Imam AbdulRahman Bin Faisal University, Community Medicine, Alkhobar, Saudi Arabia

Background and Aims:: To identify clinical and imaging characteristics on admission between WUS patients and awoke stroke patients. To correlate these findings to the possible mechanism of WUS.

Methods:: This is a prospective observational cohort study conducted at King Fahd Hospital of the University includes Acute Ischemic Stroke (AIS) presenting within five days of symptom onset, from April 2017 till March 2019. Patients were grouped into two groups; group 1: Wake-up Stroke (WUS); Group 2: awoke stroke. Comparative and correlative data analyses have been done. Descriptive statistics for continuous data have been reported as medians and interquartile ranges (IQRs) as it is a better representation of skewed data. Categorical data were compared mainly by Chi-squared tests and Fisher's Exact test where numbers were small between cells.

Results:: Among 645 patients, 448 patients fulfilling the criteria of AIS, included in the study. WUS was identified in 112 (25%). Median age was not different among the groups. There was no gender preponderance found between the two groups. Regarding comorbidities; DM, HTN, and Dyslipidemia was high in WUS group, compared to AF, history of stroke and epilepsy was more in awoke stroke group. Bihemispheric stroke was more in awoke stroke group (6% vs 2.7%; p-0.06).

Conclusions:: There were only minor differences between clinical and imaging characteristics of WUS and awoke stroke found. Circadian patterns of stroke onset were observed in all groups, stroke was more likely to occur during waking than during sleep and, in the diurnal period, during morning than during afternoon.
ACUTE IRON OVERLOAD AGGRAVATES BLOOD BRAIN BARRIER DISRUPTION AND HEMORRHAGIC TRANSFORMATION AFTER TRANSIENT FOCAL ISCHEMIA IN RATS WITH HYPERGLYCEMIA

Qian Wu¹, Siqi Guo², Junfeng Liu¹, Hengyi Xiao³, Yanan Wang¹, Yajun Cheng¹-⁴, Simiao Wu¹, Bo Wu¹, Ming Liu¹
¹West China Hospital, Sichuan University, Neurology, Chengdu, China, ²West China Hospital, Sichuan University, West China School Of Medicine, Chengdu, China, ³West China Hospital, Sichuan University, Lab For Aging Research, Center For Medical Stem Cell Biology, State Key Laboratory Of Biotherapy, Chengdu, China, ⁴Sichuan University, West China Hospital, Department Of Neurology, sichuan province, China

Background and Aims:: We aimed to verify whether acute intracerebral iron overload aggravates blood-brain barrier(BBB) damage and hemorrhagic transformation(HT) after transient focal ischemia in rats with hyperglycemia and deferoxamine(DFX) maintains the integrity of BBB and reduces a risk of HT.

Methods:: A hyperglycemia-induced HT model in middle cerebral artery occlusion(MCAO) rats were established. Animals were assigned to four groups: Sham, Vehicle, Iron overload and Iron chelator. Brain samples were collected at 24 hours after surgery to quantify the amount of hemorrhage, determine extravasation of Evans blue and IgG and detect the levels of following proteins: ferritin, metalloproteinase-9(MMP-9), zonula occludens-1(ZO-1), Occludin and Claudin-5 by western blot analysis and immunohistochemistry.

Results:: Compared to the Vehicle group, the Iron overload group had a significantly higher amount of hemorrhage and more extravasation of Evans blue and IgG. The Iron overload group had lower levels of ZO-1, Occludin and Claudin-5 and higher levels of ferritin and MMP-9 than the Vehicle group(all P<0.05). Administering DFX reduced the extension of hemorrhage and extravasation of Evans blue and IgG, reversed the MCAO-induced reduction of ZO-1, Occludin and Claudin-5 and decreased the levels of ferritin and MMP-9.

Conclusions:: Our results suggest that acute intracerebral iron overload aggravates BBB damage and HT after ischemic stroke, which provides evidence of ferritin as a potential biomarker determining iron overload status and predicting for BBB damage and HT. DFX has a remarkable effect of ameliorating iron overload, preserving BBB integrity and reducing HT, which might be a prospective neuroprotective drug for preventing HT after ischemic stroke.
AUTOMATED QUANTITATIVE ANALYSIS OF CEREBROVASCULAR REACTIVITY MEASURED BY ACETAZOLAMIDE SPECT FOR DETECTION OF ABNORMAL CEREBROVASCULAR TERRITORIES

Yeongbae Lee¹, Byungkwan Jung², Chang-Ki Kang³
¹Gil Medical Center, Gachon University College of Medicine, Neurology, Incheon, Korea, Republic of, ²Gachon University, College Of Medicine, Incheon, Korea, Republic of, ³Gachon University, Neuroscience Research Institute, Incheon, Korea, Republic of

Background and Aims:: Acetazolamide (ACZ) SPECT is a useful method to assess reduced brain perfusion but generally relies on subjective visual evaluation. This study quantitatively analyzed the distribution of voxel-based cerebrovascular reactivity (CVR) values to localize and classify the abnormal cerebrovascular territories by their severity.

Methods:: Sixty-seven acute stroke patients (39 males and 28 females) were subject to study, and their age was 39-90 (average 63.3). Nuclear medicine specialists recorded up to 4 brain regions with anomalies in the order of severity. Voxel-based CVR values were analyzed by regions to find out statistical characteristics of normal and abnormal cerebrovascular territories. Then, a machine learning method of Gaussian mixture model was used to differentiate the effects of abnormal microvessels from CVR values of a region.

Results:: Abnormal cerebrovascular territories, selected by nuclear medicine specialists, could be classified into two types (Figs. 1(a) and 1(b)). The CVR values within the first type of lesions (Fig. 1(a)) are lower than normal regions (Fig. 1(c)). In contrast, distribution of the second type of lesions (Fig. 1(b)) is similar to normal regions. Fig. 2 supports the assumption of microvascular abnormality within the second type of lesion. The machine learning could extract abnormal microvessels with low CVR value as shown in red box in Fig. 2(b) and 2(c).

Conclusions:: CVR values of abnormal cerebrovascular lesions could be classified into two groups using a machine learning method. The result suggests that CVR distribution of the second group, similar to normal regions, can occur as a result of abnormal microvessel.
CERVICOMEDULLARY CAVERNOUS HEMANGIOMA PRESENTING AS SPINAL SHOCK SYNDROME AND DYSFUNCTION: A CASE REPORT

Jenielyn Nazaire, Debbie Liquete
Baguio General Hospital and Medical Center, Neuroscience, Baguio City, Philippines

Background and Aims:: Cavernomas are rare congenital benign angiographically occult vascular malformations of brain accounting for 5-15% of all brain vascular malformations. A Cervico-medullary junction location is very rare, with only 8% cases being reported in the literature. This is a case report of a patient who presented with progressive and step-wise deterioration of spinal cord function and spinal shock syndrome. Pressure effects due to changing dynamics in the cavernous malformation resulted in mass effect over the spinal cord level as the possible mechanism. Treatment of patient with cavernous malformations of CMJ requires understanding of its natural history, local neurovascular anatomy including safe entry point to the brainstem, skull base approaches to cranio-vertebral junction and microsurgical techniques unique to its resection. This should be weighed with knowledge of the risks and indications for treatment as surgery itself causes significant morbidity.

Methods:: A case report

Results:: In this case report, the hemangioma was located at the caudal medulla extending to C4 region in the intramedullary location. but this was obscured by blood products at the time of initial imaging, making diagnosis difficult (Figure 1).
Magnetic resonance imaging was done three months after conservative management showing evidence of regression (Figure 3).

**Conclusions:** Cavernomas of brain stem and spine have more dynamic course than supratentorial cavernomas and should be considered for any case presenting as spinal shock and dysfunction. Surgery should be done only when there is appropriate indication, as surgery itself causes significant morbidity.
IMPACT OF THE FIRST STROKE ON PATIENTS AND CAREGIVERS: DEPRESSION PREVALENCE AND PREDICTORS IN A PROSPECTIVE COHORT FROM JORDAN

Belal Aldabbour¹, Majdi Al Qawasmeh¹, Samah Elamassie², Amal Abuabada¹, Khalid Abdelrahman¹, Mays Khweileh³, Mohammad Zahran¹, Haneen Qasim³, Malik Ikhaiwesh³, Mohammad Alhyasat³, Khalid El-Salem¹
¹Jordan University of Science and Technology Faculty of Medicine, Neuroscience, Irbid, Jordan, ²United Nations Relief and Works Agency (UNRWA), Health Services, Gaza, Palestinian Territory, Occupied, ³Jordan University of Science and Technology, Faculty Of Medicine, irbid, Jordan

Background and Aims:: Depression is an important neuropsychiatric complication in stroke survivors. Caregivers are susceptible to increased social and emotional burdens and a high risk for depression.

Methods:: This prospective study included 108 dyads of first-stroke survivors and their caregivers. Demographic data, clinical characteristics and other relevant variables were collected. Stroke outcome was represented by one-month modified Rankin (mRS) and Barthel Index (BI) scores. Depression screening was performed for patients and caregivers on admission and after one month using the self-reported PHQ-9 questionnaire. Changes in prevalence and severity of depression were calculated. Logistic regression analysis was conducted to evaluate for significant predictors of depression in both groups.

Results:: A total of 88 patients responded to both screenings, while 101 and 96 caregivers responded to the first and second screenings, respectively. Depression was reported by 9.09% and 23.87% of patients on admission and after one month, while the prevalence among caregivers was 8.91% and 15.62%, respectively. The increase in the numerical continuous variable for caregiver PHQ9 scores was significant (p 0.022). Significant predictors of patient PSD were the length of hospitalization (P 0.048) and caregiver depression (P 0.034). Predictors of caregiver depression were female caregiver gender (p 0.033), higher patient disability after a month (P 0.004), higher initial stroke severity (P 0.032), and caring for a patient with post-stroke depression (P 0.023).

Conclusions:: Both stroke survivors and their caregivers are at high risk of depression. Early recognition of this complication is important to improve outcomes and mitigate the negative impacts of stroke.
Background and Aims:: About 10- 15%of all ischemic strokes occur in young adults ,limited researches have specifically addressed stroke in the young, also, the etiology of ischemic stroke in the young are heterogeneous and can be relatively uncommon the purpose is to identify different risk factors of stroke in young.

Methods:: consecutive 29 patient with acute ischemic stroke in young adults were admitted to neurology department, Sohag university hospital were compared to elderly group

Results:: prevalence of Rheumatic heart disease is common in young adult ,hypertension is the most prevalent vascular risk factor.

Conclusions:: Rheumatic heart disease still prevalent in young adult in a sample of Egyptian population, hypertension is the most important modifiable risk factor,Scandinavian stroke scale on admission is a predictor of hospital mortality in young adults with acute ischemic stroke.
DYNAMICS OF RECOVERY OF COGNITIVE AND NEUROLOGICAL FUNCTIONS IN PATIENTS WITH PRIMARY AND RECURRENT ISCHEMIC STROKE IN ULYANOVSK REGION.

Rizida Sharafutdinova1, Imil Khairullin2
1Ulyanovsk State, Internal Medicine, Ulyanovsk, Russian Federation, 2Ulyanovsk State University, Internal Medicine, Ulyanovsk, Russian Federation

Background and Aims:: According to WHO statistics repeated strokes develop during the 1st year in 35% of patients and are significantly more likely to lead to disability and death. Aim. To compare degree of impairment and dynamics of cognitive and neurological functions in patients with primary ischemic stroke (IS) in VBB and patients with IS in VBB, having acute cerebral blood circulation disorders.

Methods:: 52 patients aged 39-87 years were examined in the most acute (1 day) and acute (10 days) periods of IS in VBB, 23 of them had primary IS, and 29 patients had acute cerebral blood circulation disorders. Neurological functions were investigated using the NIHSS-scale, CT-data and other laboratory and instrumental methods. Cognitive abnormalities were identified using MMSE and MOCA-test (Mann-Whitney U-test criterion was applied). The differences were considered valid when significance of p<0.05 was significant. The results are presented in form of arithmetic mean and standard deviation (M±s).

Results:: The average age of patients who underwent first IS was 60.87±11.81 years, and average age of patients with repeated IS was 61.62±11.59 years. When analyzing the data, reliable results (p<0.01) were obtained that in acute period of time patients with repeated IS had more pronounced cognitive disturbances and lower dynamics of their recovery than patients who had suffered IS for first time. Also, patients with repeated IS had more pronounced neurological deficits on both 1 day and 10 days than patients with IS for first time.

Conclusions:: Patients with repeated ischemic stroke have more pronounced cognitive and neurological impairments than patients with first time ischemic stroke. In addition, patients with repeated stroke have lower rates of recovery of cognitive and neurological function than patients with primary stroke.
ELECTRIC MYOCARDIAL INHOMOGENEITY AND STROKE: CONNECTION AND SPECIFICS.

Rizida Sharafutdinova¹, Imil Khairullin²
¹Ulyanovsk State, Internal Medicine, Ulyanovsk, Russian Federation, ²Ulyanovsk State University, Internal Medicine, Ulyanovsk, Russian Federation

Background and Aims:: The inconsistency of literature data on influence of different hemispheric localization of Cerebrovascular accident (CVA) on development of cardiac arrhythmias suggests expediency of further study of so-called “zones” of cerebral cortex associated with electrical instability of myocardium. It is known that dispersion of QT interval and fragmented myocardial activity belong to markers of electrical instability of heart and are associated with arrhythmogenesis. Aim of study. To study severity of abnormalities of parameters of electrical instability of myocardium in right and left hemispheric stroke localization in patients with hypertension.

Methods:: 111patients with left hemispheric localization of ischemic stroke and 75patients with right hemispheric stroke were examined. Hemorrhagic stroke was observed in 17patients in left hemisphere and in 13patients in right hemisphere. The average age was58,2±7,48years. For all strokes, men prevailed (64%vs.36%). For first day of stroke, all patients were evaluated for QT dispersion and fragmented myocardial activity on device "Polyspectro-8EX"(Russia).

Results:: Evaluation of the parameters of electrical instability of myocardium in patients with stroke revealed more pronounced disorders in hemorrhagic stroke of left hemispheric localization (Table 1). In ischemic stroke, the severity of electrophysiological parameters, reflecting the instability of the myocardium depending on the hemispheric localization, indicates the absence of differences.

Conclusions:: Conclusions. 1. The most pronounced disturbances in the parameters of electrical stability of the myocardium is observed in hemorrhagic stroke. 2. The severity of myocardial electrical instability in ischemic stroke is not associated with the localization of the focus.
STRUCTURAL-ELECTRICAL REMODELING OF MYOCARDIUM IN NEUROLOGICAL DEFICITS IN PATIENTS WITH ISCHEMIC STROKE: IS THERE A CONNECTION?

Rizida Sharafutdinova1, Imil Khairullin2
1Ulyanovsk State, Internal Medicine, Ulyanovsk, Russian Federation, 2Ulyanovsk State University, Internal Medicine, Ulyanovsk, Russian Federation

Background and Aims:: Theoretical and clinical questions of correlation between structural-electrical remodeling of heart and severity of neurological deficits at stroke have not been developed or remain controversial so far. Aim. To study peculiarities of structural-electrical remodeling of myocardium with severity of neurological deficit in patients with ischemic stroke (IS).

Methods:: 111 patients with IS in left and 75 patients in right brain hemispheres were examined. The average age was 56.7 ± 5.58 years. All subjects underwent an ultrasound examination of heart using ALOKA-SSD5000 apparatus (Japan) and QT-dispersion using Polyspectro-8 EX apparatus (Russia). Duration of QT-dispersion interval more than 50 ms was considered pathological.

Results:: Structural remodeling of heart in patients with IS was manifested by prevalence of high values of finite-systolic volume of LV in comparison with patients without stroke (45.8 ± 21.0 vs 37.7 ± 16.9 ml; p < 0.05), and finite-diastolic volume of LV (114.3 ± 38.5 vs 100.9 ± 35.3 ml; p < 0.05), mainly in right hemispheric localization of stroke. Hypertrophy of ventricular septum (11.3 ± 2.1 mm) and the posterior wall of LV (10.4 ± 1.8 mm) was observed irrespective of localization of stroke, which was higher in comparison with patients without stroke (9.4 ± 1.5 mm). Violations of repolarization processes and their severity were characterized by higher values of duration of the corrected QT-interval in patients with structural changes of myocardium in comparison with patients without structural remodeling (0.46 ± 0.03 vs 0.44 ± 0.02 sec; p = 0.025). The conjugation of severity of neurological deficit (7+ points on NIHSS-scale) was associated with terminal-systolic size of LV (p = 0.025) and myocardial hypertrophy (11.3 ± 1.86 vs. 10.96 ± 1.8 mm; p = 0.04) in comparison with patients with neurological deficit < 7 points (31.7 ± 3.6 vs. 30.68 ± 3.86 mm; p < 0.025). The severity of neurological deficit according to Goldstein-criteria correlated with higher values of corrected (56.0 ± 23.93 vs 41.6 ± 23.3 ms; p = 0.043) and normalized QT (17.5 ± 6.53 vs 12.8 ± 6.7 ms; p = 0.019) values in comparison with lower neurological deficit. A similar relationship was revealed by Brott-criteria.

Conclusions:: Thus, direct connection between structural-electrical remodeling of heart and neurological deficit revealed in course of study reflects cardiocerebral relationships in IS.
ASSOCIATION BETWEEN IL1RN GENE POLYMORPHISMS AND POST-STROKE INFECTION

Hae-Yeon Park¹, Hyun-Mi Oh², Tae-Woo Kim², Youngkook Kim³, Geun-Young Park⁴, Cheolki Kim⁴, Hye Mi Hwang⁴, Sun Im⁴
¹Seoul St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Department Of Rehabilitation Medicine, Seoul, Korea, Republic of, ²National Traffic Injury Rehabilitation Hospital, Yangpyeong, Republic of Korea, Department Of Rehabilitation Medicine, Yangpyeong, Korea, Republic of, ³Yeouido St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea, Department Of Rehabilitation Medicine, Seoul, Korea, Republic of, ⁴Bucheon St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Department Of Rehabilitation Medicine, Bucheon, Korea, Republic of

Background and Aims:: Many genes may affect the outcome of stroke. Interleukin-1 receptor antagonist (IL-1ra) is an endogenous immunomodulatory cytokine encoded by IL1RN on chromosome 2. Elevated plasma IL-1ra is known to predict infection early after stroke, and polymorphisms in IL1RN may influence post-stroke infection risk. However, the role of IL1RN polymorphism on post-stroke infection is controversial. This study aimed to explore whether genetic polymorphism in IL1RN is associated with the risk of post-stroke infection in post-stroke dysphagia patients.

Methods:: A total of 218 subjects were enrolled in the study, and genotyping for IL1RN rs4251961 was carried out. Infection events (aspiration pneumonia, urinary tract infection, colitis, etc.) and the history of complications (admission to intensive care unit, history of intubation, septic shock, etc.) were recorded.

Results:: Data from 206 participants were available for final analysis. The baseline characteristics of patients with and without the minor C allele of the rs4251961 are shown on Table 1. There were no significant differences in age, sex, stroke type, diabetes, hypertension, atrial fibrillation, and coronary heart diseases between the patients with and without minor C allele. Post-stroke infection risk also did not show significant differences between two groups (Table 2).

</table>
Conclusions:: Genetic polymorphism of IL-1RN failed to effectively reflect the post-stroke infection risk in post-stroke dysphagia patients. The risk of post-stroke infection may be affected by multifactorial reasons. Further long-term studies and studies of other genetic polymorphisms on infection are warranted. *This work was supported by the National Research Foundation of Korea(NRF) grant funded by the Korea government(MSIT) 2017R1C1B5017926.
ANTERIOR CIRCULATION LARGE VESSEL OCCLUSION STROKE IN SAUDI ARABIA: PREVALENCE, PREDICTORS, AND OUTCOME

Mohammed Aldriweesh¹, Ali Al Khathaami², Bayan Albdah³, Muath Alhasson⁴, Sultan Alsaif⁵, Waleed Alluhidan⁶, Faisal Almutairi⁷, Mohammed Alskaini⁷, Naser Alotaibi⁷, Saeed Alghamdi⁸

¹King Saud bin Abdulaziz University for Health Sciences, College Of Medicine, Riyadh, Saudi Arabia, ²King Abdulaziz Medical City, Ministry of National Guard Health Affairs, Division Of Neurology, Department Of Medicine, Riyadh, Saudi Arabia, ³King Abdullah International Medical Research Center, Department Of Biostatistics And Bioinformatics, Riyadh, Saudi Arabia, ⁴Qassim University, Unaizah College Of Medicine, Unaizah, Saudi Arabia, ⁵Almaarefa College, College Of Medicine, Riyadh, Saudi Arabia, ⁶Imam Muhammad bin Saud Islamic University, College Of Medicine, Riyadh, Saudi Arabia, ⁷King Abdulaziz Medical City, Ministry of National Guard Health Affairs, Riyadh, Kingdom of Saudi Arabia, Division Of Neurology, Department Of Medicine., Riyadh, Saudi Arabia, ⁸King Abdulaziz Medical City, Ministry of National Guard Health Affairs, Division Of Neurology, Department Of Medicine, Jeddah, Saudi Arabia

Background and Aims:: Anterior circulation Large Vessel Occlusion (LVO) stroke comes with significant morbidity and mortality. With the advent of endovascular interventions, its management has revolutionized. For health authorities to build systems and allocate resources, its burden, predictors, and outcome must be determined.

Methods:: We retrospectively collected data from 1,495 ischemic stroke patients in a single tertiary care center to determine anterior circulation LVO prevalence, predictors, and outcome. Patients must have radiologically proven ischemic stroke within 24 hours before arrival at the emergency department. An anterior circulation LVO stroke was defined as a new anterior circulation infarct detected on neuroimaging/vascular imaging confirming anterior circulation LVO. Data on demographics, vascular risk factors, treatment with reperfusion therapy, modified Rankin Scale (mRS) at admission, National Institute of Health Stroke Scale (NIHSS) at admission, length of stay (LOS) in days, and in-hospital comorbidities and death were collected.

Results:: We found anterior circulation LVO in 27.8% of all ischemic stroke patients. Atrial fibrillation and NIHSS at admission were the strongest predictors of LVO [OR 2.33, P = 0.0011 and OR 1.17, P < 0.0001] respectively. Occurrence of LVO was associated with worse disability score (mRS ≥ 3) [47.22 vs. 19.81% (P = 0.0073)], longer hospitalization in days [Median 9.0 vs. 3.0, P = 0.0432)], and was more likely to result in patient admission to the ICU [Mean 17.59 vs. 3.70 % (P = 0.0002)].

Conclusions:: Stroke with large vessel occlusion in Saudi Arabia is not uncommon. Its burden and outcome deserve national attention, as effective treatment is now readily available.
STROKE MIMICS: CLINICAL CHARACTERISTICS AND OUTCOME

Mohammed Aldriweesh¹, Ali Al Khathaami², Sultan Alsaif³, Bayan Albdah⁴, Muath Alhasson⁵, Wangde Alužidane⁶, Faisāl Almutairi¹, Jawaher Alotaibi⁷, Mohammed Alsaini²
¹King Saud bin Abdulaziz University for Health Sciences, College Of Medicine, Riyadh, Saudi Arabia, ²King Abdulaziz Medical City, Ministry of National Guard Health Affairs, Division Of Neurology, Department Of Medicine, Riyadh, Saudi Arabia, ³Almaarefa College, College Of Medicine, Riyadh, Saudi Arabia, ⁴King Abdullah International Medical Research Center, Department Of Biostatistics And Bioinformatics, Riyadh, Saudi Arabia, ⁵Qassim University, Unaizah College Of Medicine, Unayzah, Saudi Arabia, ⁶Imam Muhammad bin Saud Islamic University, College Of Medicine, Riyadh, Saudi Arabia, ⁷Princess Nourah Bint Abdul Rahman University, College Of Medicine, Riyadh, Saudi Arabia

Background and Aims:: Stroke mimics (SM) are often misdiagnosed as real stroke among patients who came to the emergency department with a sudden neurological deficit and negative neuroimaging. We aimed to study the prevalence and nature of stroke mimics among suspected stroke patients.

Methods:: We retrospectively reviewed all electronic health records of patients suspected of having a stroke in a single tertiary center. Also, we established a comparison between SM and stroke. Our study identified the predictors of SM by using logistic regression analysis.

Results:: Out of 1,063 patients, 131 (12.3%) had SM. The most common causes were peripheral vestibular disorder (27.4%), followed by psychogenic causes (24.4%). Stroke mimics were more common among younger individuals and women. Arterial hypertension, diabetes, and smoking were less likely to be found in SMs. At discharge, individuals with SM were more likely to be independent, had milder deficits, and shorter hospital stays. Predictors of SM were young age, female gender, mild deficit at presentation, and good functional status before the stroke.

Conclusions:: The incidence of stroke mimics is common among suspected stroke patients. Practicing physicians should consider potential diagnostic errors, especially in the hyperacute phase of the stroke. Stroke mimics should be suspected at a young age, mild deficit at presentation, and good functional status before the acute neurological deficit.
ASSOCIATION OF POSTERIOR DIVISION MCA STROKE LOCATION WITH POPULATIONAL INCIDENCE OF ATRIAL FIBRILLATION

Andreia Faria¹, Ganghyun Kim², Jeffrey Saver³, Argye Hillis⁴
¹Johns Hopkins University, Radiology, Baltimore, United States of America, ²Johns Hopkins University, Neuroscience, Baltimore, United States of America, ³UCLA, Neurology, Los Angeles, United States of America, ⁴Johns Hopkins University, Neurology, Baltimore, United States of America

Background and Aims:: Anatomical features of Middle Cerebral Artery (MCA) bifurcation favors larger emboli entering the posterior rather than anterior division[1]. As cardiac source emboli are on average larger than arterial source emboli, we hypothesize that groups with higher incidence of atrial fibrillation, a major cause of cardioembolic strokes, have more strokes in temporal and parietal lobes compared to frontal lobes. [1] Liebeskind DS, et al. Stroke.2000;31:294.

Methods:: From 1,878 patients admitted to the Johns Hopkins Stroke Center (2009- 2019) with evidence of acute or early subacute ischemic stroke (2-24h post-onset) on diffusion-weighted MRI (DWI), 482 affected exclusively the “lobar” MCA (sparing the lenticulostriates). They were classified as “frontal predominant” (n=106) if ≥75% of the stroke was in the frontal lobe, or “temporoparietal predominant” (n=220), by the same criterion. Two evaluators and a neuroradiologist defined the stroke in DWI. Differences between stroke location (frontal or temporoparietal), sex, and race-ethnicity were analyzed by Chi-square test.

Results:: The groups (frontal or temporoparietal strokes) were balanced in age and sex. Men were more likely than women to have temporoparietal strokes (74% vs 61%) versus frontal strokes (p=0.01). Similarly, white patients were more likely than black patients to have temporoparietal strokes (73% vs 58%) versus frontal strokes (p=0.01).

ULTRASOUND-GUIDED DIAGNOSIS OF AN UNCOMMON STROKE: A CASE OF GIANT CELL ARTERITIS

Sara Giannoni¹, Mariella Baldini¹, Elisa Cioffi², Elisa Grifoni², Elisabetta Bertini¹, Eleonora Cosentino², Cinzia Grisanti¹, Serena Colon¹, Leonello Guidi¹, Luca Masotti²
¹San Giuseppe Hospital, Department Of Neurology, Empoli, Italy, ²San Giuseppe Hospital, Internal Medicine, Empoli, Italy

Background and Aims:: Giant cell arteritis (GCA) is an immune-mediated vasculitis of large- and medium-sized vessels like superficial temporal arteries, extradural vertebral (VA) and carotid arteries (CA). Stroke happens in 3% to 7% of the cases and identifying GCA properly is important because potentially curative treatment exists.

Methods:: An 83-year-old woman had a sudden onset of postural instability and bilateral hypoacusia. Laboratory tests didn’t show significant pathological findings. TC-Angiography showed a filiform lumen of right VA and occlusion of V3-V4 segment of left VA, right AICA and left PICA. Brain MRI pointed out restricted diffusion lesions in bilateral cerebellar dentate nuclei, consistent with acute ischemic stroke (Figure 1).

Ultrasonography didn’t show relevant anomalies in CA; instead, VA presented an homogeneous, hypoechogenic and concentric dark area (the so-called “halo sign”) around the lumen of the bilateral V2 segment (Figure 2).
The uncommon stroke localization and the ultrasound findings suggested vasculitic etiology of lesions, like GCA. So an ultrasound examination of the TA was performed and, interestingly, it highlighted the “halo sign” also in the bilateral temporal arteries. MR-angiography confirmed the previous intracranial vascular findings. Finally, the patient performed a 18FDG-PET which highlighted increased FDG uptake of inflamed vertebral artery walls.

**Results:** Patient was treated with a high dose of iv steroids and oral antiplatelet therapy, with improvement of clinical status.

**Conclusions:** In our patient clinical diagnosis of GCA was challenging due to limited classical symptoms. Arguments in favor of arteritis were the symmetric involvement of the VA, the sonographic halo sign and atypical stroke localization.
PROSPECTIVE PILOT STUDY TO ASSESS MOTOR ACTIVITY AND THE STATE OF THE HEMOSTASIS SYSTEM IN THE ACUTE PERIOD OF ISCHEMIC STROKE DURING SYSTEMIC THROMBOLYTIC THERAPY

Yaroslava Havlovska
UMSA, Neurology, Kremenchug, Ukraine

Background and Aims:: To investigate changes in motor activity and indicators of the state of the hemostasis system in the acute period of ischemic stroke during systemic thrombolytic therapy (sTLT) and without its use.

Methods:: We examined 26 male and female patients with a clinical diagnosis of ischemic stroke, who were hospitalized on the first day of the disease to the neurological departments. Patients were divided into 2 groups: group 1 - patients who underwent sTLT (n = 11), group 2 - patients who did not receive sTLT (n = 15). To compare the coagulogram parameters, 12 healthy patients were examined (control group). Examination of patients was performed on the 1st and 14th day of the disease (clinical examination, assessment of motor activity, coagulation test). Stroke severity was determined by the overall score of the National Institutes of Health Stroke Scale.

Results:: The average age of patients in group 1 - 60.1 ± 8.2 years old, in group 2 - 61.3 ± 5.5 years old. The number of points on the NIHSS scale in group 1 was 8.8 ± 1.13 on the 1st day and 3.7 ± 0.79 on the 14th day (p < 0.05), in group 2 - 5.7 ± 0.94 on the 1st day and 3.1 ± 0.93 on the 14th day (p < 0.05). The results of the study of the coagulogram indicate a significantly higher level of soluble fibrin-monomer complexes on the 1st day on the 14th day of the ischemic stroke.

Conclusions:: In the acute period of ischemic stroke changes in the hemostasis system reflected the direction of the selected therapy. The use of systematic thrombolytic therapy in ischemic stroke led to a more severe decrease in stroke severity on the NIHSS scale, a significant increase in Barthel index.
Background and Aims:: Babinski-Nageotte Syndrome (BNS) is one of the brainstem syndromes presenting with classic Wallenberg findings with associated contralateral motor deficit. Based on our literature review, only few cases have been reported and none of them was due to aneurysmal compression of the medulla oblongata. This paper aims to present a case of a 42-year old Filipino male, married, construction worker who manifested with sudden onset of severe headache with associated vertiginous dizziness, dysphagia, dysphonia, nausea, vomiting, and right extremity numbness and hemiparesis.

Methods:: Magnetic Resonance imaging (MRI) was done revealing no evidence of acute territorial infarct or hemorrhage, and Cranial CT Angiography and Digital Subtraction Angiography showed an unruptured fusiform aneurysm of the left vertebral artery (VA) involving the proximal intracranial segment.

Results:: The clinical and radiologic evidence were consistent with a left vertebral fusiform aneurysm compressing on the medulla and clinically manifesting as Babinski-Nageotte Syndrome.

Conclusions:: Diseases of the vertebral arteries result to neurologic symptoms through different mechanisms. Direct medullary compression should be highly considered for certain patients manifesting with symptoms that are gradual and persistent. It is important to have a high index of suspicion for the presence of certain arteriopathies such as aneurysm as it can be a potential mechanism for ischemic injury by generating pressure on perforating branches. This case of Babinski-Nageotte Syndrome resulting from medullary compression from a vertebral artery aneurysm may pave way to better understand this rare disease and its corresponding treatment approach based on the mechanism of disease evolution.
COGNITIVE IMPAIRMENTS AND VASCULAR ENDOTHELIAL DYSFUNCTION IN UNILATERAL OCCLUSION OF THE CAROTID ARTERY

Sergey M. Gulyaev
Institute of General and Experimental Biology, Siberian Branch of the Russian Academy of Sciences, Laboratory Of Experimental Pharmacology, Ulan-Ude, Russian Federation

Background and Aims:: The study was aimed at determining cognitive impairments, vascular endothelial dysfunction and alterations of neurons in brain structures in unilateral occlusion of the common carotid artery.

Methods:: The experiments were carried out on Wistar rats. The animals were divided into two groups: 1 – the control group composed of sham-operated rats, 2 – rats with cerebral ischaemia. The model of cerebral ischaemia was reproduced by occlusion of the left common carotid artery. Cognitive functions in rats were assessed by means of the object recognition test and conditioned passive avoidance response. The degree of vascular endothelial dysfunction was evaluated by the number of circulating endotheliocytes and concentration of nitric oxide in plasma. Morphological studies of the brain were carried out by means of light microscopy.

Results:: It was determined that unilateral occlusion of the carotid artery in rats resulted in memory impairment revealed by cognitive tests. Cerebral ischaemia induced an elevated level of circulating endotheliocytes and a decrease of nitric oxide (p≤0.05). Morphological study demonstrated signs of vasoconstrictive reactions, microvascular endothelial oedema, as well as an increase number of damaged neurons localized in the neocortex and hippocampus on the ipsilateral side as compared with the controls (p≤0.05).

Conclusions:: Unilateral occlusion of the common carotid artery in rats resulted in cognitive impairments, damage of neurons in the neocortex and hippocampus predominantly on the ipsilateral side. Cognitive impairments and ischaemic lesions of the brain are induced by endothelial dysfunction, enhanced desquamation of endotheliocytes and prevalence of vasoconstrictive reactions resulting from decreased production of the nitric oxide.

This research was funded by the Ministry of Education and Science of Russia, grant number - 121030100227-7
HEMORHEOLOGICAL EFFECT OF HERBAL EXTRACT IN CEREBRAL ISCHEMIA-REPERFUSION

Sergey M. Gulyaev
Institute of General and Experimental Biology, Siberian Branch, Russian Academy of Sciences,
Laboratory Of Experimental Pharmacology, Ulan-Ude, Russian Federation

Background and Aims:: The aim of this study was to determine hemorheological and neuronal disorders in cerebral ischemia-reperfusion and to assess the neuroprotective effect of a complex herbal extract (Astragalus membranaceus, Scutellaria baicalensis, Phlojodicarpus sibiricus).

Methods:: Male Wistar rats were divided into three groups: sham group; ischemia-reperfusion group and herbal extract group. Cerebral ischemia-reperfusion model was induced by occlusion of common carotid arteries for 5 min followed by reperfusion for 72 h. We investigated the effect of herbal extract at a dose of 100 mg/kg on erythrocyte deformability, blood viscosity, and hemostasis parameters. After experiments, rats were euthanized and the brain was taken for histological analysis.

Results:: In rats with cerebral ischemia-reperfusion, as compared to sham, erythrocytes and trombocytes aggregation, blood viscosity were increased and erythrocyte deformability were decreased, (p<0.05). These hemorheological alterations were present in duaring 72 hrs. In rats with cerebral ischemia-reperfusion, herbal extract improved all of the above parameters (p<0.05). Cerebral ischemia-reperfusion in rats (no treated) caused injuries in the brain. The herbal extract exerted a neuroprotective effect.

Conclusions:: The results show that even short-term ischemia-reperfusion of the brain leads to hemorheological and neuronal disorders, which can be largely corrected by herbal extract. The data obtained indicate that the herbal extract has a neuroprotective effect by regulating hemorheological parameters. Thus, extract is a promising stroke prevention agent.

This research was funded by the Ministry of Education and Science of Russia, grant number - 121030100227-7.
NOTCH3 NEGATIVE CADASIL: A CASE REPORT

Muhammad Hassan¹, Muhammad Qureshi², Nuno Lobatoribeiro³
¹Worcester Royal Hospital, Stroke Unit, KEIGHLEY, BRADFORD, United Kingdom, ²Worcester Royal Hospital, Stroke Unit, Worcester, United Kingdom, ³Worcestershire Acute Hospital NHS Trust, Stroke Medicine, Worcester, United Kingdom

Background and Aims:: CADASIL is a rare disease diagnosed mainly after genetic testing of NOTCH3 mutation on chromosome 19. >170 mutations have been found till now. However, it can still be diagnosed in patients who have no NOTCH3 mutation provided they have characteristic signs and symptoms with recurrent strokes, migraine, cognitive deficits, and neuropsychiatric issues complemented by typical MRI brain findings and suggestive family history.

Methods:: 50 year old male presented with classic migraine, recurrent TIAs and strokes, rapidly progressive decline in memory and executive function since age of 37 years. He had diabetes, hypertension, asthma, anxiety and depression. His father had stroke at age<60 and cousin of similar age had migraine, cognitive decline and recurrent strokes. His son in his 20s had migraine and psychiatric problems. MRI showed lacunar infarcts bilaterally involving basal ganglia, internal capsule, thalamus, pons, and subcortical areas in frontal, parietal and occipital lobes and multifocal micro-haemorrhages. Extensive stroke in young workup including MRA head and neck, ECHO, thrombophilia and vasculitis screen was unremarkable. However, NOTCH3 gene mutation test was negative.

Results:: He was discussed in MDT with neurologist, and neuroradiologist. It was decided he should be treated as NOTCH3 negative CADASIL. Referral was done to higher centre for second opinion and they agreed with our diagnosis.

Conclusions:: Some features are more frequent in CADASIL than NOTCH3 negative cases; however, these are not pathognomonic. CADASIL can be diagnosed clinically in absence of gene mutation. Further research is needed to find out NOTCH3 variants gene mutations that may be responsible in these patients.
IN HOSPITAL MORTALITY AND SHORT-TERM OUTCOME OF ACUTE ISCHEMIC STROKE PATIENTS CONTRACTING SARS COV-2 INFECTION: EXPERIENCE FROM A DEDICATED STROKE UNIT IN BANGLADESH

A T M Hasibul Hasan
National Institute of Neurosciences and Hospital, Neurology, Dhaka, Bangladesh

Background and Aims:: In this study we intended to evaluate the influence of COVID-19 on in hospital mortality and short-term outcome of acute ischemic stroke.

Methods:: This was a hospital-based case-control study from February to May 2021 conducted in stroke unit of National Institute of Neurosciences and Hospital. Fifty consecutive ischemic stroke patients contracting COVID-19 infection was considered as cases (group-B) and 99 similar patients, negative for SARS CoV-2 on RT-PCR from nasal swab were considered for control group (group-A) following the inclusion and exclusion criteria.

Results:: Diabetes and Multiple comorbid conditions and lymphopenia were significantly (p value of <0.001) more common in Group B (1% versus 22%, 28.3% versus 56% and 5.1% versus 54%) in contrast to Hypertension and lymphocytosis which was more frequent in Group A (42.4% versus 10% and 94.9% versus 46%). The patients in group B had a significantly (p value <0.001) higher NIHSS score at admission (median IQR 7 versus 13) and longer hospital stay (median IQR 6 days versus 14 days). There was no significant difference among the groups in mRS at discharge (median IQR 3) and at 30 days with a median IQR of 2. Male stroke patients are 4.7 times more likely to die in-hospital. The risk of mortality is 5 times higher among COVID positive stroke cases.

Conclusions:: Diabetes, Multiple comorbid conditions and lymphopenia are common association in COVID positive stroke cases. The risk of mortality is 5 times higher in COVID positive stroke cases and 4.7 times among the male.
Background and Aims:: Stroke is a global public health problem. In general, there are 2 types of stroke, ischemic accounting for 80% and hemorrhagic 20% of all strokes. Currently, the opposite of this epidemiological profile is observed in the Neurology Training and Research Unit (USFR) at the Befelatanana University Hospital Center (HUC).

Methods:: We have a descriptive retrospective study conducted at the USFR neurology, CHU Befelatanana from January 1, 2017 to December 31, 2017. We have included all records whose exit diagnosis is a stroke made up with clinical and radiological confirmation.

Results:: We selected 201 male-dominated patients, 55% of whom were hemorrhagic and 45% ischemic. The average age of 51.01 for hemorrhagic stroke and 58.58 years in ischemic stroke. Growers are most affected 26.37% (n=24) in ischemic stroke and 35.45% (n=39) of hemorrhagic strokes. The majority of patients live in urban and married settings. Ischemic stroke is predominantly of cardiac origin in 32.86% (n-29) while high blood pressure (HTA) is responsible for hemorrhagic strokes in 66.36% (n -73). The average National Institute of Health Stroke Score (NIHSS) is 15.17 in cerebral ischemia and 18.32 in cerebral hemorrhage. We have 43 deaths of which 17 (17.45%) hemorrhagic fever and 26 (28.57%) ischemic. Survivors after ischemic stroke have a Rankin score ≥ 3 and 45.16% (n=42) of hemorrhagic stroke have a severe disability with Rankin score ≥ 4.

Conclusions:: The prevalence of hemorrhagic stroke associated with high blood pressure is the main feature of this pathology at the Befelatanana University Hospital.
ASSOCIATION OF ELEVATED BODY MASS INDEX WITH MORTALITY FOLLOWING ACUTE ISCHEMIC STROKE: THE OBESITY PARADOX REVISITED

Alis Dicpinigaitis¹, Chirag Gandhi², Stephan Mayer³, Fawaz Al-Mufti³
¹New York Medical College, School Of Medicine, Valhalla, United States of America, ²New York Medical College, Neurosurgery, Valhalla, United States of America, ³New York Medical College, Neurocritical Care, Valhalla, United States of America

Background and Aims:: Previous literature has identified a survival advantage in acute ischemic stroke (AIS) patients with elevated body mass indices, a phenomenon termed the “obesity paradox”.

Methods:: Weighted discharge data from the National Inpatient Sample were queried to identify AIS patients from 2015-2018. Multivariable logistic regression and Cox proportional hazards modelling were performed to evaluate adjusted and time-dependent associations between obesity (BMI ≥ 30) and clinical endpoints after controlling for acute stroke severity and comorbidity burden.

Results:: Among 1,687,805 AIS patients, 216,775 (12.8%) were obese. Compared to non-obese individuals, these patients were younger (64 vs. 72 mean years), had lower baseline NIHSS scores (6.9 vs. 7.9 mean score), and a higher comorbidity burden. Multivariable analysis demonstrated independent associations between obesity and lower likelihood of mortality (adjusted odds ratio (aOR) 0.76, 95% CI 0.71, 0.82, p<0.001; hazard ratio (HR) 0.84, 95% CI 0.73, 0.97, p=0.015), intracranial hemorrhage (aOR 0.87, 95% CI 0.82, 0.93, p<0.001), and routine discharge to home (aOR 0.97, 95% CI 0.95, 0.99; p=0.015). Sensitivity testing to account for baseline NIHSS score extended confirmed these findings. Mortality rates between obese and non-obese patients were significantly lower across stroke severity thresholds, but this difference was attenuated among high severity (NIHSS>20) strokes (21.6% vs. 23.2%, p=0.358).

Conclusions:: This population-based, cross-sectional analysis demonstrates a lower likelihood of discharge to home as well as in-hospital mortality following AIS, suggestive of a protective effect of obesity against mortality but not against all post-stroke neurological deficits in the short term. This effect may be attenuated among strokes of high severity.
Background and Aims:: ABSTRACT
BACKGROUND: The incidence of Ischemic Stroke among young adult (16-50 years) is rising and is currently estimated to constitute up to 15% of all Ischemic Stroke, the prevalence of modifiable vascular risk factors for Stroke, such as Dyslipidemia, Smoking and Hypertension are highly prevalent in young population.
Methods:: this is a prospective Analytical Study
Results:: Clinical presentation was varying from Hemiparesis 62(98.6%), Hemiplegia 18(33.75%), Dysphasia 39(48.75%), Aphasia 23(28.75%), hemisensory loss 27(33.75%), Headache 7(8.75%), Visual disturbance 7(8.75%), Dysarthria 5(6.25%), seizures 5(6.25%), Disturbed level of Consciousness 4(5%) and Sphincteric disturbance 3(3.8%).
Conclusions:: CONCLUSION: Ischemic Stroke is common among young adult males Sudanese patients, Modifiable risk factors, such as Hypertension, Diabetes Mellitus, Dyslipidemia, Smoking and Obesity were increasing due to change of life style, Diet and lack of Exercise.
Background and Aims:: This study was conducted to clarify the risk factors of unfavorable early outcomes (UEO) in acute mild ischemic stroke (AMIS).

Methods:: Patients with AMIS, defined as a National Institute of Health Stroke Score (NIHSS) < 4 and admission within 48 hours after symptoms onset, were prospectively registered. A favorable outcome was defined as a modified Rankin Scale (mRS) of 1 or lower. Risk factors of UEO were analyzed.

Results:: From Sep 01, 2015 to April 30, 2020, 629 patients with AMIS were included. At discharge, 144 patients had UEO (22.9%). Patients with UEO were older (68.1 ± 13.2 vs 63.0 ± 13.4 years, p=0.000) and with higher prevalence of hypertension (85.4 vs 76.1%, p= 0.016), and higher initial NIHSS (2.1 ± 1.0 vs 1.1 ± 1.1, p=0.000). Blood tests showed lower platelets count (217.0 ± 75.5 vs 235.4 ± 85.0 k/cumm, p=0.005), higher casual plasma glucose (151.2 ± 74.5 vs 139.3 ± 67.8 mg/dl, p= 0.007), and higher high-sensitivity C-reactive protein (0.8 ± 2.0 vs 0.5 ± 1.4 mg/l, p=0.037) in patients with UEO. In addition, patients with UEO were less likely to have dual antiplatelets (aspirin and clopidogrel) at discharge. Multivariate analysis demonstrates that higher initial NIHSS (odd ratio, 2.12, 95% CI, 1.60-2.80, p=0.000) and no dual antiplatelets at discharge (odd ratio, 1.83, 95% CI, 1.01-3.31, p=0.046) are independent risk factors for UEO.

Conclusions:: Higher initial NIHSS score and no dual antiplatelets at discharge are independent risk factors for unfavorable early outcomes.
RECOVERY TO BE REPLACED WITH ARM USE.

Jebastin Immanuel, Vasanthan Rajagopalan
The Oxford college of Physiotherapy, Neurological And Psychosomatic Disorders, Bangalore, India

Background and Aims:: About 82% of the needs expressed by stroke survivors indicated that they had a substantial need for information and struggle with understanding their condition and treatment options. Studies show that patient knowledge deficits can be a barrier to exercise adherence, which is vital for improved health outcomes and functional independence. There is a need for identifying various knowledge domains and applying strategies to specifically target them to improve exercise adherence in stroke survivors. The aim of the study is to determine the extent to which experts in the field of Neuro Physiotherapy agree with various domains of knowledge deficit in stroke survivors pertaining arm dysfunction, intervention, contextual limitations and recovery options.

Methods:: We first conducted a literature review to identify knowledge constructs needed for promoting a behavior. We ran rounds of Delphi with 8 expert neurological physiotherapists involved in stroke rehabilitation. They identified domains of knowledge relevant to promoting affected arm use after stroke. Consensus was reached after 3 rounds of Delphi.

Results:: 4 knowledge constructs based on Theoretical domains framework were knowledge of effect of lack of arm use; rationale for arm use; procedural knowledge and facilitatory contexts for promoting arm use. Experts identified various subdomains in each of these domains.

Conclusions:: The subdomains identified can be used for educating stroke survivors to promote optimal affected arm use for recovery.
IMPACT OF DELIRIUM PERSISTENCE ON STROKE OUTCOMES

Gabriel Suzart, Catarina Secundino, Daniel Silva, Ivã Taiuan Fialho Silva, Juliana Fontes, Paulo Jesus, Pedro Assis Lopes, Silas Souza, Vinicius Leal Borges Da Cruz, Pedro Antonio Jesus
UFBA, Neurology, Salvador, Brazil

Background and Aims:: Delirium is a condition that usually resolves itself, but recent studies have shown its negative impact on long term prognosis. This phenomenon is not well studied in medical literacy, so we aim to evaluate the influence of delirium persistence on stroke outcomes.

Methods:: Prospective cohort of stroke patients with symptom onset within 72 hours of admission who developed delirium during hospitalization. Delirium was assessed daily by the Confusion Assessment Method in an Intensive Care Unit (CAM-ICU). When a patient had no delirium for 48h after a positive CAM-ICU, the delirium was considered to be resolved. However, when there was another positive delirium screening in this period, delirium was classified as persistent. We assessed a composite outcome of functional dependence (measured by Modified Rankin Scale > 2) and mortality in 90 days.

Results:: Out of 121 delirium patients, 95 were followed until discharge. Our sample’s mean age was 65.8 (± 15.7) years and the frequency of persistent delirium was 67.4%. Delirium persistence was associated with increased risk of death and functional dependence in 90 days compared to non persistence (84.4% versus 42.9%; Chi²=15.9; p<0.001). Multivariate analysis showed delirium persistence as independent predictor of worse outcome (OR=5.8 [95% CI, 1.7–20.2]; p<0.01), besides NIHSS on admission.

Conclusions:: Among stroke delirium patients, the persistence of this condition during hospitalization is frequent. This phenomenon seems to predict worse outcomes in this population. From what we gather, it's the first study to prospectively investigate the impact of delirium duration over functional outcome and mortality three months poststroke.
ELECTROCARDIOGRAPHIC CHANGES AND SERUM TROPONIN LEVELS IN PATIENTS WITH ACUTE STROKE, A PROSPECTIVE COHORT STUDY IN SUDAN

Etedal Ibrahim1, Salma Taha2, Khabab Mohamed Ahmed3, Mohammed Eltahier Omer4
1Al-Neelain University, Faculty Of Medicine, Khartoum, Sudan, 2The National centre for Neurological Sciences, Neurology, Khartoum, Sudan, 3University of Khartoum, Faculty Of Medicine, Khartoum, Sudan, 4Gadarif University Faculty of Medicine and Health Sciences - Sudan, Medicine, Omdurman, Sudan

Background and Aims:: Electrocardiographic changes and elevated serum troponin are frequent findings in acute stroke. They may reflect what is known as the neuro-genic myocardial injury. However, as stroke and cardiac disease share the same risk factors, Coexistence of the two is highly susceptible. Our aim to determine the electrocardiographic changes and serum troponin level in acute stroke patients and to correlate these changes to the anatomical location and pathological type of the stroke.

Methods:: A Prospective cohort study conducted at the national center of neurological Science, from January to December 2019. Study was done at the neurological center in Sudan, The National Center of Neurological sciences. All cases presented with acute stroke during the study period were included. Non-probability sample, with total coverage during study period. 50 patients were included in the study. Data were analyzed by using (SPSS) version 25. 12 standard ECG were performed in the first hours of admission. 2 samples from each patient were obtained for serum troponin with at least 8 hours apart.

Results:: All patients had wide variants of ECG changes. But tachycardia was the most frequent one identified in 54% of patients (27/50). Half of them were found to have an anterior circulation stroke. 14% of patients (7/50) have positive troponin, ECG changes identified in all of patients who represent positive troponin 100% (7 patients). Moreover, anterior circulation stroke was recognized in all patients with positive troponin I marker.

Conclusions:: This study suggest that ECG abnormalities in patients with acute stroke are very common, especially tachycardia. The site of lesion appear to play major factor as a cause of genesis of arrhythmia. Concomitant cardiac diseases may present. Serum troponin elevation may play a role in diagnosing neuro-cardiogenic injury but, ECG appears to be more sensitive and familial.
IS THROMBOCYTOPENIA A RISK FACTOR OF IN-HOSPITAL MORTALITY AMONG PATIENTS WITH CEREBRAL INFARCTION WITHOUT ACUTE REPERFUSION THERAPY: A PROPENSITY SCORE-MATCHED ANALYSIS FROM THE MIMIC-IV DATABASE

Hong-Jie Jhou¹, Po-Huang Chen², Shu-Hao Chang³, Li-Yu Yang¹
¹Changhua Christian Hospital, Department Of Neurology, Changhua, Taiwan, ²Tri-Service General Hospital, National Defense Medical Center, Department Of Internal Medicine, Taipei, Taiwan, ³National Formosa University, Department Of Computer Science And Information Science, Yunlin, Taiwan

Background and Aims:: The aim of study is to investigate the clinical characteristics and outcomes of patients with cerebral infarction and thrombocypenia (TP) without reperfusion therapy in intensive care units.

Methods:: In the Medical Information Mart for Intensive Care IV database, patients with cerebral infarction were enrolled from 2008 to 2019 (Figure 1). TP was defined as <150 × 10⁹/L. The clinical characteristics of patients with and without TP were compared using propensity score matching (PSM). Propensity scores were estimated using the following covariates: age, sex, Charlson Comorbidity Index (CCI), Acute Physiology Score (APS) III, and HAS-BLED score. A Cox proportional hazards model was used to determine the nonlinear association between TP and in-hospital mortality in patients with cerebral infarction.
Results: Of the 1,070 patients, 141 patients (13.2%) had TP. Patients with TP were older (71.0±12.9 v.s. 68.4±14.5; P=0.048) and had higher CCI (7.3±2.5 v.s. 6.8±2.7; P=0.063), APS III (39.4±19.2 v.s. 34.3±15.9; P=0.001), HAS-BLED score (3.9±1.0 v.s. 3.7±0.9; P=0.021), and in-hospital mortality (26/141, 18.4% v.s. 112/929, 12.1%; P=0.035) than those without TP (Table 1). Platelet count did not associate with in-hospital mortality (Figure 2). After 1:4 PSM, 647 patients remained (TP group: 137, non-TP group: 510; respectively). The cohorts were well-balanced based on five covariates between the TP and non-TP groups. TP was not associated with higher in-hospital mortality (HR: 1.18, 95% CI: 0.74–1.87).

Propensity score matching by age, sex, Charlson comorbidity Index, acute physiology score III, and HAS-BLED score.
APS III: acute physiology score III; BUN: blood urea nitrogen; CCI: Charlson comorbidity Index; COPD: chronic obstructive pulmonary disease; Hgb: hemoglobin; PVD: Peripheral vascular disease; WBC: white blood cell.
#: Testing by Fisher exact test or Wilcoxon Test, respectively.
Conclusions: Thrombocytopenia could be associated with poor clinical characteristics and in-hospital mortality; however, it is not an independent short-term risk factor of in-hospital mortality among patients with cerebral infraction without reperfusion therapy.
SOCIO-DEMOGRAPHIC FACTORS AND RISK FACTORS RELATED TO ISCHEMIC STROKE SUBTYPES AND OUTCOMES IN A TERTIARY CARE HOSPITAL IN SRI LANKA.

Sathyajith Ambawatte¹, Dulmini Weerathunga¹, Athula Dissanayake², Surangi Somaratne¹, Kanishka Athukorala¹, Piyumi Wijewickrama¹
¹Ministry of health, Sri Lanka, Health Department, Colombo, Sri Lanka, ²Teaching hospital Karapitiya, Sri Lanka, Neurology, Karapitiya, Sri Lanka

Background and Aims:: Stroke is a heterogeneous, catastrophic disease. An in-depth clinical analysis of ischemic stroke(IS) risk factors and outcome is crucial for optimum management in resource-poor settings. The current study aimed to describe the acute-cerebrovascular-disease(ACVD) subtypes and subtype-categories with risk factors, severity, and outcomes.

Methods:: A prospective cross-sectional study of ACVD patients was conducted in a tertiary care center in Sri Lanka. Risk factors, severity, and outcomes of individual IS subtype and subtype-categories were studied based on the Oxfordshire-Community-Stroke-Project-Clinical classification.

Results:: Among 592 patients involved, IS was the commonest(63.3%). Partial anterior circulation syndromes(PACS) total anterior circulation syndrome(TACS), posterior circulation syndromes(POCS) and lacunar syndromes(LACS) accounted for 102(29.7%),58(16.9%), 88(25.7%) and 95(27.7%) respectively. Commonest PACS sub-category was higher-cerebral-dysfunction-with-homonymous-hemianopia(HCD+HH)(39;38.2%). Cerebellar-signs-without-long-tract-signs(CS-LTS) sub-category constituted the highest among POCS(47;53.4%). The commonest sub-category within LACS was pure-motor(PM) strokes(43;45.3%). Patients with age≥50 years(Adjusted-OR,2.439; 95%CI,1.163-5.116;P-0.018), ischemic-heart-disease(Adjusted-OR,2.520; 95%CI,1.347-4.713;P-0.004) and body-mass-index >23kg/m²(Adjusted-OR,2.607; 95% CI,1.420-4.784; P-0.002) were at 2.5 fold risk of TACS. Patients with a history of transient-ischaemic-attack(adjusted-OR,1.910; 95%CI,1.036-3.524; P-0.038) and arrhythmias(adjusted-OR,5.933; 95%CI,3.294-10.684; P<0.001) were at 1.9 and 5.9 fold higher risk for POCS respectively. A patient with hypertension was 2.3 times at risk of LACS(adjusted-OR,2.233; 95%CI,1.270-3.926; P-0.005). NIHSS(<P<0.001), mRS on admission(<P-0.001) and in 3 months(<P<0.001), deaths during hospital stay(<P-0.001) and within 28 days(<P<0.001) had a statistically significant relationship with individual stroke subtypes

Conclusions:: The comparative risk of different IS subtypes vary based on different risk factors. The findings of this study signify that sub-categories within each stroke subtypes may behave independently with regards to risk factors and outcomes, thus warranting the need for individual assessment.
MODIFIED 8DS ALGORITHM IMPROVES DOOR-TO-NEEDLE TIME IN PATIENTS WITH ACUTE ISCHEMIC STROKE ELIGIBLE FOR ALTEPLASE OR THROMBECTOMY; A PROSPECTIVE COHORT STUDY.

Mojdeh Ghabae1, Ghasem Farahmand1, Pargol Balali2, Hana Magrouni1, Fatemeh Alizadeh-Broujeni1, Kiana Amani1, Mahnaz Varedi2, Bahareh Pourghaz2, Shima Ghafoori1, Zahra Ranjar1, Fatemeh Nazari1, Mojtaba Shahbazi1
1Neuroscience Institute, Imam Khomeini Hospital Complex, Tehran University of Medical Sciences., Iranian Center Of Neurological Research, Neurology Department, Tehran, Iran, 2Tehran University of Medical Sciences, Iranian Center Of Neurological Research, Tehran, Iran

Background and Aims:: Timely restoration of cerebral blood flow using reperfusion therapy (RT) is the most effective strategy for salvaging ischemic brain tissue that is not already dead. There is a narrow window for RT since its benefit decreases over time. Intravenous thrombolysis (IVT) and mechanical thrombectomy (MTE) are key elements of acute ischemic stroke (AIS) management resulting in more favorable outcomes. Herein, we aimed to monitor risk factors, management, and outcome of patients with AIS eligible for IVT/MTE.

Methods:: In this ongoing prospective cohort study, we enroll AIS patients eligible for IVT/MTE who are referred to our Comprehensive Stroke Center within 4.5 or 6h of presenting symptoms between September 2020 and September 2021. The modified 8Ds stroke-care algorithm was used for providing patients with timely treatment. Demographic data, risk factors, baseline, and follow-up brain imaging and NIHSS, door-to-needle time (DNT), door-to-puncture time (DPT), complications, and outcome were collected using pre-prepared questionnaires.

Results:: The mean age of the 42 eligible patients for IVT/MTE who are enrolled in the study up until now was 71.4±13.1 years (45.2% male). The most common risk factors were hypertension(69.0%), diabetes(26.2%), and Atrial fibrillation (19.0%). Alteplase was administered for 64.3%, MTE was performed for 11.9% of the patients, and the remaining received bridge therapy. The median baseline NIHSS was 10.5. Median DTN and DPT were 67 and 140 minutes, respectively. In-hospital mortality was 23.8%, and most of them happened in the first week of admission.

Conclusions:: Applying the modified 8Ds helps our institution improve DTN from 76.3 in 2018 to 67 in 2021.
REVERSIBLE POSTERIOR ENCEPHALOPATHY SYNDROM IN THREE CASES

Hassane Zobiri
CHU Sétif service neurologie, Neurology, SETIF, Algeria

**Background and Aims::** Reversible posterior encephalopathy is a rare entity whose diagnosis is radioclinical, often it’s associating with headaches, confusion, nausea, convulsions and visual abnormalities; occurring in an acute or subacute manner and often reversible.

**Methods::** We report three cases of posterior reversible encephalopathy observed at the CHU Sétif, Algérie. case 1: BD, 33 years old, presented disturbances of consciousness, convulsive seizures and high blood pressure on a pregnancy. The cerebral CT has shown a bilateral occipital hypodensity and IMR showed to vasogenic edema in the posterior regions in the diffusion sequence. case 2: B.W, 26 years old, BERGER disease with end-stage renal failure and a poorly balanced hypertension. he presented headaches, vomiting, visual disturbances and restlessness with BP: 200/120 mm / Hg. During the examination, we found an HIC syndrome with bilateral blindness. Brain CT revealed bilateral occipital hypodensity, MRI revealed bilateral parieto_occipital anomalies case: 3. S.H, 37 years old, diabetic and hypertensive not followed. She presented headaches with semi-bodily convulsive seizures, BP 220/120, MRI posterior hypersignals. After treatment, 02 patients presented a clear improvement in symptoms, 1 patient kept bilateral blindness.

**Results::** The triggers are multiple, In our observation, hypertension is predominant. Brain MRI is the examination of choice for the diagnosis, showing abnormalities bilateral parieto_occipital vasogenic edema.

**Conclusions::** RPES is a syndrome that is still little understood. Its prognosis can be appalling when it is not recognized and taken care of in time. It is therefore essential to establish effective management in an emergency situation.
Background and Aims:: Shear stress is suggested as one of the mechanism that can cause arterial tortuosity. Pulsatility index (PI) is associated with local shear stress. This study aimed to describe the PI in tortuous internal carotid artery (ICA).

Methods:: This was a retrospective descriptive cross sectional study using the registry of Neurology outpatient clinic, Dr. Cipto Mangunkusumo National Central General Hospital, Jakarta, Indonesia, from January to December 2020. We evaluated the characteristic of subjects with tortuous internal carotid artery according to carotid doppler examination. Univariate analysis, Chi-Square and Independent T-test were performed to evaluate difference statistically.

Results:: There were 129 subjects with mean age of 58±11.22 years. The proportion of ICA tortuosity was 23.2% (30/129). The frequency of tortuous internal carotid artery was significantly higher in women (40.8% vs 13.8%) and dyslipidemia versus non dyslipidemia subjects (40.8% vs 13.8%). Mean of PI, PSV, EDV in tortuous ICA were 1.18±0.30, PSV ICA 73.5±26.6 cm/s, and EDV ICA 24.4±8.5 cm/s, consecutively. There was no mean difference of PI ICA between tortuous and non tortuous subjects (1.18±0.30 vs 1.2±0.35, p=0.43).

Conclusions:: The pulsatility index of tortuous ICA was not significantly different compared to non tortuous subjects. Therefore, vascular risk seemed to have no evidence causing tortuous internal carotid artery in this study.
DEPRESSION AND ISCHEMIC STROKE: DESCRIPTIVE STUDY ABOUT 50 PATIENTS

Syrine Brahim1, Walid Bouali1, Mohamed Kacem1, Rim Ben Soussia2, Samia Younes3, Lazhar Zarrouk2
1University Hospital of Mahdia, Psychiatry, chebba, Tunisia, 2University Hospital of Mahdia, Psychiatry, mahdia, Tunisia, 3Department of neurology, Mahdia, Taher Sfar university hospital, Tunisia, Department Of Neurology, Mahdia, Tunisia

Background and Aims:: Post-stroke depression is a frequent complication of stroke with a prevalence ranging from 20 to 60% which justify the importance of a better knowledge of this clinical entity. The aim of this work in to assess the frequency of depressive symptoms and to identify risk factors for the occurrence of depression following stroke.

Methods:: this is a descriptive cross-sectional study conducted at the Neurology consultation of the Mahdia University Hospital, including patients with ischemic stroke of at least 3 months, using a pre-established individual form, the Hamilton score (HDRS) and the Barthel index. Patients with an HDRS score of more than 10 are considered to have depressive symptoms.

Results:: We interviewed 50 patients, 27 men and 23 women with a sex ratio M/F =1.17. The average age was 63 years. 60% had depressive symptoms of which 26% were mild, 56% moderate and 18% severe. The average evaluation time was 14 months ranging from 3 to 24 months. We found no correlation between the severity of depressive symptoms and age of onset, gender, marital status, occupation, length of time since stroke, hemisphere deficit and rate of improvement.

Conclusions:: This confirms the value of surveillance the appearance of mood disorders in the aftermath of a stroke and underlines the benefit of the introduction of antidepressant treatment in terms of functional prognosis and mortality.
HERBAL EXTRACT PREVENTED BRAIN INJURY INDUCED BY CEREBRAL ISCHEMIA-REPERFUSION

Sergey M. Gulyaev
Institute of General and Experimental Biology, Siberian Branch of the Russian Academy of Sciences, Laboratory Of Experimental Pharmacology, Ulan-Ude, Russian Federation

Background and Aims:: Astragalus membranaceus, Scutellaria baicalensis, Phlojodicarpus sibiricus a traditional medicinal herbs, use as adaptogenic, nootropic and vascular remedies in the Oriental medicine. The aim of this work was to verify neuroprotective effect of complex herbal extract composed of Astragalus membranaceus, Scutellaria baicalensis and Phlojodicarpus sibiricus in rats subjected to cerebral ischemia-reperfusion (I/R).

Methods:: Adult Wisar rats were divided into three groups: sham, model and extract groups. Model of cerebral ischemia-reperfusion was induced by 10 min occlusion of common carotid arteries with following reperfusion. The extract was administered to rats intragastrically at a dose of 100 mg / kg once for 7 days before the experiment and 14 days after the occlusion common carotid arteries. Neurobehavioral tests (Neurological Severity Score, rotarod) were performed at 1, 3, 7 and 14 days after operation. Then, the rats were sacrificed and the brain samples were taken for morphological study.

Results:: Compared with the sham group, the scores of neurological were significantly increased, and the indicators on the rotarod test was significantly worse in rats with cerebral I/R (p<0.05). The scores of neurological were significantly decreased, and the residence time on the rotating drum was increased in the treated group compared with the model group (p<0.05). Histopathological study in extract treated rats showing markedly attenuated of neuron death (p<0.05) and arrangement of CA1 neurons as compared with the no treated rats.

Conclusions:: Herbal extract decreased neurological deficites and neuronal damage in rats with cerebral ischemia-reperfusion. The herb extract may be beneficial in the treatment cerebrovascular disorders.

This research was funded by the Ministry of Education and Science of Russia, grant number - 121030100227-7.
LDL-CHOLESTEROL AND RISK OF RECURRENT VASCULAR EVENTS IN CHINESE ISCHEMIC STROKE PATIENTS WITH AND WITHOUT SIGNIFICANT ATHEROSCLEROSIS

Bryan Chua¹, Gary Lau¹, Alexander Ng¹, Ian Leung¹, Debbie Wong¹, Anna Chan¹, Nikki Chiu¹, Ariane Chu¹, William Leung¹, Anderson Tsang², Kay Cheong Teo¹, Henry Mak³
¹University of Hong Kong, Division Of Neurology, Department Of Medicine, Queen Mary Hospital, Li Ka Shing Faculty Of Medicine, University Of Hong Kong, Hong Kong, Hong Kong PRC, ²The University of Hong Kong, Division Of Neurosurgery, Department Of Surgery, Hong Kong, Hong Kong PRC, ³The University of Hong Kong, Department Of Diagnostic Radiology, Queen Mary Hospital, Li Ka Shing Faculty Of Medicine, Hong Kong, Hong Kong PRC

Background and Aims:: Recent trials showed that a low-density lipoprotein cholesterol (LDL-C)<1.80mmol/L (<70mg/dL) was associated with a reduced risk of major adverse cardiovascular events (MACE) in Caucasian ischemic stroke patients with atherosclerosis. However, it remains uncertain whether the findings can be generalised to Asians, or that similar LDL-C targets should be adopted in stroke patients without significant atherosclerosis.

Methods:: We performed a prospective cohort study and recruited consecutive Chinese ischemic stroke patients with magnetic resonance angiography of the intra- and cervicocranial arteries performed at the University of Hong Kong between 2008-2014. Serial post-event LDL-C measurements were obtained. Risk of MACE in patients with mean post-event LDL-C<1.80 vs. ≥1.80mmol/L, stratified by presence or absence of significant (>50%) large artery disease (LAD), and by ischemic stroke subtypes, were compared.

Results:: 904 patients (mean age 69±12years, 60% men) were followed up for a mean 6.5±2.4years (mean 9 LDL-C readings/patient). Regardless of LAD status, patients with a mean post-event LDL-C<1.80mmol/L was associated with a lower risk of MACE [LAD+ve: multivariate-adjusted subdistribution hazard ratio (SHR) 0.65, 95% confidence interval (CI) 0.42-0.99; LAD-ve: 0.53, 0.32-0.88] (both p<0.05). Similar findings were noted in patients with ischemic stroke attributable to large artery atherosclerosis (0.48, 0.28-0.84), and in patients with other ischemic stroke subtypes (0.64, 0.43-0.95) (both p<0.05).

Conclusions:: A mean LDL-C<1.80mmol/L was associated with a lower risk of MACE in Chinese ischemic stroke patients with and without significant LAD. Further randomised trials to determine the optimal LDL-C cut-off in stroke patients without significant atherosclerosis are warranted.
REPETITIVE TRANSCRANIAL MAGNETIC STIMULATION EFFECTS ON HEMIPARETIC LIMB SPASTICITY IN STROKE PATIENTS: A DOUBLE BLINDED RANDOMIZED CONTROLLED TRIAL.

Hussein Mousa, Sura Albaker
alsdr teaching hospital, Neurosurgery, basra, Iraq

Background and Aims:: Background: Spasticity is known as disabling complications of the stroke interfere with daily activities. Repetitive transcranial magnetic stimulation (rTMS) is an effective technology, safe and non-invasive method of brain stimulation uses in various diseases. This study aimed to evaluated effects of rTMS on spasticity affected upper limb in post stroke patients.

Methods:: This study was a double blind controlled randomized trial. Thirty two patients were randomly allocated in two groups; conservative managements (control group) and (rTMS group) those adding rTMS. The outcome measurement were limb spasticity assessment, Modified Ashworth scale Test (MAST) for dexterity measurement active and passive range of motion (AROM and PROM). All assessments were measured at baseline (T0), immediately after the last session of intervention (T1) and one month later (T2).

Results:: Significant reduction (p<0.05) in outcome reported in the rTMS group in both T1 and T2 as compared with control group.

Conclusions:: It seems rTMS can control muscle spasticity in upper limb stroke survivors and it could be useful for therapists.
THE SOCIAL NETWORK PATTERNS AND PERCEPTIONS OF SOCIAL SUPPORT IN STROKE SURVIVORS

Athishta Tamilmaran¹, Yan Ling Low¹, Farhan Samsuri¹, Pei Ling Choo¹,²
¹Singapore Institute of Technology, Health And Social Sciences, Singapore, Singapore, ²Glasgow Caledonian University, School Of Health And Social Sciences, Glasgow, United Kingdom

Background and Aims:: Improving social networks among stroke survivors can improve their recovery and quality of life. However, there is no published baseline data regarding the patterns of social networks among stroke survivors in Singapore. This study aimed to illuminate the social network patterns of stroke survivors in Singapore and the associated satisfaction. It also examined the impact of the COVID-19 pandemic on these variables.

Methods:: A series of questionnaires were conducted online between July 2020 to February 2021. 53 community-dwelling stroke survivors in Singapore were recruited and completed the study (mean age (SD) 60.5 (12.9) years, 27 males). The Stroke Social Network Scale (SSNS) and Multidimensional Scale of Perceived Social Support (MSPSS) were used to assess patterns in social relationships.

Results:: The strength of social networks among stroke survivors was weak and weaker before (49.3±24.2) and during (45.3 ± 23.6) the pandemic respectively. Over half the stroke survivors reported feeling lonely and nearly half reported dissatisfaction with their social relationships, before and during the pandemic. 72.0% of stroke survivors did not belong to any groups in public organisations (e.g. religious groups, trade unions, exercise classes etc), indicating a lack of group membership within wider social networks. Over a third of stroke survivors yearned for greater frequency of contact with their children before and during the pandemic.

Conclusions:: Stroke survivors in Singapore had low levels of social interaction. Strategies increasing stroke survivors’ quality and quantity of social interaction with their children and the community may enhance their quality of life.
HYBERNIA POST-MECHANICAL THROMBECTOMY – ENDOVASCULAR CEREBRAL HYPOTHERMIA TRIAL IN ACUTE ISCHEMIC STROKE (POST-MTECH TRIAL)

Jae Choi¹,², Jeffrey Saver³, Raul Nogueira⁴, Sven Poli⁵, Thanh Nguyen⁶, Michael Chen⁷, Charles Matouk⁸, John Pile-Spellman¹,²
¹Hybernia Medical, LLC, Hybernia Medical, Uniondale, United States of America, ²Neurological Surgery, Brain and Spine Surgery, P.C., Neurovascular Division, Lake Success, United States of America, ³David Geffen School of Medicine at UCLA, CA, USA, Neurology, Los Angeles, United States of America, ⁴Grady Memorial Hospital, Marcus Stroke & Neuroscience Center, Atlanta, United States of America, ⁵University of Tuebingen, Neurovascular, Neurology, Tuebingen, Germany, ⁶Boston Medical Center, Interventional Neurology/neuroradiology, Boston, United States of America, ⁷Rush Medical College, Neurosurgery, Chicago, United States of America, ⁸Yale School of Medicine, Neurosurgery, New Haven, United States of America

Background and Aims:: Although significant clinical improvement is achieved with mechanical thrombectomy (MT) in large vessel occlusion (LVO) stroke patients, <1/4 patients have outcomes comparable to their baseline (pre-stroke) conditions. Therapeutic hypothermia is a promising method for acute neuroprotection, with multiple beneficial mechanisms, for which a reduction of brain temperature by several °C is required. Systemic hypothermia has been difficult to implement in stroke patients due to the long delay to reach target temperature, complications related to physiological counter-mechanisms to cold, and adverse events associated with whole body cooling. In contrast, targeted brain cooling may provide effective hypothermic neuroprotection, because 1) of more rapid brain cooling (minutes) and 2) it is safer (avoids systemic cooling).

Methods:: This is a multicenter, prospective, randomized, open, blinded endpoint, pivotal clinical trial with an investigational device, a novel endovascular system for selective intra-arterial brain hypothermia, developed by Hybernia Medical, LLC. Eligible patients are LVO stroke patients who undergo acute MT. Main objective is to determine whether selective brain cooling with Hybernia’s device following routine MT in LVO patients results in improved functional outcome (as measured with the modified Rankin Scale) compared to routine MT alone. For this sequential adaptive design clinical trial, up to 1,000 LVO stroke patients will be recruited from 40 international sites.

Results:: Trial description will be uploaded to clinicaltrials.gov in due time. Please contact the authors for more information.

Conclusions:: To determine whether selective brain cooling with Hybernia’s device following routine MT in LVO patients results in improved functional outcome compared to routine MT alone.
IMPACT OF THE COVID-19 PANDEMIC IN THE HOSPITAL CARE OF STROKE

João Paste-Silva1, Tayla Samanta Santos1, Gabriel Praxedes1, Ivã Taiuan Fialho Silva1, Fernanda Ferreira De Abreu2, Antonio Andrade2, Leonardo Melo2, Silas Souza3, Vinicius Mendez4, Pedro Antonio Jesus2

1Universidade Federal da Bahia, Fameb, Salvador, Brazil, 2UFBA, Fameb, Salvador, Brazil, 3Universidade Federal da Bahia, Neurologia, Salvador, Brazil, 4UFBA, Fameb, SALVADOR, Brazil

Background and Aims:: The Covid-19 pandemic had an impact on care and fatality rate from other comorbidities in Brazil. Stroke is one of the main causes of death in the country and early care is essential. To analyze pandemic impact in the first months of installation in Brazil on stroke care, compared to the same period in 2019.

Methods:: Ecological study, with data provided by the Ministry of Health from March to June of 2019 and 2020 and by the Brazilian Institute of Geography and Statistics. The chosen period is based on the beginning of the pandemic in Brazil and the corresponding months of 2019.

Results:: The volume of hospitalizations for stroke in Brazil decreased on average by 5.11% during the pandemic, with the greatest reduction in the Northeast (11.75%), the region with the lowest HDI. The lethality rate increased, on average, 1.48%, mainly in the South (7.5%), the region with the highest HDI in the country. Furthermore, throughout Brazil, despite the average length of stay decreased by 5.06% (mainly in the Northeast, with 7.43% reduction), the average cost per hospital stay increased by 5.11% (mainly in the North, with 7.14% increase).

Conclusions:: A change in important stroke care markers was observed, which may be a consequence of late patient care in health services. Medical care was possibly unstructured due to the pandemic, which may have generated more severe clinical conditions and higher individual costs to the health system.
THE CHALLENGES AND POSITIVE ASPECTS OF INFORMAL STROKE CAREGIVING IN SINGAPORE

Cheng Wai Josephine Wong¹, Yuan Lin Elcia Tan¹, Pei Ling Choo¹,²
¹Singapore Institute of Technology, Health And Social Sciences, Singapore, Singapore, ²Glasgow Caledonian University, School Of Health And Social Sciences, Glasgow, United Kingdom

Background and Aims:: Informal stroke caregiving can pose a high caregiver burden on stroke caregivers, however, there is a lack of such data in Singaporean stroke caregivers. This study aimed to investigate the level of caregiver burden and the positive aspects of caregiving experienced by stroke caregivers in Singapore.

Methods:: A series of questionnaires were delivered online between July 2020 to February 2021. 56 informal stroke caregivers (mean age(SD) 52.3(14.2) years, 37 males) completed the study. Measures of strain, competence and burden were assessed by three instruments: Caregiver Strain Index (CSI), Sense of Competence Questionnaire (SCQ) and Caregiver Reaction Assessment (CRA). Participants also commented on positive and negative impacts of caregiving.

Results:: Caregiving burden was high with a mean score of 64.7±27.8 on the CRA. The largest challenges reported by stroke caregivers relate to having limited personal time (51.4%), need to manage expenses of person cared for (43.3%), and having personal health issues from caregiving duties (26.7%). The corresponding strategies deployed by stroke caregivers were seeking support from family on caregiving duties and taking time-off for rest. The most positive aspects of caregiving reported were ability to show filial piety (21.2%, n = 11) and build relationships with family members (21.2%, n = 11).

Conclusions:: This study evidenced the high caregiving burden posed on stroke caregivers, with having limited personal time and needing to manage expenses being the most frequent challenges. Providing respite for stroke caregivers and focusing on positive aspects of caregiving may help to alleviate the caregiving burden.
VARIABILITY OF THE CIRCLE OF WILLIS IN NORTH AMERICAN CAUCASIAN AND MIDDLE EAST ARABIC COHORTS

Maryna Al-Fauri1, Panta Ashirbad2, Melody Abadpour3, Azmy Hadidy4
1AUC Medical School, Anatomy Department, Philipsburg, Netherlands Antilles, 2AUC Medical School, Clinical Resident, Phillipsburg, United States of America, 3AUC Medical School, Clinical Resident, Phillipsburg, United States of America, 4Hospital of University of Jordan, Diagnostic Radiology And Nuclear Medicine, Philipsburg, Jordan

Background and Aims:: The cerebral arterial circle (circle of Willis) plays an important role in the redistribution of the blood flow between the anterior and posterior territories and maintains the plasticity of the cerebral blood circulation. The heritability and prevalence of certain variants of the circle of Willis in different ethnic and racial groups are frequently disputed by authors.

Methods:: Our cross-sectional retrospective study aims to compare the patterns of the cerebral arterial circle in 64 Caucasian cadavers with 64 Arabic living individuals, by methods of anatomic dissection and magnetic resonance angiography, respectively.

Results:: The typical structure of the circle of Willis was revealed in 8.3% of the Caucasian study group, and in 22.2% of the Arabic one. The anterior part of the circle of Willis was incomplete in 6 out of 64 of the Caucasian specimens, where the anterior communicating artery was hypoplastic (6.3%) or absent (3.1%). The posterior part of the circle of Willis had a hypoplastic or absent posterior communicating artery on one side in 20, and on both sides in 12 out of 64 Caucasian specimens. In the Arabic cohort, the posterior part of the circle of Willis was incomplete in 17 out of 64 specimens, with the absence of the posterior communicating artery unilaterally (in 11 cases) or bilaterally (in 6 cases).

Conclusions:: The present study reveals that the configuration of the cerebral arterial circle and distribution of the blood flow between the anterior and posterior territories have certain differences in the Caucasian study group versus the Arabic one.
A CASE REPORT OF A BILATERAL THALAMIC HEMORRHAGE

Augusto Brenner¹, Armando Cardoso¹, Sacha Ries², Marlise Ribeiro¹,², Paulo Worm¹,³
¹Universidade Federal de Ciências da Saúde de Porto Alegre, Medicine, Porto Alegre, Brazil, ²Irmandade Santa Casa de Misericórdia de Porto Alegre, Neurology, Porto Alegre, Brazil, ³Irmandade Santa Casa de Misericórdia de Porto Alegre, Neurosurgery, Porto Alegre, Brazil

Background and Aims:: Intraparenchymal hemorrhages (IPH) are responsible for 6.5% to 19.6% of all stroke cases. Primary simultaneous IPH are responsible for 0.7% to 3% of intracerebral hemorrhages. Unilateral thalamic IPH are infrequent and even more rare when the presentation is bilateral. Our aim is to present a rare bilateral thalamic hemorrhage case.

Methods:: Case report of a 53-year-old female presenting with headache and left hemiparesthesia, followed by loss of consciousness. The patient arrived at our department with global aphasia, left hemineglect, photoreactive pupils, and left lip deviation. Her arterial pressure was at 210/110 mmHg.

Results:: Cranial CT was performed, which evidenced bilateral foci of intraparenchymal hemorrhages in the thalamus. The intracerebral hematoma appeared to compress the third ventricle, with subtle dilatation of the lateral ventricles, but there were no signs of intraventricular bleeding, nor hidrocephalus. There was no significant midline deviation. In consequence of clinical deterioration and consciousness loss to eight according to the Glasgow Coma Scale, management included orotracheal intubation, transference to the ICU, and mechanical ventilation, associated with intensive management of the arterial pressure. During hospitalization, the patient contracted infections, which were resolved through antibiotic therapy. Finally, gastrostomy was performed for hospital discharge.

Conclusions:: We describe a patient with important impairment, which can have been worsened by the acquired infections, a significant cause of mortality. To our knowledge, only five other cases of bilateral thalamic IPH were reported in Latin America, none of them in Brazil. This is the youngest woman reported in Latin America with bilateral simultaneous thalamic IPH.
Background and Aims:: Cranioplasty after DC is commonly use as the treatment for medically refractory intracranial hypertension in cerebral trauma, SAH, ICH, Tumors, where it is better studied, but also in malignant stroke(1). Even in Stroke the aims of the cranioplasty are protection of the brain, restoration of the brain's hydrodynamic conditions and cosmetics, determining a clinical outcome improvement comprehensive of neuropsychological function(2). Cranioplasty can be performed by using autologous bone or alloplastic materials and timing of cranioplasty seems to be related to the clinical outcome and it should be performed after 90 days from DC(3). Cranioplasty complications are sepsis(5%), Hematoma(19%), Sieroma(6,2%), pneumocefaus(4%), hidrocefalus(2%) and fractures(1%) but the available studies include mainly cumulative results of the illnesses previous indicated. The aim of our work is to study timing and complications of cranioplasty in a cohort of MCA malignant stroke.

Methods:: All patients with malignant MCA infarction undergone to decompressive craniectomy in Modena-Stroke Unit between January 2015 and June 2021 were evaluated. Clinical features -including mRS at 3 and 12 month follow up-, neurosurgical and neuroradiological parameters were collected.

Results:: We evaluated a total of 31 patients presenting preliminary results; 8 of them had second cranioplasty because of major complications. 12 interventions of 39 were performed with heterologous bone flap. The median time of the intervention was 186 days, and also excluding the second cranioplasty is about 162 days.

Conclusions:: Cranioplasty in patients with malignant MCA infarcts submitted to DHC is a delicate intervention affecting the clinical outcome that need specific studies.
INFLUENCE OF MULTICOMORBIDITY ON THE RESPONSE TO THROMBOLYSIS IN ISCHEMIC STROKE

Tayla Samanta Santos1, Ivã Taiuan Fialho Silva1, Fernanda Ferreira De Abreu1, Tiago Almeida1, Vinícius Mendez2, Gabriel Praxedes1, Leonardo Melo1, Joao Paste-Silva1, Antonio Andrade1, Pedro Antonio Jesus3
1Universidade Federal da Bahia, Fameb, Salvador, Brazil, 2Universidade Federal da Bahia, Fameb, SALVADOR, Brazil, 3UFBA, Neurology, Salvador, Brazil

Background and Aims:: Introduction: Thrombolysis has a high level of evidence in ischemic stroke, in which reperfusion may depend on the patient's clinical condition. The Charlson Comorbidity Index (CCI) measures the degree of comorbidities, having a prognostic value in post-stroke. Objective: Evaluate the influence of multicomorbidity on thrombolysis reperfusion in stroke patients.

Methods:: Prospective cohort of patients admitted to stroke unit between 2017 and 2020. Multicomorbidity was defined as Goldstein-modified CCI ≥ 2 points. Patients were compared for reperfusion to thrombolysis, functional disability or death at 90 days (mRS>2). Reperfusion due to thrombolysis was defined as NIHSS ≤1 or reduction ≥8 until hospital discharge.

Results:: 165 individuals were included, the mean age was 60.5 (±15.9) years. Median NIHSS at admission was 10 (7-14). Prevalence of multicomorbidity at admission was 24.1%. No difference was found comparing groups for reperfusion to thrombolysis [45.7% vs 45.8%, RR = 0.99 (95%CI 0.66 - 1.51)] and functional disability or death at 90 days [41% vs 37.5 %, RR = 1.09 (95%CI 0.70 - 1.70)]. In the multivariate analysis, multicomorbidity was not associated with worse outcomes, whether mRS>2 at 90 days [aOR = 0.76; (95% CI 0.30-1.87)] or insufficient response to thrombolysis [aOR = 0.92; (95% CI 0.40-2.14)], adjusted for age, NIHSS at admission, length of hospitalization, ASPECTS and occurrence of delirium.

Conclusions:: Conclusion: Presence of multicomorbidity was not associated with a lower response to thrombolytic treatment or greater functional disability 90 days after stroke. Our results suggest that the prognosis may be favorable in multicomorbidity patients undergoing thrombolysis.
REPERFUSION STRATEGIES IN ACUTE ISCHAEMIC STROKE: OUR EXPERIENCE AND FUTURE THERAPEUTIC PROSPECTS

Lucia Pascazio, Giorgio Liaci, Fabio Amati
Policlinico Hospital, Neuroscience, Bari, Italy

Background and Aims:: Thrombolysis is the approved treatment of the acute ischemic stroke, not always successful, the aim is understanding the ischemia pathophysiology to suppose adjuvant therapies. Methods:: 223 patients (pts.), referred to the Emergency Department, underwent intravenous thrombolysis (IV-TL) and/or endovascular treatment (EVT). Results:: 147/223 (65.9%) pts. received IV-TL; 76/223 (34%) pts. isolated EVT (42%) or associated with IV-TL (57.8%); 30 pts. (39%) exhibited complete (TICI 3) and early recanalization. Favourable outcome at three months (0-2 mRS) in 137/223 (61.4%) pts., moderate (mRS: 3) in 21/223 (9.4%) pts., unfavourable in 66/223 (29.5%) pts. Poor prognostic factors: TACS, severe atheromasia, poor collateral circulation, more complications. Positive prognostic factors: good primary collateral circulation and higher Careggi Collateral Score; higher TICI grade (p<0.005); faster procedure (p<0.001); effective lysis or compensation-induced recanalization (p< 0.005). Concerning subjects receiving EVT treatment the best outcome was obtained with associated treatment (30/44 pts. – 68%), compared to isolated treatment (9/32 pts. – 28%). Conclusions:: Reperfusion is achieved through thrombolysis and/or collateral flow with a better outcome when both events occur. Ineffective congenital collateralization or macro and microcirculation damage may impair any compensation, thus being able to prevent reperfusion and trigger reocclusion. This study highlights that, while providing satisfactory results, in subjects undergone EVT especially evident in bridging pts., the above strategies are not always successful. Therefore additional therapies should be considered using alternative thrombolitics, enzymes.
DECOMPRESSIVE HEMICRANIECTOMY (DH) IN MCA MALIGNANT INFARCTION: FIRST FINDINGS IN MODENA REGISTRY ABOUT CLINICAL AND NEURORADIOLOGICAL PROGNOSTIC INDICATORS.

Livio Picchetto¹, Laura Giacobazzi¹, Alberto Feletti², Marcella Malagoli³, Stefano Vallone³, Laura Vandelli¹, Ludovico Ciolli¹, Andrea Zini⁴, Giovanni Pavesi⁵, Guido Bigliardi¹, Stefano Meletti¹
¹Ospedale Civile di Baggiovara, AOU di Modena., Stroke Unit – Neurology Clinic, Department Of Neuroscience, Modena, Italy, ²University of Verona - AOUI Verona, Institute Of Neurosurgery, Department Of Neurosciences, Biomedicine And Movement Sciences, Verona, Italy, ³Azienda Ospedaliera Universitaria Policlinico di Modena., Ospedale Civile Di Baggiovara Neuroradiology Unit, Department Of Neuroscience, Modena, Italy, ⁴Department of Neurology and Stroke Center, Maggiore Hospital, Ircs Istituto Di Scienze Neurologiche Di Bologna, Bologna, Italy, ⁵Azienda Ospedaliera Universitaria Policlinico di Modena, Ospedale Civile Di Baggiovara Neurosurgery Unit, Department Of Neuroscience, Modena, Italy

Background and Aims:: DH in MCA malignant stroke has been demonstrated to reduce mortality over 50% in the acute phase, determining an increase in moderate-to-severe disability in the surviving patients, as compared to patients receiving medical treatment. In this preliminary analysis we want to evaluate clinical and neuroradiological prognostic indicators in patients with malignant cerebral infarction treated by DH.

Methods:: This is a single center registry of MCA malignant infarction treated by DH. Anamnestic, clinical, timing and neuroimaging pre and post intervention characteristics were collected. Follow-up assessment by mRS was at 3 and 12 months after surgery.

Results:: A total of 59pt were registered between September 2008 to June 2021. Comparing the data of the clinical outcome at 1 year with those of a pooled analysis of three European randomized clinical trials (HAMLET, DECIMAL, DESTINY I), the overall mortality of our group was higher (28.3% vs 22%), especially in case of late intervention (>48h), low GCS (<10), high volume of the ischemic lesion (>400cc), brain midline shift >10mm and additional ischemic involvement of ACA or PCA territory. Among the survivors our patients presented clinical outcomes similar to the trials one (mRS=3: 27% vs. 29%; mRS=4: 35% vs. 31%).

Conclusions:: DH in the treatment of malignant brain infarcts has changed the natural history of this disease in terms of mortality and functional outcome. Our study showed that late intervention, low GCS, high volume of the lesion (>400cc), brain midline shift >10mm and additional ischemic ACA and/or PCA involvement are associated with a higher mortality.
BACKGROUND AND AIMS:: IAD is an uncommon and underdiagnosed disease, the aim is to identify its pathophysiological mechanisms and possible alternative therapies.

METHODS:: Eight patients (pts.), referred to the Emergency Department with focal signs, were analyzed. Work-up: neurological examination, brain CT-MRI/AG, Digital-Angiography (DA) and Ultrasound.

RESULTS:: All pts. were diagnosed with cerebral ischemia. AG highlighted intradural internal carotid artery (ICA) dissection in three pts. and both intra- and extracranial ICA dissection in one pt. In one subject subarachnoid haemorrhage from rupture of intradural ICA dissecting aneurysm, treated with embolization, was observed; in another pt. dissection of the basilar artery (BA) was detected, whereas the other pts. were found to have vertebral artery dissection (VAD). Four pts. were given Actilyse, followed by mechanical thrombectomy (MT) in two subjects; one pt. underwent only BA MT. The thrombolytic was administered in all pts. with confirmed diagnosis of vessel occlusion prior to the dissection finding. Subsequent or alternative therapy was aspirin. The three-month outcome was good in all pts.

CONCLUSIONS:: The thrombolytic therapy has not caused bleeding in the small sample of examined pts., thus suggesting that it acts on the thrombotic process, without affecting the integrity of the vessel wall, although the latter is poorly equipped with elastic fibers and easily vulnerable to any noxa, probably more traumatic than pharmacologic. The study of these few cases provides elements to reflect on alternative therapeutic options that could envisage, after large retrospective studies and specific trials, the use of thrombolysis also in intracranial vessels dissections.
CONTINUING TRAINING AS THE MAIN FACTOR FOR IMPROVE OUTCOMES IN A
COMPREHENSIVE STROKE CENTER IN A DEVELOPING COUNTRY

Omar Pichardo, Omar Castillon
Centro Medico ABC, Centro Neurologico, CDMX, Mexico

Background and Aims:: Building protocols in developing countries as good as in developed countries is a different story. The treatment centers present dissimilar conditions; their infrastructure is often inferior to those in developed countries, and the healthcare models are usually deficient.

Methods:: In this retrospective observational study, medical records of all patients undergoing treatment with endovascular techniques at a Mexican hospital that implemented a mechanical thrombectomy for LVO program (stroke program) were reviewed. The selection began in February 2017 and ended in January 2020 (36 months).

Results:: Thirty-six months was the length of total data collection, which was grouped into periods of 6 months each. These groups were compared with each other, taking the 90-day mRS, the total time used in the algorithm, and the recanalization time as variables. The recanalization time had statistical significance with its decrease in the last 18 months (p = 0.035). The temporal midline was set at month 18 (July 2018). During the first 18 months, 17 (23%) patients had favorable outcomes (mRS <3), whereas in the last 18 months (second half), 45 (33%) patients with good clinical outcomes (mRS <3) were found (p = 0.0001).

Conclusions:: With logistic adaptation, creativity, but above all, permanent training, similar results to those in other parts of the world can be achieved.
LONG-TERM OUTCOMES AMONG NIGERIAN STROKE SURVIVORS; DATA FROM THE COGFAST-NIGERIA STUDY

Gabriel Ogunde¹, Rufus Akinyemi¹, Joshua Akinyemi², Adesola Oggunniyi¹, Rajesh Kalaria³
1University of Ibadan, College of Medicine, Institute For Advanced Medical Research And Training, Ibadan, Nigeria, 2University of Ibadan, College of Medicine, Epidemiology And Medical Statistics, Ibadan, Nigeria, 3Newcastle University, Translational And Clinical Research Institute, Newcastle upon Tyne, United Kingdom

Background and Aims:: Africa faces a rising burden of stroke with rising incidence and prevalence but little is known about the profile and trajectory of long-term outcomes and mortality after stroke. The aim of this study is to explore the trajectory and determinants of long-term outcomes up to four years among a cohort of stroke survivors recruited into the CogFAST-Nigeria study.

Methods:: The data were collected in a longitudinal study of stroke survivors who were prospectively recruited from the FMC Abeokuta and UCH Ibadan Nigeria. Cognitive function was measured using the vascular neuropsychological battery, depression was measured by the GDS-short form, functional dependency through the Barthel Index. Baseline enrolment was 3 months after stroke (2009-2010) and the stroke survivors were followed up for a period of four years after the baseline enrolment.

Results:: 253 stroke survivors were recruited into the study, 157 (59.7%) were males and mean age was 60.2 (±/-9.8) yrs and mean yrs of education was 10.36 (±/-4.9). The proportions with cognitive impairment were 53.2% at six months follow-up, 56.9%, 58.7%, 60.9%, and 66.7% at 1, 2, 3 and 4 years, while the proportion of those with depression were 39.3% at 3 months post-stroke, 35.2%, 35.5%, 26.7%, and 36.1% at 1, 2, 3 and 4 years. The case fatality rate was 7.5% (95% C.I = 4.82-11.4) at 6 months post-stroke, 24.8% (95% CI = 19.93-30.6), 39.4% (95% CI=3.65-45.7) and 45.3% (95% CI=39.42-51.6) at 1, 3 and 4 years follow-up.

Conclusions:: There is a need to improve stroke rehabilitation among stroke survivors including particular attention on those with recurrent stroke.
**BLOOD PRESSURE IS ASSOCIATED WITH SEVERELY LOW ADL AT HOSPITAL DISCHARGE AFTER ATHEROTHROMBOTIC INFARCTION: A RETROSPECTIVE CROSS-SECTIONAL STUDY**

Naohito Saito¹, Nishikawa Tetsuo², Tetsuo Ota³
¹Sunagawa City Medical Center, Physical Medicine And Rehabilitation, Sunagawa, Japan, ²Yokohama Rosai Hospital, Endocrinology & Diabetes Center, Yokohama, Japan, ³Asahikawa Medical University Hospital, Physical Medicine And Rehabilitation, Asahikawa, Japan

**Background and Aims::** We analyzed inpatients’ data, and investigated the effect of blood pressure on outcomes of rehabilitation after atherothrombotic infarction.

**Methods::** This retrospective cross-sectional study analyzed the data obtained from the Japan Association of Rehabilitation Database. We excluded inpatients with a past medical history of cerebrovascular diseases (CVDs) or different types of CVDs, and those without records of hypertension or Barthel Index (BI). We compared activities of daily living (ADL) between hypertensive and non-hypertensive inpatients using 10 BI activities and the total BI score at hospital discharge. BI activities were dichotomized into independent population (patients with the highest score for each activity) and their non-independent counterparts.

**Results::** Three hundred and thirty-six patients with atherothrombotic infarction were analyzed; 225 were hypertensive and 111 were not. Non-hypertensive condition was associated with high dependency of BI activities; feeding, transfers, toilet use, dressing, bowel control, and bladder control. The total BI score of hypertensive patients at discharge was higher than that for their non-hypertensive counterparts (BI 0–15 versus 20–100, \( P = 0.0003 \); BI 0–35 versus 40–100, \( P = 0.0224 \), non-continuous variables).

**Conclusions::** BI activities were used to analyze the outcome of atherothrombotic infarction after rehabilitation. Hypertension has protective effect on severely low ADL at discharge.
RELATIONSHIP OF TOOTH LOSS TO MILD COGNITIVE IMPAIRMENT AMONG MIDDLE-AGED MONGOLIANS: MON-TIMELINE STUDY

Urangoo Ganbaatar1, Uuganzaya Erdeneochir2, Puntsagdulam Byambajav3, Tsolmon Jadamba4, Oyuntugs Byambasukh5, Byambasuren Dagvajantsan6

1Department of Neurology, School of Medicine, Mongolian National University of Medical Sciences, School of Graduate School, Ulaanbaatar, Mongolia, 2Mongolian National University of Medical Sciences, School of Oral Medicine, Ulaanbaatar, Mongolia, 3Mongolian National University of Medical Science, Department of Neurology, Ulaanbaatar, Mongolia, 4Mongolian National University of Medical Sciences, Montime Research Center, Ulaanbaatar, Mongolia, 5Mongolian National University of Medical Sciences, Department of Endocrinology, Ulaanbaatar, Mongolia, 6Mongolian National University of Medical Sciences, Department of Neurology, Ulaanbaatar, Mongolia

Background and Aims:: Cognitive impairment is common in elderly people, which is why it is considered an aging disorder. However, cognitive decline – including dementia – can also occur in middle-aged people. Cognitive impairment is caused by multiple risk factors. We hypothesized that tooth loss may also be a potential risk factor among Mongolians, as oral health problems are one of the major health issues in Mongolia, especially in middle-aged people.

Methods:: In this cross-sectional study, we used the baseline data from the Mon-Timeline cohort study, including people older than 40 years of age (n=291). The amount of tooth loss was assessed by a trained researcher. Mild cognitive impairment (MCI) was defined as those participants scoring a total of £24 points on the Mini-Mental State Examination (MMSE).

Results:: Unadjusted analysis showed that having more tooth loss (>10) increased the risk of MCI by an Odds Ratio of 3.03 (1.49-6.17), as compared with having less tooth loss (£10). The association remained significant even after adjusting for covariates, suggesting that tooth loss is associated with MCI risk, independent of age, education and other socioeconomic factors. We tested the interaction effect of age and found that there was no significant interaction effect of age in the association between tooth loss and MMSE scores.

Conclusions:: In conclusion, tooth loss may play a role in the development of cognitive decline, especially in the early onset of dementia. Further studies are needed to investigate whether early tooth loss at younger ages is associated with dementia, especially in middle-aged people.
SPHENOID RIDGE MENINGIOMA PRESENTING AS ISCHEMIA STROKE

Hatim Belfquih
Avicenne hospital Marrakech, Neurosurgery, Marrakech, Morocco

Background and Aims:: Background : Ischemic stroke as the presenting feature of sphenoid ridge meningioma is extremely rare.

Methods:: Case Presentation: A 49-year-old woman presented with acute onset of left hemiparesis, dysarthria and left central-type facial palsy. Magnetic resonance imaging (MRI) with angiography (MRA) confirmed the presence of an extra-axial mass in the medial portion of the right sphenoid ridge that compressed and distorted the first segment of the right middle cerebral artery (MCA) postero-superiorly, thereby resulting in an acute cerebral infarction in the right MCA territory. Cerebral angiography demonstrated stenosis of the right proximal M1 portion.

Results:: Case Presentation: The patient underwent simpson grade III resection through the pterional approach, the vessel compression was resolved. The pathology revealed a meningothelial meningioma. She was maintained on oral aspirin at 160 mg/ day, after a 6-month rehabilitation programme, the patient recovered with mild paresis in the left upper extremity.

Conclusions:: Conclusion: We present a well documented case of sphenoid ridge meningioma causing acute cerebral infarction as a result of middle cerebral artery compression. Even it is extremely rare, the possibility of sphenoid ridge meningioma must be considered in the differential diagnosis in patients with acute infarction.
SUCCESSFUL SURGICAL MANAGEMENT OF A TENTORIAL DURAL ARTERIOVENOUS FISTULA CAUSING SPINAL CORD MYELOPATHY

Hatim Belfquih
Avicenne hospital Marrakech, Neurosurgery, Marrakech, Morocco

Background and Aims:: Background: Intracranial dural arteriovenous fistulas account for 10 to 15% of all intracranial arteriovenous malformations. Tentorial dural arteriovenous fistulas with spinal medullary venous drainage causing spinal cord myelopathy have been rarely reported in the literature. We describe a case using a temporo-pterional approach for the surgical treatment of a tentorial artery dural arteriovenous fistula causing spinal cord myelopathy.

Methods:: Case presentation: A 48-year-old male presented complaining of a 15 days history of incoordination and dizziness and from 2 days history of progressive heavy weakness of his upper and lower limbs with bowel and bladder incontinence. The patient had magnetic resonance imaging (MRI) performed along with cerebral and spinal angiography that revealed a left tentorial artery dural arteriovenous fistula with spinal medullary venous involvement down to T6.

Results:: Case presentation: Angiographic embolization was attempted, but selective catheterization was unsuccessful. The patient underwent a temporo-pterional approach with obliteration of the dural arteriovenous fistula. The post-operative angiogram confirmed complete obliteration of the dural arteriovenous fistula.

Conclusions:: Conclusion: Intracranial dural arteriovenous fistulas are a rare cause of spinal cord myelopathy. When a patient presents with suspicion of spinal dural fistula and negative spinal angiography, an intracranial origin should be suspected and a cerebral angiogram performed. Skull base approaches along with intraoperative angiography provide an alternative modality for obliteration of the dural arteriovenous fistula nidus, thereby eliminating the venous congestion and hence the spinal cord ischemia.
COVID-19 LOCKDOWN AND TELE-EDUCATION TOOLS AT A NEUROLOGY RESIDENCY. A QUASI-EXPERIMENTAL STUDY

Roberto Rodríguez-Rivas
National Institute of Neurology and Neurosurgery, Neurology, Ciudad de México, Mexico

Background and Aims:: COVID-19 is an infectious disease caused by the SARS-COV2 virus discovered in 2019. Since its detection in Wuhan-China, it has spread all over the world causing emergency lock-downs in many countries. Mexico declared national emergency in March leading to disruption of neurology training programs at the National Institute of Neurology and Neurosurgery (INNN). This study aims to evaluate Tele-educational interventions implemented to continue those programs.

Methods:: This is a quasi-experimental study. Sample population of Neurology residents consisted of 23 trainees. The intervention was a Headaches’ Tele-educational module. Diagnostic and final tests were conducted to assess resident’s improvement. Primary outcome was improvement in headaches’ knowledge measured by the change in grades. Residents of each year were evaluated separately as secondary outcome.

Results:: Mean initial score was 67.02 (SD +/- 20.17) while mean final was 78.64 (SD +/- 9.21). Showing a difference of +11.62 points [CI 4.31-18.9 p 0.003]. (Figure 1)

First-year resident’s showed a median difference of 18.05 points (CI [4.165-31.915] p= 0.013) while second-year residents showed 4.125 points difference(CI [0.0001-6.940] p=0.044). The residents who improved the most were 1st-year. (Figure 2)
The performance in each item-category was measured. The lowest improvement was observed in the “Treatment” category while “Physiopathology” showed the highest. Significant improvement in all categories was observed (p=0.028). (Figure 3)
Conclusions:: In conclusion, Tele-educational interventions showed promising results when evaluating neurology residents' knowledge. But a proper control group and longer evaluating times are lacking. However, these results show that the change in paradigm can be applied to more topics without sacrificing neurological learning objectives.
Background and Aims:: Neurophobia is the fear of neuroscience and clinical neurology, inability to utilize the basic neurological knowledge at the bedside. Most of the general practitioners display less confidence when dealing with neurological cases. The exact reasons for neurophobia are not well known and it likely as a result of multiple contributory factors. Our study aimed to assess the attitude toward Neurology and to explore the reasons for this attitude.

Methods:: A self-administered, previously validated questionnaire was distributed among 393 students and interns in Sudan from July 2020 to February 2021. In this cross-sectional study, the questionnaire included demographic data and 12 statements to examine attitudes toward neurology using a Likert scale.

Results:: Participants’ mean age was 25.5 years. The students constituted 56.2% of the study population. 53% of our participants were not considering neurology as a future career. Almost 9% strongly agreed that difficulty to elicit signs in neurology is a barrier from taking neurology as a career, while 16.5% disagree that neurology has limited treatment. Most importantly, the long training time in neurology and the emotional difficulty in taking care of patients was the most cause of preventing participants from pursuing a neurology career (54% and 34% respectively). Higher number of students consider neurology as career when compared to interns (p value = .003). In addition, when compared neurology difficulty among occupations groups, medical officer was the most category that consider neurology difficult (p value = .014).

Conclusions:: Neurology was perceived as a difficult medical specialty and the reasons behind this attitude is wide ranging.
NEUROPHOBIA AMONG MEDICAL STUDENTS IN SUDAN

Mohamed Elnaeim¹, Ismat Babiker², Awab Elnaeim²
¹Alzaiem Alazhari University, Medicine, Khartoum, Sudan, ²University of Medical Sciences and Technology, Medicine, Khartoum, Sudan

Background and Aims:: To describe factors that contribute to students’ perception towards neurology, and their views on how to improve neurology training.

Methods:: A cross-sectional computerized survey was conducted among 171 medical students from Bahri University, Sudan, in the period from 8th, January 2018 to 30th, January 2018. The questionnaire included demographic data and 16 statements to assess: their neurology teaching experience, factors that would drive them toward or away from neurology, and their views on how to improve neurology training at their medical school.

Results:: Females constituted 87.7% of participants. The mean age was 21.93 (SD +/- 1.24) years. The majority of participants (83%) were not decided on their future career, and 31% of them stated that they would not consider neurology as a career. Almost half of medical students considered neuroscience and neurology teaching unsatisfactory (46%). More than half (56.8%) found neuroanatomy as well as neurological diagnosis to be contributing to neurology being perceived as a difficult subject. Of Our participants, 60% though that there are limited treatment in neurology, and 46% considered neurology outcome to be poor. Among the participants, 64.9% thought that neurology as a career choice provides good financial reward and 85.9% thought that it provides good research opportunities. Most students thought that better lectures (80.7%), better bedside teaching (82.5%), and longer time schedules allocated to neurology (90.7%) would improve their neurology training.

Conclusions:: Although there is generally unfavorable behavior towards neurology among our studied group, there was a large percentage that would consider it as a career.
EDUCATIONAL STRATEGIES IN A NEUROLOGICAL-NEUROSURGICAL FACILITY: VIRTUAL COURSE IN ENCEPHALIC VASCULARIZATION

Joana Martins¹, Beatriz Barreto¹, Maria Martins², Maria Lima³, Mariana Acioly⁴, Viviane Fragoso⁵, Flaviana Maciel⁵, Ana Melo⁵
¹Hospital Pelópidas Silveira Recife, PE – 50730-680, Brazil, Neurology, Recife, Brazil, ²Hospital Pelópidas Silveira Recife, PE – 50730-680, Brazil, Director Of Research And Education, Recife, Brazil, ³Hospital Pelópidas Silveira Recife, PE – 50730-680, Brazil, Neurological Clinic Coordinator, Recife, Brazil, ⁴Hospital Pelópidas Silveira Recife, PE – 50730-680, Brazil, Administrator And Technical Nurse In Research - Bank Of Clinical Images/picture Archiving And Communication System, Recife, Brazil, ⁵Hospital Pelópidas Silveira Recife, PE – 50730-680, Brazil, Continuing Education – Classroom Tutor, Recife, Brazil

Background and Aims:: Educational challenges in tertiary, neurological-neurosurgical facilities involve keeping staff updated, while holding firmly to the basic tenets. Knowledge of encephalic vascularization is essential to all in this scenario. Objective :To describe the creation of an online course on encephalic vascularization

Methods:: HPS-IMIP/SES/SUS has a customized educational platform (“Pelopidas Digital” Virtual-Teaching-Platform (PD-VTP) designed to provide short, point-of-care video-tutorials and tests on subjects of interest to Unit's personnel. PD-VTP is available through intra/internet (pelopidasdigital.imip.org.br). The basic unit of the PD-VTP is a module, formed by a) introduction, b) learning objectives, c) 05-minute tutorial video/video-text, d) test and e) recommended reading. Modules can be grouped into courses. The virtual course “Encephalic Vascularization” was created following Tutorials and Guides of Board of Teaching and Research HPS.

Results:: Three domains of knowledge were considered for virtual training in cerebral vascularization: 1) Anatomo-radiologic correlation of arteries and, 2) Veins and venous sinuses, 3) Clinical implications.

Conclusions:: Creation of a virtual course on cerebral vascularization is an attractive tool for dissemination of knowledge. It may involve trainees as tutors once familiar with the technological tools and supported by institutional educational teams. Health education in digital learning environments such as PD-VTP 1) accelerates training of members of therapeutic team, 2) allows for periodic audits and certification, 3) is unlimited in amount of times professionals can consult its contents and may 4) engage trainees and staff members as tutors, involved in creating virtual tools for education in neurology.
COGNITIVE AND PSYCHO-EMOTIONAL DISORDERS IN PERSONS WITH FUNNEL CHEST DEFORMATION

Olga Yuryk
Institute of Traumatology and Orthopaedics, Laboratory Of Orthopaedics And Pain Problems, Kyiv, Ukraine

Background and Aims:: Funnel chest deformation (FCD) is a manifestation of connective tissue dysplasia. The aim of our study was to identify the nature of some disorders of higher nervous activity under this pathology.

Methods:: 43 patients with FCD were examined within the preoperative period. We used the following scales: Mini Mental State Examination (MMSE), Montreal Cognitive Assessment (MoCA) and Hospital Anxiety and Depression Scale (HADS).

Results:: The mild cognitive impairments were found in 12 patients (57%), moderate ones in 6 patients (29%) and 3 patients (14%) had no abnormalities in the psycho-emotional sphere. These disorders were more pronounced in persons with FCD of the II and III degree. The mean values of the MMSE and the MoSA decreased in persons with mild cognitive impairments. The mild modal-nonspecific mnestic disorders were observed. The largest number of errors occurred when naming date and reproducing the unrelated words, both directly and delayed. The direct reproduction of the memorized material was especially decreased. The decrease in intellectual flexibility was also noted in persons of the II degree. According to the HADS data, there was an increase in the incidence of anxiety and depression in most of the examined patients, especially in persons of the II degree. The signs of clinically severe depression were found in 2 patients (10% of examined persons). The subclinical depression was detected in 11 patients (52% of examined persons).

Conclusions:: The anxiety-depressive emotional disorders predominated in persons with funnel chest deformations, and they were combined with mild cognitive impairments in the vast majority of patients.
OBJECTIVE INDICATORS OF VISUAL EVOKED POTENTIALS IN CHILDREN WITH COGNITIVE IMPAIRMENTS

Nargiza Mirdjuraeva, Maktuba Gulyamova, Shaanvar Shamansurov
Tashkent Institute for Advanced Medical Training, Child Neurology, Tashkent, Uzbekistan

Background and Aims: Cognitive impairments are an urgent problem in neurology. The impairment of cognitive activity leads to learning difficulties, deviant behavior, psycho-emotional disorders and, as a consequence, social maladjustment and a decrease in the child’s quality of life. Purpose: to assess the degree of cognitive impairments in children using VEP.

Methods: Materials and methods: we examined 65 children in two groups: Group 1 - 30 children with mental retardation, Group 2 - 35 children with ADHD. The VEP technique was applied to all the children. We measured the peak latency of the waves (PL) – the time from the moment of the stimulus onset to the top of the wave, which characterizes the velocity of the impulse conduction through the visual analyzer. In children of Group 1, the peak latency of the P1 component was 59.3 m/s (N = 68.9), which indicated a decrease in the impulse conductance through the visual analyzer at the level of the cerebral cortex. The peak latency of the N1 wave in Group 2 was 83.0 m/s, (N = 72.0), which indicated a violation of the connections between the subcortical system and the cerebral cortex.

Results: In applying the VEP technique, reliable results were obtained, which should be taken into account in the differential diagnosis of ADHD with delayed psychological development.

Conclusions: An increase in VEP latency indicates a slowdown in the conduction of a nerve impulse at different stages of the visual analyzer, which can serve as an additional diagnostic criterion in assessing cognitive functions in preschool children.
Background and Aims:: Our study was aimed at studying cognitive impairments in children with mental retardation and children with attention deficit hyperactivity disorder (ADHD), using psychological testing validated in the Republic of Uzbekistan.

Methods:: We examined 60 children in two groups: Group 1 - 30 children with ADHD, and Group 2 - 30 children with mental retardation. The psychoneurological status was assessed through evaluation of memory, thinking, perception, attention, psychoemotional, speech sphere, gnosis and praxis. In psychological testing of cognitive processes, the analysis of testing was assessed using a point-based system. It should be noted that the methods of psychological testing (S.P. Glukhova, R.I. Sunnatova) have been adapted and validated in Uzbekistan. We assessed their significance in the course of providing outpatient care to children. To study perception, memory, thinking, and attention, “Who is Hidden in the Pictures?”, “10 Things”, “Pre-Cut Pictures” and “Correction Test” techniques were used.

Results:: The analysis of testing in children with ADHD showed a moderate decrease in the level of attention and perception, with the preservation of thinking and memory processes.

Conclusions:: The overall score was 30-32 points (high level of development). The assessment of the psychological development of children with delay in psychoverbal development was 12-16 points, which indicated a low level of cognitive processes (memory, thinking).
THE PREVALENCE OF NEUROLOGICAL SYMPTOMS & PSYCHIATRIC MANIFESTATIONS OF TETRAHYDROCANNABINOL (THC) AMONG CANNABIS USERS IN PSYCHIATRIC FACILITIES IN KHARTOUM STATE, SUDAN 2021

Mohammed Alhassan Alwalid¹, Yasir Hamed², Aziza Alrayah³, Hayat Bashir¹, Leenah Mohammed⁴, Hager Awadelseed⁵, Roaa Taha⁶, Alaa Elmalik⁷, Roaa Sidahmed⁷, Samar Attaellfadeel¹, Mawahib Elsheikh³, Wishah Mohammed⁶, Mwaez Ibrahim⁷, Mihad Omer⁸, Rowaie Mohamed³, Khabab Mohamed Ahmed², Abbasher Hussien², Mohamed El Mahi⁸

¹Univerity of Khartoum, Faculty Of Medicine, Omdurman, Sudan, ²University of Khartoum, Faculty Of Medicine, Khartoum, Sudan, ³Ahfad University for Women, Faculty Of Medicine, Omdurman, Sudan, ⁴Alzaiem Alazhari University, Faculty Of Medicine, Khartoum, Sudan, ⁵National Ribat University, Faculty Of Medicine, Khartoum, Sudan, ⁶Ahfad University for Women, Faculty Of Medicine, Khartoum, Sudan, ⁷Ahfad University for Women, Faculty Of Medicine, bahri, Sudan, ⁸Hayat center for psycho-social treatment and rehabilitation, Psycho-social Treatment And Rehabilitation, Khartoum, Sudan

Background and Aims:: Cannabis refers to three group of plants with psychoactive properties. It can contribute to wide range of neurological and psychological manifestations. To study the prevalence of neurological symptoms & psychiatric manifestations of tetrahydrocannabinol among cannabis users in psychiatric facilities.

Methods:: This is an observational analytical cross sectional hospital based study that was conducted at psychiatric clinics in three hospitals in Khartoum state among 34 adults chosen as total coverage for 4 weeks, using The Edinburgh Neuro-symptoms Questionnaire, Mini international neuropsychiatric interview 5th edition and DSM-V.

Results:: All of the 34 were males, the mean age was 27.53 years. All of the users have psychiatric symptoms (bipolar disorders 29.4%, OCD 41.2%, psychotic feature 35.8%, major depressive disorder 67.6%, anxiety-like symptoms 61.8%, social phobia 44%, panic attack 38.2%, ideation of suicidality 47.1% and 23.5% planned to suicide). The 34 have neurological symptoms (17.6% experienced loss of consciousness (20.6% of them had convulsions), status epilepticus 11.8%, limb weakness 32.4%, numbness and altered sensation 29.4%, memory problems 64.7%, fatigability 58.8%, tremor 26.5%, lack of concentration 52.9%, blank spells during the day 47.1%, pain almost every day in more than one part of the body 29.4, vision disturbance 35.3%, tinnitus 14.7%, difficulty in swallowing and feeling of something stuck in the throat 11.8%, difficulty in speaking 35.3% and 11.8% had stutter at age of 16).

Conclusions:: The issues of cannabis should be taken seriously, because it is a great contributor to wide range of neurological and psychiatric manifestations.
A PHASE 2, DOUBLE-BLIND, PLACECO-CONTROLLED STUDY OF THE SAFETY AND EFFICACY OF MICROBIAL ECOSYSTEM THERAPEUTIC-2 (MET-2) IN PATIENTS WITH MAJOR DEPRESSION: PROTOCOL AND PRELIMINARY RESULTS

Arthi Chinna Meyyappan, Roumen Milev
Queen's University, Psychiatry And Neuroscience, Kingston, Canada

Background and Aims:: Introduction: Recent studies have investigated the potential of treatments that modify the gut microbiome, such as fecal microbiota transplantation (FMT) and probiotics, in individuals with psychiatric illnesses. The aims of this double blind randomized controlled trial was to investigate the safety and efficacy of a novel gut microbiome therapeutic, Microbial Ecosystem Therapeutic-2 (MET-2), in people with depression.

Methods:: In this trial, sixty adults diagnosed with Major Depressive Disorder will be recruited. Participants will consume orally once daily an encapsulated microbial therapeutic, containing 40 strains of bacteria purified and lab-grown from a single healthy donor stool, or a placebo alternative for 6 weeks. Participants will be assessed on a biweekly basis in order to evaluate the safety and efficacy of the therapeutic using clinical scales and questionnaires.

Results:: Findings: The therapeutic has been found from earlier studies to be generally safe and tolerable, with limited adverse events and side effects, and no serious adverse events. We expect participants' mood symptoms to improve over the course of their involvement in the study as a result of changes in their gut microbiome composition and immune marker levels.

Conclusions:: The findings of this study will be the first to provide evidence for the role of microbial ecosystem therapy in treating depression in comparison to a placebo alternative.
FUNCTIONAL NEUROLOGICAL DISORDERS MIMING A STROKE: MANAGEMENT IN THE ACUTE PHASE

Giulia Bellavita, Paola Caruso, Giovanni Furlanis, Mariana Ridolfi, Marcello Naccarato, Paolo Manganotti
Cattinara University Hospital, ASUGI, University of Trieste, Trieste, Italy, Neurology Unit, Department Of Medical, Surgical And Health Sciences, Trieste, Italy

Background and Aims:: The prompt recognition of stroke symptoms is mandatory in the emergency department (ED) in line to guarantee the right acute reperfusion therapy. Intravenous thrombolysis remains the first line therapy suggested, it may consent vessel recanalization and neurological deficit regression. Stroke mimics (SM) can account for up to 25% of all acute stroke presentations. Among stroke mimics functional neurological disorder are increasing overtime. The rate of false-positive diagnoses of ischemic stroke, "stroke mimic", ranges from 1.3% to 25% in patients not treated with thrombolysis.

Methods:: In our retrospective analysis we isolated 24 patients suffering of a functional neurological disorder that were admitted in our Stroke Unit for a sudden focal neurological deficit.

Results:: All patients with functional neurological disorder were first evaluated in the ED, than admitted in our Stroke Unit, in 9 cases thrombolysis was performed and was safe. In line with previous studies, patients with functional neurological disorder were young, mostly with family or personal history of neurological and psychiatric pathology.

Conclusions:: In the ED is quite difficult to discriminate a stroke from a psychogenic stroke mimic but physicians have to decide in a short period which treatment start quickly. Thrombolysis is safe in SM. We describe the experience of our stroke unit in the recognition and management of acute neurological deficit due to functional neurological disorder. More data are required to draw up a right diagnostic protocol that may guide clinicians in the proper selection of patients that would benefit from thrombolysis.
THE EFFECT OF BRAIN GYM TOWARDS ANXIETY LEVEL OF ELDER PEOPLE IN RURAL AREAS OF YOGYAKARTA, INDONESIA

Cempaka Thursina¹, Sri Sutarni¹, Daffa Wicaksana², Giga Alkarani¹
¹Universitas Gadjah Mada, Neurology, Yogyakarta, Indonesia, ²Universitas Gadjah Mada, Faculty Of Medicine, Public Health, And Nursing, Yogyakarta, Indonesia

Background and Aims:: In 2012 The National Statistical Committee of Indonesia stated that the number of elder people in Yogyakarta was at 13.04% of all Indonesian populations. The elder people need more attention and safe medications which may affect their physical and psychological bodies. Some elder people may suffer from any emotional imbalance, including anxiety or mood disorders. The prevalence of anxiety in individuals 55 years old or more is 2.8%. One of the effective ways to control and maintain the emotional level is a brain-stimulating activity or known as brain gym. This study aims to find out the effect of brain gym on the level of anxiety in elder people in the rural areas of Yogyakarta, Indonesia.

Methods:: This was a community-based analytical study with quasi-experimental and using pre and post-test one-group design. The level of anxiety was measured with Hamilton Anxiety Rating Scale (HARS) before and after the brain gym. The brain gym was performed on each respondent for 2 months with the duration of each session was 30 minutes every twice a week.

Results:: The results from 26 respondents were that the mean score of HARS before brain gym was 9.38 ± 6.01 or categorized as mild anxiety. After brain gym for 2 months, the mean score of HARS was 5.12 ± 5.24 or categorized as no anxiety. The results also showed that brain gym had the significant effect of lowering the level of anxiety (p=0.006).

Conclusions:: Brain gym had a significant effect on lowering the level of anxiety of elder people in rural areas of Yogyakarta, Indonesia.
IDENTIFYING SOCIOECONOMIC, PSYCHIATRIC, AND BIOLOGICAL RISK FACTORS IN PSYCHOGENIC NONEPILEPTIC SEIZURES

Rachel Gorenflo¹,², Richard Ho¹,², Enrique Carrazana¹,², Jason Viereck¹,², Kore Liow¹,², Arash Ghaffari-Rafi¹,²
¹Hawaii Pacific Neuroscience, Clinical Research Center, Honolulu, United States of America, ²University of Hawai‘i at Mānoa, John A. Burns School Of Medicine, Honolulu, United States of America

Background and Aims:: PNES make up 20-30% of diagnoses for intractable epilepsy, resulting in incorrect treatment and unnecessary medical cost. The aim of this case-control study is to identify risk factors associated with the development of PNES, which could potentially aid with earlier disease recognition.

Methods:: To identify socioeconomic and medical risk factors unique to PNES, a retrospective case-control study was conducted at an epilepsy center in Hawaii. After excluding patients without a video EEG, 101 patients were identified. Two sets of randomly-selected controls were utilized: 303 unmatched and 202 matched by age, sex, and race.

Results:: PNES median age was 43 (IQR 30-54), 16 years younger than controls (95%CI:12.00-21.00), p=7.95x10⁻¹². Median household income was $3760 (95%CI:0.00029-10935;p=0.0054) less amongst PNES patients.

¹Compared to unmatched controls
Conclusions: There are socioeconomic and racial disparities that play a role in the development of PNES.
FXTAS SYNDROME: NEUROPSYCHIATRIC FEATURES

Charfi Rihab1, Khadija Sonda Moalla2, Nouha Farhat3, Olfa Hedjii3, Salma Sakka4, Sawsan Daoud3, Hanene Hajkacem2, Mariem Damak3, Chokri Mhiri5
1CHU Hbib Bouguiba Sfax Tunisie, Of Neurology, Sfax, Tunisia, 2Universal Hospital Habib Bourguiba, Neurology, Sfax, Tunisia, SFAX, Tunisia, 3CHU habib bourguiba Sfax, Neurology, sfax, Tunisia, 4UNIVERSITY HOSPITAL CENTER HABIB BOURGUIBA, Neurology, SFAX, Tunisia, 5Habib Bourguiba university hospital, Neurology, Sfax, Tunisia

Background and Aims:: Le syndrome de tremblement et d'ataxie associé à l’X fragile (FXTAS) est une maladie neurodégénérative développé par des porteurs d’une prémutation dans le gène fragile X mental retardation 1 (FMR1). To study the neuropsychiatric profile and paraclinical features of FXTAS patients.

Methods:: All patients underwent a neuropsychological assessment, brain MRI and an ENMG study.

Results:: We included 3 patients with sex-ratio 0.5. Cerebellar ataxia was the initial manifestation in all patients with an onset age of 50 years. Pyramidal signs and peripheral neuropathy were present in two patients respectively. Mean MMSE was 26/30 with executive function deficits, anxiety and depression in all patients. Brain MRI showed bilateral hyperintensities of the middle cerebellar peduncles (MCP sign) on FLAIR images in all patients.

Conclusions:: FXTAS has a high penetrance in males and variable penetrance in females in accordance with their X-inactivation ratio. It usually manifests in the early 60s, typically beginning with intention tremor followed by cerebellar ataxia. However, up to 20% of FXTAS patients can develop ataxia without concomitant tremor like in our patients. Cognitive deficits include executive and/or attentional dysfunction. Behavioural features associated with the premutation alleles include anxiety, obsessive–compulsive traits and depression. They usually worsen with cognitive decline. MCP sign is the hallmark of FXTAS correlating with motor symptoms as well as cognitive and behavioural features. FMR1 premutations are associated with a variety of manifestations and phenotypes. Neuropsychiatric problems are quite common in carriers and usually present early in life, which could be problematic and requiring medical treatment.
PSYCHOSIS AS AN UNUSUAL BEGIN OF CREUTZFELDT – JAKOB

Charfi Rihab¹, Salma Sakka², Rim Smaoui³, Olfa Hdiji³, Sawsan Daoud², Khadija Sonda Moalla², Nouha Farhat², Mariem Damak², Chokri Mhiri⁴
¹CHU Hbib Bouguiba Sfax Tunisie, Of Neurology, Sfax, Tunisia, ²Universal Hospital Habib Bourguiba, Neurology, SFAX, Tunisia, ³CHU habib bourguiba Sfax, Neurology, sfax, Tunisia, ⁴Habib Bourguiba university hospital, Neurology, Sfax, Tunisia

Background and Aims:: Creutzfeldt-Jakob disease (CJD) is an extremely rare and devastating disease characterized by rapid neurological deterioration in a healthy individual. The classic clinical presentation of CJD includes rapidly progressive dementia, myoclonus, pyramidal, extrapyramidal and cerebellar signs. Although it is less frequent that the disease begin with non-specific psychiatric signs.

Methods:: Retrospective study of a patient diagnosed with CJD

Results:: We reported the case of a 66-year-old woman without personal or familial psychiatric history. Initial symptoms included delusions of persecution, depressed mood, memory loss, and a strange sensation. His sons stated that his cognitive problems had worsened significantly in the previous two weeks and associated with visual, auditory and sensory hallucinations. The physical examination was significant for perseverance, agnosia and apraxia associated with depressed mood and loss of vital momentum. His muscle tone was normal at all four extremities. Magnetic resonance imaging showed high signal intensity in the bilateral caudate, putamen and left frontotemporal cortex in T2-weighted and diffusion-weighted imaging. Studies on cerebrospinal fluid were also performed. The number of cells, glucose and proteins were within normal limits its 14-3-3 protein level was positive.

Conclusions:: Our patient was diagnosed with probable CJD, based on internationally-agreed diagnostic criteria. This fatal neurological disease occurs in sporadic, familial and acquired forms. Psychiatric symptoms are considered rare; in early stages of the disease they are found in up to 40% of the cases. However, presentation as a pure psychotic condition over so many months of development is not typical.
SNEEZING AS CONVERSION DISORDER: DIFFERENT FACES OF THE SAME FRAGILITY.

Federica Reina¹, Antonio Marino¹, Giovanna Martina Nocera¹, Mariarita Capizzi¹, Antonina D’Amico¹, Edvige Correnti¹, Renata Pitino², Daniela Buffa³, Vincenzo Raieli²
¹Università degli studi di Palermo, Scuola Di Medicina E Chirurgia, Palermo, Italy, ²ARNAS Civico Palermo, P.o. Di Cristina - Child Neuropsychiatry Dept, Palermo, Italy, ³ARNAS Civico Palermo, P.o. Di Cristina - Child Neuropsychiatry Dept, Palermo, Italy

Background and Aims:: Sneezing is a common symptom that can be caused by many factors such as foreign substances, allergies, chemical irritants and other less common factors. Intractable paroxysmal sneezing is a very rare condition and just a small number of cases have been reported. The majority of these studies are mainly referred to adolescent female patients and some children, in which intractable sneezing had psychogenic origins. Common clinical features of conversion disorders, like headache and pseudo-seizures, can rotate to time or manifest even in the same patient simultaneously. The aim is present a case of psychogenic intractable sneezing occurred in an adolescent patient.

Methods:: The sneezing, persisted for several consecutive days, used to be continuous whereas open eyes, except during sleep, with a frequency of once every 5-60 seconds. The patient had a past medical history of gastralgia and tachycardia during last 8 month and headache started when the girl was 12 years old. Although ordinary examinations showed a regular clinical state, psychogenic stressors were recognized so she started anxiolytic drugs and supportive counselling. A series of psychiatric conversations were needed to convert symptoms into verbal externalizations with a progressive improvement of headache and cessation of sneezing.

Results:: The case perfectly describes an intractable paroxysmal sneezing disorders. Psychological counselling was one of the most beneficial therapy, whereas the others showed conflicting results.

Conclusions:: Psychogenic intractable sneezing is a real and debilitating disease. When ordinary examinations and investigations showed a regular clinical state, psychogenic stressors must be explored to make the correct diagnosis.
INVESTIGATING THE GENDER DIFFERENCE AND PREVALENCE OF DEPRESSION AMONG PATIENTS WITH FIBROMYALGIA AT THE NPZR

Elif Cindik-Herbrüggen\textsuperscript{1}, Rahman Demirkol\textsuperscript{2}
\textsuperscript{1}NPZR- Neuro-Psychiatric Center Riem (Neuro-Psychiatrisches Zentrum Riem), Psychosomatik/psychotherapie, Munich, Germany, \textsuperscript{2}NPZR, Psychiatry, München, Germany

Background and Aims:: Chronic pain among patients with FM may cause feeling of hopelessness and depression. According to a current meta-analysis a lifetime depression frequency among people with FM was % 65 (J.S.Loge-Hagena, et al., 2019). Additionally, fibromyalgia is more common in women (% 4.2) than men (% 0.2) (Mas, Carmona, Valverde, Ribas, & Group, 2008). This study aimed to investigate the prevalence of depression in patients with FM treated at the Neuro-Psychiatric Center in Riem (NPZR).

Methods:: A total of 96 FM patients (19.8%, n=19 male and 80.2%, n=77 female) diagnosed with FM were selected from patient files between 2015 and 2021. Clinical interviews and the Beck Depression Inventory (BDI) had been conducted in FM patients to measure the level of depression.

Results:: The sample showed a significant gender difference with 80.2% female patients, 49% of participants were between 51 and 60 years old. The study sample showed a high prevalence of severe depression (85.4%). Tinnitus, and migraine were the most common comorbidities (both 12.5%). 57.3% of patients enrolled in 2015 still continue their treatment.

Conclusions:: The ongoing research is in line with previous studies: FM patients are mainly female and older than 50 and demonstrate high levels of depression and comorbidities such as Tinnitus and Migraine.
A ‘SHOULDER TAP’ TEST FOR FUNCTIONAL GAIT DISORDERS: A SIGN OF ABNORMAL ANTICIPATORY BEHAVIOUR

Diego Kaski¹, I Zimianiti², J Coebergh³
¹University College London, Centre For Vestibular And Behavioural Neuroscience, Department Of Clinical And Movement Neurosciences, Institute Of Neurology, London, United Kingdom, ²University College London, Centre For Vestibular And Behavioural Neurosciences, Institute Of Neurology, London, United Kingdom, ³St. George’s NHS Foundation Trust, Neurology, London, United Kingdom

Background and Aims:: Functional gait disorders (FGDs) involve gait abnormalities that are internally inconsistent and incongruent with other neurological disease. The clinical pull (or retropulsion) test is widely considered the gold standard in evaluating postural instability in patients with neurological gait disorders. Here, we describe the range of postural responses to the pull test in patients with functional gait disorders (FGDs) and explore the utility of the ‘shoulder tap test’ in these patients.

Methods:: Patients with a diagnosis of FGD were identified from movement disorders clinics at Ashford St Peter’s and St George’s University Hospitals NHS trusts. Reactions to being ‘tapped’ at the shoulders or pulled were retrospectively analysed using clinical records. For the shoulder tap test, patients were instructed that “on the count of three please try to keep upright if you are moved backwards” and that they were allowed to take as many steps as needed to avoid falling.

Results:: Thirty-one patients with FGDs in whom responses were documented to either shoulder tap, pull test, or both were included in the analysis. All patients in whom a shoulder tap was performed (n=25) had an abnormal response, including taking multiple steps (n=9), significant body sway or a startle response (n=4), falling into the examiner’s arms (n=7), or anticipatory body movement before being tapped (n=4). Abnormal responses to pull were documented in 14/17 patients (82.35%).

Conclusions:: The ‘shoulder tap test’ was abnormal in all patients with FGD, even in those with a normal pull test, and may reflect postural hypervigilance and abnormal expectation in these individuals.
IMPACT OF COVID-19 PANDEMIC ON THE ACUTE CONFUSIONAL SYNDROME BY THE LIAISON PSYCHIATRY SERVICE OF HOSPITAL DEL MAR

Maria Calls Samora1, Silvia Oller Canet1, Fernando Dinamarca Cáceres1, Diego García Hernández1, Alba Llimona González1, Guillem Deus García2, Carla Llimona Sánchez1, Francesc Casanovas Martínez1, Ana Pérez Oms1

1Hospital del Mar, Psiquiatría, Barcelona, Spain, 2Hospital del Mar, Medicina Interna, Barcelona, Spain

Background and Aims:: Introduction: Coronavirus Disease 19 (COVID-19) pandemic has had a profound worldwide impact on health. Since the outbreak the most common neuropsychiatric complication has been Acute Confusional Syndrome (ACS). Aim: To describe characteristics of the admitted patients attended by the liaison psychiatry service for ACS during the COVID 19 pandemic. Clinical and sociodemographic variables were described.

Methods:: Material and Methods: We conducted an observational, descriptive study. All patients attended by the liaison psychiatry service of Hospital del Mar, between February and April 2020, with ACS diagnosis were included. Results are described in terms of mean, standard deviation and proportion, depending on each variable.

Results:: We included 62 patients with acute confusional syndrome; 35 were men (56.5%), with a mean age of 71.71 years (standard deviation [SD]:11.3). The mean stay of hospital admission was 41.19 days [SD: 38.039]. The mean number of consultations carried out was 6.5 [SD: 5.422]. Half of our sample (52.5%) had confusional symptoms for 8 days. 50 patients presented complications during admission (80.6%), of which 43 patients developed infectious complications (69.4%). Almost the entire sample (59 patients) had a history of chronic diseases (95.2%). 54 patients (88.5%) had potential risk factors associated with acute confusional syndrome including: active infection in 46 (74.2%), hypoxemia in 25 (40.3%), isolation in 24 (39.3%) and previous cognitive impairment in 15 (24.6%).

Conclusions:: During the first pandemic crisis of COVID-19 confusional patients had many complications and many risk factors associated such as active infection, hypoxemia and isolation (which in turn are symptoms of COVID-19).
HIGH BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) AND NEGATIVE PSYCHOLOGICAL FLEXIBILITY AS POTENTIAL PREDICTORS OF EARLY FATIGUE SYNDROME IN HEALTHY FEMALES.

Nalinee Yingchankul  
Faculty of Medicine, Chiang Mai University, Family Medicine, Muang, Thailand

Background and Aims: Fatigue is one of the most common non-specific symptoms complaints in an apparently healthy person. Recent studies showed that enhancing psychological flexibility could improve fatigue interference. Our study aims to explore the association of fatigue with psychological flexibility and related biomarkers.

Methods: A cross-sectional study gathered data from a baseline characteristic mindful volunteer. Each participant was self-evaluated with the questionnaire of fatigue and psychological flexibility. They have also been evaluated by potential factors causing fatigue as sleep quality by the Pittsburgh sleep questionnaire and self-evaluated sleep quality, depression by PHQ-9. The participants were evaluated potential biomarkers related to psychological flexibility including HRV, serum cortisol, and BDNF within one week after responding to the questionnaire.

Results: The evaluation was done on 47 healthy females including 22 nurses and 25 occupational therapy students, mean age 29.70 ± 12.55 years. The prevalence of fatigue is 38.30%. The bivariate analysis comparing fatigue and the non-fatigued group showed higher negative psychological flexibility score (15.44 ± 5.81 vs 9.14 ± 4.19, p=0.001), higher PSQI score (8.39 ± 2.95 vs 5.97 ± 2.67, p=0.006) and higher BDNF (7.60 ± 3.46 vs 5.69 ± 3.74, p = 0.04) in the fatigue group. The multivariate analysis showed the independent factors associated with fatigue including negative psychological flexibility (OR 1.31, p=0.03) and high BDNF (OR 1.33, p=0.05).

Conclusions: Our study supported the previous finding that psychological flexibility was an independent association with fatigue. BDNF showed association with fatigue which may be the potential biomarkers for detecting early fatigue conditions.
THE LANGUAGE OF SCIENTIFIC VALIDATION IN TRANSLATIONAL NEUROSCIENCE: FROM THE HERMENEUTICS OF THE SYMPTOM TOWARDS A CONTINUUM PARADIGM

José Ignacio Hernández
Universidad de Mendoza, Facultad De Ciencias Médicas, Mendoza, Argentina

Background and Aims:: The current challenge in the biological study of Neuropsychiatry - particularly, in Major Depressive Disorder - consists of avoiding exercising a reductionism in the language of psychopathology by naturalizing its symptomatology (Berrios, 2011). For this, it is essential to observe the conceptual aspects inherent to the validation of the methods applied in their study. However, it is paradoxical to recognize that, in numerous neurobiological research projects, this observation is hardly considered relevant due, fundamentally, to the heterogeneous conceptual evolution that experimental validation criteria present. The general objective of this work is to develop a study with logical and chronological rigor of the conceptual evolution of the validation criteria applied to experimental models in the basic research of Depression.

Methods:: A posteriori, this task will involve a pertinent bibliographic review, in order to rethink the meaning of scientific understanding from the creative power of words (Lacan, 2017).

Results:: The language of psychopathology is based on the implications that the subject's discourse manifests in the organization of their own psychic body, because their unconscious has the structure of a language (Lacan, 2017). Consequently, basic research of Depression requires a translational continuum approach (Belzung, Lemoine, 2011) that allows to revalue the hermeneutical dimension of the symptom.

Conclusions:: Finally, the notion of scientific understanding is inherent to the conceptual validation of the investigation methodology (Geyer, Markou, 1995), as it is in words where reside the concepts that constitute the time of the phenomena (Lacan, 2017) which will be known by virtue of their symbolic nature.
WORKPLACE VIOLENCE AGAINST DOCTORS IN KHARTOUM STATE, SUDAN 2020

Salih Hamza¹, Muna Elamin², Khalid Ahmed³, Yassin Abdalla¹, Tbyan Alkabashi⁴, Khadija Muhmmed⁵, Radi Alhusseini⁶, Khabab Mohamed Ahmed⁷, Sidieg Mohammed⁸, Ahmed Mohammed Mustafa⁸

¹Faculty of Medicine and Health Sciences, Omdurman Islamic University, Internal Medicine, Omdurman, Sudan, ²Faculty of Medicine and Health Sciences, Omdurman Islamic University, Community Medicine, Khartoum, Sudan, ³Faculty of Medicine and Health Sciences, Omdurman Islamic University, Microbiology Department, Khartoum, Sudan, ⁴Omdurman Islamic University, Faculty Of Medicine, Khartoum, Sudan, ⁵Faculty of Medicine and Health Sciences, Omdurman Islamic University, Anatomy Department, Khartoum, Sudan, ⁶Alzaeim Alazhari University, Medicine, Khartoum, Sudan, ⁷University of Khartoum, Faculty Of Medicine, Khartoum, Sudan, ⁸Omdurman Islamic University, Faculty Of Medicine And Health Sciences., Khartoum, Sudan

Background and Aims:: Workplace violence against health care workers and especially doctors are now clearly taken as a rapidly rising health problem in Sudan with great political and legal issues concerns. This study aimed to explore the prevalence of verbal and physical workplace violence, the major factors associated with it, and its consequences reported by medical staff at Khartoum, Sudan governmental hospitals 2020.

Methods:: This is a cross-sectional survey. Self-administered questionnaires were used to collect data on aspects of workplace violence against doctors in Khartoum, Sudan governmental hospitals. An online questionnaire were distributed randomly in online doctor's groups. The data were analysed by SPSS version 26.

Results:: About 195 (50%) participants experienced one type of violence, either physical or non-physical. The assailants were mostly males in the age group of 19-35 years (70.2%), most of them were under no influence (60.8%). The most frequent consequence of violence was anger and the majority treat themselves, 79.1% of the respondents did not report the incident mostly because it was useless and from their experience, no action would be taken.

Conclusions:: Approximately one in every two doctors has experienced some degree of violence either physical or non-physical violence or both, and it was negatively reflected on their psychological status as well as their work performance.
A SYSTEMATIC REVIEW OF OVERLAPPING AFFECTED BRAIN AREAS IN SEVERE MENTAL DISORDERS ADULT INPATIENTS

Augusto Brenner1,2, Felipe Cesar Claudino2,3, Luisa Burin2,3, Victória Scheibe2,4, Bárbara Padilha2,5, Gianfranco De Souza1,2, Juliana Duarte2,6, Neusa Rocha2,3
1Universidade Federal de Ciências da Saúde de Porto Alegre, Medicine, Porto Alegre, Brazil, 2Hospital de Clínicas de Porto Alegre, Center Of Clinical Research, Porto Alegre, Brazil, 3Universidade Federal do Rio Grande do Sul, Psychiatry, Porto Alegre, Brazil, 4Universidade Luterana do Brasil, Medicine, Canoas, Brazil, 5Universidade Federal do Rio Grande do Sul, Medicine, Porto Alegre, Brazil, 6Universidade Federal do Rio Grande do Sul, Radiology, Porto Alegre, Brazil

Background and Aims:: In severe presentations, major depressive disorder (MDD), schizophrenia (SZ), and bipolar disorder (BD) can be categorized as severe mental disorders (SMD). Despite the clinical attributes that outline them, studies have demonstrated overlapping genetic, biological, and environmental aspects, including neuroimaging findings. Our aim is to evaluate structural magnetic resonance imaging and computed tomography findings in adult inpatients diagnosed with SMD and hospitalized at psychiatric wards.

Methods:: PubMed, Embase, PsycInfo, Cochrane Library, and Web of Science were searched up to May 27th, 2021, using predefined terms and criteria. Articles were screened and extracted by two independent groups, with third-party raters for discrepancies. Quality of evidence was evaluated with the Newcastle-Ottawa Scale. Synthesis was made by qualitative analysis. This study is registered on PROSPERO (CRD42020171718) and followed the PRISMA protocol.

Results:: 35 studies were included, of which none was considered to likely introduce bias in our analyses. Overlapping areas in MDD, SZ, and Affective Psychosis (AP) patients, which include BD and MDD with psychotic features, are presented in the inferior temporal and cingulate gyri. MDD and SZ disorders had commonly affected areas in the inferior and middle frontal gyri, transverse temporal gyrus, insula, and hippocampus. Considering the analyses of SZ and AP, commonly affected areas were found in the temporal pole.

Conclusions:: Overlapping affected areas among SMD patients are reported, but the heterogeneity of studies’ designs and findings are still a limitation for clinically relevant guidelines. New neuroimaging resources and longer longitudinal designs with bigger samples are necessary to enable reliable pathophysiological data of SMD patients.
Background and Aims: Impaired social cognition is frequent in individuals with schizophrenia (IS); however, how far predicting the intentions of others is affected is unclear. We have previously shown that healthy individuals can predict social intentions and adapt their behaviour, whereas individuals with prediction deficits, like autism spectrum disorder, fail to do so. This study aims to assess prediction deficits in IS using a novel neuropsychological method.

Methods: We included 9 IS and 4 healthy controls (adults). All participants played a game where they interacted with a virtual agent while intercepting a target that moved downwards on the screen at different x-offsets. The agent displayed three different behaviours, neutral, invasive, or passive, which are representative of social intentions. To analyse this interaction, we extracted psychometric curves based on the subject’s responses and obtained the point at which the subjects displayed a 50% probability to move towards the target (Fig. 1 and 2). Its shift from the centre indicates the bias induced by the agent's behaviour.
**Results:** Our preliminary results show that both groups adapted to the agent’s behaviour. However, only IS displayed a significant difference in a shift from the neutral behaviour and a close to significant difference in the invasive behaviour compared to the control group (Fig. 3).

**Conclusions:** By analysing the responses to social behaviours we assessed whether IS present prediction deficits. The results demonstrated a tendency for IS to react differently to “invasive behaviour” compared to controls. This resonates with the notion that IS might attribute intentions differently than healthy individuals.
ANALYSIS OF POPULATION DISTRIBUTION OF GENOTYPES RELATED TO METABOLIC SYNDROME INDUCED BY ANTIPSYCHOTIC DRUGS

Yan Zhang, Xiaohua Cui
Xi'an Mental Health Center, Pharmacy Lab, Xi'an, Shaanxi, China

Background and Aims: To explore the relationship between different genotypes of antipsychotic drugs and metabolic syndrome, and to analyze the distribution characteristics of population in western China.

Methods: To collect a 3 armour hospital patients with mental disorders caused by drug metabolic abnormalities, a total of 202 cases, the application of self-made questionnaire survey general demographic data, height, weight, duration, hospitalization time, drug usage, etc., according to the course, use according to the Chinese medical association suggested that suitable for China's syndrome diagnostic criteria identified patients with MS. Data statistical analysis software was used to summarize and analyze different genotypes.

Results: 1. There were differences between the C/C, -/C, -/ - genotypes of HTR1ARS6295 and the therapeutic effect of antipsychotic drugs on patients with metabolic syndrome. 2. People with metabolic syndrome caused by antipsychotics had a worse response rate than those with genetically guided mental disorders, with an overall response rate reduced by 23.85%. 3. Metabolic syndromes induced by antipsychotics appeared to be undifferentiated across all genotypes, but polymorphisms of DRD3rs6280, HTR2ARS6513, and MC4RRS17782313 were different from metabolic syndromes induced by antipsychotics. C/T gene mutation in DRD3RS628, A/A gene mutation in MC4RRS1772313, and T/T gene mutation in HTR2ARS6513 are more likely to produce metabolic syndrome under antipsychotic treatment. 4. The number of cases of metabolic syndrome screened out in this study was small, so the number of patients with different genotypes was small or 0, which affected the overall judgment.

Conclusions: DRD3rs6280, HTR2ARS6513 and MC4RRS17782313 were found with metabolic syndrome.
PET-MRI FINDINGS IN IDIOPATHIC INFLAMMATORY MYOSITIS: A FIRST STUDY

S G Manu¹, Atchayaram Nalini¹, Seena Vengalil¹, Chandana Nagaraj², Saraswati Nashi¹, B N Nandeesh³
¹National Institute of Mental Health and Neurosciences, Department Of Neurology, Bangalore, India,
²National Institute of Mental Health and Neurosciences, Department Of Neuro Imaging And Interventional Radiology, Bangalore, India,
³National Institute of Mental Health and Neurosciences, Department Of Neuropathology, Bangalore, India

Background and Aims:: We sought to determine the utility of PET-MRI in diagnosing Idiopathic Inflammatory Myositis (IIM), and look for correlation between FDG uptake and clinical, pathological and laboratory parameters.

Methods:: A retrospective, observational study was conducted on twenty-two patients of IIM, having positive serum autoantibodies, who underwent PET-MRI (3-Tesla SIEMENS Biograph MR scanner) from 2017-2020. Thirty patients who underwent PET-MRI for detection of systemic metastasis, without muscle involvement formed the control group.

Results:: In the IIM cohort, Female:Male ratio- 1.44, mean age at diagnosis- 42.23 ± 12.02 years, and the mean duration of illness- 8 ± 6.4 months. 72.73% patients had moderate to severe, predominantly proximal limb weakness. Serum autoantibodies identified were Mi2B(40.9%), PL-7(9.1%), PL-12(9.1%), SRP(13.64%), Ro-52(36.36%), PM-Scl, U1-RNP, ANA(27.27%). Whole body PET-MRI showed a sensitivity of 100% with 86.7% specificity in diagnosing IIM, using SUVmean Ratio to quantify FDG uptake. FDG uptake was maximum in pelvic girdle followed by pectoral girdles. Multivariate regression analysis showed severity of muscle weakness, MiB2A antibody positivity and creatinine kinase levels had significant positive correlation with FDG uptake in PET-MRI (P value- 0.002, 0.014, 0.032 respectively for limb FDG uptake). FDG uptake also showed good correlation with histopathological features (severity of muscle inflammation, interstitial edema) and muscle MRI (muscle edema in T2-STIR), but there was no significant association with treatment response.
Conclusions:: Current study confirms that PET-MRI is a promising diagnostic modality for IIM and it reflects the severity of myositis. Further it can identify malignancy as small as 7mm. One patient with Dermatomyositis had carcinoma ovary in our cohort.
Background and Aims:: The coronavirus disease 2019 (COVID-19) pandemic has severe implications for individuals' health, daily activities, and economy worldwide. We launched a web-based questionnaire survey on May 11, 2020, to clarify the impact of COVID-19 on patients with muscular dystrophy.

Methods:: We inquired about impacts on medical care, home/facility services, daily life, support, health conditions, and infection with severe acute respiratory syndrome coronavirus 2.

Results:: By the end of February 2021, 663 participants completed the survey. Approximately 28% of patients postponed regular consultations, and 23% of patients who underwent consultations more than once a month used telephone consultations. Two of 97 patients with Duchenne muscular dystrophy taking steroids had reduced their doses. A shortage of ventilator accessories and infection protection equipment occurred following the onset of COVID-19, and this shortage had a significant impact on medical care and infection prevention measures. The lives of most school-aged patients were affected because of school closures and remote learning. More than 20% of patients reported physical or mental complaints. Some patients with mild disease complained of deteriorating motor performance due to decreased rehabilitation and the avoidance of going out. Some patients with advanced-stage disease complained of an increased care burden due to reduced service use and mental stress due to information flooding and restrictions in visiting family or friends. Two patients contracted and recovered from COVID-19.

Conclusions:: COVID-19 has significantly affected the activities and quality of life of patients with muscular dystrophy. We will continue this survey and analyze the longitudinal changes.
ACUTE HYPOKALIEMIC MYOPATHY DUE TO CHRONIC LICORICE INGESTION: A CASE REPORT.

Jessica Beretta, Alessandro Zilioli, Irene Florindo, Giovanni Pavesi
Neurosciences Unit, Department Of Medicine And Surgery, University Of Parma, Parma, Italy

Background and Aims:: Glycyrrhetinic acid, a steroid-like glycoside contained in licorice, has a mineralocorticoid activity by inhibiting the enzyme that transforms cortisol into cortisone (11β-HSD2) resulting in overactivity of mineralocorticoid receptors. This pseudohyperaldosteronism condition may result in a severe hypokalemia and impairment of muscle lipid metabolism with rhabdomyolysis.

Methods:: We report the case of a 57-year-old woman who developed subacute proximal symmetrical flaccid tetraparesis associated with generalized muscle pain, peripheral paresthesias and areflexia.

Results:: EMG showed spontaneous activity with recruitment of small amplitude, short duration and polyphasic motor units and interference facilitation (myopathic pattern with necrosis signs). Blood examinations were suggestive of rhabdomyolysis (iperCPKemia and increase of other cytolisis indexes), with severe hypokaliemia (1.7 mmol/L), metabolic alkalosis, low serum aldosterone concentration and plasma renin level. ECG showed sagging of the S-T segment, depression of T wave and elevation of U wave. Repeated careful history-taking revealed chronic daily ingesting of tablets of pure licorice and licorice-containing herbal teas for years. The intake was stopped and the patient was treated with organic potassium salts by intravenous and oral route, with complete recovery and normalization of laboratory parameters in a few weeks.
Conclusions: Mineralocorticoid activity of licorice is well-known but severe acute hypokaliemic myopathy due to chronic ingestion has rarely been reported. Clinical severity may depend on daily dosage, duration of use and different individual susceptibility. We suggest that this clinical entity, often underdiagnosed, should be considered in the differential diagnosis of acute flaccid tetraparesis with hypokaliemia to avoid life-threatening diagnostic and therapeutic delay.
A PATIENT WITH NEUTRAL LIPID STORAGE DISEASE WITH MYOPATHY (NLSD-M): A CLINICAL AND GENETIC STUDY

Barbara Risi1,2, Stefano Cotti Piccinelli1,2, Anna Galvagni2, Nicola Necchini1,2, Alessandro Padovani1,2, Massimiliano Filosto2,3

1Unit of Neurology, Asst Spedali Civili, Brescia, Italy, 2Department of Clinical and Experimental Sciences, University Of Brescia, Brescia, Italy, 3NeMO-Brescia, Clinical Center For Neuromuscular Diseases, Brescia, Italy

Background and Aims:: Neutral lipid storage disease with myopathy (NLSD-M) is an autosomal recessive disorder characterized by triglyceride-containing cytoplasmic droplets in leukocytes and muscle tissue. Usually, it presents with adult onset slowly progressive proximal muscle weakness associated with hypertrophic cardiomyopathy.

Methods:: We studied a 42-year-old patient presenting with progressive proximal upper limb weakness since age 38. Clinical examination showed both asymmetrical (right>left) proximal upper limb weakness and difficulty in walking on heels. Mild weakness of both orbicularis oculi muscles was also observed.

Results:: Diffuse cytoplasmatic accumulation of lipid droplets was detected on muscle biopsy and Jordan anomaly, a well-known NLSD marker, was found by peripheral blood smear. Genetic analysis displayed a novel homozygote deletion in the PNPLA2 gene (exon2: c[45_47del]) causing the [Gly16Del]. Both unaffected parents harbored the heterozygote deletion. Upper-limb muscle MRI showed atrophy of the supraspinatus and infraspinatus muscles, especially on the right side. Cardiac focal inferolateral intramural fibrosis was noted by MRI as a possible manifestation of lipid accumulation. However, no cardiac involvement was clinically detected.

Conclusions:: Our study suggests that 1) distal muscle involvement can be present in NLSD-M, 2) in Italian patients cardiac involvement is usually mild, differently from Far East subjects in which it is frequent and often leads to heart transplantation, 3) infraspinatus muscle is one of the most radiologically affected muscles and 4) Italian families usually harbor private mutations. Moreover, our patient presents with orbicularis oculi muscle weakness, indicating that facial muscles can also be involved and confirming clinical heterogeneity of this disease.
Background and Aims:: Colchicine is derived from the corms of Colchicum autumnale. The drug has been used therapeutically for more than 200 years in the treatment of various diseases such as Gout, Familial Mediterranean Fever (FMF), and Behcet’s disease; yet, its myotoxicity adverse reaction has not only been documented before 1996 in the British National Formulary. Colchicine induced myopathy has been described in patients with chronic renal failure and patients who are using a concomitant drug like a statin. However, pure myopathy caused by Colchicine never been reported from Saudi Arabia.

Methods:: Case Report and literature review.

Results:: This report describes a 64-year-old patient who presented with upper and lower limb weakness after two weeks of taking Colchicine for his recently diagnosed gout arthritis. He had a proximal weakness, and his muscle enzymes were very high. Furthermore, the needle electromyographic examination (EMG) demonstrated abundant fibrillations, myotonic discharges, and myopathic motor units. Two weeks after colchicine cessation, his weakness improved dramatically with normalization of CK and disappearance of myotonic discharges in the repeated EMG.

Conclusions:: This report presents the first case in Saudi Arabia that demonstrates the typical clinical presentation of Colchicine induced myopathy. Colchicine-induced myopathy is an infrequent toxic complication. Therefore, clinicians should be aware of this rare side effect, as clinical suspicion is the most important diagnostic clue, and the only effective treatment is the termination of the Colchicine.
MUTATIONAL SPECTRUM OF DYSFERLINOPATHIES IN A LARGE INDIAN COHORT

Saraswati Nashi\textsuperscript{1}, Kiran Polavarapu\textsuperscript{1}, Ram Murthy Anjanappa\textsuperscript{1}, Veeramani Preethish Kumar\textsuperscript{1}, Seena Vengali\textsuperscript{1}, Gotham Arunachal\textsuperscript{2}, Akshata Huddar\textsuperscript{1}, Gopikrishnan Unnikrishnan\textsuperscript{1}, Mainak Bardhan\textsuperscript{1}, Sanita Raju\textsuperscript{3}, Atchayaram Nalini\textsuperscript{1}

\textsuperscript{1}NIMHANS, Department Of Neurology, Bangalore, India, \textsuperscript{2}NIMHANS, Department Of Human Genetics, Bangalore, India, \textsuperscript{3}NIMHANS, Neurology, BANGALORE, India

Background and Aims:: One hundred and twenty three patients clinically diagnosed with dysferlinopathy underwent genetic analysis to identify the spectrum of mutations in a Large Indian cohort

Methods:: Next generation sequencing was used for genetic testing

Results:: Median age at onset=21 years(2-50 years, Q1-17,Q3-25), median duration illness=48 months (3 - 288 months, Q1-24, Q3-72). M:F=2.2:1. Among these pathogenic/ likely pathogenic were:101 homozygous, 11 compound heterozygous variations in DYSF.Further, from remaining 11 cases[1 had compound heterozygous with one pathogenic mutation and one VUS, 1 carried compound heterozygous with one pathogenic and benign variant, 2 had homozygous VUS and 7 had single heterozygous variant with 5 being pathogenic/ likely pathogenic and 2 VUS. Three had additional variations in other genes-CHRNE (Homozygous, Pathogenic), CAPN3 (Heterozygous, likely pathogenic,) LAMA2 (Heterozygous, VUS,). From sample of 123, 84 variants were identified in DYSF, including, 76 pathogenic/likely pathogenic, 6 VUS and 2 benign, according to ACMG classification. Thirty nine novel variants identified, (36 pathogenic/likely pathogenic and 3 VUS) and 45 known variants (40 pathogenic/likely pathogenic, 3 VUS and 2 benign). Among 76 pathogenic/likely pathogenic variants, 21 were missense (9 novel), 17 frameshift (12 novel), 12 nonsense (4 novel), 4 in-frame deletion (2 novel) and 2 exonic deletion (both novel) mutations. Five pathogenic variations were in exon 29 , and p.Arg1064His was most recurrent mutation (13 homozygous and 2 compound heterozygous).

Conclusions:: We describe the spectrum of mutations and the most recurring mutation in a large single center cohort of Indian population suspected to have Dysferlinopathy.
MAGNETIC RESONANCE IMAGING OF MUSCLES IN ANTI-MI2B INFLAMMATORY MYOSITIS AND CORRELATION WITH CLINICAL FINDINGS

Sridhar S¹, Saraswati Nashi¹, Karthik Kulanthaivelu¹, Kiran Polavarapu², Seena Vengali¹, Veeramani Kumar², Akshata Huddar³, Gopikrishna U³, Leena Shingavi¹, Mainak Bardhan⁴, Atchayaram Nalini¹
¹National institute of Mental Health and Neurosciences, Neurology, Bengaluru, India, ²NIMHANS, Neurology, BENGALURU, India, ³NIMHANS, Neurology, bengaluru, India, ⁴National Institute of Mental Health And Neurosciences (NIMHANS), Neurology, Bengaluru, India

Background and Aims:: We sought to determine Magnetic resonance imaging (MRI) characteristics of muscles in Anti-Mi2b Inflammatory Myositis, and look for correlation between imaging findings with clinical parameters.

Methods:: A retrospective, observational study of sixteen patients of anti-Mi2b positive inflammatory myositis, who underwent lower limb MRI-axial STIR, T1 sequences (1.5 T Aera ; SIEMENS healthcare MR scanner) from 2017-2020. Manual Muscle Testing-8 (MMT 8) was used for clinical severity, modified Stramare scoring to grade muscle edema and modified Mercuri scale for muscle atrophy on MRI.

Results:: In this cohort, F:M=1, median age at diagnosis 46.5 years (Q1=34.25,Q3=54.25), median duration of illness 10 months (Q1=3,Q3=34.5). The most severely affected muscles were vastus intermedius, vastus lateralis followed by iliacus, iliopsoas. Gluteus medius and minimus muscle edema showed significant correlation with Creatine kinase(CK), however, there was no significant correlation between muscle edema of most muscles and MMT-8, CK. MMT-8 did not correlate with CK values by Spearman ’s rho test. There was a trend towards correlation of muscle edema in rectus femoris, semitendinosus and soleus with CK. None of the muscles had atrophy of grade > 3. All showed fascial edema in thigh muscles.

Conclusions:: This study showed preferential severe affection of Hip and thigh muscles, however most of these muscles on Stramare scoring did not show significant correlation with MMT. Gluteal muscles showed correlation with CK. Fascial edema was uniform. we are planning to do larger study to conclude these findings.
Background and Aims: Myotonic dystrophy (DM1) is a multisystem disease that involves several organs including brain and muscles. Foot drop, gait alteration, and high risk of falling are core features of the disease. Rehabilitative approaches may benefit from a deeper understanding of how foot drop impairs gait. This pilot study aims to evaluate foot drop by merging clinical and kinematic analysis.

Methods: A cohort of 39 patients with genetically confirmed DM1 and able to walk without any support was evaluated. Quantitative muscle test and six-minute walk test (6MWT) were performed. In addition, 13 patients and 11 healthy controls (HC) underwent the 10-meter Walk Test while wearing kinematic sensors at the legs. An amplitude analysis (AR) and a power spectral density analysis (PR) of the ankle angles during gait were performed, conducting to a severity index (Norm2). Descriptive statistics, t-test, and correlation test were analyzed.

Results: A direct correlation was found between foot dorsiflexors strength (FDS) and 6MWT ($p<0.01$) in the DM1 cohort. The kinematic analysis differentiates well DM1 from HC. AR, PR, and Norm2 showed a good inverse correlation with FDS ($r = -0.86$ $p<0.001$).

Conclusions: Foot drop is a core feature of DM1 and exposes patients to reduced mobility and a greater risk of falling. Dorsiflexors strength loss correlates with a poorer performance at functional outcomes such as 6MWT. The kinematic analysis may improve patients’ stratification based on strength loss and functional capacity. These findings further clarify how foot drop affects gait and help to create a tailored rehabilitation program for each DM1 patient.
Mainak Bardhan1, Ram Murthy Anjanappa1, Kiran Polavarapu2, Veeramani Kumar1, Saraswati Nashi1, Seena Vengalil1, Akshata Huddar1, Gopikrishnan Unnikrishnan1, Tanushree Chawla1, Gautham Arunachal3, Atchayaram Nalini1

1National Institute of Mental Health And Neurosciences (NIMHANS), Neurology, Bengaluru, India, 2Children's Hospital of Eastern Ontario Research Institute; Division of Neurology, Department of Medicine, The Ottawa Hospital; Brain and Mind Research Institute, University of Ottawa, Ottawa, Neurology, ottawa, Canada, 3National Institute of Mental Health And Neurosciences (NIMHANS), Human Genetics, Bangalore, India

Background and Aims:: Sarcoglycanopathies are autosomal recessive forms of Limb-girdle muscular dystrophies (LGMD) caused by mutations in SGCA, SGCB, SGCG, and SGCD. The genetic architecture of sarcoglycanopathies in Indian patients is inadequate. In the present study, we aimed to investigate the clinical manifestations and the genetic basis of patients who are suspicious of being affected by sarcoglycanopathies.

Methods:: Detailed Clinical examination and lab investigations were done. NGS was performed in probands and family members with suspected LGMD.

Results:: A total of 37 different variants were detected in sarcoglycan genes in 72 cases (39 male, 33 female, age 5-50 years). 46 probands have consanguineous parentage. Thirty-one variations were predicted to be pathogenic /likely pathogenic, 24 (77%) are known, 7 (23%) are novel. These confirmed the clinical diagnosis in a total of 63 (88.73%) probands with biallelic variations [SGCA-18; SGCB-33; SGCG-7; SGCD-5], a single heterozygous variant in one patient. The most common mutation was c.544A>C (p.Thr182Pro) in SGCB, which was detected in 20 patients (27.77%). The majority of pathogenic mutations were homozygous (n=29; 96.6%), while compound heterozygous and single heterozygous mutations were once each. Variants in 7 cases were of uncertain significance (5 cases) and benign (2 cases) nature. 16 patients (six harbors c.544A>C (p.Thr182Pro) in SGCB) have loss of ambulation at the mean age of 14.1±9.1 years, after about 8.7±7.3 years into the illness. Only 2 patients had cardiac symptoms and one had respiratory system involvement.

Conclusions:: Our study suggests mutations in SGCB are the most common, followed by SGCA, SGCG, and SGCD, expanding the mutational spectrum. This is the first study with a large cohort of genetically confirmed sarcoglycanopathy patients in India.
PHENOTYPE GENOTYPE CHARACTERIZATION OF FKRP MUTATIONS IN AN INDIAN COHORT OF LIMB GIRDLE MUSCULAR DYSTROPHY

Gopikrishnan Unnikrishnan, Mainak Bardhan, Akshata Huddar, Seena Vengalil, Saraswati Nashi, Hansashree Padmanabha, Ram Murthy Anjanappa, Kiran Polavarapu, Leena Shingavi, Veeramani Preethish Kumar, Gayathri Narayanappa, Atchayaram Nalini
National Institute of Mental Health And Neurosciences (NIMHANS), Neurology, Bengaluru, India

**Background and Aims:** Mutations in the FKRP (Fukutin Related Protein) gene produces variable phenotypes including Limb Girdle Muscular Dystrophy Type R9 (formerly LGMD2I). It has been rarely reported in South Asian population. We studied a cohort of Indian patients with LGMD2I to elucidate the mutation spectrum and possible genotype–phenotype correlation.

**Methods:** Next-Generation Sequencing was performed in probands and family members with suspected LGMD.

**Results:** A total of eight patients (M: F = 4:4) were genetically diagnosed to have FKRP-R-CMD. The median age of onset was 30 months and age at presentation was 5 years (range 1.5-17 years). Putative disease-causing SNPs identified were as follows: hom. c.1343C>T/p.P448L (n=2), hom. c.646C>T/p.R216W (n=1), hom. c.160C>T/p.R54T (n=1), het. c.1060_1061inv/p.G354P (n=1), hom. c.650C>A/p.P217Q (n=1), het. c.942_943insC/p.C317Lfs*73 (n=1), het. c.933_934del/R312Lfs*77 (n=1) in exon 4 of the FKRP gene. Of these c.1343C>T and c.160C>T are previously reported and others are novel SNPs. Three subjects with heterozygous SNP are included as the clinical phenotype and histological findings strongly suggest features of FKRP related dystroglycanopathy. Delayed milestones, progressive proximal weakness was noted in 5 (62.5%), limb girdle phenotype was seen in 3/8 (37.5%), calf pseudohypertrophy was seen in 6/8 (75%), and consanguinity was present in 3/8 (37.5%) patients. Creatinine kinase was markedly elevated in all with a median of 8519.5 U/L (24-229 U/L). Cardiomyopathy was noted in one patient (12.5%).

**Conclusions:** The novel variations identified in this study expands the mutational spectrum of LGMDR9. As of now, this is the first study of genetically confirmed patients with LGMDR9 from India.
DIAGNOSIS OF ANXIETY AND DEPRESSION IN PATIENTS WITH MYASTHENIA GRAVIS

Ivan Ternovykh1, Olga Kreis2, Yuri Gavrilov3, Philipp Valko4, Yulia Valko4, Patimat Isabekova5, Tatiana Alekseeva7
1Almazov National Medical Research Centre, Neurology And Psychiatry, Saint-Petersburg, Russian Federation, 2North-Western State Medical University, Department Of Neurology, Saint-Petersburg, Russian Federation, 3Institute of Experimental Medicine, Department Of General Pathology And Pathological Physiology, Saint-Petersburg, Russian Federation, 4University Hospital Zurich, Department Of Neurology, Zurich, Switzerland, 5Almazov National Medical Research Centre, Neurology, Saint Petersburg, Russian Federation

Background and Aims:: Mood disorders are the most common comorbidity in patients with myasthenia gravis (MG). In particular, anxiety and depression are not often diagnosed and treated. The aim is a comprehensive assessment of anxiety and depression in MG patients, using newly validated Russian versions of international questionnaires.

Methods:: The study included 73 patients with MG and 230 control subjects. For fatigue, anxiety and depression evaluation were used Fatigue Severity Scale (FSS), Fatigue Impact Scale (FIS), Beck Depression Inventory (BDI), Spielberger–Khanin State Trait Anxiety Inventory (STAI).

Results:: The studied patient cohort revealed clinically significant fatigue (69.9 %), moderate to severe depression (20.5 %), a high level of personal (64.4 %) and situational anxiety (27.4 %). The average FSS score ≥4.0 was found in 84.1% of patients with depression and 45.8% of patients without depression (p = 0.002). The results of the FSS showed a stronger correlation with the somatic subscale BDI (r = 0.588, p <0.001) than with the cognitive-affective subscale BDI (r = 0.293, p = 0.02). In our study we found that the presence of depression in patients with MG significantly increase fatigue indicators.

Conclusions:: Depression may increase muscle weakness and fatigue in patients with myasthenia gravis, despite the absence of correlation between the severity of the disease and the psychosocial subscale FIS, but psychosocial fatigue is the strongest predictor for the development of depression. Symptoms of depression can mimic the symptoms of myasthenia gravis and remain underestimated. Clinicians should pay more attention to evaluation of psychological state in these patients.
LIMB-GIRDLE MUSCULAR DYSTROPHY D2 AND CYTOKINES: A LINK TO HTV1 RESISTANCE

Corrado Angelini
Azienda Ospedaliera di Padova, Neurosciences, Padova, Italy

Background and Aims:: To detect plasma cytokines changes in trasportinopathy LGMD-D2, with mutation in TNPO3 gene, encoding for transportin-3 protein, a nuclear import receptor for serine/arginine-rich proteins determining HIV-1 immunity, by unknown mechanism(s).

Methods:: This Luminex study was done in 4 patients expressing two different mutations: an Italian-Spanish family, the others of Hungarian stock. Plasma from 4 LGMDD2 patients and 4 controls were measured in duplicate. The expression levels of TNFRSF8, IFN-beta, IL-1-alpha, MMP-1, MMP-10, uPAR, IFN-alpha, IFN-gamma, IL-1beta, MMP-8, MMP-12, CCL2 JE (MCP-1), CCL18 (MCP-2), CD163,GRO-beta, mip-2, IL-1 RI, S100A8, ICAM-1, CD106, CCL7, MCP-3, MARC, CCL20,MIP-3 alpha, GRO alpha, CXCL5,IL-8/CXCL8 and S100A9 were measured by Multiplex Luminex Assay using two custom-made plates (R&D Systems). Cytokines concentration was calculated through Bio-Plex 200 System software or by manual interpolation. Statistical analysis was performed with the nonparametric Mann–Whitney test using GraphPad Prism v9 software.

Results:: The expression levels of IFN-beta were reduced 25-fold (p<0.005) in LGMDD2 versus controls, while IFN-alpha increased 2.05-fold. The level of GRO-beta was increased 1.65-fold (p<0.05), in LGMDD2, GRO-alpha was slightly modified (0.9-fold reduction). TNFRSF8 and ICAM-1 were 1.58-fold and 2.15-fold(p<0.001) enhanced, respectively, in LGMDD2. The levels of S100A8 (p<0.001) and S100A9 (p<0.005) were reduced 6-fold and 25-fold respectively, expression of IL1RI was 2-fold reduced (p<0.05) in LGMDD2 versus controls. IL1b levels were similar, IL1a was 2.52-fold increased in patients, CXCL5 was 1.51-fold enhanced,CXCL8 was 1.7-fold reduced, but not significantly. CCL7 (p<0.01) was increased 3.44 fold, CCL2 (p<0.05) decreased 1.47 fold in patients.

Conclusions:: Despite the low number of samples, significant changes in several cytokines were observed.
LONGITUDINAL, QUANTITATIVE ASSESSMENT OF HAND MUSCLE STRENGTH DECAY IN MYOTONIC DYSTROPHY TYPE 1 (DM1)

Erica Frezza, Giulia Greco, Giulia Tammam, Mariangela Goglia, Roberto Massa
Tor Vergata University of Rome, Department Of Systems Medicine, Rome, Italy

Background and Aims:: Hand muscle weakness is a core feature of DM1 and outcome measures assessing finger pinch and grip strength should be available for natural history and trial studies.

Methods:: We longitudinally evaluated self-assessed hand muscle strength with a hand-held dynamometer (HDD) in 115 consecutive DM1 patients of either gender. Three-finger pinch and handgrip strength were annually recorded in both hands with an up to six-year follow up. Descriptive statistics, t test and correlation were performed.

Results:: Within-case coefficient of variance (CV) was 7 ± 7 % (mean±SD) for pinch and 7.2 ± 6.8 % for handgrip. Median values of pinch and handgrip were markedly reduced at baseline for both male and female patients as compared to sex-matched normal values. Patients who showed abnormal baseline values of pinch (80%) and handgrip (98%) were evaluated for annual rate of progression. At follow-up, patients’ values for both measures were significantly (p< 0.01) decreased at each assessment compared to baseline. Mean annual loss rate was of 8.1±2.9 % for pinch and 7.2 ± 2.7% for handgrip.

Conclusions:: Our results show that three-point pinch grip and handgrip, measured by HHD, reliably detect the baseline condition and the longitudinal progression of hand muscle power loss in DM1. These measures, therefore, seem suitable for being used as clinical outcomes within the timeframe of short-term natural history studies and clinical trials in DM1.
BULBAR ONSET MYASTHENIA GRAVIS: DIAGNOSTIC CHALLENGES AND MISSED OPPORTUNITIES

Ayat Allah Farouk¹, Shereen Fathy², Aya Shekhany³
¹Kasralainy Cairo university, Neurophysiology, cairo, Egypt, ²kasralainycairo university, Neurology, cairo, Egypt, ³kasralainy, Cairo University, cairo, Egypt

Background and Aims:: Myasthenia gravis (MG) is a frequently encountered neuromuscular junction (NMJ) disorder in clinical practice with a prevalence of 5 to 15 cases per 100,000 Ocular symptoms are the presenting sign of the disease in 50% to 75% of patients, bulbar plus ocular symptoms in 23.17% & Myasthenic patients presenting with isolated bulbar symptoms are mostly about 20.73% When a patient comes with acute bulbar symptoms especially with dysphonia, it will lead to diagnostic dilemma as there are good number of causes, apart from laryngeal myasthenia which is an uncommon aetiology, as stroke, demyelinating neurological diseases, toxicity, infection and other causes.

Methods:: This is a case series report of isolated bulbar onset myasthenia gravis which is rarely found, all presenting with dysphonia as an initial manifestation of bulbar myasthenia, we could reach the diagnosis of bulbar onset myasthenia gravis (serologically and/or electrophysiologically by EMG, NCV, repetitive supramaximal stimulation and single fiber EMG) and exclude other common causes of acute bulbar weakness.

Results:: SFEMG was the highest diagnostic test in our cases especially when done to the bulbar muscles, even when the RNS test was negative and the serology showed borderline results

Conclusions:: Considering MG as one of the potential differential diagnoses among cases of new onset or recurrent unexplained bulbar symptoms, is of high importance as it gives good recovery outcome and the patient become nearly normal after treatment.
CLINICAL AND GENETIC PROFILE OF DUCHENNE AND BECKER MUSCULAR DYSTROPHY PATIENTS IN THE FAR WEST OF ALGERIA

Oussama Dendene, Zahira Barka Bedrane, Selma Merini, Mehdi Bouchenaki, Ikram Brinkane, Salim Benosman, Kamel Tlemssani, Djaoued Bouchenak Khelladi

centre hospitalo universitaire, Neurology, Tlemcen, Algeria

Background and Aims:: Duchenne's (DMD) and Becker's (BMD) muscular dystrophy are the principal causes of myopathy in male children. It is linked to a mutation in the dystrophin gene and is inherited in an X-linked mode. The aims of our study are to describe the clinical and genetic phenotype of BMD and DMD patients in the far west of Algeria.

Methods:: Our study is prospective carried out in the neurology department of Tlemcen university hospital between January 2018 and December 2020. We collected the personal and family history, clinical and paraclinical data assays of muscular enzymes, ENMG). Analysis of the DMD gene was performed by the following techniques: MLPA and Next Generation Sequencing (NGS).

Results:: 32 patients had the clinical phenotype of dystrophinopathy including 19 patients with a mutation in the DMD gene. The median age of our patients was 10 years with a mean age of onset of 4 years and 9 months. Inbreeding was found in 79% of cases, 15.7% had similar cases in the family. 79% of the patients had a clinical DMD phenotype, 21% a clinical BMD phenotype. All of our patients had a high CPK level and myopathic involvement in ENMG. DMD was observed in 79% of cases and BMD in 21% of cases. The initial symptomatology of our patients was: 84% for motor disorders; 26% for pseudo-hypertrophy of the calves, 10% for delayed walking and 5% for Hyper CKemie. Deletions were observed in 84.2% of cases, duplications in 5.3% of cases and point mutations in the remaining 10.5% of cases.

Conclusions:: Our study is the first carried out on dystrophinopathies in the far west of Algeria. Although our sample is small, genetic study has shown the heterogeneity of dystrophinopathies in our region.
THE OMMAYA CATHETER AS A TREATMENT FOR PAIN AND CHEMOTHERAPY IN MENINGEAL CARCINOMATOSIS PATIENT

Mariane Ferreira, Eduardo Pessoa Júnior, Caroline Rincolato, Letícia Rigoti, Marina Coronetti, Caio Goulart, Carolina Panis, Carlos Rodrigues
Universidade Estadual do Oeste do Paraná, Ccs Centro De Ciências Da Saúde, Francisco Beltrao, Brazil

Background and Aims:: Meningeal carcinomatosis consists of focal or multiple malignant metastases of extraneural solid tumors in the leptomeninges and subarachnoid space. It’s a rare complication and neurological symptoms include headache and nonspecific nerve palsy. The standard diagnosis is obtained by the presence of malignant cells in the cerebrospinal fluid cytology. The prognosis is poor, the treatment is limited and aims at palliating symptoms and stabilizing or partial improvement in neurological status.

Methods:: This study aims to report a case of treatment for pain and chemotherapy in meningeal carcinomatosis patients by Ommaya catheter use.

Results:: Man, 56 years old. Diagnosed 6 months before with intestinal adenocarcinoma, had been treated by surgery, chemotherapy, and radiotherapy. He showed severe pain syndrome, mainly headache, refractory to systemic opioid and non-opioid analgesic therapy. The cerebrospinal fluid cytology confirmed the diagnosis of carcinomatous meningitis. The patient was submitted to palliative treatment with an Ommaya catheter (OC) for intrathecal chemotherapy and opioid analgesic. The OC reservoir was placed under the scalp and attached to a catheter that ends in the lateral cerebral ventricle. Thus, medicines were injected directly into the intracerebroventricular space optimizing the treatment. The Brazilian public health care “Sistema Único de Saúde” (SUS) supported all treatments.

Conclusions:: The OC possibility a safe and effective therapy for the palliative treatment of refractory pain at-home care in meningeal carcinomatosis patients, despite this the OC is unusual in Brazil.
PALLIATIVE CARE FOR PATIENTS WITH DEMENTIA AND COVID-19: ANALYSES FROM A MAJOR REFERRAL HOSPITAL IN SOUTH AMERICA

Tulio Correa¹, Joyce Sobreira², Áurea Simão³, Flavia Yarshell³, Fernanda Anbar³, Ricardo Tavares De Carvalho⁴
¹Universidade Federal de Pelotas, Faculty Of Medicine, Pelotas, Brazil, ²Universidade Federal do Maranhão, Faculty Of Nursing, São Luís, Brazil, ³Santa Casa de São Paulo, Faculty Of Medical Sciences, São Paulo, Brazil, ⁴Hospital das Clínicas da Universidade de São Paulo, Division Of Palliative Care, São Paulo, Brazil

Background and Aims:: People with dementia are at higher risk of developing severe COVID-19 and worse virus-related outcomes. In addition, triage systems in pandemics have low sensitivity for the need of palliative care, not allowing appropriate end-of-life support to many patients. The aim of this study was to evaluate the palliative care offered to patients with dementia and COVID-19 in a major referral hospital in South America.

Methods:: Descriptive study of adult patients with COVID-19 from a major referral hospital in the city of São Paulo, Brazil. Dementia was screened searching medical records for ICD F02-03. Patients were screened for the need for palliative care through Supportive and Palliative Care Indicators Tool (SPICT). Data were analyzed using Microsoft Excel 2016.

Results:: The sample was composed of 21 (37.5%) males and 35 (62.5%) females with median [IQR] age of 81 [72-88] years. In addition, 24 (42.8%) were from the wards, 23 (41.1%) from the emergency room, and 9 (16.1%) from the ICU. Regarding SPICT criteria, 52 (92.9%) were at risk of deteriorating and dying. Of the patients who met SPICT criteria, 28 (53.8%) had access to palliative care during hospitalization. By the end of the study, 29 patients (51.8%) died and 27 (48.2%) were discharged. Of the patients who died (n=29), seven (24.1%) did not have access to palliative care.

Conclusions:: In our study, there was a high mortality rate between patients with dementia and COVID-19, although a considerable percentage of them did not have access to palliative care before dying.
Background and Aims:: During the COVID-19 pandemic, many patients with stroke face delayed access to acute care. Also, they delayed getting in chronic stroke-related problems or complication management due to avoiding hospital visits and decreasing the number of service healthcare providers and service units from adaptation to the pandemic. Therefore, relative poor prognosis cases are higher in some areas and some periods. The aim is to guide palliative healthcare teams to manage end-of-life care in stroke during the COVID-19 crisis.

Methods:: This study is a narrative review of palliative stroke care among the COVID-19 pandemic.

Results:: The National Institutes of Health Stroke Scale (NIHSS) is the essential tool for evaluation. The scores 20 or higher should access palliative care consultation early because high scores can predict poor outcomes in both the short and long term. The palliative care approach for stroke is multidisciplinary collaboration. The goal and core of palliative care will be set based on individual formal or informal advanced care plans. The intensive safety awareness for a rehabilitation program, follow-up plan, complication monitoring for healthcare teams, caregivers, family members, close contact persons, and the patient himself should be developed and appropriately improved.

Conclusions:: Active multidisciplinary teams cooperate with assisted telemedicine, and virtual evaluation by specialists play significant roles in palliative care among COVID-19 situations.
THE IMPACT OF COVID-19 PANDEMIC ON DISEASE SEVERITY AND QUALITY OF LIFE IN PARKINSON’S DISEASE

Alvee Saluja, Jasmine Parihar, Divyani Garg, Rajinder Dhamija
Lady Hardinge Medical College, New Delhi-110001, Neurology, New Delhi, India

Background and Aims:: Background and Aims-The challenges being faced during the lockdown period may worsen motor or non-motor symptoms in Parkinson’s disease (PD). This study was undertaken in order to investigate the impact of lockdown on the disease activity, caregiver perceptions and the quality of life of Parkinson’s disease patients.

Methods:: Materials and Methods-This cross-sectional study was conducted from June till September 2020. Sixty four PD patients and caregivers were interviewed telephonically after obtaining consent. The responses were recorded by means of a structured questionnaire. Non-motor symptoms scale (NMSS) and the Parkinson Disease Questionnaire-8 (PDQ-8) were applied. PDQ-8 severity index (PDQ-8 SI) scores were expressed as percentage of the raw PDQ-8 score out of the total score. SPSS 20.0 was used for statistical analysis.

Results:: Results-Out of 64 patients, 39 (60.9%) were males and 25 (39.1%) were females. The overall median age was 65 (55.25-69.75) years. The median duration was 48 (30-84) months. Twenty six (40.6%) patients reported symptomatic worsening during the lockdown period. Slowness in activities of daily living and walking worsened in 15 (57.7%) and 14 (53.8%) patients respectively while tremors increased in 12 (46.2%) patients. Mood and sleep disturbances were the most common non-motor symptoms to worsen. Increase in non-motor symptoms and the NMSS total score were independent predictors of PDQ-8 scores. Increase in non-motor symptoms during the lockdown was an independent predictor of the highest quartile of PDQ-8 SI scores.

Conclusions:: Conclusions-Motor and non-motor symptoms have worsened in PD patients during the lockdown. The increase in non-motor symptoms was independently associated with poorer quality of life among PD patients during the lockdown.
EMERGENCY DEPARTMENT ATTENDANCES FOR SEIZURES: THE SARS-COV-2 PANDEMIC IMPACT.

Marta Cheli¹², Alessandro Dinoto², Sasha Olivo², Marinella Tomaselli¹, David Stokel¹, Franco Cominotto², Francesco Brigo⁴, Paolo Manganotti²
¹University of Trieste, Neurology Clinic, Trieste, Italy, ²University of Trieste, Clinical Unit Of Neurology, Department Of Medicine, Surgery And Health Sciences, University Hospital And Health Services Of Trieste – Asugi, University Of Trieste, Strada Di Fiume, 447, 34149 Trieste, Italy, Trieste, Italy, ³ASUGI, Emergency Department, Cattinara University Hospital, Trieste, Italy, ⁴Franz Tappeiner Hospital, Department Of Neurology, Merano (BZ), Italy

Background and Aims:: The spreading of SARS-CoV-2 pandemic had an impact both on the healthcare organization and both on how people with COVID-unrelated acute and chronic conditions sought for medical assistance, in particular for condition requiring admission to Emergency Departments (EDs).

Methods:: We performed a retrospective study evaluating the frequency and features of ED attendances for seizures, in the University Hospital of Trieste, Italy, during the first lockdown period (March 10th-April 30th 2020). To define the possible pandemic impact, we compared the lockdown period to a matched period in 2019 and to a period of identical length preceding the lockdown (January 18th-March 9th 2020). Data were retrospectively collected: age, sex, triage code, admission by ambulance, required hospitalization, first seizure, seizure semiology and diagnostic tests performed (EEG or CT) of each patient.

Results::

![Graph showing ED admissions and associated data]

We found, during lockdown, a significant decrease in total ED attendances (4664) when compared to the matched control (10424) and to the pre-lockdown (9522) periods. Similarly, a reduction was detected for seizure attendances: 37 during lockdown and 63 and 44 respectively during the two other time periods. Interesting we found that more patients attended the ED with first seizures (p = 0.013), and a higher number of EEGs (p = 0.008) and CT brain scans (p = 0.018) were performed during lockdown; a trend favouring a more frequent transport to the ED by ambulance (p = 0.061) was also noted during lockdown period.

Conclusions:: The pandemic had a relevant impact on how patients with seizures accessed the ED.
THE PARADOXICAL IMPACT OF COVID-19 ON PEOPLE WITH POSTSTROKE APHASIA

Francesca Pisano¹, Alberto Giachero²-³, Cristian Rugiero², Melanie Calati², Paola Marangolo¹,⁴
¹University Federico II, Department Of Humanities Studies, Naples, Italy, ²Fondazione Carlo Molo Onlus, Aphasia Experimental Laboratory, Turin, Italy, ³University of Turin, Dipartimento Di Psicologia, Turin, Italy, ⁴IRCCS Fondazione Santa Lucia, Aphasia Laboratory, Rome, Italy

Background and Aims:: The coronavirus pandemic (COVID-19) is affecting people’s health with severe psychological consequences. One of the leading causes of long-term post-stroke disability worldwide is Aphasia. The language deficits of person with aphasia (PWA) cause a long-lasting negative impact on social communication and psychosocial wellbeing. The aim of the current study was to analyze the impact of the COVID-19 outbreak in PWA.

Methods:: 73 post-stroke PWA and 81 matched controls were enrolled in this study. All patients were in the chronic phase and they were already discharged from rehabilitation services before the COVID-19 emergency with different degrees of linguistic impairments. All participants were administered the Hospital Anxiety and Depression Scale (HADS). PWA also completed the Stroke and Aphasia Quality of Life Scale-39 (SAQOL-39).

Results:: In all participants, results showed a significant increase of depression and anxiety between pre and during COVID-19. Surprisingly, we found lower levels of depression and anxiety in PWA than in the healthy group. Moreover, a significant deterioration was also present in PWA in the communication and psychosocial scales of the SAQOL-39. Interestingly, these findings were independent of the degree of aphasia severity.

Conclusions:: This evidence masks a dramatic situation which affects post-stroke PWA. Given that language deficits severely impact on social communication and psychosocial wellbeing in this population, these conditions had paradoxically limited the effects of the coronavirus. Thus, our findings point to the urgency of implementing new tools, including telerehabilitation, which would allow PWA to practice their communication skills avoiding further deterioration.
UNRAVELING THE NEUROPSYCHOLOGICAL DISORDERS IN THE POST-COVID 19 SYNDROME: DYSEXECUTIVE SYNDROME AND SUBJECTIVE COGNITIVE COMPLAINT

Massimiliano Ruggeri¹, Monica Ricci², Carmela Gerace², Michela Pagliaro¹
¹C.A.R. Rehabilitation Center, Cardiovascular Rehabilitation Unit, Rome, Italy, ²San Camillo Forlanini Hospital, Unit For Cognitive Disorders And Dementia, Rome, Italy

Background and Aims:: A considerable amount of recovered COVID-19 patients complain of long-term cognitive sequelae mainly in attention and memory. However, most of the few previous studies failed to clarify these cognitive syndromes, and their etiopathogenesis is much debated. The aim of this report is to contribute to the identification of the neuropsychological disorders in the post COVID-19 syndrome, and hypothesize a putative underlining etiopathological mechanism.

Methods:: Two male adult patients underwent standard and computerized neuropsychological assessment two months after recovery from COVID-19 interstitial pneumonia. Case 1 suffered a severe SARS, requiring CPAP and helmet NIV, and reported episodes of heart failures. Case 2 instead reported a mild SARS that was treated with oxygen therapy.

Results:: Both patients complained of mental fatigue, slowness, decreased concentration, and memory failures. Case 1 cognitive evaluation showed mild impairments in working memory, processing speed, short-term and episodic memory, while it was normal in Case 2. Both patients had mild mood abnormalities. No neuroimaging examinations were conducted yet at that time.

Conclusions:: The cognitive profiles of our patients were compatible with a mild dorsolateral dysexecutive syndrome in Case 1, and a subjective cognitive disorder in Case 2. The results suggest impairments of the dorsolateral prefrontal cortex and subcortical circuitry in both cases. The severity of the cognitive outcomes seems to be associated with the severity of SARS but not with mood disorders. We cautiously hypothesize that both patients might have suffered cognitive failure as a consequence of subclinical hypoxic insult to the brain.
DIFFERENTIAL DIAGNOSIS OF CACOSMIA AND DYSGEUSIA IN COVID-19 PANDEMIC. CLINICAL CASE REPORT.

Maria Vasilieva, Irina Bejenari, Stanislav Groppa
Emergency Institute, Neurology, Chisinau, Moldova

Background and Aims:: Olfactory and gustatory dysfunctions were presented in a high percentage of COVID-19 cases. Most of them are represented by quantitative disorders. Qualitative alterations were established in a small proportion. During the Covid-19 pandemic, there is a need to make a differential diagnosis (DD) of olfactory and gustatory disorders.

Methods:: Clinical case of a 64-year-old man presented with dairy food cacosmia and dysgeusia for the last two weeks, and night sweats. From medical history we found that our patient recovered from COVID-19 infection, one month ago.

Results:: Based on some studies, patients with COVID-19 infection, presented moderate to severe olfactory or gustatory dysfunctions for long-term, in convalescent period. It's important to make a DD of smell and taste impairments and choose the necessary treatment. Esophageal candidiasis was diagnosed in our patient. After 21 days of antifungal treatment cacosmia and dysgeusia disappeared. HIV test was negative. Some studies presented that COVID-19 infection is linked with a continuous reduction in lymphocytes along the disease. We hypothesized that immunodeficiency in COVID-19 infection and antibiotic therapy could be the trigger for esophageal candidiasis in our case.

Conclusions:: Our case report highlighted the importance of smell and taste disorders DD, in COVID-19 pandemic. Dairy food cacosmia and dysgeusia can be a sign of esophageal candidiasis. That's why, convalescent COVID-19 infection patients should be monitored for a long-term period.
COVID-19 RELATED ATAXIA AND MYOCLONUS: PARA- OR POST-INFECTIOUS DISORDER?

Matteo Grazzini¹, Elisa Giorli¹, Massimiliano Godani², Antonio Mannironi², Stefano Grisanti³, Arduino De Lucia⁴, Domanica Rizzi⁴, Silvia Morbelli⁵, Teresita Aloe⁶, Angelo Schenone⁶, Diego Franciotta⁷, Luana Benedetti³  
¹Sant'Andrea Hospital, Department Of Neurology, La Spezia, Italy, ²Sant'Andrea Hospital, Department Of Neurology, La Spezia, Italy, ³IRCCS, Ospedale Policlinico San Martino, Department Of Neurology, Genova, Italy, ⁴IRCCS, Ospedale Policlinico San Martino, Department Of Anaesthesia And Intensive Care, Genova, Italy, ⁵IRCCS, Ospedale Policlinico San Martino, Nuclear Medicine Unit, Genova, Italy, ⁶IRCCS Ospedale Policlinico San Martino, Interventional Pulmonology Unit, Genoa, Italy, ⁷IRCCS Ospedale Policlinico San Martino, Autoimmunology Laboratory, Genova, Italy

Background and Aims:: Since the onset COVID-19 pandemic, several post-infectious neurological disorders have been reported, among which at least ten cases showed movement disorders consisting of tremor, myoclonus, ataxia. We report a case series of three patients who developed these symptoms after the SARS-CoV-2 infection.

Methods:: Patients' data were collected from medical records during COVID-19 pandemic. Diagnosis of COVID-19 was supported by RT-PCR on nasopharyngeal swab.

Results:: Three male patients (mean age 63 years) developed generalized myoclonus and ataxia. In two patients the disorder appeared 30 and 24 days after the onset of the SARS-CoV-2 infection, respectively, while in the other case the neurological symptoms began at the same time. The clinical pictures showed a rapidly worsening course. Brain MRI did not reveal abnormalities in any patients at the disease onset. On day 70 the imaging control showed mild cerebellar atrophy in one patient. A brain¹⁸F-FDG-PET scan disclosed a bilateral fronto-mesial hypometabolic pattern in one patient. RT-PCR for SARS-CoV-2 in CSF, tested in two cases, resulted negative. EEG and ENG did not reveal relevant abnormalities, as well as CSF analysis, including immunoblot. Two patients were treated with intravenous immunoglobulin infusion (IVig) and one patient with plasmapheresis (PEX). They subsequently improved during the course of few weeks.

Conclusions:: Myoclonus and ataxia possibly occur as COVID 19 postinfectious as well as parainfectious immune-mediated disorder. Indeed, IVIG or PEX were effective in all three patients. This kind of disorders have been described as postinfectious events, in contrast, we report, to our knowledge, the first parainfectious case.
A CASE OF LIMBIC ENCEPHALITIS WITH CSF DETECTION OF SARS-COV2 VIRUS: IMMUNE-MEDIATED MECHANISM OR DIRECT VIRAL DAMAGE?

Arianna Braccia¹, Francesca Carta², Domenico Fiorillo³, Ginevra Tecilla¹, Edward Cesnik⁴, Elisa Fallica⁴, Vittorio Govoni¹, Rosario Cultrera¹
¹Clinical Neurology, University Of Ferrara, Ferrara, Italy, ²Azienda ospedaliera universitaria Sant’Anna (Ferrara), Neurologia, Ferrara (FE), Italy, ³University of Ferrara, Sant’Anna Hospital, Clinical Neurology, Ferrara, Italy, ⁴Neurology Unit, St Anna University Hospital, Ferrara, Italy

Background and Aims:: Pathogenesis of neurologic syndromes COVID 19-related could be categorized in four mechanisms: direct viral damage, para/post-infectious effect, complications of prolonged illness. We present a case of limbic encephalitis (LE) with concurrent detection of SARS-CoV2 virus in cerebrospinal fluid (CSF), which makes the individuation of a unique etiological mechanism insidious.

Methods:: A 70-year-old man was hospitalized with respiratory symptoms and confusional state. A chest CT-scan and nasopharyngeal swab demonstrated COVID-19 infection; non-contrast brain CT-scan was unremarkable. Neurological examination revealed right focal signs and vigilance fluctuations; EEG showed nonspecific mild background activity slowing, basic CSF investigations resulted negative and total-body CT-scan excluded tumours. Brain MRI showed T2-FLAIR hyperintensity in the mesial temporal lobes, strongly supporting the hypothesis of limbic encephalitis. So the patient underwent to a second lumbar puncture to test the autoimmune panel (negative).

Results: Liquoral PCR for SARS-CoV2 RNA resulted positive. After treatment with 5 days- IV bolus dose of metiprednisolone and a cycle of IV immunoglobulin therapy, he had a slight improvement, especially concerning alertness and cognition. Two months follow-up brain MRI was superimposable to the precedent.
Conclusions: Majority of cases of LE with positive testing for specific antibodies are negative for RT-PCR for SARS-CoV2 tested on LCR(1). In this case, the presence of the virus in CSF supports a direct neural damage; conversely, the answer to immunomodulant treatment could suggest an immunological role; previous autopsy results of patients with SARS-CoV1(2) evidenced the presence of viral RNA in brain tissue, particularly accumulating in and around the hippocampus.

Background and Aims: In addition to the problems it causes in the acute phase, coronavirus infection is bothering physicians and scientists worldwide with its complex complications. Aim: To analyze the complications and clinical manifestations observed in the maxilla-facial area of patients who have undergone Covid-19.

Methods: Clinical analysis was carried out in 67 patients who visited to the multidisciplinary clinic of Tashkent Medical Academy for 6 months. The mean age of patients was 61±2.3 years, including 38 women (56.7%) and 29 men (43.3%). Patients were hospitalized 1-3 months after the onset of acute Covid-19 infection. The analysis was based on patients’ clinical status, medical history, complaints, and diagnosis.

Results: Mild complication observed in patients: acute aphthous stomatitis developed in 12 (17.9%) patients, in 29 (43.2%) patients inflammatory infectious complications (abscess, phlegmon) in the soft tissues developed independently. Inflammation of salivary glands was found in 7 (10.4%) patients, 36 patients (53.7%) had osteomyelitis of the maxilla (im.1), 37 patients (55%) were hospitalized with cavernous sinus thrombosis (im.2).

In addition to inflammation, patients had neurological symptoms including headache, dizziness, and so on. Facial nerve paresis in 14 (21%) patients, paresthesia of the trigeminus nerve in 28 (41.8%) patients (n. ophthalmicus - 38 (57%), n. maxillaris - 40 (60%), n. mandibularis - 2 (3%)), paresthesias of the 1st and
2nd horn together in 41 (61%) patients.

Conclusions:: Considering that Covid-19 disease leads to severe and long-term complications in the late stages, it is needed to develop measures to prevent complications in patients with predisposition to complications (elderly and chronic comorbidities)
SPONTANEOUS INTRACEREBRAL HEMORRHAGE AFTER ANTICOAGULATION THERAPY IN A 57-YEAR-OLD MAN WITH SARS-COV-2 INFECTION: A CASE REPORT

Fakhrurrazy Fakhrurrazy\textsuperscript{1}, Pagan Pambudi\textsuperscript{1}, Husnul Khatimah\textsuperscript{2}, Lily Runtuwene\textsuperscript{1}, Steven Gunawan\textsuperscript{1}, Among Wibowo\textsuperscript{1}, Muhammad Dafif\textsuperscript{1}
\textsuperscript{1}Ulin Hospital, Neurology, Banjarmasin, Indonesia, \textsuperscript{2}Lambung Mangkurat University, Biomedics, Banjarmasin, Indonesia

\textbf{Background and Aims::} Anticoagulation regimens are now being considered for COVID-19. Anticoagulation is known to increase the risk for adverse bleeding events, of which intracerebral hemorrhage (ICH).

\textbf{Methods::} Case Report

\textbf{Results::} We report a 57-year-old man was admitted to hospital due decreased oxygen saturation, increased blood glucose levels and RT-PCR of oropharyngeal swab confirmed COVID-19. The patient had a previous history of type 2 DM and ischemic stroke. The first 5 days, the patient was receiving a prophylactic dose of low molecular weight heparin, enoxaparin, then continued with unfractionated heparin. The patient also received antiplatelet clopidogrel and convalescent plasma. The laboratory results are leucocyte 18.9 K/\mu\text{L}, ureum 79 mg/dL, creatinine 2.0 mg/dL, D-Dimer 0.22 \mu\text{g/mL}, INR 1.03, NLR 15.82, ALC 547, HbA1C 9.2, blood glucose level 336 mg/dL, CRP 41.2 mg/dL. On day ten of hospitalization, the patient had sudden right-sided hemiplegia and Broca's aphasia. A CT head demonstrated an ICH in the left basal ganglia with a volume approximately 77cc. Three days later the patient's condition had decreased consciousness and a craniotomy was performed. After being intubated for 4 days post craniotomy, because his condition improved, he was extubated. On day nine after surgery, the patient's condition decreased to coma, a repeat chest X-ray showed a worsening of the bilateral infiltrates and pleural effusion. His oxygen requirement was progressively increasing, so he was shifted to mechanical ventilation again.

\textbf{Conclusions::} The risk of intracerebral hemorrhage in patients with COVID-19 is of paramount importance to inform the risk-benefit assessment of the use of anticoagulation in this patient.
CLINICAL ANALYSIS OF COMPLICATIONS OF CAVERNOUS SINUS THROMBOSIS IN COVID-19 PATIENTS

Dilnoza Bobamuratova¹, Shukhrat Boymuradov¹, Yokubjon Kurbanov¹, Dilshoda Akramova²
¹Tashkent Medical Academy, Otolaringology & Stomatology, Tashkent, Uzbekistan, ²Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: Serious complications such as cavernous sinus thrombosis have been reported in patients with coronavirus disease. Objective: to study and analyze the clinical course of cavernous sinus thrombosis in patients who underwent Covid-19

Methods:: Clinical analysis performed in 52 patients who applied to the multidisciplinary clinic of Tashkent Medical Academy over a period of 10 months. The mean age of patients was 60 ± 3.5 years, of them 28 women (53.8%) and 24 men (46.2%). The patients were hospitalized 1-2 month after infection, all tested positive for coronavirus (PCR, IFA). Clinical and laboratory examination of the patients, MRI-angiographic studies, medical history, complaints, and diagnosis were performed.

Results:: According to analysis, septic cavernous sinus thrombosis was 75-80% and aseptic cavernous sinus thrombosis was 20-55%. Notably, the predominance of neurological symptoms in patients was unilateral in the head and face, unilateral chronic hemorrhagic sinusitis, and unilateral eye socket syndrome, loss of eyesight. In patients, despite complex treatment, the inflammatory process was chronic. In the process of inflammation we noted 38% of cases of soft tissue phlegmon, 70% of cases of transient necrosis with aseptic inflammation of the upper jaw, 55% of cases of orbital phlegmon (pictures). Patients complained of headache (85%) and general weakness (77%), discomfort (72%), loss of sensitivity in face - 70%, mouth cramps (100%), facial nerve palsy
Conclusions: in complication in patients with Covid-19 cavernous sinus thrombosis the process is characterized by progressive development on one side of the head and face. Complex treatment of patients requires multidisciplinary rehabilitation measures
BEHAVIOR AND AWARENESS OF MULTIPLE SCLEROSIS PATIENTS DURING COVID-19 PANDEMIC IN A TERTIARY CENTER IN EGYPT

Mona Nada¹, Sherif Hamdy¹, Maged Abdel Naseer², Hatem Shehata¹, Nevin Shalaby², Amr Hassan², Sandra Ahmed², Nahlia Merghany², Sara Shazly², Sara Abdo², Samah Ahmed², Nouran Mahmoud², Ebtehal Ibrahim²
¹Cairo University, Neurology, Cairo, Egypt, ²Cairo University, Neurology, Cairo, Egypt

Background and Aims:: Knowing that assessing patient awareness and knowledge about the coronavirus is important in recognizing gaps and offering better efforts especially in patients with chronic illness like MS patients, this study aims to investigate the knowledge, attitudes and practices of MS patients during COVID-19 pandemic.

Methods:: A telephone-based survey which recruited patients from Kasralainy Multiple Sclerosis Unit database, Cairo University hospitals from March 2020 till July 2020. It included 127 patients and an Arabic questionnaire was conducted which consisted of 14 questions including: Demographic data; MS related data, Data related to COVID-19 and attitude and awareness related to COVID-19

Results:: Near quarter of the patients were still working in their current jobs, only 12.8% on current leave due to Covid-19 while the majority were non-employed (66.4%). The majority of patients (64%) were compliant to their medications. Treating physician advised to stop DMT in 20.4% while 10.2% of patients stopped due to fear of side effects. Only 16.54% of the patients developed COVID-19 symptoms. The majority (89.2%) avoided visiting any medical institution. Different ways of communication were used by patient when any medical advice was needed. Facebook and WhatsApp applications represented almost half of the tools used to communicate.

Conclusions:: Patients with MS report increased awareness of COVID-19 precautions with high rate of DMT compliance.
Background and Aims:: The ongoing coronavirus disease 2019 (COVID-19) pandemic caused by severe acute respiratory syndrome coronavirus (SARS-CoV)-2 is having unprecedented effects in healthcare systems, economies and society. Although the respiratory tract is the primary target of SARS-CoV-2, emerging evidence suggests that the virus may also invade the central nervous system (CNS), leading to numerous neurological issues. In particular, people with Alzheimer’s disease (AD) are vulnerable group at risk of contracting COVID-19 and present more severe forms and worse outcomes. Given the high prevalence of AD individuals affected by COVID-19, the aim of was to review common underlying etiological factors that may contribute to the acceleration of neurodegenerative processes in SARS-CoV-2-infected patients.

Methods:: PubMed database was searched for publications before 1st April 2021 using the keywords: “Alzheimer’s disease” AND “COVID-19” AND “SARS-CoV-2”.

Results:: Inflammatory biomarkers, including IL-1, IL-6 and galectin-3 (Gal-3) are associated with high risk for developing COVID-19 and with the progression of AD. Moreover, SARS-CoV-2 infection exhibit high plasma levels of neurofilament light chain protein (NfL) and glial fibrillary acidic protein (GFAP), known as biochemical indicators of neuronal injury and glial activation in AD. Interestingly, the presence of the Apolipoprotein E (APOE) ε4 allele represents a risk factor for both diseases.

Conclusions:: Current literature suggests the existence of a synergistic relationship between COVID-19 and AD. The identification of potential biomarkers for the early identification of COVID-19 in patients with high risk of developing AD as well as the management and development of novel therapeutic strategies against both diseases.
RISK FACTORS FOR COVID-19 VACCINE HESITANCY AT A NEUROSCIENCE CENTER: QUALITY IMPROVEMENT SURVEY

Michelle Pang¹, Tate Higashihara¹, Kimberly Teehera¹, Frances Morden¹, Connor Goo¹, Kyung Moo Kim¹, Rachel Lew¹, Kayti Luu¹, Cori Sutton¹, Shaina Yamashita¹, Catherine Mitchell², Enrique Carrazana², Jason Viereck¹,², Kore Liow¹,², Arash Ghaffari-Rafi¹

¹University of Hawai‘i at Mānoa, John A. Burns School Of Medicine, Honolulu, United States of America, ²Hawaii Pacific Neuroscience, Clinical Research Center, Honolulu, United States of America

Background and Aims:: This quality improvement (QI) survey aimed to identify risk factors for COVID-19 vaccine hesitancy among patients with a neurological disorder.

Methods:: A telephone QI survey was conducted of randomly selected adult Hawaii Pacific Neuroscience patients between January 22 and February 13, 2021. The survey assessed vaccine perception in relation to over 30 sociodemographic variables and medical comorbidities. Nonparametric univariate and multivariable logistic regression models with alpha < 0.05 were utilized.

Results:: From the 1494 patients contacted, 363 were respondents, with 81.34% planning to vaccinate. Odds of COVID-19 vaccination acceptance were significantly lower for patients on Medicaid (0.42, IQR: 0.22, 0.82; $X^2 = 7.18, p = 0.0074$), with drug use (0.32; IQR: 0.11, 0.96; $X^2 = 4.73, p = 0.030$), whose primary source of COVID-19 information was social media (0.26, IQR: 0.11, 0.63; $X^2 = 10.71, p = 0.001$), and who did not receive the most recent influenza vaccine (0.20, IQR: 0.11, 0.36; $X^2 = 33.38, p = 7.57 \times 10^{-9}$). After multivariable logistic modeling, the best predictors of declination were use of social media as a primary source of COVID-19 information, concerns of vaccine safety, self-perception of a preexisting condition compromising vaccination safety, not receiving the influenza vaccine within the past year, having completed some high school education, being a current smoker, and having no history of cerebrovascular accident.

Conclusions:: Patients with neurologic disorders present with unique risk factors for vaccine hesitancy, which may require special attention and vaccine counseling.
COGNITIVE IMPAIRMENT IN PREVIOUSLY INDEPENDENT COVID-19 PATIENTS: THE TIP OF THE ICEBERG?

Giulia Gamberini, Fabio Giuseppe Masuccio, Claudio Marcello Solaro
Mons. Luigi Novarese Hospital, Dept. Of Rehabilitation, Moncrivello (VC), Italy

Background and Aims:: Several pathologies other than pulmonary disease have been attributed to COVID-19. No data are available on the cognitive status of postCOVID-19 subjects without a history of cognitive impairment.

Methods:: Out of 285 subjects admitted to the Internal Medicine COVID Unit from November 2020 to January 2021, 48 patients [median age=73.5(23.25); 24M/24F] were recruited and evaluated with MoCA Test HAM-D, HAM-A; an evaluation of blood oxygen saturation and heart rate was performed before and after the assessment. Inclusion criteria were: radiologically confirmed symptomatic COVID-19 pneumonia, positive reverse transcription-polymerase chain reaction nasopharyngeal swab, being independent at home before the infection (Barthel Index=100), not being previously diagnosed with cognitive impairment/neurological diseases, no delirium episodes during COVID-19 acute phase, no mechanical ventilation need and no oxygen supplementation at the time of evaluation.

Results:: The median score of MoCA test was 20.5(8) and no subjects showed relevant anxiety [median HAM-A score=5.5(9)] and/or depressive symptoms [median HAM-D score=5(7.5)]. According to MoCA score, the sample was divided into two groups: 34 subjects with MoCA<23 (Impaired Group) and 14 subjects with MoCA≥23 (Normal Group). MoCA was correlated to age (p=0.0002; b=-0.571).

Conclusions:: The MoCA reveal that cognitive impairment is present in previously independent subjects and it is more detectable in subjects older than 65 years compared to younger. No data are available to determine whether COVID-19 will lead to cognitive dysfunction related to the sub-acute phase of the infection or to an increase of long-term cognitive impairment, therefore a follow-up will be crucial.
COGNITIVE AND NEUROPSYCHIATRIC FEATURES OF COVID-19 PATIENTS AFTER HOSPITAL DISMISSION: AN ITALIAN PILOT STUDY

Veronica Cian, Alessandro De Laurenzis, Chiara Siri, Anna Gusmeroli, Margherita Canesi
Moriggia Pelascini Hospital, Department Of Parkinson’s Disease, Movement Disorders And Brain Injury Rehabilitation, Gravedona ed Uniti, Italy

Background and Aims: Recent studies suggest cognitive, emotional, and behavioral impairments occur in patients after SARS-CoV-2 infection. However, studies are still few and to our knowledge, without a control group. This study aims to assess the prevalence of neuropsychological and neuropsychiatric impairment in patients after hospitalization.

Methods: We enrolled 17 Covid+ patients (M/F:12/5; age: 53,59±12,32yrs; education 11,88±3,6yrs) who needed hospitalization but no IC, about 18 days post dismission, and 17 Covid- matched controls (M/F:11/6; age: 53,82±12,34yrs; education: 12,59±3,77yrs). Neuropsychological and neuropsychiatric assessments were conducted via teleneuropsychology with the following tests: MMSE, CPM47, RAVLT, CDT, Digit-Span Forward/Backward, Verbal fluencies; BDI-II, STAI, AES. People with previous cognitive impairment, neurological or psychiatric conditions were excluded. Clinical and demographics were collected. Comparison between groups was conducted using parametric or non-parametric tests according to data distribution (T-test, Mann Withney-U test; Chisquare).

Results: Among Covid+, 82% had at least one pathological test (vs 30% in Covid-: p=0,001) and significantly worst performances than Covid- in Digit Backward (4,05±1,2 vs 4,8±1 p=0,046), RAVLT Learning (42±9,4 vs 49,4±7,9 p=0,018), RAVLT Recall (8,1±2,9 vs 10,6±2,5 p=0,013), Semantic Fluencies (43,7±7,3 vs 50,6±6,8 p=0,008). STAI-Y2 was higher in Covid- (32,6±7,4 vs 40,5±7,9 p=0,005).

Conclusions: Patients Covid+ assessed by teleneuropsychology showed a vulnerability in some memory and executive functions (working memory, learning and recall, semantic memory). Intriguingly, anxiety was higher in the control group. Our findings, therefore, confirm an impact of Covid-19 on cognition even in patients who did not need IC. Follow-up is needed to evaluate if these difficulties can recover with time.
COGNITIVE AND AFFECTIVE DISORDERS IN CRITICAL SARS-COV-2 PATIENTS AND CAREGIVERS

⁶IRCCS Istituto delle Scienze Neurologiche di Bologna, Italy, Irccs Istituto Delle Scienze Neurologiche Di Bologna, Italy, BOLOGNA, Italy

Background and Aims:: We investigated cognitive and affective disorders in patients with SARS-CoV-2 hospitalized in Intensive Care Unit (ICU). Caregivers quality of life, psychological distress and satisfaction with the information received by health-care professionals were assessed.

Methods:: From March 1 to April 30, 2020, 22 consecutive patients with SARS-CoV-2 infection, confirmed by PCR on oronasopharyngeal swab, requiring ICU admission were recruited together with a caregiver. Patients with previous cognitive disorders were excluded. Three months after ICU discharge, patients underwent a comprehensive neuropsychological evaluation and filled out validated questionnaires.

Results:: Seven of 22 resulted mildly cognitively impaired. Memory was the most impaired domain, followed by attention and verbal fluency. Three out of 22 patients reported an average high level of anxiety but no depression. Quality of life was mild impaired for 19 patients. Lower performances at MoCA were related to higher APACHE score at T0 (r = -0.44; p < .04). Lower performances in working memory, short- and long-term memory and verbal fluency were correlated to longer ICU stay, duration of mechanical ventilation and longer treatment with opioid and antipsychotics drugs (r > -0.48; p < .04). Long term memory performances were related to higher Sequential Organ Failure assessment (SOFA) score and longer treatment with propofol and benzodiazepines (r > -0.53; p < .02). Higher patient’s anxiety was correlated to higher psychological distress of the caregiver (r = -0.64; p < .001). Higher SOFA score is related to lower caregiver quality of life and lower satisfaction with information received (r > -0.53; p < .02).

Conclusions:: At 3 months from ICU admission, cognitive and psychological distress sequelae can be observed in SARS-CoV2 ICU patients.
ITALIAN BOTULINUM TOXIN NETWORK RECOMMENDATIONS FOR SAFE TREATMENT OF BOTULINUM TOXIN INFILTRATION DURING THE COVID-19 PANDEMIC: A VIDEO PRESENTATION

Background and Aims: Overview The physician and the patient come into close contact during treatments with botulinum toxin, increasing the chances of infection with the SARS-CoV-2 virus. What do we need to do to make the treatment safe and reduce the risk of contagion?

Methods: Botulinum toxin infiltration procedure Instructions for the Patient Wear non-sterile gloves and a surgical mask, and do not touch handles, surfaces or other objects. Dress and undress in the appointed place Instructions for the physician/paramedical staff Remove all jewelry and personal items, Wash hands for 20'', Put on PPE Physicians and nurses must put on a first pair of gloves, shoe covers, a cap, a disposable gown, an FFP2 mask, and protective glasses or a face mask and, lastly, a second pair of gloves.

Results: After treating each Patient the physician must remove the second pair of gloves, the disposable gown, and the protective glasses or face mask and sanitize them all. Lastly, he or she may remove the first pair of gloves. If the treatment takes place in the vicinity of the oral cavity, head or neck, the FFP2 mask must also be replaced. Medical Workers must clean all surfaces with which the Patient has been in contact at the end of each treatment session and, cover the most exposed surfaces with disposable barriers. As a final recommendation, the premises should be ventilated frequently.

Conclusions: Summary When these instructions are properly followed, they make the botulinum toxin infiltration procedure safe for the patient and the medical staff
BIOCHEMICAL BLOOD ANALYSIS OF PATIENTS WITH COVID-19 COMPLICATED BY Cavernous Sinus Thrombosis.

Dilnoza Bobamuratova, Yokubjon Kurbanov, Shukhrat Boymuradov, Dilshoda Akramova
Tashkent Medical Academy, Otolaringology & Stomatology, Tashkent, Uzbekistan

Background and Aims:: Serious complications such as cavernous sinus thrombosis and osteonecrosis of the jaw have been reported in elderly and diabetic patients with covid-19. Dysmetabolism is a risk of developing such complications, severity of pathology and long-term treatment. Our aim was to study metabolic changes in the blood in diabetic patients suffered covid-19 complicated by cavernous sinus thrombosis.

Methods:: Clinical analysis was carried out in 52 patients who applied to the multidisciplinary clinic of Tashkent Medical Academy for 4 months. The mean age of patients was 60 ± 3.5 years, of them 28 women (53.8%) and 24 men (46.2%) with complications trombosis of cavernosis sinuses. Patients were hospitalized an average of 1 month after the onset of acute Covid-19 infection.

Results:: According to the analysis septic cavernous sinus thrombosis was 73.2%, aseptic cavernous sinus thrombosis - 26.8%. Biochemical analysis of the serum content of total protein and albumin was carried out, which caused the decrease of indicators to the lower limits of the norm in the blood. The mean increase in glucose was 13.7 ± 0.44 (r < 0.001), ALT (32 ± 0.24 U/L); AST (24 ± 0.44 U/L). creatinine was found the upper limit of norm. High-density lipoproteins (1.09 ± 0.16) decreased, and low- and very-low-density lipoproteins (4.78 ± 0.59) and atherogenicity indices were increased.

Conclusions:: Change in a number of biochemical parameters (hypoproteinemia, dyslipidemia) and other metabolic disorders can aggravate the severe course of the underlying disease. Metabolic disorders (dyslipidemia) leads to vascular occlusion, increases microcirculatory disorders, negatively affect the outcome of treatment.
THE BENEFIT OF A SHORT-STAY NEUROLOGICAL OBSERVATION UNIT IN THE COVID-19 ERA.

Matteo Paolucci, Sara Biguzzi, Chiara Bomprezzi, Francesco Cordici, Flavio Di Stasio, Rossella Infante, Luca Mancinelli, Simonetta Morresi, Emanuela Postiglione, Francesca Preda, Michele Romoli, Rossana Terlizzi, Maria Vitiello, Marco Longoni
"M. Bufalini" hospital, Neurology, Cesena, Italy

Background and Aims:: Acute neurological symptoms are responsible for 5-15% of referral to the Emergency Department (ED). Since the COVID-19 outbreak, our stroke network shifted toward a mothership model with direct transport of stroke patients to the Comprehensive Stroke Center ("M. Bufalini" hospital, Cesena, Italy). To handle the increase in referrals due to mothership and guarantee a neurological fast-track in the ED, the Neurology service opened a four-bed Short-Stay Neurological Observation Unit (SSNO or “OBI Neuro”). We retrospectively analyzed the performances of SSNO after one year of activity.

Methods:: We evaluated one-year (1st April 2020 - 31st March 2021) SSNO patients’ admissions, discharge destinations, diagnosis and mean length of stay.

Results:: We managed 556 patients in the SSNO. Of these, 280 (50.4%) were discharged at home, 248 (44.6%) were admitted as in-patients, 20 (3.6%) were transferred to other hospitals, 8 (1.4%) self-discharged. Among patients admitted as in-patients, 91 (36.7%) were admitted in the Neurology ward, 135 (54.4%) were admitted in the Stroke Unit, the remaining (8.9%) in other wards of the hospital. The most common diagnoses were stroke (32.3%), seizure (20.4%), TIA (13%) and headache (7.4%); all other diagnoses individually represented less than 5% of the total. The mean stay of length was 11.5 h (14.4 h for discharged patients and 7.3 h for admitted as in-patients).

Conclusions:: The SSNO was feasible and strategic in managing stroke referrals in a mothership model and lifting the burden of neurological patients from the ED during the COVID-19 pandemic.
Background and Aims:: Acute Disseminated Encephalomyelitis (ADEM) is an immune-mediated demyelinating disease of the Central Nervous System clinically defined by acute polyfocal neurological syndrome usually following a monophasic course. ADEM often occurs after infections, but 5-10% of cases are preceded by vaccinations. Several cases of ADEM after SARS-CoV-2 infection have been described, whereas no cases have been reported after administration of mRNA/adenovirus COVID-19 vaccines. Here, we describe a suspected case of ADEM presenting two weeks after receiving the first dose of ChAdOx1 nCoV-19 vaccine.

Methods:: Case report

Results:: A 45-year-old man developed numbness in his hands two weeks after receiving the first dose of ChAdOx1 nCoV-19. His condition worsened in a few days: numbness extended to the upper limbs, trunk and legs and he progressively experienced visual acuity deficits, dysarthria, dysphagia, clumsy right hand movements and urge incontinence. Symptoms persisted for one week but then spontaneously improved. At admission to our unit, MRI showed large T2-weighted hyperintensities in the pons (which appeared swollen), right thalamus and multiple spinal cord segments. All lesions, except the thalamic and a single spinal area, were contrast-enhancing. Cerebrospinal fluid revealed mild lymphocytosis with no tumor cells or infectious agent detected at PCR. Serology for infectious/autoimmune diseases and total-body CT resulted negative. Clinical and neuroradiological improvement ensued right after a 5-day course of high-dose IV methylprednisolone.

Conclusions:: The diagnostic work-up suggests a diagnosis of ADEM, a disease whose association with vaccines is well-known. This is the first description of a possible association with an adenovirus COVID-19 vaccine.
CHARACTERISTICS AND OUTCOMES OF COVID-19-RELATED STROKES: A RETROSPECTIVE STUDY IN A TERTIARY HOSPITAL

Majdi Al Qawasmeh¹, Yaman Ahmed², Omar Nsour², Ethar Hazaimeh¹, Aref Qarqash², Omar Jbarah¹, Khalid El-Salem¹
¹Jordan University of Science and Technology, Faculty of Medicine, Neuroscience, Irbid, Jordan, ²Jordan University of Science and Technology, Faculty Of Medicine, Irbid, Jordan

Background and Aims:: The hypercoagulable state that the COVID-19 elicits can lead to acute thrombotic complications including ischemic stroke. Here we describe the clinical profile, neuroimaging findings, interventions, and outcomes of COVID-19-related stroke patients in a tertiary hospital.

Methods:: This is a retrospective study of all COVID-19-related stroke patients who were hospitalized between November 2020 and March 2021 at King Abdullah University Hospital (KAUH) during the peak period in Jordan. Clinical characteristics, laboratory and neuroimaging data, interventions, and outcomes were collected. SARS-CoV-2 infection was confirmed in all patients by RT-PCR testing.

Results::

\[
N = 17
\]

- Minor (0-4): 5
- Moderate (5-15): 9
- Severe (21-42): 3
A total of 17 COVID-19-related stroke patients were identified, with a mean age of 70.8 ± 9.4 years and a male percentage of 47.1% (8/17). All of them were ischemic strokes. COVID-19-related stroke patients had high peak D-dimer and troponin levels with a median of 4.13 (IQR: 11.81), and 0.041 (IQR: 0.105), respectively. The mean duration of hospital stay was 11.9 ± 9.2 days. Seven patients died in the hospital (41.2%), while 10 patients had a modified Rankin score of ≤ 4 at discharge. 

**Conclusions:** Cryptogenic and cardioembolic stroke patients were more severe with higher mortality and morbidity rates in comparison with other COVID-19-related strokes. Further studies are needed to determine the safety and efficacy of therapeutic and prophylactic anticoagulants in stroke patients with COVID-19 infection.
PATIENT SATISFACTION WITH TELEVISIT IN CHRONIC NEUROLOGIC DISORDERS DURING COVID-19 PANDEMIC

Irene Rosellini¹, Marika Vianello¹, Anna Palmieri¹, Silvia Guidoni¹, Federico Giopato¹, Anna Ghazaryan¹, Matteo Fuccaro¹, Alberto Terrin¹, Roberta Vitaliani¹, Maria Rigoni¹, Francesco Pietrobon², Domenico Bonifati¹
¹Ca' Foncello Hospital, Neurocardiovascular, Treviso, Italy, ²AULSS2, Socio-health District South, Treviso, Italy

Background and Aims:: Covid-19 pandemic has boosted telemedicine in medical clinical practice. Experiences in the management of chronic neurological disorders are limited as well as patient opinion. During Covid-19 pandemic we evaluated patients' satisfaction and opinion about televisits in a large group of patients with chronic neurological disorders.

Methods:: All patients with chronic neurological disorders who had a virtual visit during the first phase of pandemic were invited to fill an online anonymous questionnaire about their global satisfaction and regarding the following issues: continuity of care, possibility to stay at home, doctor-patient relationship, the future of teleconsultation after pandemic and understanding of medical informations.

Results:: We received 123 questionnaires among 232 e-mail (response rate 53%). Almost all (120 out of 121 patients, 99%) were satisfied with the overall experience with video-consultation. Comprehension of medical information was the same for 113 out of 122 patients (93%) and also the doctor-patient relationship was the same for 107 out of 122 respondents (88%) or better for 10 (8%). Ninety-three percent of patients (112 out of 120) were keen to integrate televisits with the traditional modality and only 11 out of 121 patients (9%) judged televisits as an option to discard. As a whole 114 out of 122 respondents (93%) would suggest this modality to other patients.

Conclusions:: Our large cohort of patients with chronic neurologic disorders rated experience with televisits satisfactory. Comprehension of medical information and doctor-patient interaction was considered good. Eventually patients are keen to integrate this modality with traditional follow-up visits.
NO IMPACT OF COVID-19 LOCKDOWN ON CLINICAL STATUS OF ELDERLY WITH COGNITIVE IMPAIRMENT OR DEMENTIA USING A STRUCTURED PHONE-BASED ASSESSMENT

Salvatore Caratozzolo¹, Andrea Scalvini¹, Sonia Bonacina¹, Maura Cosseddu¹, Rosanna Turrone¹, Alessandro Padovani²
¹ASST Spedali Civili di Brescia, Neurology Unit, Dept. Clinical And Experimental Sciences, University Of Brescia, Brescia, Italy, ²University of Brescia, Dept. Clinical And Experimental Sciences, Brescia, Italy

Background and Aims:: Aim of the study was to investigate by a standardized telemedicine protocol the impact of prolonged lockdown on cognitive and behavioral symptoms of dementia (BPSD) in a consecutive series of patients with cognitive decline.

Methods:: The study was carried out in patients with dementia who were periodically visited at the CDCD of ASST Spedali Civili. This study took place from April 01 to May 31 2020.Among the information collected: Clinical Dementia Rating Scale, a telephone version of Mini Mental State Examination (Itel-MMSE), the NPI-Q. The Perception of quality of life was investigated by both the caregiver and the patient (EQ5D) and by the Zarit Burden Inventory.

Results:: Overall, 90/108 completed the evaluation and the final sample included 52/90 females, with mean age 78.9 (SD 7.3), mean education 7.8 (SD 3.8) and mean duration of disease of 3.5 (SD 1.9) years. A significant aggravation since last in presence visits was found in 34/90 patients (37.1%), largely coincident with caregivers reporting (27/34, 79,%). A significant difference between the two groups was observed on NPI-Q stress scale (p<.0001) and on Zarit Burden Inventory (p<.0001). By logistic analysis, caregivers’ stress was significantly associated with patient CIRS score, duration of illness and NPI-Q total score at baseline

Conclusions:: This is one of the few studies to investigate the impact of SARS-CoV-2 related lockdown by comparing cognitive, functional and behavioral data collected by telemedicine. According to this study, patients did not suffer a significant clinical impact but multimorbidity, duration of illness and severity BPSD at baseline predicted caregivers distress.
THE EFFECTS OF THE COVID-19 PANDEMIC AND QUARANTINE MEASURES ON THE LIFESTYLES AND MENTAL HEALTH OF OLDER ADULTS AT INCREASED RISK OF DEMENTIA.

Simona Gabriella Di Santo, Flaminia Franchini, Angela Martone, Serena Sannino, Roberta Beltrami, Fulvio Adorni, Carlo Caltagirone

1IRCCS Fondazione Santa Lucia, Dipartimento Di Neurologia Clinica E Comportamentale, Rome, Italy, 2Università degli Studi di Roma 'Tor Vergata', Dipartimento Di Neuroscienze, Rome, Italy, 3Italian National Research Council, Institute Of Biomedical Technologies, Segrate (MI), Italy

Background and Aims:: A complete lockdown was adopted in Italy in Spring 2020 to limit the spread of the COVID-19 pandemic. Older adults, especially those with mild cognitive impairment (MCI), may be particularly prone to adopt unhealthy lifestyles and suffer mental health consequences from quarantine. This study aimed to explore the impact of COVID-19 and quarantine on lifestyles and mental health of seniors at increased risk of dementia.

Methods:: 126 Community-dwelling seniors with subjective cognitive decline or MCI (56%) were twice phone-interviewed 6-8 weeks after the lockdown beginning and 6-months later, after the easing of quarantine measures and school reopening. Data regarding health and COVID-19-related variables, cognition, depression, anxiety, apathy, physical activity (PA), mediterranean diet (MD), and leisure activities (LAs) was collected.

Results:: During lockdown, over 1/3 of participants reduced PA and MD adherence; 1/6 decreased mental-stimulating LAs; 1/5 were depressed, 1/10 anxious and 1/10 apathetic. Around 60% of them completed the second interview: almost 9/10 reported having not returned to pre-pandemic daily habits, 45% took less care of their health than before COVID-19. Compared to quarantine, only 16% increased PA and 21% increased adherence to MD, 81% resumed social LAs, but 45% decreased mental-stimulating LAs. Prevalence of depression and anxiety did not change significantly, while apathetic individuals nearly tripled and 72% of respondents achieved higher apathy scores compared to their first interview.

Conclusions:: The quarantine and protracted COVID-19 emergency led seniors to unhealthy lifestyles - which were mostly maintained even after reopening - and increased apathy, which may impact on their future risk of dementia.
FACEMASK HEADACHE: A NEW NOSOGRAPHIC ENTITY AMONG HEALTHCARE PROVIDERS IN COVID-19 ERA

Laura Rapisarda¹, Francesco Fortunato¹, Antonio De Martino¹, Oreste Marsico¹, Giulio Demonte¹, Antonio Augimeri², Angelo Labate¹, Antonio Gambardella¹, Michele Trimboli¹
¹AOU Mater Domini, Magna Graecia University, Department Of Medical And Surgical Sciences, Institute Of Neurology, Catanzaro, Italy, ²Biotecnemed S.CaR.L., , Catanzaro, Italy

Background and Aims:: SARS-CoV-2 is a novel infectious agent causing Coronavirus disease 2019, which has been declared as pandemic in March 2020. Personal protective equipment has been mandatory for healthcare workers in order to contain the outbreak of pandemic disease. Mild neurological disturbances such as headache have been related to the extensive utilization of facemask. This study aims to examine headache variations related to the intensive utilization of facemask among a cohort of healthcare professionals in a setting of low-medium risk of exposure to SARS-CoV-2.

Methods:: This is a cross-sectional study amongst healthcare providers from different hospital and clinics in Italy. Each participant completed a specifically-designed self-administered questionnaire. Headache features and outcome measures' change from baseline were evaluated over a four-months period, in which wearing facemask has become mandatory for Italian healthcare workers.

Results:: A total of 400 healthcare providers completed the questionnaire, 383 of them met the inclusion criteria. The majority were doctors, with a mean age of 33.4±9.2 years old. Amongst 166/383 subjects, who were headache free at baseline, 44 (26.5%) developed de novo headache. Furthermore, 217/383 reported a previous diagnosis of primary headache disorder: 137 were affected by migraine and 80 had tension-type headache. A proportion (31.3%) of these primary headache sufferers experienced worsening of their pre-existing headache disorder, mainly for migraine frequency and attack mean duration.

Conclusions:: Our data showed the appearance of de novo associated facemask headache in previous headache-free subjects and an exacerbation of pre-existing primary headache disorders, mostly experienced by people with migraine disease.
COVID-19 INFECTION, DEPRESSION, AND ISCHEMIC STROKE

¹“Dr. Carol Davila” Central Military Emergency University Hospital, Neurology, Bucharest, Romania, ²Central Military Emergency University Hospital – Neurosurgery Clinic, Carol Davila University of Medicine and Pharmacy, Neurosurgery, Bucharest, Romania, ³National Institute of Endocrinology Cî Parhon, Endocrinology, Bucharest, Romania, ⁴Central Military Emergency University Hospital – Neurology Clinic, Titu Maiorescu University, Neurology, Bucharest, Romania

Background and Aims:: Many recent studies have shown increasing evidence connecting COVID-19 infection with acute thrombotic events, and in particular with ischemic strokes. There are several theories regarding this association, such as alterations in lipid metabolism or platelet aggregation, injury of the endothelial cells, or massive cytokine release, leading to cytokine storm and hypercoagulation. The biological and social consequences of this infection can also lead to psychiatric afflictions, most frequently anxiety and depression being described. This study aims to highlight the possible connections between COVID-19 infection, depression, and ischemic stroke.

Methods:: We observed the case of a 48-year-old patient who presented with left hemibody paresthesia and motor deficit on the left side of the body. Two months prior, he presented a COVID-19 infection, followed by a major depressive episode. Clinical, neurological, and neuroimaging examinations were performed to establish the diagnostic. We also analyzed the existing risk factors and possible etiologies. The patient had a history of hypertension, hypercholesterolemia, obesity, and smoking.

Results:: Following investigations, the diagnosis of acute ischemic thalamic stroke was established. Although there have been more risk factors identified, a causative event that led to the decompensation of these conditions was searched. The post-COVID-19 infection status and recent depression episode represent reasonable presumptive causal factors.

Conclusions:: The relation between the acute ischemic thalamic stroke, previous COVID-19 infection, and subsequent depressive episode was considered to be plausible.
ROLE OF AN INTENSIVE INPATIENT REHABILITATION PROGRAM IN FUNCTIONAL RECOVERY AFTER GUILLAIN-BARRE’ SYNDROME RELATED OR NOT TO COVID-19

Claudio Marcello Solaro¹, Virginia Tipa¹,², Giulia Gamberini¹, Marco Invernizzi², Fabio Giuseppe Masuccio¹
¹Mons. Luigi Novarese Hospital, Dept. Of Rehabilitation, Moncrivello (VC), Italy, ²University of Eastern Piedmont, Dept. Of Health Sciences, Novara, Italy

Background and Aims:: Several cases of Guillain-Barre Syndrome (GBS) have been related to COVID-19, without data on the functional outcome after intensive rehabilitation. We aimed at presenting the results of rehabilitation in patients with COVID-19-related or not GBS.

Methods:: All the patients admitted in 2020 for GBS in a rehabilitation facility have been evaluated with Barthel index (BI), GBS-Disability Scale (GBS-DS) and Medical Research Scale-Sum Score (MRC-ss) at admission and at discharge, after an intensive rehabilitation program.

Results:: In 2020, three COVID-19-related (3F; mean age 72.33 years) and five non-COVID-19-GBS (2M/3F; mean age 73.2 years) were admitted. In non-COVID-19-GBS a high Acute Motor Axonal Neuropathy (AMAN) prevalence was detected [4 AMAN, 1 AMAN/Acute Inflammatory Demyelinating Polyradiculopathy (AIDP) mixed form]. Non-COVID-19-GBS experienced a high complications rate, with two deaths due to sepsis. At discharge, BI ameliorated in the three survivors (0-65, 35-70; 5-20) as MRC-ss (15-38; 43-52; 33-48). GBS-DS decreased in only two cases (4-2; 4-2; 4-4), with one patient regaining independent walking. COVID-19-GBS (2 AIDP, 1 AMAN) did not experience complications. Two AIDP patients recovered autonomous walking at discharge, with BI (25-95; 35-85) and MRC-ss (48-60; 36-59) rising, and GBS-DS decreasing (3-2; 3-2). In the only AMAN form, a light augment in BI (5-15) and MRC-ss (36-40) was noticeable, without GBS-DS reduction GBS-DS (4-4).

Conclusions:: COVID-19-related GBS had a better clinical outcome than non-COVID-19-GBS. However, epidemiological considerations cannot be deemed due to the small sample. More follow-up studies are warranted for the functional recovery evaluation of these patients.
PROLONGED COGNITIVE DEFICITS AFTER COVID-19

Background and Aims:: Cognitive deficits are a common complication of COVID-19. Multiple factors associated with the illness and its treatment may contribute to cognitive deficits. In this study, we analysed neuropsychological data from a cohort of patients recovering from COVID-19 hospitalization who required different types of oxygen/ventilation therapy.

Methods:: We recruited 77 (aged 22–77 years; 57 males) patients hospitalized for complications of SARS-CoV-2 infection in different COVID units, which had required different oxygen (O₂) therapy (no-O₂ = 9, low-flow O₂=35, CPAP=26, intubation=7). Participants underwent neuropsychological testing with the Brief Repeatable Battery of Neuropsychological Tests (BRB-NT) about 5 months after hospital discharge.

Results:: Of all participants, 64% showed deficits in at least one test of the BRB-NT; the most affected functions were processing speed (41.6% of participants) and delayed verbal recall (27.3%). O₂ therapy with CPAP was associated with worse verbal memory performance (p=0.033), compared to no-O₂ therapy. Attention and processing speed deficits were not associated with type of O₂ therapy (p=0.889), but correlated with thromboplastin (aPTT) ratio (r=0.298, p=0.019). Worse delayed visuospatial recall was associated with hyposmia (p=0.011) and dysgeusia (p=0.035).

Conclusions:: Cognitive deficits are frequent, persistent, and disabling even for five months following hospitalization for COVID-19. Therefore, neurological and neuropsychological monitoring should be put in place after discharge to help mitigate the effects of these symptoms, improving the quality of life of COVID-19 survivors.
THE NEUROLOGICAL MANIFESTATIONS OF COVID19, THE MOST EXTENSIVE REVIEW OF PUBLISHED CASE REPORTS

Hamad AlDraye
KFSHRC, Neurosciences, Riyadh, Saudi Arabia

Background and Aims:: The spectrum of neurological involvement in COVID-19 has been rapidly reported during this pandemic in order to support fellow colleagues in prompt identification and management. This is the most extensive review of published case reports of neurological manifestations of COVID19. The aim of this study is to assess the frequency of neurological manifestations and complications, identify the neurodiagnostic findings, and compare these aspects between severe and non-severe COVID-19 cases.

Methods:: A systematic search of PubMed, Scopus and Google Scholar databases was conducted for studies published between the 1st of January 2020 and March 2021. We included all published studies that were English or translated to English, patients from all demographics with a confirmed COVID19 infection (either non-severe or severe) and had sufficiently documented investigation efforts to reach a diagnosis of a neurological manifestations. The main outcomes of the study were to identify the frequency and nature of neurological manifestations and complications, and the neuro-diagnostic findings in COVID-19 patients.

Results:: 389 articles were included with a pooled sample size of 45,340 patients. The mean age was 55 years and 63% were males. The most common neurological manifestations were a combination of minor symptoms such as Myalgia, taste and smell impairment, headache, dizziness and most prominent major manifestations were vascular episodes, encephalopathy, seizures, neuropathies and Gullian Barre Syndrome.

Conclusions:: Neurological involvement is common in COVID-19 patients (whether non-severe or severe). Prompt identification and management of these cases would improve outcome and decrease morbidity.
CRITICAL ILLNESS NEUROPATHY IN SEVERE COVID-19

Tommaso Bocci1,2, Laura Campiglio1, Manuela Zardoni1, Silvia Coppola3, Elisabetta Groppo1, Davide Chiumello4, Alberto Priori1,2

1“Aldo Ravelli” Center for Neurotechnology and Experimental Brain Therapeutics, Department Of Health Sciences, International Medical School, University Of Milan, Milan, Milano, Italy, 2III Clinical Neurology Unit, University of Milan, San Paolo University Hospital, ASST Santi Paolo e Carlo, Department Of Health Sciences, Milan, Italy, 3Intensive Care, Anesthesia and Resuscitation Unit, Asst Santi Paolo & Carlo And Department Of Health Sciences, University Of Milan, Milan, Milan, Italy, 4Intensive Care, Anesthesia and Resuscitation Unit, Asst Santi Paolo & Carlo And Department Of Health Sciences, University Of Milan, Milan, Milano, Italy

Background and Aims:: Neurological complications of COVID-19 have received a growing attention; few studies have described neurophysiological findings in COVID patients during their stay in Intensive Care Units (ICUs). We assessed the presence of either critical illness neuropathy (CIP) or myopathy (CIM) in ICU patients. The mean time of hospitalization in ICU was 17.2 ± 4.1 days.

Methods:: Patients underwent a bilateral examination of the median, ulnar, deep peroneal and tibial motor nerves and of the median, ulnar, radial and sural sensory nerves. F-waves were recorded from abductor hallucis and abductor digiti minimi muscles. Needle electromyography (EMG) was performed for distal and proximal muscles. Direct Muscle Stimulation (DMS) was applied to the deltoid and tibialis anterior; peak to peak amplitudes and onset latencies of the responses evoked by DMS (DMSamp, DMSlat) or by motor nerve stimulation (MNSamp, MNSlat) were compared. The ratio MNSamp to DMSamp (NMR) and the MNSlat to DMSlat difference (NMD) were evaluated.

Results:: Nerve conduction studies showed an axonal neurogenic pattern, with low SAPs and CMAPs amplitudes, as confirmed by needle EMG. MNSamp and NMR were significantly reduced when compared to controls (p < 0.0001), whereas MNSlat and NMD were increased (p = 0.0049; see Figure 1).
Conclusions:: COVID patients suffered from a critical illness neuropathy (CIP), differently from the previous literature showing a higher prevalence of myopathy in non-COVID ICU patients. That could have implications for the functional recovery and rehabilitation strategies of COVID patients, thus delaying ICU discharge, also highlighting novel insights into the neuropathology of COVID-19.
BILATERAL FOOT-DROP SECONDARY TO DEMYELINATING NEUROPATHY POST-COVID-19 INFECTION: A CASE REPORT

Elisabetta Maida¹, Giuseppina Miele¹, Federica Matrone², Vincenzo Todisco², Simona Bonavita¹
¹University of Campania “Luigi Vanvitelli”, II Clinic of Neurology, Department Of Advanced Medical And Surgical Sciences, Napoli, Italy, ²University of Campania Luigi Vanvitelli, Department Of Advanced Medical And Surgical Sciences, Napoli, Italy

Background and Aims: Covid-19 may cause several neurological symptoms and signs. We present the case of a 27-yo male with bilateral foot-drop after COVID-19.

Methods: A 27-yo male was diagnosed at the end of November 2020 with mild COVID-19. Twenty days later, he presented subacute right hallux paresthesia, extending to the leg and thigh followed by motor impediment in right dorsal foot flexion. In January 2021 similar symptoms involved the contralateral leg and subacute paresthesia developed in the upper limbs. Neurological exam showed steppage gait, conjugate nystagmus in right gaze, hypostenia of the lower and of the right upper limb and severe reduction of the right foot dorsiflexion. Infectious and autoimmune serological work-up was normal; CSF showed IgG 4.2mg/dl (n.v. <3.4) with no oligoclonal bands; Q Alb: 0.62 (n.v.< 0.45). Brain and spinal MRI showed a T2/FLAIR hyperintense lesion at the level of the bulbous-medullary junction. Nerve conduction study/electromyography showed a bilateral neuropathy of the peroneal nerves with segmental demyelination at the level of the fibular head and of the median nerves bilaterally at the level of the carpus. PMP22 gene was investigated, and no mutation was found. Nerve ultrasound did not show any alterations along the course of the peroneal nerves.

Results: Methylprednisolone sodium succinate was administered i.v. (1000 mg/d for five days). The neurological exam after one month showed a partial recovery.

Conclusions: There is a considerable need for studies regarding the potential impact of COVID-19 on the nervous system regarding pathogenesis, prognosis, and severity of disease.
ADEQUATE ACCESS TO MECHANICAL THROMBECTOMY DURING COVID-19 PANDEMIC IN LESSER POLAND VOIVODESHIP IN POLAND

Pawel Wrona¹, Tomasz Homa¹, Agnieszka Slowik², Ewa Wlodarczyk¹, Roman Pulyk¹, Tadeusz Popiela³, Paweł Brzegowy³, Bartłomiej Łasocha⁴
¹University Hospital, Department Of Neurology, Cracow, Poland, ²Jagiellonian University, Department Of Neurology, Cracow, Poland, ³Jagiellonian University, Chair Of Radiology, Cracow, Poland, ⁴University Hospital, Department Of Radiology, Krakow, Poland

Background and Aims:: Many studies have shown that COVID-19 pandemic decreased the access to mechanical thrombectomy (MT) in acute ischemic stroke (AIS) patients. We studied, if the pandemic affected the access to MT in Lesser Poland Voivodeship (LPV) located in southeastern Poland (3.36 million of inhabitants).

Methods:: In LPV patients with AIS are admitted to the nearest stroke unit in the region (15-unit Stroke Network), where intravenous thrombolysis is performed. Those fulfilling the criteria for MT are admitted to the Comprehensive Stroke Unit at the University Hospital in Krakow. We compared the number of MT performed within 12 months before pandemic outburst, from March 2019 to February 2020 with the number of MT performed during pandemic, from March 2020 to February 2021. We also compared the time from stroke onset (SO) to groin puncture (GP) during the two studied periods.

Results:: 146 had MTs performed during pre-pandemic period and 182 during the pandemic period. The number of MTs in the consecutive months of both periods was similar up to November. The number of MT doubled from December 2020 to January 2021 as compared to the same period of time a year earlier. The mean SO-GP times were similar in both analyzed periods.
Conclusions:: In LPV the number of MTs during COVID-19 pandemic was similar or even higher as compared to the corresponding pre-pandemic period. The time of the access to MT was not affected by the COVID-19 pandemic. Our results reflect the efficiency of the local medical system for stroke care, irrespectively of the COVID-19 challenges.
COMPARISON OF DISEASE PROFILES AND OUTCOMES OF PATIENTS WITH NEUROLOGICAL DISORDERS WITHOUT AND WITH COVID-19: AN AMBISPECTIVE COHORT STUDY

1LTMGH, Sion, Neurology, Mumbai, India, 2AIIMS, New Delhi, Neurology, New Delhi, India, 3AIIMS, New Delhi, Neurology, Delhi, India, 4AIIMS, New Delhi, Anaesthesia, Delhi, India, 5AIIMS, New Delhi, Medicine, Delhi, India

Background and Aims:: We aimed at comparing the clinical and laboratory characteristics, along with survival and functional outcome in the form of modified Rankin scale at 3 ± 1 month follow-up, between the COVID-19 negative and positive patients, with a neurological illness.

Methods:: Ambispective cohort study - included patients presenting with a neurological disorder, tested positive for COVID-19, and admitted to the hospital’s COVID-19 centre, from April to September 2020. Demographic, clinical, biochemical and treatment profiles of these patients were compared with COVID-19 negative patients admitted to the neurology wards. Information about three months outcome after discharge was assessed telephonically. Data on survival and disability status in the form of mRS were collected.

Results:: Of a total of 235 patients enrolled from emergency services with neurological disorders, 81 (34.5%) were COVID-19 positive. Mean (SD) age was 49.5 (17.3) years and majority of the patients were male (62.98%). Commonest neurological diagnosis was Acute Ischemic Stroke (AIS)(42.98%). Chronic kidney disease (CKD) patients were more likely to be COVID-19 positive (COVID-19 negative: 4 (2.6%) versus COVID-19 positive: 11 (13.8%), p-value: 0.001). The in-hospital mortality was higher among COVID-19 positive patients (COVID-19 negative: 12 (7.8%) versus COVID-19 positive: 29 (35.8%), p-value: <0.001). There were 15 (13.8%) deaths at three months follow up in the COVID-19 negative versus 4 (12.1%) in COVID-19 positive patients (p-value: 1.00). Overall three-month mRS was higher in the COVID-19 positive group assessed via Cochran-Mantel-Haenszel test (p-value <0.001).

Conclusions:: Patients with neurological disorders presenting with COVID-19 infection had worse outcomes, including in-hospital mortality and three months disability.
Background and Aims:: Recent reviews on the effect of COVID-19 suggest a significant increase in the prevalence of cognitive dysfunction that affects the ability to return to daily functioning. This could be explained by various reasons: (1) Direct neurological damage of Coronaviruses that may penetrate into the brain and cerebrospinal fluid due to increased permeability of the blood-brain barrier or by the infection of peripheral or olfactory neurons. In particular, the hippocampus, a region involved in mnemonic mechanisms, could be a region of great vulnerability; (2) Hypoxia related to respiratory distress syndrome associated with cerebral atrophy and ventricular enlargement and (3) Psychological symptoms manifesting in anxiety, depression or post-traumatic stress syndrome.

Methods:: We propose the analysis of the neuropsychological profile in people infected by SARS-CoV2 and the follow-up at 6 months from the first evaluation. A comprehensive neuropsychological battery was included. Psychological variables (anxiety and depression), verbal and visuospatial memory, attentional functions and processing speed, executive functions and visuospatial functions are explored. Data from medical history and neuroimaging data are collected.

Results:: To date, the main cognitive deficits found are: moderate decreasing in processing speed, impairment of executive functions or difficulties in the information retrieval processes.

Conclusions:: The neurological effect of COVID-19 infection might not be limited to the more well-known symptoms as anosmia or dysgeusia, neuropathies, or exacerbation of pre-existing disease. Cognitive symptoms could be part of the persistent COVID picture and significantly interfere with the work and social activity of those affected. Identifying these symptoms can help us identify therapeutic targets for early neuropsychological rehabilitation.
PROTECTIVE ROLE OF PRE-EXISTING CEREBROVASCULAR DISEASES IN LOCAL SPREAD OF COVID-19 INFECTION IN JAPAN

Masako Kinoshita¹, Kazuaki Sato¹, Hiroya Ohara², Balachandar Vellingiri³, Shawn Green⁴, Masami Tanaka⁵
¹National Hospital Organization Utano National Hospital, Neurology, Kyoto, Japan, ²Minami-nara General Medical Center, Neurology, Yoshino, Japan, ³Bharathiar University, Human Genetics And Molecular Biology, Tami Nadu, India, ⁴Harbor-UCLA Medical Center, Cardiology, California, United States of America, ⁵Kyoto Min-Iren Chuo Hospital, Kyoto Ms Center, Kyoto, Japan

Background and Aims:: It is proposed that various pre-existing medical conditions, including cerebrovascular diseases, might increase a risk for severity of coronavirus disease 2019 (COVID-19). The cumulative number of COVID-19 cases in Japan is relatively low, therefore the effect by cerebrovascular diseases can be distinct from that in Western countries. We analyzed the relationship between the local number of patients with pre-existing cerebrovascular diseases per population and local prevalence of patients with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection.

Methods:: Data on SARS-CoV-2 infection and the estimated number of patients who received medical treatment for cerebrovascular diseases in each prefecture were obtained from the official notifications database of Japan. We analyzed the association between the ratio of patients with each disease and the prevalence of SARS-CoV-2 infection.

Results:: The ratio of patients with cerebrovascular diseases per population showed a significant negative correlation with the prevalence of SARS-CoV-2 infection (Spearman's rank correlation, p<0.01).

Conclusions:: The current study suggests that pre-existing cerebrovascular diseases may play a protective role against local spread of SARS-CoV-2 infection, possibly attributed to common use of angiotensin-converting enzyme inhibitors and angiotensin receptor blockers.
THE NEUROLOGICAL PRESENTATIONS ASSOCIATED WITH COVID-19: A RETROSPECTIVE SINGLE-CENTER CLINICAL STUDY IN THE REPUBLIC OF DAGESTAN, RUSSIA

Zukhra Gadzhieva, Zaira Khamidova, Teyli Magomedova, Zaira Kaplanova
GBU RD RDC, Neurology, Makhachkala, Russian Federation

Background and Aims: Numerous studies have demonstrated that patients with COVID-19 may develop neurological complications, including headaches. Despite this, the available data on the clinical characteristics of affected patients remain limited. The purpose of the study was to analyze the characteristics of headaches in COVID-19 patients examined outpatiendly.

Methods: A retrospective single-center study of the patients with confirmed COVID-19 was conducted from 1st May to 30th June 2020. Epidemiological, demographic, clinical, laboratory and radiological data were collected and analyzed. All patients were divided into 4 groups based on their chest CT scans: CT-0 - no evidence of pneumonia, CT-1<25% involvement, CT-2–25-50%, CT-3–50-75%, CT-4>75%.

Results: 175 COVID-19 patients were enrolled during the study period. The mean age was 49.8±12.3 years (64% females). The leading neurological signs were fatigue (81.2%), headache (64.6%), anosmia/ageusia (54.8%/52.0%), anxiety/depression (58.8%/57.7%). The main features of headache were bilateral localization (72.5%), a pressing quality (69.1%), onset in the frontal and periorbital regions (60.2%) and spontaneous regression after the acute phase of the disease. 57.5% of the patients had no previous history of any primary headache. Headache intensity, according to the VAS, was significantly higher in patients with more severe lung damage (p=0.033), probably due to hypoxia.

Conclusions: Most of the neurological manifestations were comparable in frequency to those reported in the literature. The incidence of headache in our population was higher than reported in the literature, possibly due to the higher rate of primary headache history in our sample of patients compared to available studies.
Background and Aims:: Coronavirus disease (COVID-19), caused by "severe acute respiratory syndrome coronavirus 2" (SARS-CoV-2), is characterized by a severe respiratory illness with multisystemic involvement. An increasing number of papers has described electroencephalographic patterns in COVID patients. That is of critical importance not only to corroborate the neuroinvasion sustained by SARS-CoV-2, but also to plan therapeutic strategies, either aggressive or not, for the treatment of seizures. We described four patients with COVID-19 disease, sharing common clinical, EEG and surface electromyographic (poly-EMG) abnormalities.

Methods:: four patients with COVID-19 were enrolled. None of them had a previous history of epilepsy. In each patient, EEG was performed and, in three cases, jerks were also recorded by surface poly-electromyography (poly-EMG).

Results:: Bilateral, symmetric, lateralized periodic discharges (LPD) was recorded in three patients, predominantly in the midline and parasagittal regions. Surface poly-EMG showed synchronous myoclonic jerks, involving the cranial muscles, paralleled by a lack of jerk-locking at EEG-EMG polygraphy, without any correlation between clinical myoclonus and epileptiform discharges and without a proximal-to-distal gradient of appearance.

Conclusions:: This is the first case series of combined EEG and poly-EMG patterns associated to COVID-19 infection, suggesting the presence of a myoclonus of sub-cortical origin, not explained by brain lesions, neither by the hypoxic damage.
Background and Aims:: COVID-19 is a rapidly emerging respiratory disease caused by SARS-CoV-2. Numerous studies have demonstrated that patients with COVID-19 may develop neurological complications. Despite this, the available data on the clinical characteristics of affected patients remain limited. The purpose of the study was to present the clinical manifestations and predictors of severe outcome of COVID-19 patients examined outpatiently at the Diagnostic Center of the Republic of Dagestan, Russia.

Methods:: A retrospective single-center study of the 175 patients with confirmed COVID-19 was conducted from 1st May 2020 to 30th June 2020. Epidemiological, demographic, clinical, laboratory and radiological data were collected and analyzed. All patients were divided into 4 groups based on their chest CT scans: CT-0 - no evidence of pneumonia, CT-1 <25% involvement, CT-2 – 25 to 50%, CT-3 – 50 to 75%, CT-4 > 75% involvement.

Results:: 175 COVID-19 patients were enrolled during the study period. The mean age was 49.8±12.3 years. Female was the dominant sex (64%). The leading neurological signs were fatigue (81.2%), headache (64.6%), anosmia/ageusia (54.8%/52.0%), anxiety/depression (58.8%/57.7%). A comparative analysis revealed no significant differences in the prevalence of neurological symptoms in patients with different severity of lung involvement. Older age, female sex and comorbidity – obesity, arterial hypertension and diabetes mellitus were estimated as higher risk factors for severe form.

Conclusions:: The first Russian retrospective study of COVID-19 adult patients was presented. There were no patients in our cohort with a new-onset neurologic event. The main neurological manifestations were comparable in frequency to those reported in the literature.
NEURON SPECIFIC ENOLASE IN A SARS COV2 PATIENT

Ottone Frangipane Hospital, Laboratory, Ariano irpino (AV), Italy, ¹⁵S. Ottone Frangipane Hospital, First Aid, Ariano irpino (AV), Italy, ¹⁶S. Ottone Frangipane Hospital, Neurology, Ariano irpino (AV), Italy, ¹⁷Criscuoli Hospital, Laboratory, S. Angelo dei Lombardi, Italy

Background and Aims:: Neuron-specific enolase (NSE) is a dimeric, intracellular, glycolytic enzyme, which is released after stroke, cardiac arrest, traumatic brain injury. Serial assessment of its level may help in identification of patients at risk of poor outcomes, in decision making on intensive care, rehabilitation or palliative treatments.

Methods:: An 80 years-old male patient came to our observation for confusion. At past case history, chronic coronary syndrome in aortic-coronary by-pass, mild-moderate mitral failure, paroxysmal atrial fibrillation, pulmonary emphysema, type II diabetes mellitus, recent SARS CoV2 were reported.

Results:: Level of NSE was high (30,8 ng/ml). Episodes of O2 saturation below 90%, decreased lymphocyte absolute counts and g globulins were still present. IgM and IgG titers and nasopharyngeal swab were negative. Electroencephalogram showed dysrhythmia, with diffuse slow waves. Chronic cerebrovascular disease was evident at neuroimaging.

Conclusions:: Our observations confirm our previous finding on worst outcomes after CoV2 infection in immunodepressed patients with comorbidities. We highlight that NSE may be a useful marker to assess the clinical course in anoxic encephalopathy. However, it is dependent on the ratio between neuronal and glial cells. Low levels do not rule out ongoing damage. In elderly patients, S100, a calcium-binding, astroglial protein may be more consistent. On the other hand, the brief half-life of the latter (25 minutes) compared to the longer half-life of former marker (30 hours) may limit detection. Both may implement clinical and radiological findings, especially in ventilated and sedated patients. Lastly, they may add further information for ethical, social and legal issues.
NICOTINE, CYTOKINE STORMS AND COVID-19

Xavier Boland¹,², Luiz Dratcu²
¹Maudsley Hospital, Acute Psychiatry, London, United Kingdom, ²South London and Maudsley NHS Foundation Trust, Acute Psychiatry, London, United Kingdom

Background and Aims:: The association of smoking with chronic obstructive pulmonary disease and cardiovascular disease puts smokers at increased risk of complications of COVID-19. Counterintuitively perhaps, several reports have found reduced prevalence of current smokers among patients admitted to hospital with COVID-19, suggesting a protective effect of active smoking against severe COVID-19.

Methods:: We report on an frail elderly man with a longstanding history of bipolar affective disorder associated with heavy smoking, alcohol dependence and multiple medical co-morbidities, including chronic obstructive airways disease and recurrent pulmonary sepsis, who contracted COVID-19 during his inpatient stay for treatment of a manic episode.

Results:: Against expectations and despite multiple risk factors for severe COVID-19, he fully recovered without the need treatment or respiratory support.

Conclusions:: We discuss the potential impact of his substantial use of nicotine replacement therapy during his inpatient stay on the eventual outcome of his illness. Nicotine, an α7-nACh receptor agonist, may boost the cholinergic anti-inflammatory pathway and hinder the uncontrolled overproduction of pro-inflammatory cytokines triggered by the SARS-CoV-2 virus, which is understood to be the main pathway to poor outcomes and death in severe COVID-19. While further research is required, evidence of a protective effect of nicotine against complications of COVID-19, although still speculative, would be strong argument for ensuring smokers are routinely provided adequate nicotine replacement on admission to hospital. More importantly, it would be yet another reason to persuade smokers to switch to nicotine replacement therapy, and ultimately quit.
SELF-REPORTED OLFACTORY DYSFUNCTION IN MEXICAN HEALTHCARE WORKERS DURING THE FIRST SIX MONTHS OF THE COVID-19 PANDEMIC: A NATIONWIDE ONLINE SURVEY STUDY

Guillermo Delgado-García¹, Germán Fajardo-Dolci², Mayela Rodríguez-Violante³, Teresita Corona³
¹University of Calgary, Department Of Clinical Neurosciences, Calgary, Canada, ²UNAM, School Of Medicine, Mexico City, Mexico, ³National Institute of Neurology and Neurosurgery, Clinical Laboratory Of Neurodegenerative Diseases, Mexico City, Mexico

Background and Aims:: After the first reports of olfactory dysfunction (OD) in the context of COVID-19, a rise of OD was described in different countries. Therefore, the Mexican Academy of Medicine, in conjunction with the National Institute of Neurology and the School of Medicine (UNAM), launched last April a nationwide online survey to describe the frequency and characteristics of self-reported OD in self-identified healthcare workers (HCWs) from Mexico.

Methods:: This 45-question instrument was based on the one previously reported by Bagheri et al. Non-probability sampling was used. The survey was distributed through official social media and institutional mailing lists. Only HCWs were included in this analysis.

Results:: Among 2702 responders, 1295 (47.9%) HCWs (784 women) completed the survey (median age 32 years). 126 (9.7%) HCWs reported OD in the last month. Of these HCWs with OD, 76 (60.3%) were previously healthy. Fever and/or chills before or during OD were reported by 43 (34.1%) HCWs. 75 (59.5%) HCWs reported respiratory symptoms before OD. In the last month, 61 (48.4%) HCWs also reported any kind of gustatory dysfunction. 57 (45.2%) HCWs reported having treated patients with COVID-19. Of them, 28 (22.2%) were diagnosed with COVID-19, but only 3 reported having been hospitalized due to COVID-19. In total, 35 of all the HCWs who completed the survey were diagnosed with COVID-19, and 80% reported OD in the last month.

Conclusions:: In this survey, less than 10% of Mexican HCWs reported OD during the first six months of the COVID-19 pandemic.
GIULIAN BARRÉ- MILLER FISHER SYNDROME RELAPSE DURING SARS-COV2 INFECTION- A CASE REPORT

Giuseppina Barbella, Simone Tonietti, Massimo Suardelli, Fabio Frediani
San Carlo Borromeo Hospital, ASST Santi Paolo e Carlo, Neurology And Stroke Unit, Milano, Italy

Background and Aims:: Miller Fisher Syndrome (MFS) is an uncommon variant of the spectrum of Guillain Barré Syndrome (GBS). MFS relapses are rare and often described after long asymptomatic intervals. GBS-MFS spectrum has been reported in association with SARS-COV2 infection. We present a SARS-COV2 associated GBS-MFS relapse.

Methods:: We detail patient's characteristics and compare with previous reports.

Results:: A 60-year-old man, diagnosed with GBS-MFS in March 2020, was admitted at Emergency Department in February 2021 with incomplete asymmetric ophthalmoplegia, ataxia, areflexia, four limbs weakness and paraesthesia and mild bifrontal oppressive headache. CSF analysis was unremarkable. Nerve conduction studies on day 7 showed a motor demyelinating polyneuropathy. Serum anti-GQ1b IgG antibodies were negative. Molecular SARS-COV2 test was positive although he was asymptomatic, except for mild fever three days after onset, at the same time with neurological symptoms worsening. Blood tests revealed mild leukopenia and CRP elevation. He was treated with intravenous low dose dexamethasone, subcutaneous enoxaparin for 10 days and with intravenous immunoglobulins for 5 days. Neurological symptoms resolved after 20 days, concurrently nasopharyngeal swab tested negative. Compared to previous reported SARS-COV2 associated GBS-MFS, in our case neurological symptoms came first, with para-infectious rather than post-infectious immune mediated mechanism. Latency of not SARS-COV2 triggered relapses was longer (median 7 years) with usually positive anti-GQ1b IgG antibodies.

Conclusions:: To the best of our knowledge, this is the first GBS-MFS recurrence description during SARS-COV2 infection. Its underlying immune mechanism seems to differ from SARS-COV2 related monophasic reports, with shorter latency and probably different antibody profile than not-SARS-COV2 linked relapses.
RACE AND SEX DIFFERENCES IN COVID-19 VACCINATION HESITANCY AMONGST PATIENTS WITH NEUROLOGICAL DISORDERS IN HAWAII

Shaina Yamashita¹, Tate Higashihara¹, Kimberly Teehera¹, Frances Morden¹, Connor Goo¹, Michelle Pang¹, Kyung Moo Kim¹, Rachel Lew¹, Kayti Luu¹, Cori Sutton¹, Catherine Mitchell², Enrique Carrazana², Jason Viereck², Kore Liow², Arash Ghaffari-Rafi¹
¹University of Hawai‘i at Mānoa, John A. Burns School Of Medicine, Honolulu, United States of America, ²Hawaii Pacific Neuroscience, Clinical Research Center, Honolulu, United States of America

Background and Aims:: This quality improvement (QI) project was conducted in order to better understand how demographic factors may influence the likelihood of COVID-19 vaccination hesitancy and declination in patients with neurological disorders in Hawaii.

Methods:: Adult patients who had visited Hawaii Pacific Neuroscience (HPN) between January 1, 2019 to January 1, 2021 were contacted through a telephone QI survey to assess COVID-19 vaccination hesitancy in relation to patient race and sex. Over 30 different sociodemographic variables and medical comorbidities were examined. Statistical analysis utilized univariate and multivariable logistic regression to determine variables associated with vaccine acceptance.

Results:: Amongst all sex and race strata, odds of COVID-19 vaccine acceptance were significantly lower for those perceiving the vaccine as unsafe. After multivariable logistic modeling, the strongest predictors of vaccine hesitancy were identified. For females, predictors included concerns of vaccine safety (p=0.0094) and the self-perception of a pre-existing medical condition contraindicating vaccination (p=0.00050). Amongst males, predictors included not receiving the flu vaccine within the past year (p=0.037), perception that COVID-19 is not a severe illness (p=0.037), and being politically conservative (p=0.034). For Whites, predictors included concerns of vaccine safety (p=0.044) and a high school education only (p=0.037). Amongst Asians, predictors included concerns of vaccine safety (p=0.0066) and the self-perception of a pre-existing medical condition contraindicating vaccination (p=0.014). For Native Hawaiians/Pacific Islanders, the only predictor was a positive depression screening (p=0.040).

Conclusions:: Patients with neurological disorders exhibit different predictors for vaccine hesitancy, dependent upon race and sex. Hence, tailoring vaccine education per race and sex may increase outreach effectiveness.
POSTCOVID-19 NEUROLOGICAL SYNDROME: A PROSPECTIVE STUDY AT 3600 METERS ABOVE SEA LEVEL IN LA PAZ BOLIVIA

Juan Carlos Duran¹,², Juan Pablo Duran²
¹Universidad Mayor de San Andres, Physiology, La Paz, Bolivia, ²Neurocentro, Neurologia, La Paz, Bolivia

Background and Aims:: Background. COVID-19 is the newest, most publicized, widely read, best known and controversial infectious disease. There are few publications on post-covid neurological complications in patients who attend neurological outpatient consultation. We present a case report of the population of La Paz, Bolivia, elevation 3600 meters above sea level.

Methods:: Methods. A prospective study was conducted from March 2020 to March 2021. Medical records of 5070 patients who attended outpatient neurological consultation were analyzed. We describe the new-onset neurological manifestations of 237 consecutive patients with laboratory-confirmed SARS-CoV-2 infection and submit a review of their medical histories by a neurologist.

Results:: Results. Of these 5070 neurological patients, 3280 were women (64.7%) and 1790 were men (35.3%); 237 of these patients presented post-covid neurological manifestations (4.67%). 151 were women (2.97%), 86 were men (1.69%). 41% had CNS involvement (headache, vertigo, seizure, memory disorders, tremor), 57% had PNS involvement (paresthesia, weakness, painful polyneuropathy, trigeminal neuralgia), 45% musculoskeletal involvement (myalgia, polyarthralgia) and 35% neuropsychiatric compromise (anxiety, depression, insomnia). The majority (78%) presented 2 to 4 symptoms.

Conclusions:: Conclusions. The "post-covid neurological syndrome" represents a diagnostic challenge for the clinical neurologist due to the multiple manifestations: central and peripheral nervous system, musculoskeletal and neuropsychiatric symptoms, without structuring a classic semiology, intense and constant headache, insomnia, anxiety and unexplained depression in patients without prior history. The response to classic treatment is variable, since the symptoms can be varied and wide-ranging (resembling a moth bite). We are just beginning to learn about this complex, novel and highly infectious disease.
EXACERBATION OF SYRINGOMYELIA/SYRINGOBULBIA SYMPTOMS AFTER COVID-19: CASE REPORT

Wolfgang Trillo Alvarez1,2, Claudio Ibañez Escalante2, Gabriel Calderón Paiva2, Joaquin Molina Acosta2, Joshua Medina Suárez2, Luis Delgado Villanueva2, Edgar Carrillo Monteagudo2, Ximena Flores Callohuanca2, Adriana Escalante Mercado2, Juan Valdivia Pino2
1UNIVERSIDAD CATOLICA DE SANTA MARIA, Human Anatomy, Arequipa, Peru, 2SINAPSIS-UCSM, Neurosciences, Arequipa, Peru

Background and Aims: In syringomyelia there is a known Substance P (SP) overexpression, predominantly in the external laminae of the dorsal horn. It has been hypothesized that several infections, particularly COVID-19, may increase the expression of the TRPV1 gene in lung, producing an increment of SP and IL-6, which would involve an alteration of the spinal trigeminal nuclei responsible for its secretion. The aim is to report the first case of exacerbation of syringomyelia/syringobulbia symptoms after a COVID-19 infection.

Methods: A 42-year-old Hispanic female patient with history of syringomyelia/syringobulbia with Chiari malformation treated with decompressive surgery in 2019, presented to clinic in June 2020 complaining of close to 8 months of pain in the left upper limb, after suffering COVID-19 infection in August. One month later, the pain increased exacerbated by exertion, along with cold allodynia and tinnitus. Physical examination showed hypertension, anomic aphasia, cold allodynia with left hemitremor; dysesthesias, pain and weakness in left upper limb; lower limbs hyperreflexia; and bilateral Hoffman and Marinescu. Bloodwork showed elevated ESR and CRP. SARS-CoV-2 IgM and IgG were positive. MRI showed Chiari Malformation and syringomyelia/syringobulbia.

Results: The patient received COVID-19 treatment improving all features. Anecdotally when corticosteroids were weaned off pain returned; imposing a new corticosteroid regimen after which pain subsided returning to her daily living activities.

Conclusions: This is the first case report of an exacerbation of syringomyelia/syringobulbia symptoms after COVID-19. We propose substance P as a key mediator for this kind of features.
Background and Aims:: SARS-CoV-2 induces an immunological response that can trigger encephalitis and several movement disorders like chorea, opsoclonus, myoclonus, tremor and ataxia. SARS-CoV-2 receptor protein ACE-2 is expressed in the brain and its gene is closely related to the dopamine decarboxylase gene, which catalyzes the conversion of L-DOPA into dopamine which can be altered in COVID-19. The aim is to report a case of COVID-19 presenting with choreiform movement disorder as the core neurological complication.

Methods:: A 86-year-old hispanic male with COVID-19 presented with persistent nocturnal dyspnea, buccopharyngeal dystonia, dysarthria, night sweats, dry mouth, generalized pruritus, insomnia, headache and involuntary movements. Followed by sialorrhea with dysphagia and dystusia. Physical examination showed hypoacusia, tangential thinking, frontal release signs, facial and upper limbs choreiform movements with lip smacking, tongue biting, facial, upper limbs weakness and lower limbs paresthesias, diminished deep tendon reflexes and Romberg’s. Bloodwork showed elevated glucose, ESR, CRP, CPK, ferritin, fibrinogen and D-dimer. SARS-CoV-2 IgM and IgG were positive. MRI showed fronto-parietal subcortical ischemic lesions, as well as at the centrum semiovale, and faint hyperintensity of the claustrum and the rostral putamen.

Results:: The patient received treatment for COVID-19 with corticosteroids, and overcame the infection. Involuntary choreiform movements disappeared improving the rest of his symptoms.

Conclusions:: Chorea movement disorders should be taken into account as a neurological complication of SARS-CoV-2 infection as we report in this case.
DAILY CHRONIC HEADACHE DUE TO GIANT CELL ARTERITIS POST COVID-19: CASE REPORT

Wolfgang Trillo Alvarez1,2, Jonatan Escalante Ortiz2, Melissa Llaiqui Condori2, Gabriel Calderón Paiva2, Joshua Medina Suárez2, Claudio Ibañez Escalante2, Edgar Carrillo Monteagudo2, Adriana Escalante Mercado2, Pedro Chirinos Mamani2, Joaquin Molina Acosta2

1UNIVERSIDAD CATOLICA DE SANTA MARIA, Human Anatomy, Arequipa, Peru, 2SINAPSIS-UCSM, Neurosciences, Arequipa, Peru

Background and Aims:: Anxiety disorders, migraine, and vasculitides, such as Giant Cell Arteritis (GCA), may occur following several viral infections, including SARS-CoV-2 and they present an emerging challenge for clinical neurologists in the current COVID-19 pandemic. Its mechanisms include endothelial cell inflammation, apoptosis and dysfunction. We report a case of chronic headache due to GCA accompanied by anxiety disorder and probable inflammatory bowel disease following COVID-19 infection. The aim is to report a case of a daily chronic headache due to GCA accompanied by anxiety disorder following COVID-19 infection.

Methods:: A 44-year-old Hispanic female who denied previous history of COVID-19 presented with persistent, intense, dull-oppressive, occipital-temporal, crown-like irradiation headache accompanied by mouth-face weakness, and amaurosis-like visual disturbances. Other symptoms included anxiety attacks, insomnia, stress and hearing discomfort. Anxious behavior and mood changes persisted with oppressive chest pain, nausea and vomiting. Physical examination showed tachycardia, jaw claudication, pain in occipital and right temporal region and at the temporal artery, tinnitus, bilateral cervical trigger points, positive Marinescu and Romberg’s. Bloodwork showed negative ESR and CRP, positive ANA 1/160 and elevated calprotectin. SARS-CoV-2 IgM was positive. Doppler ultrasound of the right temporal artery showed a positive halo sign, thus giant cell arteritis diagnosis was established, and regular treatment was initiated.

Results:: The patient underwent partial resolution of the symptoms after receiving corticosteroids, paroxetine, propanol, topiramate, and a gluten-free diet.

Conclusions:: Autoimmune diseases, like giant cell arteritis, could appear in patients with an unknown or asymptomatic history of COVID-19. SARS-COV2 infection should be considered as a trigger of postinfectious vasculitides.
STATUS EPILEPTICUS AND COVID-19: A SYSTEMATIC REVIEW

Background and Aims:: Among the symptoms included in the SARS-CoV-2 infection-related coronavirus Disease (COVID-19), neurological manifestations have been frequently reported. In this systematic review, we summarized the available data on clinical features, diagnosis, and therapy of COVID-19-related Status Epilepticus (SE)

Methods:: We performed a systematic search of the literature to identify data on demographics, clinical, neurophysiological, and neuroradiological data of patients with COVID-19 related-SE. The following electronic databases and data sources were systematically searched: MEDLINE (accessed through PubMed), EMBASE, and Google Scholar (from December 2019 to January 2021). In all databases we used the following search strategy: ("epileptic state" OR "epileptic state") AND ("coronavirus disease 2019" OR "coronavirus disease 2019"). We included all studies reporting cases of SE in the context of COVID-19 syndrome in patients with or without a previous history of epilepsy, published in English, and reporting individual patient data. Non-peer reviewed papers were excluded. We used regression models (linear or logistic) with a stepwise forward method to identify features associated with mortality or severity of SE.

Results:: Thirty-nine articles were included with a total of 47 cases of SE associated with COVID-19. Age, time between the acute respiratory phase of SARS-CoV-2 infection and SE onset, and hospitalization correlated with a higher SE severity as assessed by quantitative validated scales.

Conclusions:: SE can be a neurological manifestation of SARS-CoV-2 infection. Although a possible association between SE and COVID-19 has been reported, the exact mechanisms are still not fully understood. Systemic inflammatory syndrome due to cytokine release could play a role in COVID-19 related SE.
Impact of COVID-19 Pandemic on Incidence of Health-Care Associated Infections in Neurology Intensive Care Unit (ICU) and Its Associated Mortality – A Retrospective Cohort Study

Pachipala Sudheer, Deepti Vibha, Mv Padma Srivastava, Manjari Tripathi, Achal Kumar Srivastava, Rohit Bhatia, Mamta Singh, Vishnu V Y, Roopa Rajan, Awadh Pandit, Rajesh Singh, Animesh Das, Anu Gupta, Arunmozhimaran Elavarasi, Divya Mr, Ayush Aggarwal, Bhargavi Ramanujam
All India Institute of Medical Sciences, Neurology, Delhi, India

Background and Aims: Health care-associated infections (HCAI) are leading cause of mortality in Intensive Care Unit (ICU). The coronavirus disease 2019 (COVID-19) pandemic has led to mandatory use of masks and personal protective equipment (PPEs) in addition to standard infection control practices. This may additionally lead to benefit in the decrease of HCAI besides decreased risk of transmission of COVID-19. Aim: To compare the incidence of HCAIs and in-hospital mortality among patients admitted in the neurology ICU during the COVID-19 pandemic period and pre-pandemic period.

Methods: In a retrospective cohort study design, patients admitted to the Neurology ICU during the initial five months of the Covid-19 pandemic period (1st April – 31st August 2020) and the same calendar months of the prior year in the pre-pandemic (1st April – 31st August 2019) period were included. The prevalence of HCAIs and in-hospital mortality in these groups was compared.

Results: Forty-seven patients in the pandemic period and 52 patients in the pre-pandemic period were admitted in the Neurology ICU during the study period. The prevalence of HCAI was 72.3% in the pandemic period and 69.2% in the pre-pandemic period (p value: 0.73). The median person days of antibiotics during the pandemic period was 49 (31-71) days as compared to 60.5 (25-110) days during the pre-pandemic period (p value: 0.41). The mortality during the pandemic and pre-pandemic period was 27.6% and 40.4% respectively (p value: 0.18).

Conclusions: The augmentation of infection control practices prevented the spread of Covid-19 but could not provide additional improvement in HCAI prevention.
NEUROLOGICAL COMPLICATIONS OF COVID-19: A MONOCENTRIC EXPERIENCE OF A NEUROLOGICAL OUTPATIENT CLINIC

Stefano Grisanti1, Cristina Schenone1, Erica Biassoni1, Giacomo Bavestrello2, Matteo Pardini1, Teresita Aloe3, Elena Tagliabue3, Emanuela Barisone3, Angelo Schenone1, Luana Benedetti1

1University of Genoa, Department Of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal And Child Health (dinogmi), Genoa, Italy, 2University of Genoa, School Of Medicine And Surgery, Genoa, Italy, 3IRCCS Ospedale Policlinico San Martino, Interventional Pulmonology Unit, Genoa, Italy

Background and Aims:: Since the onset of the COVID-19 pandemic, numerous central and peripheral nervous system complications related to the virus have been observed. Here we present a case series of neurological complications from our outpatient clinic dedicated to patients with previous SARS-CoV-2 infection.

Methods:: We set up a “Neuro-COVID Outpatient Clinic” in November 2020 for the management of patients referred by the Pneumology Unit of our Hospital and who complained of neurological symptoms.

Results:: Up to the date (April 2021) from a total number of 319 patients who referred to the Pneumology Clinic, we have collected data from 62 patients (31 female) with a mean age of 59 years (18 – 80 years). Of these, 53 patients were previously admitted to our ICU or to the Pneumology Department. The most frequent complications (27) were those related to peripheral nervous system including plexopathies, critical ill neuropathies, and isolated cranial nerve palsies. Six patients developed previously unreported headache and 5 dizziness, while 16 patients complained of memory impairment. A patient developed symptoms of Myasthenia Gravis with anti-AchR antibodies. We observed two cases of myoclonus and cerebellar ataxia. An 18-year-old patient suffered of ischemic stroke in the absence of other risk factors. Twenty-two patients developed anosmia, and 8 of these still present anosmia after 6 months from the infection.

Conclusions:: Neurological complications related to SARS-CoV-2 infection are far from rare. Some of these are to be referred to the long hospitalization but others could be the consequence of parainfectious or postinfectious mechanisms.
PERSISTENT AURA-LIKE VISUAL PHENOMENON AS THE UNIQUE MANIFESTATION OF COVID-19 POST-INFECTIOUS WHITE MATTER LESION: A CASE REPORT.

Federica Matrone¹, Alessandro D'Ambrosio¹, Mario Risi¹, Alvino Bisecco¹, Rocco Capuano¹, Gioacchino Tedeschi¹, Antonio Gallo²
¹University of Campania Luigi Vanvitelli, Department Of Advanced Medical And Surgical Sciences, Napoli, Italy, ²University of Campania "Luigi Vanvitelli", Department Of Advanced Medical And Surgical Sciences, Napoli, Italy

Background and Aims:: A visual aura lasting longer than 1 week is defined as persistent. Cortical spreading depression (CSD), a propagating wave of neuronal depolarization, followed by long lasting suppression of cortical activity, is the electrophysiological phenomenon thought to underlie migraine visual aura. Disorders which alter the state of neuronal excitability may increase brain’s susceptibility to CSD by lowering the threshold for neuronal depolarization.

Methods:: A 29-year-old woman was admitted to our department reporting subacute onset, three weeks before, of persistent vision of shining, colored lights in right visual hemifield. Two weeks before the onset of symptoms she was diagnosed with asymptomatic COVID-19. Medical history was remarkable for migraine with aura.

Results:: Neurological examination and blood tests were unremarkable. Computerized campimetry showed decreased retinal sensitivity in right visual hemifield. Brain and spinal cord MRI showed a unique, round, post-contrast enhancing lesion in left peritrigonal white matter (involving left optic radiation). CSF analysis showed type3 oligoclonal bands (evidence of systemic and intrathecal immune activation). EEG showed left temporo-occipital (sometimes generalized) sharp waves. Neither a trial with diazepam nor a treatment with IV methylprednisolone were effective on visual symptoms. She started lamotrigine (100mg/daily) with progressive improvement of symptoms.

Conclusions:: This case showed how an acquired structural abnormality, such as an inflammatory post-infectious white matter lesion, can alter the state of neuronal excitability and increase brain’s susceptibility to cortical depolarization, thus manifesting with positive symptoms, i.e. an aura-like persistent phenomenon. Hence, any change in aura pattern and frequency, even in migraineurs, requires exclusion of secondary forms.
Background and Aims:: Describe the neuropsychiatric symptoms in 300 patients requiring hospitalization surviving at the largest COVID-19 care center 3 months after discharge.

Methods:: An exhaustive neurological evaluation was performed on 300 patients 3 months after hospital discharge following COVID-19 at the national institute of respiratory diseases in Mexico City, a COVID-only institution for the time being. All patients underwent a neurological symptom survey, complete neurological examination, cognitive evaluation with MoCA and MMSE screening tests, and some laboratory tests, by 2 expert neurologists. The patients were stratified as follows: mild COVID those who only required the use of nasal prongs during hospitalization, moderate COVID those who required high oxygen flows with the use of a reservoir mask, high-flow nasal prongs, and severe COVID those who required advanced management of the airway during hospitalization.

Results:: The mean age was 58 years +/- 13 years, 69% of the patients were male, 15% were health personnel. No comorbidity was statistically significant between groups. The main manifestations are hyposmia, dysgeusia, dizziness, vertigo, headache, myopathic pain, affective symptoms, insomnia, cognitive complaint, and arthralgias, with a statistically significant difference in sensorimotor neuropathy and neuropathic tremor in severe patients. Mean MoCA scores in mild patients were 27 while in moderate and severe patients 25 points. MMSE scores were 28 in mild patients, 27 in moderate to severe patients.

Conclusions:: Adequate follow-up of post-covid patients is needed for symptomatic surveillance and to prevent long-term sequelae.
Background and Aims:: Subjects with Myasthenia Gravis (MG) could be at risk for severe complications with Coronavirus Disease (COVID-19), even though few data are available. The aim of the present study is to describe the clinical characteristics and outcomes in patients with MG and COVID-19 and identify clinical factors associated with COVID-19 severity and risk of hospitalization, requirement of respiratory support and death.

Methods:: We retrospectively analyzed demographic variables and clinical characteristics of 63 MG patients (F 47.6%; M 52.4%, mean age 53 ± 16 y) who were diagnosed with COVID-19 based on a PCR test from a nasopharyngeal swab and/or SARS-CoV-2 serology. Main outcomes were the need of hospitalization, the requirement of respiratory support and death for COVID-19.

Results:: Overall 5 patients deceased for Covid infection (7.9%). As in general population, older age (p <0.001) and hypertension were independently associated with hospitalization, whilst obesity (p 0.022) was associated with poorer outcome disregarding hospitalization. Only Myasthenia Gravis Foundation of America (MGFA) class was correlated with worst outcome (p 0.010). Interestingly no correlation was found between immunosuppressant treatment at baseline and severity and outcome of infection.

Conclusions:: Most MG patients in this study fully recovered from Covid-19 and experienced milder forms of infection. Neuromuscular disease was well controlled, at most with increasing steroid dose briefly. Independent risk factors correlated with severity disease and poor outcome were similar to general population. Patients with highest MGFA class have an additional risk for severe disease course and deserve special attention.
Background and Aims:: Since the outbreak of COVID-19 that is caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) in 2020 throughout the world, a lot of aspects of people’s lives are affected including their psychological status. Follow-up assessment of survivors of this infection showed that they had multiple psychological disorders including depression, panic attacks, obsessive compulsive disorder, and post-traumatic stress disorder.

Methods:: A Narrative Review of Mechanisms

Results:: It is estimated that more than one-third of patients with COVID-19 experience neuropsychiatric symptoms, including headache, paresthesia, and disturbed consciousness. Among patients affected by COVID-19, there are different mechanisms that can cause cognitive dysfunction. COVID-19 can affect the central nervous system (CNS) directly by invasion and indirectly by inducing hypoxia, inflammation, and delirium. The pandemic and fear of infection can also cause anxiety which impairs the cognition as well.

Conclusions:: By assessing the patients’ cognition and knowing the higher probable cause of cognitive impairment, we can form a better strategy to better treat the impairment. Cognitive behavioral therapy can be effective in reducing the anxiety and cognitive rehabilitation therapy (CRT) can be used to lower the detrimental effects of cognitive impairment caused by COVID-19.
Background and Aims:: During SARS-CoV-2 pandemic people with multiple sclerosis (PwMS) may experience a worsening due to increased anxiety and depression, reduction in rehabilitation, and less strict connection to MS centres. The aim of our study was to describe the self-reported impact of SARS-CoV-2 pandemic and lockdown on PwMS.

Methods:: On June 2020, we enrolled PwMS who underwent teleconsult during the lockdown phase (March-May 2020). Self-rated worries for pandemic, perception of change in anxiety, depression, fatigue and spasticity was asked, as well as changes in weight, physical activity and food intake. We compared patients with and without reported increase in: spasticity, anxiety, depression and fatigue. Binary logistic regression analyses were applied including significant variables. Statistical significance was set at p<0.05.

Results:: Ninety-three MS patients were enrolled (71% female, 77% RR, median age 50.3y, mean disease duration ≈13y). Many patients reported an increase of anxiety (36.6%), depression (34.4%), fatigue (26.9%) and, spasticity (18.3%), weight (47.3%) and 63.4% of patients reported reduction of physical activity; moreover 59.1% and 43% reported particular worries for the pandemic and the perception of greater impact on PwMS of the pandemic compared to general population, respectively. In the multivariate models, anxiety was predicted by depression, particular worries for SARS-CoV2 pandemic and reduction in physical activity; depression by anxiety; fatigue by reduction in physical activity; spasticity by EDSS.

Conclusions:: The self-reported impact of pandemic on PwMS was deep in terms of increased depression, anxiety, fatigue and spasticity, mainly related to reduction in physical activity and pre-existing disability.
Background and Aims:: Telemedicine in multiple sclerosis (MS) is promising, particularly for patients with high disability and difficulties to reach the treating centre. During SARS-CoV2 pandemic, teleconsults are gaining a central role. The aim of the present study was to report our single-center experience and to verify the effectiveness of teleconsults in diagnosing relapses and rating progression.

Methods:: During the first lockdown phase (March-May 2020) all the pre-planned consults were converted in teleconsults. The evaluation focused on new symptoms or worsening of known symptoms, disability (PDDS), patients' satisfaction of such assessment modality (rated form 0 to 10). Patients were then re-evaluated in person within 6 months. We verified the changes in disability and the accuracy of teleconsults in diagnosing MS relapses.

Results:: Eighty-four patients underwent teleconsult and were re-evaluated in person within 6 months after the lockdown (69% female, mean age 50.5±11.0y, mean disease duration 13.0±9.7y 78.6% relapsing-remitting disease form, 76.2% on disease modifying treatment). Median pre-lockdown EDSS was 1.5 (range 0-8) median EDSS post lockdown was 2 (1-8) (p=0.836); median PDDS during lockdown was 1.5 (0-8). A single disease relapse was detected with teleconsults. In the post lock-down in person evaluation no additional undiagnosed relapses were detected. Patients' reported satisfaction was very high (median 10, range 8-10).

Conclusions:: Teleconsult in MS patients allowed us to guarantee a regular neurological follow-up during pandemic lockdown. No unreported relapses were missed, no significant disability changes were reported nor detected compared to pre-lockdown evaluation. Finally, patients' satisfaction of this modality was very high.
THE OUTBREAK OF METHANOL INTOXICATION DURING COVID-19 PANDEMIC: PREVALENCE OF BRAIN LESIONS AND ITS PREDISPOSING FACTORS

Mehrdad Roozbeh¹, Mahtab Ramezani²
¹Shahid Beheshti University of Medical Sciences, Brain Mapping Research Center, Tehran, Iran, ²Shahid Beheshti University of Medical Sciences, Loghman Hakim Hospital, Neurology, Tehran, Iran

Background and Aims:: During the COVID-19 pandemic, methanol-containing beverages’ consumption has risen because people mistakenly believed that alcohol might protect them against the virus. This study aimed to evaluate the prevalence and predisposing factors of brain lesions in patients with methanol toxicity and its outcome.

Methods:: A total of 516 patients with confirmed methanol poisoning were enrolled in this retrospective study, of which 40 patients underwent spiral brain computed tomography (CT) scan.

Results:: The presence of unilateral or bilateral brain necrosis was significantly higher in the non-survival group (p = 0.001). Also, intracerebral hemorrhage (ICH) and brain edema were prevalent among patients that subsequently died (p = 0.004 and p = 0.002, respectively). Lower Glasgow Coma Scale (GCS) was related to a higher mortality rate (p = 0.001). The mortality rate in chronic alcohol consumption was lower than the patients who drank alcohol for the first time (p = 0.014).

Conclusions:: increasing the number of methanol poisoning and its associated mortality and morbidity should be considered a threat during the COVID-19 pandemic.
THE PROBABILITY OF NEUROCOGNITIVE DISORDERS IN PATIENTS AT THE POSTCOVID STAGE

Oleg Boev1,2,3
1Stavropol State Medical University, Head Of The Department Of Psychiatry, Psychotherapy And Medical Psychology, Stavropol, Russian Federation, 2Stavropol State Medical University, Head Of The Department Of Clinical Psychology, Stavropol, Russian Federation, 3Stavropol Regional Clinical Psychiatric Hospital No. 1, Head Of The Department Of Psychiatry, Stavropol, Russian Federation

Background and Aims:: Актуальность постковидных расстройств у больных обусловлена отсутствием данных о механизмах возникновения нейрокогнитивных расстройств.

Methods:: Material and methods of research. We examined 22 people who had suffered from COVID-19, which made up two groups. The first main group – 10 patients with clinical signs of mild cognitive impairment (LCN), the second comparative group – 12 patients without clinical signs of LCN. To detect LCN, neuropsychological tests MMSE were used, tests were performed: "establishing patterns", visual-spatial function, semantic mediation and generalization. In the comparative analysis, the nonparametric criterion χ2 was used, based on the null hypothesis that there are no differences between the compared groups.

Results:: The results obtained. If in group 2 there was a positive dynamics of cognitive functions of patients in the form of a statistically significant (p<0.05) increase in the number of correctly completed tasks on the MMSE test on average 27.9 ± 1.3, D= 10.3%; p < 0.05, "+" 2.6 points, then in group 1 there was no positive dynamics (p<0.05). In group 2, there is an increase in words called in one repetition, averaging 1.3 words (20.3%), while in group 1 patients there is a negative trend (p<0.05). In the "digit repetition test", the increase in the total score of reproduced digits both in the forward order (+2.2 points, 5.0% in contrast to the patients of group 1) and in the reverse order (+3.2 points, 8.5% in contrast to group 1) was significant (p<0.05). The "Complex figure" revealed a significant (p<0.05) decrease in the time spent on the task in patients of group 2 (-6.3 seconds; 10.5% compared to group 1; p<0.05).

Conclusions:: Thus, Covid-19 causes LCN in patients in at least 50% of cases.
IMPACT ON AIR POLLUTION IN DELHI AND INCIDENCE OF STROKE IN LIEU OF COVID-19 LOCKDOWN

Sakshi Sharma¹, Mv Padma Srivastava²
¹ALL INDIA INSTITUTE OF MEDICAL SCIENCE, Neurology, NEW DELHI, India, ²AIIMS, New Delhi, Neurology, Delhi, India

Background and Aims:: Exposure to air pollution is now well recognized by scientists, media and the population as a major public health issue. The Delhi air flux is the most pernicious consequences of indiscriminate industrialisation and urbanisation. The significant improvement in the air quality of Delhi region was observed due to strict implementation of lockdown. During the lockdown period, improvement in ambient air quality helped us in circumventing the coronavirus community spread.

Methods:: Cross Sectional Study was designed. All strokes within 2-weeks from onset & within one year of event were screened & recruited. PM2.5 was measured in areas of Delhi in using the help of DCPCB. Incidence of recurrent stroke was assessed during the covid-19 lockdown period. Stroke severity was calculated on the basis of NIHSS, mRS scale.

Results:: 50 patients recruited. Out of them 6 patients had recurrent stroke (min-3 & Max-6) in last one year. The mean age for patients was 52.3±11.2 years with a mean NIHSS of 5.86±1.3 and mean mRS of 1.04±0.07. The higher level of PM 2.5 was 230 and minimum was 65 during the Covid-19 Lockdown period i.e March-May-2020. We found that the higher level of PM 2.5 is associated with incidence of Stroke. Maximum six recurrent attack reported by single patient when PM2.5 level was ≥650 from October2019-January2020. 2 patients with history of severe RHD reported recurrent attack during the lockdown period.

Conclusions:: Increased level of air pollution particles matter effects on brain and increased the recurrent incidence of stroke. PM2.5 decreased during the lockdown period and less recurrent stroke reported at same time.
Background and Aims:: The present pandemic caused by the Novel Coronavirus 2 (SARS-CoV-2) is predominantly but not restricted to respiratory illness. Neurological complications in the acute phase have been well characterized like Encephalopathy, psychosis, stroke but there is paucity of data about post covid presentations. We aim to study the various neurological syndromes seen in Covid19 patients following discharge.

Methods:: From July 2020 to December 2020, 1150 Laboratory confirmed Covid 19 cases were admitted and treated in a tertiary care hospital. Patients who developed Neurological syndromes after discharge and within 6 weeks were studied.

Results:: During the follow-up period, A total of 1150 Covid 19 positive patients treated in the IP department. Out of these 10 patients with severe ARDS requiring ventilator died, one patient died of MI, 5 people bedridden at discharge. Among the survivors a total of 19 (1.6%) Patients presented with neurological complaints within 6 weeks of discharge. Of these Ischemic Stroke-2, Hemorrhagic Stroke-1, ADEM-1, Optic neuritis – 2, Epilepsy -1, GB syndrome -1, Persistent Headache -2, Bell’s Palsy-1, Sensorineuronal deafness – 2, Severe fatigue -3, Myalgias -2, Severe vertigo -1. There were 12 Male and 7 Female, age ranged from 40 yrs to 65yrs (Median -54yrs), Co-mobidities: Diabetes – 12, Hypertension – 7.

Conclusions:: SARS- CoV2 infection can cause neurological complications in both acute phase as well as in the follow up period. The pathophysiology need to be studied to plan for the management and prevention of these disabling neurological syndromes.
PATHOMORPHOLOGICAL CHANGES OF THE BRAIN IN PATIENTS WITH COVID-19

Background and Aims:: COVID-19 is a global disease and was characterized as a pandemic by the WHO and the coronavirus is caused also damage nervous system. The aim of this study was to investigate the brain tissue of patients who died from COVID-19.

Methods:: We investigated the brains of 15 patients who died from complications of COVID-19. All patients had a positive test for SARS-CoV-2. Information from the autopsy protocol included macroscopic and microscopic characteristics of brain and general autopsy findings. We used immunohistochemistry staining for astrocytes, microglia and T-lymphocytes in the cortex, basal ganglia, brainstem and cerebellum.

Results:: All patients died in hospitals and had a median age of 65 years (range, 47–80 years), 66,7% male and 33,3% women. Cause of death of most cases was viral pneumonia as the underlying condition. Neuromorphological studies showed fresh ischemic infarction in three (20%) patients with focal encephalolysis. Hypoxic manifestations with neuronal loss in the frontal lobe, basal ganglia, hippocampus, cerebellum were present. In most of cases the arteriolosclerosis with perivascular rarefaction was present. The reactive astrogliosis with positive astrocytic marker GFAP was seen in all cases but showed variable degrees. The perivascular activation of microglia and the microglial nodules with CD68 positive cells were in the cortex, basal ganglia, hippocampus, brainstem, but less in cerebellum. And perivascular infiltration by CD3 was most pronounced in the brainstem.

Conclusions:: Thus, the morphological changes of the CNS associated with Covid-19 include ischemic infarction with encephalolysis, astrogliosis, microgliosis, perivascular infiltration by CD3 in different regions of the brain.
MUSCLE MANIFESTATIONS AND CK LEVELS IN COVID INFECTION: RESULTS OF A LARGE COHORT OF PATIENTS INSIDE A PANDEMIC COVID-19 AREA

Anna De Rosa¹, Elena Pinuccia Verrengia², Ivan Merlo³, Federico Rea³, Gabriele Siciliano⁴, Giovanni Corrao³, Alessandro Prelle²
¹ASST Nord Milano, Unit Of Neurology, Milan, Italy, ²AO Ospedale Civile di Legnano, ASST Ovest Milanese, Legnano, Italy, Neurology-stroke Unit, Legnano (MI), Italy, ³University of Milano-Bicocca Milan, Italy, National Centre For Healthcare Research & Pharmacoepidemiology, Milan, Italy, ⁴University of Pisa, Neurology Unit, Pisa, Italy

Background and Aims:: Objective: to investigate both muscular manifestations and CK levels in a large cohort of patients with COVID-19 infection and to determine whether hyperckemia is associated with morbidity and mortality.

Methods:: Data of 615 patients discharged from ASST Ovest Milanese (Milan, Lombardy, Italy) with final diagnosis of COVID-19 infection were retrospectively extracted from electronical medical records from 21 February to 1 May 2020. Patients were descriptively analyzed with respect to the following variables: sex, age, muscular manifestations (myalgia and/or arthralgia), fatigue, respiratory involvement (SARS pneumonia or respiratory failure) and history of falls. Association between patients’ characteristics and CK levels was investigated. In addition, the proportion of patients who died following access to the ER was calculated. Finally, the effect of CK levels and other patients’ features on mortality was estimated using a logistic regression model.

Results:: 176 (28.6%) patients had raised serum CK levels. CK levels were significantly associated with history of falls, male gender, SARS pneumonia, respiratory failure and in-hospital death. No correlation was found between hyperckemia and muscular manifestations.

Conclusions:: Our study provides preliminary evidence that hyperckemia is associated with respiratory failure and fatal outcome in patients with COVID-19 infection. In these patients, among other testing, CK dosage is recommended.
ASYMPTOMATIC PERIPHERAL NEUROPATHY IN PATIENTS WITH SARS-COV-2 INFECTION

Erika Schirinzi1, Ilaria Gandoglia1, Andrea Assini1, Klaudio Rikani1, Giacomo Siri2, Emanuele Pontali3, Massimo Del Sette1
1Galliera Hospital, Neurological Unit, Genoa, Italy, 2Galliera Hospital, Scientific Coordinator Office, Genoa, Italy, 3Galliera Hospital, Infectious Diseases Unit, Genoa, Italy

Background and Aims:: Several neurological complications related to SARS-CoV-2 infection have been reported. The involvement of peripheral nervous system (PNS) consists in the development of immune-mediated neuropathies such as Guillain-Barré Syndrome. In this study we aim at assessing the presence of asymptomatic abnormalities in peripheral nerves conduction during the acute phase of COVID19 and, their correlation with blood circulating inflammatory markers.

Methods:: Thirty-nine patients with COVID19 were assessed by electroneurographic study of lower limbs and blood tests within one week of hospital admission (T0) and after 30±10 days (T1).

Results:: Electroneurographic changes were found at least on one nerve at T0 in 12 patients, consisting of axonal or demyelinating changes. Two biological markers were found to be significantly correlated with the presence of neuropathic changes: Reactive Protein C and lymphocyte count. Patients with pathological electrophysiology at T0 showed significant improvement of electrophysiological parameters at T1. The improvements in electroneurographic data were significantly correlated with the trend of laboratory parameters, in particular with fibrinogen, D-Dimer, ferritin, C Reactive protein and lymphocytes. None of the patients with neuropathic changes developed clinical evidence of a full-blown peripheral neuropathy over time.

Conclusions:: Our study shows that asymptomatic alterations of the PNS can be found during the acute phase of COVID19. These alterations significantly improve after 20-40 days from the acute phase of infection and that the improvement correlates significantly with the trend of laboratory parameters. Further studies are needed to evaluate possible long-term neurological complications and the predictive value of subclinical damage of PNS in the acute phase of infection.
NEUROCovid: Can CSF immune reactivity give new insight on neurological manifestations in COVID-19 patients?

Federica Boso1,2, Giovanni Piccoli2, Bruno Giometto1,3
1A.P.S.S. Trento, Neurology Unit, Trento, Italy, 2University of Trento, Department Of Cellular, Computational And Integrative Biology, Povo, Italy, 3University of Trieste, Department Of Medicine, Surgery And Health Sciences, Trieste, Italy

Background and Aims:: Neurological manifestations have been increasingly associated with COVID-19, but there is little evidence of a direct viral pathogenesis. Clinical heterogeneity and confounding factors also impair the search for alternative mechanisms. Therefore, we studied the CSF of 13 patients with neurological symptoms during the acute phase of their hospitalization, looking for clues suggesting a specific dysimmune phenomenon.

Methods:: CSF underwent conventional analysis and RT-PCR for SARS-CoV-2; a in-house HEK293 cell-based assay was also arranged to identify anti-spoke antibodies. Albumin ratio, IgG index and oligoclonal bands were also assessed, along with a screening for autoimmune antibodies. First, commercial immunofluorescence and lineblot were used to detect common neuronal surface and intracellular antibodies, respectively; secondly, immunohistochemistry was performed on rat brain sections; lastly, CSF was incubated with fixed murine neuron and astrocyte cultures to confirm a potential auto-reactivity.

Results:: CSF analysis disclosed a slightly increased protein level with a non-significant cell count (0-10 cells/μL). Neither SARS-CoV-2 nor common neuronal antibodies were detectable in the CSF, but we recognized anti-spoke IgGs. 69% of the samples also showed neuropil staining, some of which had a common staining pattern involving the hippocampal dentate gyrus. Rodent primary cultures confirmed the presence of autoreactive antibodies against epitopes that are expressed in cortical neurons and/or astrocytes in most samples.

Conclusions:: A strong immunoreactivity against spike protein was found in the CSF of those patients, even without a significant blood brain barrier permeability. The detection of autoreactivity with two different techniques could thus represent a dysimmune response to COVID-19 infection, perhaps suggesting molecular mimicry.
PAEDIATRIC TRANSVERSE MYELITIS DURING COVID-19 ASYMPTOMATIC INFECTION: A CASE REPORT

Eleonora Grasso¹,²,³, Lorena Matonti¹, Costanza Neri¹, Sara Torresi¹, Armando Di Ludovico¹, Paola Ajdina²,³, Valeria Pozzilli²,³, Carmela Salladini¹, Rita Greco¹, Valentina Tomassini²,³
¹“SS Annunziata” University Hospital, Department Of Paediatrics, Chieti, Italy, ²MS Centre, Department Of Clinical Neurology, “ss. Annunziata” University Hospital, Chieti, Italy, ³University G. D'Annunzio of Chieti-Pescara, Department Of Neuroscience, Imaging And Clinical Sciences, Chieti, Italy

Background and Aims:: Paediatric Transverse myelitis (TM) is a rare, demyelinating immune-mediated disorder of the Central Nervous System. Its immunopathogenesis is not completely understood. Viral infections are recognised triggers that precede TM in 66% of cases. Although uncommon, neurological involvement with spinal cord damage can occur following SARS-CoV2 infection. Although the co-occurrence of TM and SARS-CoV2 is more frequently observed in adults, children may also be affected.

Methods:: We report a paediatric case of TM during SARS-CoV2 asymptomatic infection.

Results:: A 12-year-old boy complained of severe nuchal pain that lasted for a few hours and was followed by hyposthenia on the right hemisoma persisting for approximately 12 hours. Brain MRI scan was normal. Spinal cord MRI demonstrated a T2/FLAIR hyperintense lesion, enhancing post-contrast, at C2 level. CSF and blood microbiology and virology were negative. CSF SARS-CoV2 genoma sequencing and oligoclonal bands were negative. Serology for AQP4 and anti-MOG antibodies was negative. Acyclovir, azithromycin and high dose intravenous methylprednisone were also administered for 8 days. The patient completely recovered and was discharged after 11 days with steroid tapering. He had a follow-up spinal cord MRI a month later that returned normal.
Conclusions: Neurological complications during SARS CoV2 infection are rare in children, but may occur as a consequence of dysimmunity possibly triggered by SARS CoV2.
THE FIRST YEAR OF NEUROLOGY AND COVID 19: THE IMPORTANCE OF UNDERSTANDING NEUROLOGICAL AND BIOPSYCHOSOCIAL SYMPTOMS IN ACUTE AND POST NEUROCOVID DISEASE

Matilde Leonardi1, Andrea Pilotto2, Davide Sattin1, Alberto Raggi1, Silvia Schiavolin1, Francesca Magnani1, Claudia Toppo1, Erika Guastafierro1, Martina Cacciatore1, Fabiola Silvaggi1, Viviana Cristillo2, Stefano Cotti Piccinelli2, Nicola Zoppi2, Giulio Bonzi2, Stefano Gipponi2, Alessandro Padovani2

1Fondazione IRCCS Istituto Neurologico Carlo Besta, Neurology, Public Health, Disability, Milan, Italy, 2ASST Spedali Civili di Brescia, Neurology Unit, Dept. Clinical And Experimental Sciences, University Of Brescia, Brescia, Italy

Background and Aims:: After the first year since its first reporting Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), causing Coronavirus disease 2019 (COVID-19), has infected nearly 120 million people and resulted in almost more than 2 million deaths globally. After one year from the first report of neurological symptoms in a Chinese patient, more than 55 countries to date have reported symptoms including impaired taste or smell, headache, dizziness, delirium, agitation, stroke, hypoxic ischaemic brain injury, seizures, coma, meningo-encephalitis, Guillain-Barré syndrome, myalgia, amongst others. Consequences seen in the follow-up periods of COVID-19 infection are also becoming more and more apparent mostly with reports of persistent problems with smell or taste, cognitive impairment, headaches, confusion, difficulty concentrating and sleep disturbance

Methods:: Recently more and more studies on long term consequences of acute Covid are being published, such as the Study NEXT, a longitudinal study done in a population of hospitalized patients in Brescia

Results:: first studies show that not only clinical but also biopsychosocial effects are becoming increasingly important as long as more data are collected

Conclusions:: Although further research is needed to understand which patients are most vulnerable to neurological manifestations in the acute, long or post COVID-19 disease, however after this first year it is clear that neurological, biopsychosocial and mental health data need to be not only collected but also analysed in a manner that could help the understanding of characteristics, timing, and severity of neurological manifestations of COVID-19.
BELL’S PALSY FOLLOWING POST COVID-19 INFECTION MYOCARDITIS IN PREGNANCY: THE FIRST CASE REPORT

Pramith Ruwanpathirana¹, Thisari Athukorala², Vithoosan Sahathevan¹, Bimsara Senanayake¹, Mohommed Rishard²
¹National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka, ²De Soysa Hospital for Women, University Professorial Unit Of Obstetrics And Gynaecology, Colombo, Sri Lanka

Background and Aims:: Lower motor neurone facial nerve palsies are a rare complication of SARS-CoV-2 infection. Bell’s palsy following COVID myocarditis has been reported previously but whether they are associated is not known. We report the first case of the above combination in pregnancy.

Methods:: A 27-year-old Sri Lankan in her 2nd pregnancy complicated with pregnancy induced hypertension since POA of 26 weeks presented at 30 weeks with fever, productive cough and exertional dyspnoea for 4 days. She was tachypnoeic (RR - 40/min) and tachycardic (PR – 120/min). There was a left-sided mild pleural effusion (later confirmed by ultrasound) with clear lung fields. (SpO₂ - 97%). The ECG had widespread T inversions and ST-depressions, 2D-Echo had global hypokinesia with a thin rim of pericardial fluid. Serum troponins were marginally elevated (0.4ng/ml). She had a neutrophil leucocytosis with elevated ESR (120mm/1st hour), CRP(291mg/l) and D-dimers (1249ng/ml). Deep vein thrombosis and pulmonary embolism were excluded by imaging. Blood and urine cultures were negative. The SARS-COV-2 PCR was weakly positive with a strong positivity for COVID antibodies. Serology for enterovirus, rickettsia, Legionella and Mycoplasma were negative. She had an uneventful recovery after a hospital stay of 2 weeks managed symptomatically and with prophylactic antibiotics.

Results:: One-week post-discharge she presented a left sided Bell’s palsy without other neurological signs, symptoms; a phenomenon reported by many. She was treated with Galvanic stimulation and oral steroids for 10 days and made an uneventful recovery in 2 weeks.

Conclusions:: COVID in pregnancy is a predisposition to Bell’s palsy. It’s association with myocarditis should be sought.
COVID-19: THE NATURE OF PAIN IN COMPLICATIONS OF THE MAXILLOFACIAL REGION.

Akmal Kholmuratov¹, Dilnoza Bobamuratova², Yokubjon Kurbanov¹
¹Tashkent medical academy, Neurology, Tashkent, Uzbekistan, ²Tashkent Medical Academy, Otolaringology & Stomatology, Tashkent, Uzbekistan

Background and Aims:: Patients with coronavirus disease have severe complications in the form of thrombosis, facial bone necrosis. Purpose: monitoring of the nature of pain syndrome in maxillofacial region of patients with Covid-19

Methods:: Clinical analysis was carried out in 50 patients who applied to the TMA clinic. The average age of patients was 60 ± 9.0 years, including 27 women (54%) and 23 men (46%), with diagnosis of cavernous sinus thrombosis, osteomyelitis of jaw 1–3 months after the onset of acute Covid-19 disease. During the 10-day period of hospitalization and 6 months of rehabilitation, the pain was assessed according to a 10-point criterion (pain load - 0 points, very strong - 10 points) through the questionnaire.

Results:: N. Facialis paresis was in 39 patients, paresthesia of the 3rd corneal nerve in 28 patients. Local pain was observed in 15% of the head, 50% irradiated to facial nerve and 35% in the area of facial inflammation. After the first 10 days of treatment, pain decreased from 10 to 2.5 points in 35% of patients. Severe pain was observed in 10% of patients (8-10 points), and in 25% of patients, the average simultaneous pain in the local jaw area remained within 3.5 ± 0.38 (p≥0.05). In 15% of patients, the headache persisted up to 4-5 (on average) points, in 15% of patients the headache completely disappeared. The mean pain score was 2.6 ± 0.3 (p ≥ 0.05) in all patients older than 6 months.

Conclusions:: In patients undergoing COVID 19, with thrombosis, facial necrosis severe pain persisted long time.
Background and Aims:: The research team decided to investigate: Structure, etiology, and features of the course of epilepsy syndrome in patients admitted to hospital with suspected or confirmed coronavirus infection and concomitant and/or concomitant diagnosis of epilepsy syndrome (call an ambulance for development of seizure\ seize in presence of emergency doctor)

Results:: 12% (7) reported a fatal outcome (seizures in acute stroke period\ epilepsy+severe covid-19// symptomatic epilepsy - metastases in brain + covid-19)
In 81% (46), covid-19 was successfully treated. In 7% (4), a transfer to another specialized hospital.
1. Patients are unable to report whether they have had previous epilepsy episodes - 17.6% (10);
2. An epilepsy episode developed for the first time - 33.3% (19)
3. Epilepsy episodes have been reported before - 49.1% (28).

According to the etiology of the epilepsy syndrome (on classification 1):
1. The background of acute neurological disorder (cerebral edema: acute stroke period// newly detected large brain mass) – 7%(0-4-0)
2. The background of exogenous intoxication by alcohol and psychoactive substances - 25.5% (6-4-11);
3. Unclear etiology - 19.3% (4-7-0);
4. Poststroke seizure – 12.3% (0-3-4);
5. Idiopathic epilepsy – 8.8% (0-0-5);
6. Symptomatic epilepsy (the background of brain masses) – 8.8% (0-0-5); 7. In the structure of other diseases - 5.3% (0-0-3).

Conclusions:: -Frequency of admission “covid-19 + epilepsy syndrome” less in comparison over the same period;
-The etiology of exogenous intoxication still predominates; -The mortality in the cohort is not higher than in other groups.
UNUSUAL BRAIN MRI FINDING IN A PATIENT WITH COVID-INDUCED PERSISTENT CACOSMIA

Gaia Fanella¹, Simone Beretta¹, Francesco Pasini¹, Claudio Baiata¹, Andrea De Vito², Gianpaolo Basso³, Carlo Ferrarese¹,⁴
¹University of Milano-Bicocca, Neurology, Ospedale San Gerardo, Monza, Italy, ²University of Milano-Bicocca, Neuroradiology, Monza, Italy, ³University of Milano-Bicocca, Medicine & Surgery, Monza, Italy, ⁴University of Milano-Bicocca, School Of Medicine And Surgery, Monza, Italy

Background and Aims:: Olfactory dysfunction is emerging as a key symptom of COVID-19 along with other neurological complications. Herein we describe a case of persistent cacosmia with an unusual finding on brain MRI.

Methods:: In March 2020, a 50-year-old woman with no relevant medical history developed fever, dry cough, diffuse muscle pain, sudden onset of anosmia and ageusia. She was diagnosed with Covid-19 by positive result on PCR analysis. Her clinical course was uncomplicated. Anosmia and ageusia started improving after two months. However, during the recovery phase she started perceiving distorted and unpleasant smells in response to stimuli (cacosmia) as well as sudden unpleasant smell sensations without any odorant stimuli (phantosmia). These symptoms persisted for 9 months, therefore she was referred to our neurology clinic.

Results:: Neurological objective examination was normal. EEG with olfactory stimulation showed a normal pattern. Brain MRI was performed after 10 months from the onset of symptoms. 3D FLAIR images showed an evident cortical hyperintensity in the medial olfactory stria and in the adjoining cortex of the subcallosal gyrus (Figure 1 – 2).
Conclusions:: This report shows an unprecedented signal alteration on MRI in a patient with persistent cacosmia and phantosmia 10 months after Sars-Cov2 infection, reinforcing the hypothesis of Sars-Cov2 neurotropic propagation through the olfactory system.
A POST COVID-19 GUILLAIN-BARRE SYNDROME

Evgenii Vladislavov  
MU-Sofia, Neurology, Sofia, Bulgaria

**Background and Aims::** Guillain-Barré syndrome consists of clinical syndromes that manifest as an acute or subacute autoimmune inflammatory polyradiculoneuropathy with resultant weakness and diminished reflexes. It is also part of so-called Yuki syndrome. Its annual incidence is 1-2/100000. The exact cause of Guillain-Barre syndrome is unknown. But two-thirds of patients report symptoms of an infection in the six weeks preceding. These include respiratory or gastrointestinal infection (EBV, C.jejunii) or Zika virus. Smaller studies have suggested a link between COVID-19 and GBS. But when researchers compared the number of GBS cases recorded in the UK's National Health Service database in 2016 to 2019 to the number recorded in the first half of 2020, they found the annual incidence was 40% to 50% lower during the pandemic.

**Methods::** The patient had physical examination, imaging, blood tests.

**Results::** A 66 old man was admitted in the hospital 20 days after COVID-19 infection with complaints of paraesthesias and weakness in the legs, low back pain and feeling of incomplete miction, lasting for 5 days. The examination revealed also areflexia in the legs. Later complaints in the hands were added. CSF showed 1 g/l protein and normal cells. The diagnosis GBS was settled after EMG and CSF examination and proper treatment was started with good outcome.

**Conclusions::** The relation between COVID-19 and GBS is far from any prove, but its absence is still controversial. There are number of cases of GBS after COVID-19 infection, but this still can be only coincidence.
Background and Aims:: We describe the headache pattern during the acute stage of COVID-19 as well as the headache after discharge at 3 months of hospitalization in 400 in an exclusive COVID-19 care center in Mexico City.

Methods:: A complete neurological assessment was performed 3 months after discharge, obtaining the type of headache, pattern, duration and intensity of the headache as well as the presence of previous headache. Data on persistent headache after COVID-19 or after hospital discharge were also obtained for 400 patients with positive PCR for SARS-CoV-2.

Results:: Of the 400 patients evaluated, 49.3% had recent onset headache. The distribution of pain was Holocranial (42.6%), Hemicranial (11.5%), Bifrontal (31.1%), Occipital (14.8%), Bitemporal (23.0%). The type of pain was Oppressive (63.3%), Pulsatile (21.7%), Stabbing (18.3%). With a duration of less than 7 days (25.0%), 1-2 weeks (31.7%), less than 1 month (6.7%), 1 month to 3 months (8.3%), still have it (28.3%), 71% of the patients had moderate to severe headache. Less than 7% had headache prior to COVID-19 of these 50% had migraine. 38.7% presented post COVID headache, 66% still presented headache at 3 months, of Holocranial localization (33.3%) and bitemporal 25% oppressive in 62% and mild to moderate.

Conclusions:: Post COVID-19 headache is very prevalent and can be very disabling. Recognizing and treating this sequela is very important as it can improve the quality of life for survivors of this pandemic.
NEUROLOGICAL COMPLICATIONS OF COVID-19: A TUNISIAN SERIES

Saoussen Zmantar¹, Mariem Mhiri², Mouna Aissi², Rihab Ben Dhia², Mahbouba Frih²
¹Fatouma Bouguiba Monastir hospital, Neurology, sousse, Tunisia, ²Fattouma Bourguiba Hospital in Monastir, Neurology, Monastir, Tunisia

Background and Aims:: A number of neurological disorders have been reported to be associated with the novel corona virus: COVID-19 (acute or post) including acute stroke, encephalitis, convulsions, peripheral neuropathy and rarely myelitis.

Methods:: It’s a retrospective study carried out at the neurology department of Fatouma Bouguiba Monastir hospital including patients who had SARS-CoV-2 infection with neurological complications, between September 2020 and February 2021.

Results:: We included 7 patients, the middle age was 58.14 years and the sex ratio is 2.5. A viral RNA PCR from a nasal swab was performed in 6 patients who returned positive and a chest CT scan was done in a single case showing sequel of Covid-19. The time from COVID-19 symptoms to neurological symptoms was between 5 days and 3 weeks. Central nervous system involvement was found in 5 patients: 4 cases had an ischemic stroke; these patients were older, had cardiovascular comorbidities (arterial hypertension, diabetes mellitus and obesity) and had more severe respiratory impairment. A case of acute transverse myelitis has been reported in which we did not detect SARS RNA in the CSF. The case of myelitis is among the rarest reported cases worldwide. Peripheral nervous system involvement was found in 2 patients. The outcome was good in all patients.

Conclusions:: Neurologic complications associated with SARS-CoV-2 infection are polymorphic. It is important to recognize potential neurologic manifestations and complications of the noval corona virus especially when some of which can be rapidly progressing and require urgent intervention.
LACK OF CONCENTRATION AND ITS CORRELATION WITH COVID-19 IN MEDICINE ACADEMICS.

Vhirgine Helena De Oliveira Staut Federle¹, Marcelo Wilot Hettwer², Fernanda Garcia Passos³, Francinny Kelly¹, Monai Oliveira⁴
¹Sao Caetano do Sul University, Sao Paulo, Neurology, São Paulo, Brazil, ²Municipal University of São Caetano do Sul, Medical School, São Paulo, Brazil, ³Sao Caetano do Sul University, Sao Paulo, Neurology, Sao Paulo, Brazil, ⁴São Caetano do Sul University, São Paulo, Neurology, São Paulo, Brazil

Background and Aims:: The emergence of COVID-19 and its global expansion, put the world into an emergency and unprecedented scenario. Social detachment seems to be the most effective preventive form so far, and this has led to significant changes in medical education and human behavior. This work aims to evaluate the concentration of medical school students and its relation with the social and psychological changes during the COVID-19 pandemic.

Methods:: Online questionnaire was answered on the Google Forms by 153 volunteer medical students from the Municipal University of São Caetano do Sul. The students are from first to fifth year of medical school. Written approval was granted.

Results:: A question was asked: Did you have difficulty concentrating during the quarantine? The answers were: 5,2% said YES, 64,7% had difficulties in many moments, 8,5% said NO and 21,6% had difficulties in rare moments.

Conclusions:: In such a delicate moment as the current one, the great stress generated in medical students, caused important changes in mood and social behavior, culminating in a difficulty in concentrating in most of the interviewees.
THE INFLUENCE OF COVID 19 ON MEDICAL STUDENTS MEMORIES

Fernanda Garcia Passos, Thiago Fernandes, Vhiginea Helena De Oliveira Staut Federle, Francinny Kelly, Marcelo Wilot Hettwer, Monai Oliveira
Municipal University of São Caetano do Sul, Medical School, São Paulo, Brazil

Background and Aims:: A pandemia de Covid 19 trouxe muitas mudanças na vida de muitas pessoas, incluindo estudantes de medicina. Por ser uma situação inesperada, muitas pessoas têm seus estilos de vida, estudos e empregos afetados. Portanto, este trabalho tem como objetivo analisar como a memória de estudantes de medicina foi afetada durante uma pandemia.

Methods:: Um questionário online foi aplicado a 153 estudantes de medicina que foram voluntários, entre eles, alunos do primeiro ao quinto ano. Obtivemos aprovação por escrito. Os alunos responderam à pergunta: Você teve alguma alteração de memória durante a quarentena?

Results:: The percentages of the answers was: 49.7% of the volunteers replied that their memory is the same. 34.6% answered that they have some memory difficulty. 9.8% said that the memory is a little better. 4.6% replied that their memory is severely impaired e 1.3% replied that the memory is much better.

Conclusions:: A maioria relatou nenhuma mudança na memória, e outra grande parte relatou dificuldade de memória. No entanto, também houve um número considerável de melhorias relatadas. Isso mostra que apesar de ser um momento estressante para todos por causa da pandemia, o processo de formação da memória é individual e afetado pelo ambiente subjetivo de cada um.
MILD COVID-19 INFECTION ASSOCIATES WITH PERSISTENT NEUROLOGICAL SYMPTOMS

Lucas Scardua Silva¹, Italo Aventurato¹, Rafael João¹, Mateus Henrique Nogueira¹, Brunno De Campos¹, Mariana Brito¹, Marina Alvim¹, Gabriel Schmitt¹, Jhulia Gabriela Sousa², Guilherme Ludwig³, Cristiane Rocha⁴, Thierry Kaue¹, Beatriz Amorim¹, Vinicius Boldrini⁵, Natália Silva⁵, Sophia Baptista⁵, Alessandro Farias⁵, Leonílde Maria Santos⁵, Fernando Cendes¹, Clarissa Yasuda¹
¹University of Campinas, Department Of Neurology/neuroimaging Laboratory, Campinas, Brazil, ²University of Campinas, Department Of Radiology, Campinas, Brazil, ³University of Campinas, Institute Of Mathematics, Statistics And Scientific Computing, Campinas, Brazil, ⁴University of Campinas, Molecular Genetics Laboratory, Campinas, Brazil, ⁵University of Campinas, Autoimmune Research Lab, Campinas, Brazil

Background and Aims:: Little is known about post-covid-19 neurological symptoms. We aimed to assess neurological manifestations of post-COVID-19 patients and their relation to severity.

Methods:: We performed a cross-sectional analysis of 779 consecutive COVID-19 patients (PCR-confirmed) in the post-acute stage (585 women, median age 42, median interval post-infection 48 days). All participants filled the form (https://forms.gle/vgoyHQ6wftkucgtM8). We performed a multinomial logistic regression with cross-entropy optimization to predict subject cluster using sex, treatment modality (outpatient (696), non-ICU inpatient (52) and ICU inpatient (31)) and age groups as regressors. SciPy 1.5.2 and Scikit-Learn 0.23.2 Python packages were used for the analyses.

Results:: Most of the participants were polysymptomatic (18.6% were asymptomatic, 19.6% had one symptom, 17.1% had two symptoms, and 44.7% presented three or more symptoms), including fatigue (48%), headache (34%) and memory problems (29.8%). Cluster analysis divided the 779 individuals into five clusters of subjects (anosmia predominant, oligosymptomatic, polysymptomatic, headache predominant and fatigue/memory predominant), and four clusters of symptoms (headache, fatigue/memory issues, anosmia/ageusia and miscellaneous symptoms). Regarding treatment, the non-ICU inpatients (compared to the outpatients) were less likely to be in the anosmia-predominant cluster (p=0.04); the ICU inpatients (compared to the outpatients) had a higher probability of being in the fatigue-memory cluster (p=0.001). Women presented a higher chance to be in the headache cluster (p<0.001) and a lesser chance to be in the oligosymptomatic (p<0.001) and fatigue-memory predominant (p=0.02) groups.

Conclusions:: Anosmia seems associated with milder manifestations, and the fatigue-memory group appears associated with ICU admission. Women presented more headache and were more polysymptomatic than men.
SEVERE NEUROLOGICAL MANIFESTATIONS OF PATIENTS INFECTED WITH THE SARS-COV-2: REGISTRY IN INTENSIVE CARE UNIT.

Leticia Olguín-Ramírez¹, Victor Sánchez², Michel Martínez-Resendez³
¹Escuela de Medicina y Ciencias de la Salud, Tecnológico de Monterrey, Neurology, Monterrey, Mexico, ²Escuela de Medicina y Ciencias de la Salud, Tecnológico de Monterrey, Intensive Care Unit, Monterrey, Mexico, ³Escuela de Medicina y Ciencias de la Salud, Tecnológico de Monterrey, Infectology, Monterrey, Mexico

Background and Aims:: Introduction The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has been associated with many neurological manifestations, mainly encephalitis, meningitis, acute cerebrovascular disease (ischemic and hemorrhagic), Guillain Barré syndrome (GBS) and seizures. Background In late December 2019 a novel coronavirus was identified in China causing severe respiratory disease. The virus causing the infection has been named - severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). Symptoms are mainly respiratory, around 40% may manifest with mild neurological symptoms.

Methods:: Methods We included 35 patients with SARS-CoV2 infection hospitalized in Intensive Care Unit, with presentation of severe neurological events.

Results:: Results Our hospital (San José, Tecnológico de Monterrey) has treated 2,920 patients infected by COVID19 in 1 year, 351 patients have required intubation, 1.19% have severe neurological manifestations and the reported mortality is 11.4%. This cohort includes 82% males, median age 57.9 (+/- 14.96 years), first day of consultation by the neurology service was 22.21 (+/- 19.8 days), most frequent neurological presentation was encephalitis in 31.4%. The rest of neurological events were 5.7% myasthenic crisis, 2.9% microangiopathy, 5.7% guillain barre syndrome, 11.4 % status epilepticus, 22.9% STROKE, and around 20% presented Posterior reversible encephalopathy syndrome (PRES) and Autonomic dysfunction in ‘long COVID’.

Conclusions:: Conclusion Reports of severe neurological involvement in COVID-19 are increasing, which makes this problem particularly relevant to neurological critical care therapy. The nervous system can be directly or, more frequently, indirectly be involved. We anticipate that these neurological events will represent a large proportion of primary and secondary care consultations in coming months.
Background and Aims:: Fatigue and “brain fog” are frequently complained by patients even after mild COVID-19. We investigated whether these symptoms could be related to central neurological dysfunctions.

Methods:: Sixty-seven patients complaining of fatigue and/or “brain fog” and 22 healthy subjects (HS) were enrolled. Fatigue, perceived exertion (evaluated after motor task) and “brain fog” were evaluated. Global cognition and executive functions were assessed with Montreal Cognitive Assessment (MoCA) and Frontal Assessment Battery (FAB). Attention was measured with Sustained Attention, Stroop and Navon computerized-tasks. Transcranial magnetic stimulation (TMS) of the primary motor cortex (M1) evaluated resting motor threshold (RMT), motor evoked potential (MEP) amplitude, and cortical silent period (SP). Intracortical activity was evaluated with paired-pulse TMS protocols including short-interval intracortical inhibition (SICI), reflecting GABA_A-mediated inhibition, long-interval intracortical inhibition (LICI), a marker of GABA_B receptor activity, and short-latency afferent inhibition (SAI) that indexes central cholinergic transmission.

Results:: Patients reported high level of perceived fatigue, exertion and “brain fog”. MOCA and FAB highlighted poorer performances in patients than HS. At computerized tasks, both, sustained and executive attention were impaired. Patients presented higher RMTs, lower MEPs amplitude and longer SPs, as compared to HS, concurring with a reduced M1 excitability. LICI and SAI were impaired, indicating altered GABA_B- and cholinergic neurotransmission.

Conclusions:: Overall, our results demonstrate, in long COVID-19, an important link between fatigue, “brain fog” and central nervous system dysfunctions, characterized by frontal lobe cognitive impairments and altered neurotransmission.
DIFFERENTIAL CHARACTERISTICS IN THE MANAGEMENT OF ACUTE CONFUSIONAL SYNDROME SECONDARY TO COVID-19 PNEUMONIA.

Alba Llimona González, Silvia Oller Canet, Fernando Dinamarca Cáceres, Diego García Hernández, María Calls Samora, Íñigo González
Hospital del Mar, Psiquiatria, Barcelona, Spain

Background and Aims:: Acute Confusional Syndrome (ACS) is the most common neuropsychiatric complication in COVID-19 infection. Its management is still a challenge because the data and recommendations based on the evidence are limited. To describe the differential characteristics of the hospital management of ACS in patients with COVID-19 pneumonia compared to ACS secondary to other causes.

Methods:: An observational descriptive study has been carried out in patients with ACS who have required assessment by the liaison psychiatry service of Hospital del Mar between February to April 2020. The sample was divided in 2 groups (with and without COVID-19 pneumonia). Chi-square and Fisher's tests were used for comparisons.

Results:: The total sample was 62 patients, 26 of them diagnosed with COVID-19 pneumonia. The duration of ACS was longer in COVID-19 patients, mean of 12.68 days (SD 13.64). Dexmetomidine (26 vs 0) and olanzapine (13 vs 3) were used more frequently in COVID-19 patients, p<0.001. In COVID-19 patients a greater number of different antipsychotic drugs were used, mean of 2.40 (SD 1.323), and they received less family support (4) compared to non-COVID-19 (22), p <0.005.

Conclusions:: ACS associated with COVID-19 pneumonia in the patients in our sample is more difficult to manage than ACS associated with other pathologies, similar to which described in other series. It is related to a longer duration of the confusional symptoms and difficulties for control it.
MORPHOLOGICAL CHANGES IN THE SPINAL CORD TISSUE IN PATIENTS WITH GUILLAIN-BARRÉ SYNDROME ASSOCIATED WITH COVID-19.

Daria Sitovskaia¹, Yulia Zabrodskaia¹, Oleg Verbitskiy², Yulia Petrova³, Tatiana Sokolova¹
¹Polenov Russian Scientific Research Institute of Neurosurgery – branch of Almazov National Medical Research Centre, Department Of Pathology, Saint-Petersburg, Russian Federation, ²City Mariinskiy Hospital, Neurosurgery, Saint-Petersburg, Russian Federation, ³City Mariinskiy Hospital, Pathology, Saint-Petersburg, Russian Federation

Background and Aims:: Коронавирус может преодолевать гематоэнцефалический барьер (ГЭБ) и проявлять нейроинвазивные свойства. Точные механизмы проникновения в центральную нервную систему еще полностью не изучены, но сейчас предполагается четыре пути передачи. Первый из них - обонятельные нервы. Второй путь проникновения вируса в центральную нервную систему - клеточная инвазия. В этом случае моноциты и макрофаги, инфицированные коронавирусом, проникают через ГЭБ и опосредуют нейроинвазию. Эндотелиальные клетки BBB - третий возможный путь нейроинвазии; они способны экспрессировать два типа рецепторов - ACE2 и CD209L. Четвертый возможный путь проникновения вируса в нервную систему - это трансинаптическая передача через периферические нервы. Objective: To study morphological changes in the spinal cord in Guillain-Barré syndrome in patients with COVID-19

Methods:: Autopsy material from 3 patients with confirmed Guillain-Barré syndrome due to COVID-19.

Results:: Histological examination of the spinal cord material revealed that the structure of the nuclei is sharply disturbed, large foci of neuronal loss up to complete devastation, single preserved neurons, numerous shadow cells, pronounced edema, sharp depression of the neuropil, axonal degeneration, amyloid bodies.

Conclusions:: SARS-CoV-2 can damage spinal cord tissue, causing severe damage and death. Perhaps the virus is able to persist in the form of inactive fragments for a long time, the disease can recur in susceptible individuals when appropriate conditions arise.
COGNITIVE FOLLOW-UP IN COVID-19 RELATED ENCEPHALOPATHY TREATED WITH IMMUNOGLOBULINS

Maria Tappatà1, Francesca Santoro1, Lilia Volpi2, Lorenzo Ferri3, Ivan Panzera4, Roberto Michelucci2
1IRCCS ISNB, Neurology, BOLOGNA, Italy, 2IRCCS Istituto delle Scienze Neurologiche di Bologna, Department Of Neurology, Bologna, Italy, 3Bellaria Hospital, Bellaria Hospital, Bologna, Italy, 4IRCCS ISNB Istituto delle Scienze Neurologiche di Bologna, Neurology, BOLOGNA, Italy

Background and Aims:: Covid-19 can manifest through a pletora of neurological manifestations1, among which of particular interest is Covid-19-related encephalopathy (CRE)2. Treatment with intravenous immunoglobulins (IVIG) has been proposed3 but no study is currently available for long-term follow-up.

Methods:: We evaluated 3 CRE patients 6 months after infection resolution. Two patients had a comprehensive neuropsychological assessment, while the third underwent a phone interview.

Results:: All our patients had normal brain MRI, diffuse slowing of EEG tracings and also aspecific cerebro-spinal fluid results. The first patient, a 55-year-old female who had a confusional state, soon after the IVIG course scored 23.2 on the Mini Mental State Examination (MMSE). At follow-up, MMSE was 27.3 but the patient had deficits in memory and fluency and complained of sleep disturbance. Patient 2, a 76 year-old male who also presented with confusion, had 21.7 on MMSE after IVIG. At 6 month-repeat evaluation, his MMSE was 27.2 but deficits in frontal functions were present. The third patient, a 70 year-old female already diagnosed with dementia, had a baseline MMSE of 19, and during Covid-19 presented akinetic mutism. At follow-up she was back to her previous status, but she complained about severe insomnia.

Conclusions:: All patients showed a remarkable positive effect after IVIG, nonetheless they reported various long-term sequelae: the 2 patients who could be tested had both cognitive deficits, and 2 patients out of 3 reported sleep difficulties. These data need confirmation by follow up cognitive studies in further cases.
Background and Aims:: To prospectively assess neurological manifestations in patients with confirmed COVID-19 requiring hospitalization, and to analyze them according to the clinical outcome.

Methods:: At hospital admission, neurological examination was performed on 105 patients (aged 57. ±13 years; 31 women), with an evolution time of 9.8 ±3.5 days and no history of neurological disease, but t2 diabetes (36%), high blood pressure (36%) and overweight/obesity (81%), After follow-up until discharge, comparisons between survivors/deceased patients were performed using “t” test.

Results:: At admission; the SOFA score was 0-16 (median 3) and 21 (20%) patients required immediate respiratory support with sedation (RASS -2--5, median -5; Glasgow 3- 15, median 3); at the end of follow-up 60 (57.8%) patients died. Somatosensory and cerebellar dysfunctions were infrequent, while mental dysfunction (particularly acalculia) was frequent; 22 patients (21%) had delirium and 7 (6%) showed pyramidal signs. Anecdotic report of anosmia and dysgeusia was more frequent in surviving than in deceased patients (75% versus 53% & 50% versus 36%, p >0.05); however, evaluation of the first cranial nerve (excluding sedated patients) showed more frequent impairment in those who died than in survivors (28% versus 9%); cranial nerve impairment decreased during the first 3 days of hospitalization (dexametasone was administered to all the patients). Neurological manifestations were more frequent in patients with diabetes (p<0.05), in whom persistent hyperglycemia and thrombocytopenia were observed.

Conclusions:: In patients with late hospitalization due to COVID-19, neurological manifestations may be more frequent in those with diabetes and might be related to a negative outcome.
YOUNG WOMAN WITH PERSISTENT HEADACHE A WEEK AFTER COVID-19 VACCINATION - 
REPEATED INVESTIGATION IS CRUCIAL

Björn Wolf¹, Patrick Heinz¹, Tobias Neuscheler², Axel Geiger², Jens Metrikat¹
¹Armed Forces Hospital Ulm, Neurology, Ulm, Germany, ²Armed Forces Hospital Ulm, Neuroradiology, 
Ulm, Germany

Background and Aims:: Cases of cerebral venous sinus thrombosis (CVST) with concomitant 
thrombocytopenia were reported in young women following administration of COVID-19 Vaccine 
AstraZeneca (AZD1222/ChAdOx1-S). CVST is a rare but potentially fatal event, to be included in the 
differential diagnosis of headaches.

Methods:: Case report of a previously healthy, 18-year-old, female soldier who presented with NSAID-
resistant frontal headache and remittent nausea in our casualty department 7 and 9 days after her first 
AZD1222-vaccination. No-smoker, no intake of oral contraceptives or other drugs reported.

Results:: First visit, day 7 post vaccination: Neurological examination and laboratory results were 
unremarkable, except for elevated D-dimers (4.12mg/l [<.55]) and CRP (.6mg/dl [<.5]). Platelets: 150/nl
[150-450]. SARS-CoV2-IgG: negative. Dual-energy CE-CCT/CTA revealed no CVST or other pathological 
findings. The patient was discharged. Second visit, day 9 post vaccination: Persisting headache. No focal 
deficit, no petechiae. Thrombocytopenia (55/nl). D-dimers 15.29mg/l, CRP 1.1mg/dl. CCT now showed 
clear CVST (superior sagittal/transverse/sigmoid sinuses). Admitted to our Stroke Unit, treatment started 
with fondaparinux and immunoglobulins (PF4-heparinELISA-positive vaccine-induced 
thrombotic thrombocytopenia, VITT). Seizures were treated with levetiracetam. Because of progressing CVST and 
additional parenchymal bleeding we performed endovascular mechanical thrombectomy. Recanalisation 
was achieved. Platelet-count normalized. Patient recovered.

Conclusions:: Persisting headache after application of COVID-19 vector-based vaccines should be 
taken seriously even in healthy young women with no apparent vascular risk factors, initially normal 
platelet-count and unremarkable cerebral imaging. Reevaluation with repeated investigation 
(examination/laboratory/imaging), if neurologic symptoms persist, might be crucial to detect suspected 
CVST. Early and extensive therapy with IVIG and endovascular mechanical thrombectomy needs further 
evaluation in these cases.
A CASE OF GUILLAIN-BARRÉ SYNDROME AFTER COVID-19 VACCINATION

Francesca Di Pede¹, Anna Covolo², Edoardo Della Sala², Giulio Gadaleta², Claudio Gojani², Marco Laudadio², Claudia Ledda², Diego Garbossa³, Adriano Chio¹,⁴, Maria Claudia Vigliani⁴, Andrea Calvo¹,⁴ ¹University of Turin, Als Centre, “rita Levi Montalcini” Department Of Neuroscience, Turin, Italy, ²University of Turin, “rita Levi Montalcini” Department Of Neuroscience, Turin, Italy, ³University of Turin, Neurosurgery Unit, “rita Levi Montalcini” Department Of Neuroscience, Turin, Italy, ⁴AOU Città della Salute e della Scienza of Turin, Neurology 1, Turin, Italy

Background and Aims:: ChAdOx1-S (Vaxzevria, formerly known as AstraZeneca) is an adenoviral vector vaccine against coronavirus disease 2019 (Covid-19). To date, a number of side effects have been reported in association to this vaccine, in particular thrombosis.

Methods:: Review of the patient’s medical history.

Results:: We describe a case of Guillain-Barré Syndrome (GBS) after administration of a single dose of ChAdOx1-S in a 57-year-old man, with no history of other plausible risk factors for this neurological condition. Clinical presentation was consistent with the GBS variant known as bifacial weakness with paraesthesias; diagnosis was confirmed by neurophysiological and cerebrospinal fluid (CSF) findings. During hospitalization, blood tests showed electrolytic alterations suggestive of syndrome of inappropriate secretion of antidiuretic hormone (SIADH). According to published guidelines, our patient promptly received a course of intravenous immunoglobulins (2 g/Kg over 5 days), without any complications and gradual clinical improvement. To our knowledge, this is the first report of GBS associated to ChAdOx1-S vaccine. Given the importance of monitoring adverse drug reactions after commercialization, this case was reported to AIFA (Agenzia Italiana del Farmaco) via online procedure.

Conclusions:: The spectrum of effects due to Covid-19 vaccines has to be deeply investigated.
IMPACT OF COVID-19 PANDEMIA ON THE CARE OF PATIENTS WITH SPINAL CORD INJURIES (SCI): AND ITALIAN SURVEY.

Giorgio Scivoletto¹, Giuliana Campus², Elena Andretta³, Sauro Biscotto⁴, Jacopo Bonavita⁵, Adriana Cassinis⁶, Ernesto Losavio⁷, Antonino Massone⁸, Maria Onesta⁹, Maria Pagliacci⁴, Tiziana Redaelli⁶, Oreste Risì¹⁰

Lucia, Spinal Cord Unit, Rome, Italy, ²Ospedale Marino, Unità Spinale Unipolare, Cagliari, Italy, ³Ospedale Generale di Dolo, Servizio Di Urologia, Venezia, Italy, ⁴Azienda Ospedaliera di Perugia, Unità Spinale Unipolare, Perugia, Italy, ⁵Villa Rosa, Unità Operativa Di Riabilitazione, Trento, Italy, ⁶Grande Ospedale Metropolitano, Unità Spinale Unipolare, Milano, Italy, ⁷ICS Maugeri, Unità Spinale, Bari, Italy, ⁸Ospedale Santa Corona, Unità Spinale Unipolare, Pietraligure, Italy, ⁹Ospedale Cannizzaro, Unità Spinale Unipolare, Catania, Italy, ¹⁰ASST Bergamo Ovest, Ssd Urodinamica, Bergamo, Italy

Background and Aims:: To assess how Covid-19 impacted the clinical practice specialized SCI units.
Methods:: Survey circulated to the personnel of specialized SCI centers in Italy.
Results:: Two hundred people answered the survey. Most of them (63%) reported that during the last year there has been a reduction of the number of new SCI and a reduction of the number of beds available for patients with SCI. In 68% of the centers patients with SCI and Covid were admitted, but mostly (47%) after a negative swab. In all units Covid screening is regularly performed. Almost all the visit of relatives to the patients were suspended. Despite all these precautions, 52% of the respondents reported that some patients were found positive during their stay in the unit. Most of them (58%) (depending on the clinical situation) were transferred to Covid units. 95% of the respondents reported that the precautions adopted against the virus changed working modalities, halting some aspects of the clinical practice (e.g. outdoors activities, formal meetings with the relatives, caregivers training, evaluation of architectural barriers at patients home) and causing an increased length of stay, also due to the difficulties to transfer the patients to nursing home, and to the difficulties experienced by the patients to obtain all the necessary equipment. However, none of the respondents reported an impact on patients outcomes, especially in daily living independence.
Conclusions:: The outpatients activities have been impacted too and this reflected in an increase of complications related to SCI, in particular pressure ulcers, pain, spasticity, anxiety and depression.
A CASE OF NEUROMYELITIS OPTICA SPECTRUM DISORDER (NMOSD) AND ACUTE MYOSITIS FOLLOWING SARS-COV-2 INFECTION

Stefania Barone, Laura Rapisarda, Lucia Manzo, Alessandro Mechelli, Angelo Pascarella, Pietro Bruno, Marliisa Pasquale, Michele Trimboli, Paola Valentino, Antonio Gambardella
Magna Graecia University, Institute Of Neurology - Department Of Medical And Surgical Sciences, Catanzaro, Italy

Background and Aims:: Neurological manifestations of COVID-19 have been described. We report a case of seropositive NMOSD and acute myositis following SARS-CoV-2 infection.

Methods:: A previous healthy 35-years old man was admitted for NORB, a month after paucisymptomatic SARS-CoV-2 infection. Nasopharyngeal tests for SARS-CoV-2 was negative and serological IgG and IgM were positive. The neurological examination showed left eye blindness and myalgia. Blood examination showed elevated CK (>1000 UI/l), positive ANA (1:640) and anti-TPO (>1300 U/ml). Brain MRI showed T2/FLAIR left optic nerve hyperintensity with contrast enhancement. The EMG revealed signs of acute myogenic damage. He received intravenous methylprednisolone with poor recovery on vision but full recovery on muscle symptoms. Four months later he present NORB in contralateral eye; MRI showed optic chiasm hyperintensity, serum anti-AQP-4-antibodies were positive, EMG and CK were normalized. The patient received intravenous steroids and Immunoglobulins and started rituximab. Nevertheless, three months later he developed the area postrema syndrome, he was retreated with intravenous steroids and immunoglobulins and achieved a complete recovery. In March 2021, he underwent the second course of rituximab with clinical and radiological stability.

Results:: The patient was diagnosed with seropositive NMOSD, presented with recurrent NORB and area postrema syndrome, associated to acute myositis and autoimmune tiroiditis after SARS-CoV-2 infection.

Conclusions:: We supposed that SARS-CoV-2 may cause a post-infectious autoimmune response directed against AQP4 and other target (the muscle, the tiroid gland). Post-infectious autoimmunity is a potential mechanism in a subset of patients with COVID-19-related neurologic disease. Further research is needed to clarify this association.
THE IMPACT OF THE COVID-19 PANDEMIC ON CHILDREN AND FAMILIES UNDERGOING EPILEPSY SURGERY

Melissa Chavez-Castillo¹, Michelle Gratton¹, Maryam Nouri¹, Andrea Andrade²
¹Children’s Hospital, London Health Sciences Centre, Paediatric Neurology, London, Canada, ²Schulich School of Medicine and Dentistry, Western University, Paediatrics, London, Canada

Background and Aims:: The COVID-19 pandemic has had a significant impact on how healthcare is delivered to patients with epilepsy. Epilepsy surgery is a strategy with high reported satisfaction rates but can be a stressful road for patients. We aimed to determine significant challenges faced by the families of children undergoing epilepsy surgery during the pandemic.

Methods:: Cross-sectional study that included pediatric patients that underwent epilepsy surgery at Children’s Hospital/LHSC comparing two groups. We collected data at follow-up using a prespecified questionnaire asking to evaluate difficulties on a scale of 0-4. Questions focused on seizure activity, concerns over procedure delay, changes in hospital regulations, fear of exposure to COVID-19 and virtual appointments.

Results:: Thirty-five surgeries were planned from March 2020 to February 2021, but only 12(34%) were performed (60% decrease vs. 2019). Out of the 12 families, 11 answered the survey. The most challenging aspect was ongoing seizure activity while waiting for surgery expressed by 10/11 families. Four caregivers ranked it as considerably/extremely challenging. Limitations in the number of allowed-in-hospital visitors were deemed significantly/extremely challenging by 5/11(45%), and fear of being exposed to COVID-19 was low in 6/11(54%) families. Two families reported extreme challenges while telemedicine consults.

Conclusions:: These findings show how the pandemic impacted epilepsy surgery patients. The number of surgeries was reduced considerably throughout the pandemic, with subsequential increased seizure activity and emotional burden on patients. Parents with no additional support expressed the most challenges but felt safe with the implemented COVID-19 measures. Most families were comfortable using telemedicine protocols. Limitations include a small sample size.
Background and Aims:: In March 2020, WHO declared Novel Coronavirus Disease (COVID-19) outbreak to be a pandemic. All countries were given the call to take prompt actions to reduce spread of infection and save lives. The prevalence of the disease rose exponentially world wide. When it comes to the new SARS COVID 19, the understanding of the disease was poor, especially among the non medical folk. Social media was flooded with information and several of them were not tested for authenticity. Accurate information is the key to protect oneself, one's family as well as one's society and break the chain in the spread of the misinformation and the disease.

Methods:: In June 2020, we conducted a study among the students of an engineering college to assess the knowledge about Covid 19. An online questionaire with 29 open ended questions was mailed to 700 students and faculty. The questionaire included demographics, fund of information, risk factors, prophylaxis, protection and mode of transmission of SARS-CoV-2.

Results:: 416 subjects ages ranging from 18- 53 years participated in the study. 22.8% believed that COVID-19 is caused by bacteria. 12.5% believed that it affects the elderly only. 41.1% believed it is airborne. 37.7% considered it unsafe to go to hospitals for medical attention though 80.5% believed that if they have cough or fever, they should get tested. 46.6% believed a vaccine for COVID-19 has already been launched.

Conclusions:: Our study results showed several lacunae in the levels of knowledge regarding COVID-19 except for the co-morbidities being risk factors for COVID-19.
MYOSITIS ASSOCIATED TO COVID-19 MIMICS AN ACUTE EXACERBATION IN MYASTHENIA GRAVIS PATIENT

Antonio De Martino, Stefania Barone, Domenico Santangelo, Giuseppe Magro, Federico Tosto, Angelo Pascarella, Lucia Manzo, Pietro Bruno, Marilisa Pasquale, Paola Valentino, Antonio Gambardella
Institute of Neurology, University “Magna Graecia”, Catanzaro, Italy, Department Of Medical And Surgical Sciences, Catanzaro, Italy

Background and Aims:: Coronavirus disease 2019 (COVID-19) is an acute infection of the respiratory tract spread into a global pandemic. Emerging case reports have described neurological manifestations in patients with COVID-19 infection including headache, seizure, Guillian-Barré syndrome and encephalitis. Here we report a case of a patient affected by myasthenia gravis (MG) who developed a severe myositis post COVID-19.

Methods:: A 45 years-old woman affected by MG since she was 30, presented to our Neurological Department reporting severe weakness prevalent in upper limbs, diffuse myalgia, dysphagia and dyspnea started two months after COVID-19 infection.

Results:: We administered intravenous immunoglobulin (IVIG) in suspecting of MG aggravation, however without clinical improvement. A full blood panel showed elevated Creatine-Phosphokinase (CPK) and Lactate-dehydrogenase (LDH) levels. Autoimmune screening revealed low level of complement C3, positive antibodies anti-Nuclear (ANA) and anti-Phospholipide (aPL), included anti-Cardiolipin (aCL) and anti-β2-glycoprotein I (aβ2GPI). Electromyographic (EMG) examination showed: diffuse spontaneous activity with positive sharp wave (PSW), fibrillation potential, small and short motor unit action potentials (MUAPs) in quantitative analysis, suggesting acute myopathic pattern. We performed therapy with intravenous Methylprednisolone for five days with full clinical recovery. One month later, EMG features were significantly improved.

Conclusions:: Viral infection is a well-known cause of myositis described also in patients with COVID-19, probably due to the expression of ACE-2 on the muscle cells. To our knowledge, this is the first case in literature of myositis associated to COVID-19 infection in MG patients. We want to underline how myositis symptoms could mimic an acute exacerbation of MG leading to harmful misdiagnosis.
IMPACT OF COVID-19 PANDEMIC ON ACUTE STROKE CARE-DATA ANALYSIS FROM THE RES-Q REGISTRY 2020 IN N. MACEDONIA

Anita Arsovska¹, Robert Mikulik², Natan Bornstein³
¹University Clinic of Neurology, Urgent Neurology, Skopje, North Macedonia, ²University Clinic of Neurology, Department Of Clinical Neurology, Skopje, Czech Republic, ³Shaare Zedek Medical Center, Brain Division, Jerusalem, Israel

Background and Aims:: Since 2017, the Department of Urgent Neurology at the University Clinic of Neurology in N. Macedonia has implemented the Angels Initiative and the RES-Q Registry, in order to evaluate and optimize the quality of care of acute stroke patients. The aim was to analyze acute stroke data in 2020 and evaluate the impact of COVID-19 pandemic on acute stroke care.

Methods:: Database categories entered in 2020 in the RES-Q registry were compared in 4 consecutive quarterly periods. We used a statistical analysis to estimate the NIHSS reporting, CT-time and the number of IVT procedures; carotid artery imaging, prescription of antithrombotics and statins, median discharge mRS and median hospital stay.

Results:: Quarterly analysis showed significantly reduced number of acute stroke admissions by 34% and 85%, decreased number of IVT procedures by 40% and 100% in the 3rd and 4th quarter, respectively (p<0.05). DTN time was prolonged by 30.5% in the 3rd quarter (p<0.05). Carotid artery imaging was reduced by 100% in the 4th quarter (p<0.05). Median hospital stay was prolonged for 8 days in the 4th quarter (p<0.05). These findings were consistent with the increased number of COVID-19 patients and implemented epidemiologic measured in the country in the second half of 2020. Other analysed parameters of quality of stroke care were not affected (p>0.05).

Conclusions:: COVID-19 pandemic has had significant impact on acute stroke care with reduced number of admissions and decreased number of IVT treatment with prolonged DNT and longer hospital stay.
BENIGN COVID-19 IN AN AGGRESSIVE CASE OF AQUAPORIN-4 NEUROMYELITIS OPTICA TREATED WITH TOCILIZUMAB.

**Background and Aims::** Neuromyelitis optica (NMO) with antibodies (Abs) against aquaporin-4 (AQP4) is an astrocytopathy with severe spinal attacks resulting in mobility impairment. Relapse prevention is mandatory with immunosuppressants or anti-CD20 monoclonal Abs. Aggressive AQP4-Ab NMO could benefit by blocking the interleukin 6 (IL6) pathways with Tocilizumab. This IL6 inhibitor improved patient outcome in severe COVID-19 pneumonia.

**Methods::** Our case is a 52-year-old woman severely disabled by aggressive AQP4 NMO unresponsive to rituximab. One year after disease onset, she was bed-bound with tetraparesis related to several spinal attacks, mostly at the cervical level. She was repeatedly treated over the months with intravenous steroids, plasma exchange, and immunoglobulins. Meantime, two cycles of cyclophosphamide, and then three administrations of rituximab obtained no conclusive benefit on the inflammatory activity. Consequently, she started a third-line treatment with tocilizumab and finally stabilized after the two administrations.

**Results::** On intensive rehabilitation, she progressively improved her right arm function and became able to be on wheel-chair. In this context, she developed fever and cough with no evidence of pneumonia and recovered in one week. Two nasopharyngeal swabs for SARS-CoV-2 resulted positive (day 1 and day 10) and a third negatized at day 14. This mild COVID-19 infection resolved spontaneously without sequelae. On day 15 she continued with her monthly Tocilizumab infusions.

**Conclusions::** In our case, Tocilizumab was effective in preventing NMO relapses as a third-line treatment and resulted safe during COVID-19 pandemic.
COVID-19 ASSOCIATED STROKE: CLINICAL FORMS AND FEATURES OF THE DISEASE

Makhsudjan Ataniyazov, Gulnora Rakhimbaeva, Shokhida Gazieva
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims: To study the forms and features of the clinical duration of ischemic stroke in patients with coronavirus infection (COVID-19).

Methods: Analyzed 76 cases of ischemic stroke in two groups. The main group (n=34; 44.7%) patients with ischemic stroke, in combination with COVID-19. The comparison group patients (n=42; 55.3%) with ischemic stroke without clinical and laboratory confirmations of COVID-19. For confirmation of the diagnosis were used MSCT of the brain and laboratory PCR diagnostics.

Results: The average age of patients in the main group was 65.4±2.3 and in the control group was 68.7±1.8 years old. Comparison by sex showed that in both groups was a significant predominance of men in proportion with 2:1. The subtypes of ischemic stroke in the main group was dominated with unspecified and cardioembolic subtypes – 47.1% (n=16) and 23.5% (n=8), respectively. Atherothrombotic and lacunar subtypes were in 20.6% (n=7) and 8.8% (n=3) patients, respectively. In control group patients, the proportion of atherothrombotic subtype was 54.8% (n=23), cardioembolic – 19.0% (n=8), unspecified – 9.5% (n=4) and lacunar – 16.7% (n=7). The severity of ischemic stroke according to the NIHSS scale in the main group averaged 20.13±8.16 more than in the control group 12.3±7.61, P <0.001. Assessment of the disability degree according to the Rankin scale showed that in the main group higher number than the control group with 6.00 and 4.00 respectively.

Conclusions: In ischemic stroke with COVID-19 patients, age characteristics have not been established. The predominant subtypes of the ischemic stroke in COVID-19 patients were unspecified and cardioembolic subtypes.
DE NOVO STATUS EPILEPTICUS IN COVID-19

Francesca Gilio, Francesca Gragnani, Isabella Pestalozza, Antonella Biasiotta, Susanna Almonti, Steno Rinalduzzi
S.Pertini Hospital ASL Rome 2, Neurology And Neurophysiopathology Unit, rome, Italy

Background and Aims:: Neurological complications have been described in COVID-19. We present three COVID-19 patients (2 men, 74-78 years; woman 63 years) with acute de novo status epilepticus (SE) presentation in the period between November 2020 and March 2021.

Methods:: All patients (nasopharyngeal swab for SARS-CoV-2 was positive, chest CT showed interstitial pneumonia) presented sudden onset of seizures/confusional state. Only one patient had a past medical history of epilepsy with seizure freedom from 35aa. Two patients had negative CT brain; scalp EEG showed widespread epileptic activity; in one patient the EEG showed right temporal PLEDS and positive brain CT / MRI for right temporal-basal inflammatory lesion. CSF analysis for SARS-Cov-2 and neurotropic pathogens was negative.

Results:: All patients were treated according to COVID-19 protocols (clexane, corticosteroids), O2 (as needed), Aciclovir (10mg/Kg/day); intravenous immunoglobulin (0.4g/Kg/day) were administered in one patient; benzodiazepines and antiepileptic drugs (Levetiracetam, Valproic Acid, Lacosamide according to SE protocols) were used as rescue-therapy. All patients presented seizures remission; one patient experienced rapid overall clinical improvement, while the other, despite the neurological improvement, showed a worsening of the pulmonary-respiratory condition.

Conclusions:: The SE/confusional state can be the initial presentation of SARS-CoV-2 infection. A mechanism related to the systemic inflammatory syndrome in COVID-19 has been hypothesized, but further data are needed for understanding the SE COVID-19 related pathogenetic mechanisms. Early EEG is decisive for the correct diagnostic-therapeutic process, especially in non-convulsive forms.
Background and Aims: In COVID-19, blood clotting increases, the process of thrombus formation is the cause of aseptic thrombosis of the cavernous sinus. A decreased immunity and inflammatory processes of the face, paranasal sinuses also leads to septic complications. Aim. Diagnostics of thrombosis of cerebral vessels and venous sinuses in patients after COVID-19

Methods: In the multidisciplinary clinic of the TMA in 36 patients with a diagnosis of cavernous sinus thrombosis. The average age of patients was 60 ± 8 years, of which 26 were women (57.8%) and 19 were men (42.2%). All patients underwent MRI of the brain with angiography (MRT GE Optima 1.5 Tesla, USA)

Results: 38% developed non-infectious thrombosis, 52% of patients developed an inflammatory complication of the maxillofacial region after the acute phase of COVID-19 led to cavernous sinus thrombosis. With MRI in standard modes, signs of venous thrombosis can be detected: an increase in the signal intensity from the altered sinus (the most cavernous sinus, rarely the inferior cavernous and sigmoid sinuses), the venous sinuses are asymmetric. In 84%, blood flow in the remaining sinuses is preserved. When conducting MR venosinusography, a decrease in the signal from the blood flow along the affected side, as well as a compensatory increase in the signal from the blood flow, and vasodilation on the opposite side are revealed.
Conclusions: MRI contrast angiography is an informative method for determining the state of blood supply and the place of a thrombus in a vessel. In the treatment complications, it is necessary to restore the blocked vascular permeability.
CASE REPORT: COVID-19 AND BENIGN INTRACRANIAL HYPERTENSION

Ilirjana Zekja¹, Malbora Xhelili¹, Eti Muharremi², Vojsava Leka², Jera Kruja¹,³
¹Faculty of Medicine, UM Tirana, Albania, Neurology, Tirana, Albania, ²Neurology service, Neurlgy, Tirana, Albania, ³Faculty of Medicine, UMT, Neurology, Tirana, Albania

Background and Aims:: Neurological complications are not rare in patients who survived COVID-19. On the other hand, ophthalmologists say that ocular manifestations should not be neglected.

Methods:: We report the case of a 45-year-old male patient COVID-19 positive one month ago, without any other comorbidities, who presents in the Emergency Room in a stuporous state and bilateral midriasis after a tonic bilateral epileptic seizure. Two hours later he was lucid and oriented, without any focal neurological deficit but bilateral midriasis persisted. The patient complained severe, holocranial throbbing headache with dizziness, nausea and significant visual blurring. Ophthalmological examination reveals bilateral optic disc oedema, peripapillary hemorrhagic petechiae and venous tortuosity. Brain MRI, Angio- MRI and EEG resulted normal. The patient is treated with a high-dose of corticosteroids for three days and acetazolamide. After treatment he has no other complaints and the headache is less severe. We scheduled a follow-up with fundoscopy, after being treated with acetazolamide for 10 days.

Results:: Headache is one of the frequent neurological symptoms associated with COVID-19. In the absence of evidence of infectious or vascular disease, pseudotumor cerebri should be considered. Several studies suggest that patients with COVID-19 have vascular retinal lesions, including flame shaped haemorrhages, peripapillary petechie and acute retinal ischaemia.

Conclusions:: Further research is needed for COVID-19 and the possible neurological or ocular complications. It is important to consider pseudotumor cerebri in a patient with severe headache after COVID-19 and to perform a fundoscopy if indicated.
COHORT STUDY OF NEUROLOGICAL COMORBIDITIES AND COVID-19-RELATED CASE FATALITY

Gabriele Imbalzano1, Alberto Romagnolo1, Carlo Alberto Artusi1, Roberta Balestrino2, Claudia Ledda1, Francesco De Rosa2, Franco Riccardini4, Elisa Montanaro1, Marco Bozzali1, Mario Rizzone1, Maurizio Zibetti1, Leonardo Lopiano1

P.o. Molinette, Torino, Italy

Background and Aims:: Neurological involvement in Coronavirus disease-2019 (COVID-19) is widely recognized. However, the role of pre-existing neurological comorbidities in modulating COVID-19-related mortality still remains unclear. This cohort study evaluates the COVID-19-related case fatality rate (CFR) of patients with neurological diseases.

Methods:: We retrospectively evaluated all patients consecutively admitted to our hospital with a diagnosis of COVID-19 between March and April 2020. Demographic and clinical data, including 30-day survival, were retrieved. We used a multivariate regression analysis to estimate the association between neurological diseases and COVID-19-related mortality. Then, we compared the CFR and survival curves of two cohorts (patients suffering vs. those not suffering from neurological disease), matched through the propensity score (PS). Age and other comorbidities were considered for PS calculation. We applied a 1:1 matching for the entire neurological cohort and, separately, for cerebrovascular, neurodegenerative, and other neurological diseases.

Results:: Among 332 patients, 75 (22.6%) were affected by neurological disease (n=29 cerebrovascular, n=26 neurodegenerative, n=20 others). From the regression analysis, they resulted with a 2.5-fold increase of COVID-19-related mortality. From the cohort analysis, CFR resulted 2-fold higher in patients with neurological disease (48.0% vs. 24.0%; p=0.002). CFR was significantly higher in patients with neurodegenerative diseases compared to matched individuals (73.9% vs. 39.1%; p=0.017), while CFR increase in patients with cerebrovascular diseases did not reach full statistical significance (48.3% vs. 41.4%; p=0.597).
Conclusions: Neurological comorbidities, in particular neurodegenerative diseases, increase significantly COVID-19-related case fatality, indicating a clear priority for viral screening, access to care facilities and vaccination in these populations.
NEUROLOGICAL MANIFESTATIONS IN PATIENTS WITH SYMPTOMATIC COVID-19 ADMITTED TO THE BAFOUSSAM REGIONAL HOSPITAL, CAMEROON

Yannick Fogang Fogoum¹, Michel Noubom², Paul Cédric Mbonda³, Daniel Gams Massi⁴, Joseph Kamtchum-Tatuene⁵
¹Faculty of Medicine and Pharmaceutical Sciences, Neurology, Dschang, Cameroon, ²Faculty of Medicine and Pharmaceutical Sciences, Clinical Biology, Dschang, Cameroon, ³Faculty of Medicine and Biomedical Sciences, Neurology, Yaoundé, Cameroon, ⁴Douala General Hospital, Internal Medicine, Cardiology, Douala, Cameroon, ⁵University of Alberta, Neuroscience, Edmonton, Canada

Background and Aims:: Although the main manifestations of COVID-19 are respiratory, several neurological symptoms and complications have also been reported. The pandemic seems to have some epidemiological specificities in sub-Saharan Africa, and this may be reflected in the type and frequency of neurological symptoms. This study aimed to report neurological manifestations associated with symptomatic COVID-19 in a sub-Saharan African setting.

Methods:: We conducted a retrospective review of symptomatic PCR-confirmed COVID-19 cases admitted to the Bafoussam Regional Hospital between March and September 2020. Patients’ files were reviewed at discharge by a consultant neurologist. Socio-demographic characteristics, co-morbidities, symptoms on admission, neurological symptoms during hospitalization, management, and in-hospital outcome were recorded. Comparisons between patients with and without neurological symptoms were performed using Fisher’s exact and Mann-Whitney U test.

Results:: We enrolled 177 symptomatic patients (68% men). Mean age was 54.6 ± 17.8 years (range 2-99 years). Co-morbidities were present in 57.6% of patients, including hypertension (27.1%) and diabetes mellitus (25.4%). Neurological symptoms were found in 113 (63.8%) patients. The most frequent were headache (39.0%), myalgia (35.6%), anosmia (11.9%), impaired consciousness (10.7%) and delirium (5.6%). Regarding the presenting symptoms, fever was more frequent in patients with neurological symptoms than in those without (81.4% versus 50.0%, p< 0.001), while digestive symptoms were less frequent in patients with neurological symptoms (0.9% versus 9.4%, p= 0.004).

Conclusions:: Neurological manifestations are frequent and heterogenous in patients with symptomatic COVID-19. Further studies are needed to clarify the pathophysiology of neurological symptoms in COVID-19 and their impact on patients’ long-term outcome.
THE CLAISTRUM SIGN IN A PARAINFECTIOUS COVID 19 ENCEPHALITIS

Background and Aims:: Various neurological symptoms and manifestations associated with COVID-19 have been described. Imaging findings on brain MRI scans were reported as being unspecific, apart from acute necrotizing encephalopathy. Here, we present the first Italian case of parainfectious autoimmune encephalitis in a Covid 19 patient with a specific MRI pattern, responsive to steroid treatment.

Methods:: An otherwise healthy 61-year-old woman presented to the Emergency Department for an acute confusional state with drowsiness and impaired speech.

Results:: Even in the absence of fever or respiratory symptoms a RT-PCR test for SARS-CoV-2 using a nasopharyngeal swab was positive. Chest CT disclosed a mild interstitial pneumonia. Arterial blood gases was normal. Neurological examination exhibited mutism, slowness in executing orders, bilateral postural tremor, upper right arm weakness. Electroencephalography showed generalized delta slowing. Cerebrospinal fluid analysis revealed normal white-cell count, a mild increased protein concentration with negative test results for neurotropic viruses and also for Sars-CoV2. Tests in serum and CSF were negative for antineuronal antibodies whereas the serological test for Covid 19 was positive. Brain MRI showed FLAIR hyperintensities bilaterally but especially on the left side of the putamen, the claustrum, the insula cortex and the fronto-temporal cortex, without diffusion reduction or postcontrast enhancement. Thus, suspecting an autoimmune encephalitis, an high-dose steroid treatment was started followed by a tapering per os and a complete clinical and neuroradiological recovery was observed.

Conclusions:: The peculiar imaging pattern with the claustrum sign identified in our Covid 19 patient probably reflects an autoimmune phenomenon that might resolve with prompt recognition and appropriate therapy.
INSOMNIA IN POST COVID-19 HOSPITALIZED PATIENTS

Raul Anwar Garcia Santos¹, Monica Rodriguez Rodriguez², Raul Rodriguez Cruces³, Ana Sofía Ramírez García Luna⁴, David Agustín Fernández Lopez⁴; Alan Aldair Ibarra Fernández⁴
¹Instituto Nacional de Enfermedades Respiratorias, Neurology, Mexico City, Mexico, ²INER/CENI, Neurology, Mexico City, Mexico, ³McGill University, Montreal Neurological Institute, Montreal, Canada, ⁴NATIONAL INSTITUTE OF RESPIRATORY DISEASES, Neumology, Mexico City, Mexico

Background and Aims:: to describe the presence of sleep disorders in patients after hospitalization for COVID-19. 117 studied people under follow-up at the National Institute of Respiratory Diseases (INER) in the outpatient clinic. Patients with mild, moderate or severe symptoms of Covid-19 was carried out. A multiple regression model with backward selection was carried out to evaluate the effects of each of the neurological symptoms as risk factors in the development of insomnia. P values less than 0.05 were considered statistically significant.

Methods:: To descriptive the analysis of Mexican population patients with mild, moderate and severe symptoms of Covid-19 was carried out. A multiple regression model with backward selection was carried out to evaluate the effects of each of the neurological symptoms as risk factors in the development of insomnia. P values less than 0.05 were considered statistically significant.

Results:: 117 subjects were included, 36 (31%) women and 81 (69%) men, 58 ± 13 years of age, divided between groups according to severity, mild n = 17 (15%), moderate n = 27 (23%) and Severe N = 73 (62%) The comorbidities between the included groups did not present statistical differences, DM 2, overweight, Obesity, morbid obesity, heart disease, pneumopathy and hypothyroidism. Post-covid insomnia, pre-covid heart disease regardless of the groups with a prevalence of 9.9% with a p = 0.041. Patients with cognitive complaints had a 68.4% prevalence of insomnia p = 0.015. In patients with anxiety, the prevalence of insomnia was 68% p = 0.001.

Conclusions:: The symptoms found during covid-19 in our population are similar to those published in the international literature. The patients with the highest prevalence of insomnia were have pre-covid heart disease, anxiety, and cognitive complaints.
ANALYSIS OF DELAYED ADMISSION TO HOSPITAL IN ACUTE STROKE PATIENTS BEFORE AND DURING THE PANDEMIC COVID-19 IN BISHKEK, KYRGYZSTAN

Inna Lutsenko¹, Gulnura Abdumanapova²
¹Kyrgyz State Medical Academy, Online And Distance Education, Bishkek, Kyrgyzstan, ²Novosibirsk Neurological Center, Neurology, Novosibirsk, Russian Federation

Background and Aims:: Stroke services worldwide experienced the drop and barriers in admissions of patients to acute stroke departments in COVID-19 pandemic time. We aimed to analyze how lockdown due to the pandemic affected the number of admissions of acute stroke.

Methods:: Logistical parameters in 479 medical records of patients with acute stroke, examined by emergency teams of the Emergency Medical Center in Bishkek (EMCB) were analyzed retrospectively in 4 months: December 2019, January 2020 ( prepandemic months) and July and August 2020 (highest COVID-infection rates) in Bishkek, Kyrgyzstan.

Results:: Only 50,1% of cases were recognised as “strokes” by the emergency dispatcher and the correct team was sent to the patient. The mean time from the stroke onset till emergency team arrival was 15.6 ± 15.4 hours and the shortest median time (4.5 h) was in a group with the highest NIHSS score, p=0.01. In July 2020 (highest COVID infection rates in Kyrgyzstan) in 27.8% of cases an accepted stroke call was transferred by the dispatcher to the ambulance team within 90 minutes. 27.7% of stroke patients refused to be hospitalized in the pandemic time and in 8.3% of cases, patients were not hospitalized due to the lack of places in duty hospitals.

Conclusions:: Prolongation in aid to stroke patients is caused with low stroke recognition by population,
overload of emergency teams and patients refusal of the hospitalisation. COVID-19 pandemic in Kyrgyzstan though stimulated to train 91 emergency doctors in NIHSS and this scale was implemented in pandemic in prehospital settings.
AUTOIMMUNE LIMBIC ENCEPHALITIS RELATED TO SARS-COV-2 INFECTION: CASE-REPORT AND REVIEW OF THE LITERATURE

Chiara Milano¹, Silvia Canovetti¹, Enrico Tagliaferri¹, Francesco Turco¹, Stefano Verdenelli², Lorenzo Nesti², Marta Franchi¹, Enrica Bonanni¹, Francesco Menichetti², Duccio Volterrani³, Mirco Cosottini¹, Gabriele Siciliano¹, Chiara Pizzanelli¹
¹University of Pisa, Department Of Translational Research And New Technologies In Medicine And Surgery, Pisa, Italy, ²University of Pisa, Infectious Diseases Unit, Pisa, Italy, ³University of Pisa, Nuclear Medicine Unit, Pisa, Italy

Background and Aims:: SARS-CoV-2 infection is associated with a wide spectrum of neurological complications, including encephalitis. Most cases showed features consistent with a central nervous system (CNS) cytokine-mediated damage. However, few cases arguing for an autoimmune mechanism have been described, mainly as single reports or sparse in large case series involving other CNS manifestations. In this paper, we described a case of definite autoimmune limbic encephalitis (LE) COVID-19 related and reviewed the existing literature on other reported cases.

Methods:: Two weeks after the onset of COVID-19 infection, a 74-year-old woman presented with subacute confusion and focal motor seizures with impaired awareness, starting from left temporal region. Cerebrospinal fluid analysis revealed hyperproteinorrachia. Brain MRI showed bilateral T2/FLAIR hyperintensities in both hippocampi and total body PET/TC scan revealed hypermetabolism in basal ganglia bilaterally. A diagnosis of autoimmune LE was made. Thus, high dose corticosteroids and antiseizure medications were started, with a marked improvement of neurological conditions.

Results:: We systematically reviewed the literature to identify all well-documented cases of definite autoimmune LE (according to Graus criteria) in patients with COVID-19 infection, identifying other five cases exhibiting a good response to immunomodulating therapy.

Conclusions:: A very limited number of autoimmune LE have been described until now. It is important to monitor neurological symptoms in COVID-19 patients and to consider the possibility of an autoimmune LE, in particular when altered mental status and seizures appear late in the disease course. This allows to promptly start the appropriate treatments and avoid unnecessary delays.
Background and Aims:: Background: SARS-CoV-2 infection has been associated with various neurological manifestations. Since patients affected by SARS-CoV-2 infection present coagulation and immune system dysregulation, ischemic or haemorragic stroke is not uncommon, irrespective of respiratory distress. The occurrence of focal neurological deficits during SARS-CoV-2 infection suggests acute stroke but if other symptoms like headache, cortical blindness, seizure and altered mental status are present, Posterior Reversible Encephalopathy Syndrome (PRES) should be also considered in the differential diagnosis. Antithrombotic treatment, the alteration of endothelial function and coagulopathy due to COVID-19 and PRES leading to the breakdown of blood-brain barrier may then contribute to the occurrence of brain haemorrhage.

Methods:: We describe the case of a COVID-19 patient who developed bilateral haemorrhagic stroke of occipital lobes suggestive of haemorrhagic PRES. We then reviewed the available literature about haemorrhagic evolution of PRES in COVID-19.

Results:: We describe clinical and radiological features of five COVID-19 patients who developed haemorrhagic PRES.

Conclusions:: Coagulopathy and endothelial dysfunction resulting from the massive release of cytokines during the host immune response may be key factors in the pathogenesis of COVID-19-related PRES. Antithrombotic therapy and the leakage of the BBB can subsequently increase the risk of haemorrhagic transformation of the lesioned brain tissue. A prompt diagnosis of PRES is mandatory, since the timely interruption/reversal of antithrombotic therapy may be a key determinant for a good prognosis.
COVID-19 AND STROKE: CASE REPORT

Radi Tofaha Alhusseini¹, Abbasher Hussien², Khabab Mohamed Ahmed³, Al Hussien Mohamed Ahmed⁴, Amira Abdelgailî⁵, Mohamed Malekaldar⁶, Mohamed Mohamed Ahmed⁷
¹University of Alzaiem Alazhri, Anatomy, Khartoum, Sudan, ²University of Khartoum, Internal Medicine, Khartoum, Sudan, ³University of Khartoum, Faculty of Medicine, Khartoum, Sudan, ⁴AlYarmouk college, Faculty Of Medicine, Khartoum, Sudan, ⁵Alneelen university, Community Medicine, Khartoum, Sudan, ⁶Omdurman teaching hospital, Internal Medicine, Omdurman, Sudan, ⁷Al Neelain University, Medicine, Khartoum, Sudan

Background and Aims:: Introduction: Covid-19 is associated with common neurological diseases including stroke. It is believed that covid-19 can cause hypercoagulability state which can induce thrombotic events which may predispose for stroke. Objective: To document the effect and outcome of Covid-19 infection in patients with stroke.

Methods:: A 62 years Sudanese male known diabetic, hypertensive, hypercholesteremia, presented to the casualty with left sided weakness. Full medical history and physical examination was done, routine and specific investigations were done

Results:: The patient presented with left sided weakness, started suddenly. Both left upper and lower limbs were affected at the same time. He became completely paralyzed within less than six hours. Deviation of the mouth to the right side is noted. Physical examination reviled weakness in the left side of the body (left upper and lower limbs) where the power was grade zero in both limbs plus hypotonia and areflexia. His wife mentioned that two days prior to admission he started to complain of loss of taste, sore throat and intermittent high grade fever and for that he was given antimalarial without response. investigations were: Complete hemogram rather than lymphopenia no abnormalities were detected, ECG: left ventricular hypertrophy plus left access deviation, Chest X-ray showed evidence of cardiac enlargement and mid zonal pneumonia, chest showed an evidence of bilateral ground glass appearance. Test for COVID-19 was positive, CT brain showed an evidence of right Cerebral infarction, D-dimer is elevated.

Conclusions:: Strokes are being reported as a complication of COVID-19 due to the hypercoagulability state induced by Covid-19 infection.
ATYPICAL CEREBROVASCULAR COMPLICATIONS OF COVID-19

Tarek Rageh¹, Moustafa Othman², Mohamed El-Barody³, Ahmed Nasreldein¹
¹Assiut University, Neurology, Assiut, Egypt, ²Assiut University, Radiology, Assiut, Egypt, ³Assiut University, Radiology, Assiut, Egypt

Background and Aims:: Many neurologic complications were recognized with COVID-19. Cerebrovascular disorders were one of these complications. In our case report we describe two cases presented with atypical cerebrovascular presentations associated with COVID-19. The first case presented with right cavernous sinus thrombosis, right cavernous portion of the internal carotid artery partial thrombosis with bilateral basal ganglia microbleeds. The second case presented with multiple hemorrhagic infarctions as a first presentation.

Methods:: Case 1: 45 years old male admitted to the emergency unit complaining from fever, associated with respiratory symptoms, and generalized body aches. CT chest showed bilateral ground glass appearance (CORAD-5). SARS-CoV-2 PCR sample from nasopharyngeal swab was positive. Two weeks later patient developed painful diminution of vision in the right eye, which progressed to complete loss of vision. Later, patient developed right ophthalmoplegia, right 5th and 7th nerve palsies, left sided hemiparesis, bulbar symptoms with marked emotional liability. MRI, MRA and MRV showed right cavernous sinus thrombosis, right partial thrombosis of carotid artery and bilateral basal ganglia microbleeds. Case 2: COVID-19 positive 62 old female presented to ER unit with Fever and acute onset confusional state. MRI Brain showed multiple hemorrhagic infarctions (figure 1).
Results: The symptoms of the first case like bulbar, left sided heaviness were improved, while loss of vision and ophthalmoplegia did not improve. The second patient died few hours after diagnosis.

Conclusions: Cavernous sinus thrombosis and hemorrhagic infarctions could be associated with or complicate COVID-19 infection.
THE CORRELATION BETWEEN DEPRESSION AND ANXIETY WITH COGNITIVE FUNCTION OF NURSE IN ISOLATION ROOM FOR CORONAVIRUS DISEASE-19 IN RSUP HJ. ADAM MALIK MEDAN

Ranintha Surbakti¹, Iskandar Nasution¹, Fasihah Fitri²
¹North Sumatera University, Neurology, Medan, Indonesia, ²North Sumatera University, Neurology, Jakarta, Indonesia

Background and Aims:: Coronavirus disease-19 has psychological impact on health workers, depression and anxiety are the most common psychological problems and may affect cognitive function. The research aimed to determine the correlation between depression and anxiety with cognitive function in nurses working in the isolated ward and to compare them with nurses not working in isolated ward.

Methods:: This study was a cross-sectional study using consecutive total sampling technique, at Covid-19 isolated ward at General Hospital H Adam Malik Medan, March 2021. We included all nurses providing services to Covid-19 patients. We assessed depression, anxiety, and cognitive function using BDI, BAI, and MocA-Ina.

Results:: This study involved 72 participants. The mean age of nurses working in the isolated ward was 33 (24 - 52) years old. The Median of BDI 5 (0 - 37), BAI 3 (0 - 22), and MocA-Ina 26 (18 – 30). There was correlation between depression and cognitive function (p = 0.02, r = -0.273), no correlation between anxiety and cognitive function (p = 0.46, r = -0.088). There was no difference in depression (p = 0.324), anxiety (p = 0.332), and cognitive function (p = 0.210) between nurses working in the isolated ward and nurses not working in isolated ward.

Conclusions:: Depression is significantly associated with cognitive functions in nurses working in the isolated ward. These results suggest that depression intervention is needed to prevent cognitive dysfunction.
TRIGEMINAL NEURALGIA POST COVID 19. PRELIMINARY REPORT AND CLINICAL CONSIDERATION

Emanuele Caggia, Jole Bongiorno, Maria Ventura, Valeria Lingenti, Valentina Maci
ASP 7 Ragusa, Neurologia, ragusa, Italy

Background and Aims:: Covid-19 is a single RNA virus that enters the host cells after binding to the Angiotensin-converting enzyme 2 (ACE2). The symptomatic picture of SARS-CoV2 is dominated by respiratory disease. However, the spread of the virus, is not circumscribed considering that ACE2 receptor expression is also detected in other tissues, including the CNS. Neurological impairment is more likely in patients with more severe infection, and the most frequently encountered neurological pathologies were acute cerebrovascular disease, impaired consciousness, and impaired taste and sense of smell. Painful neuralgia was less frequent. The aim of our study is to evaluate the possible correlation between Covid-19 infection and trigeminal neuralgia.

Methods:: From November 2020 to March 2021, 10 cases of trigeminal neuralgia arising after Covid-19 infection were observed. 7 women and 3 men aged 30-55 years with mild-to-moderate infection that did not require hospitalization. Painful symptoms mainly involved the II branch of the V cranial nerve. All patients had brain magnetic resonance imaging (MRI), blink reflex, and VAS pain scale, performed

Results:: Neuroradiological and neurophysiological investigations showed no pathological data, while pain assessment with VAS showed values between 6 and 8. All patients underwent medical therapy with CBZ.

Conclusions:: The loss or reduction of taste and/or smell could suggest that the virus reaches the CNS through the olfactory nerve, localizing in the brainstem. This could also explain the involvement of other cranial nerves
Background and Aims:: Introduction: Guillain-Barré syndrome is an acute polyradiculoneuropathy which is immune mediated. It’s considered as a life-threatening by the respiratory affection and the dysautonomia. It is commonly reported as an adverse event after campylobacter jejuni infection and following vaccination.

Methods:: We report two cases of GBS, after receiving the first dose of Astrazeneca COVID-19 vaccine.

Results:: Cases description: First case of a 70 years old woman, presenting progressive, symmetric, ascending flaccid tetraparesis with bladder dysfunction which have occurred three weeks after the first dose of Astrazeneca covid-19 vaccine. The cerebrospinal fluid showed an albuminocytologic dissociation, electrophysiological studies showed an acute inflammatory demyelinating polyradiculoneuropathy. Second case of a 68 years old woman, presenting three weeks after the first dose of Astrazeneca covid-19 vaccine a progressively descending, symmetrical and synchronous tetraplegia, preceding 4 days before by diffuse headaches with multiple cranial pairs affection and bladder dysfunction. The cerebrospinal fluid showed an albuminocytologic dissociation, electrophysiological studies showed an acute inflammatory axonal and demyelinating polyradiculoneuropathy.

Conclusions:: Conclusion: Many cases of GBS after vaccines has been reported including one case following Pfizer covid-19 vaccine, yet the physiopathological mechanisms are not completely elucidated.
EFFICACY OF AMANTADINE IN PATIENTS HOSPITALIZED WITH COVID-19: STUDY PROTOCOL OF A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL

Leonardo Lopiano¹,², Carlo Alberto Artusi¹,², Marco Bozzali³, Antonio Ancidon⁴, Giovannino Ciccone⁵, Francesco De Rosa⁶, Nicola Vanacore⁴
¹A.O.U. Città della Salute e della Scienza di Torino, Neurology 2 Unit, Turin, Italy, ²University of Torino, Department Of Neuroscience “rita Levi Montalcini”, Turin, Italy, ³University of Torino, ⁷Department Of Neuroscience, Torino, Italy, ⁴Istituto Superiore di Sanità, National Center For Disease Prevention And Health Promotion, Rome, Italy, ⁵AOU Città della Salute e della Scienza di Torino (Molinette) e CPO - Piemonte, Ssd Epidemiologia Clinica E Valutativa Clinical Trial Center E Clinical Trial Quality Team, Turin, Italy, ⁶AOU Città della Salute e Scienza, Ipartimento Di Scienze Mediche Sc Malattie Infettive U, Turin, Italy

Background and Aims:: In 2019, the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) began circulating worldwide and caused the coronavirus disease 2019 (COVID-19). To date, no highly effective treatments are available. Amantadine, an old, cheap and safe drug, is currently used for Parkinson’s disease and multiple sclerosis, as well as being known for its antiviral action. Recent reports suggested a possible efficacy of amantadine against SARS-CoV-2. The proposed treatment, upon demonstration of efficacy and safety, could be easily administered even in developing countries for its low cost (Eudract n. 2021-001958-60).

Methods:: Enrollment of 380 participants requiring hospitalization with a recent onset of mild or moderate COVID-19. Two arms with 190 patients each will be treated with standard of care (SOC) + amantadine or SOC + placebo for 14 days. Patients will be monitored until discharge and assessed at day 30, 60 and 90 after randomization. Upon progression, patients will be followed up, but treatment will be discontinued. Study endpoints: 30 day mortality (primary), 30 day admission to Intensive Care Unit or death, worsening of clinical symptoms within 14 days, negativization for SARS-CoV-2 at day 14.

Results:: A reduction of 30-day mortality from 15% (SOC + placebo) to 7% (SOC + amantadine) is hypothesized.

Conclusions:: There are few independent and valid studies successfully concluded during the pandemic. The hope is that the evidence from this study will contribute to increasing the treatment options for COVID in the early stages of infection.
THE ITALIAN NATIONAL SURVEY ON COVID-19 IN NURSING HOMES DURING THE FIRST WAVE OF THE PANDEMIC

Flavia Lombardo¹, Ilaria Bacigalupo¹, Emanuela Salvi², Eleonora Lacorte¹, Paola Piscopo³, Antonio Ancidoni¹, Giulia Remoli¹, Guido Bellomo¹, Marco Canevelli¹, Nicola Vanacore¹
¹National Institute of Health, National Center For Disease Prevention And Health Promotion, Rome, Italy, ²National Institute of Health, Pharmacoepidemiology Unit, National Centre For Drug Research And Evaluation, Rome, Italy, ³National Institute of Health, Rome, Italy, Department Of Neurosciences, Rome, Italy

Background and Aims:: The SARS-CoV-2 pandemic had a strong impact on the most vulnerable categories such as older people, who paid the highest price. Nursing homes (NH) have been the epicenter of the pandemic. In NHs about a quarter of residents have dementia.

Methods:: The survey started on March 24, 2020 and reached 3292 out of the 3417 NHs present in Italy (source: the Dementia Observatory of the Italian National Institute of Health).

Results:: As of May 5, 2020, 1356 NHs (41.2% of the total) filled in the questionnaire via web, on a voluntary basis. A total of 29% of NHs reported SARS-CoV2 infection among residents (mean: 18.7 cases per 100 residents, range: 0.5-86.9) or staff, with frequency reaching 68% when including people with flu-like symptoms. Overall, 7.4% of the 9154 deceased subjects and 18.2% of the 5292 hospitalized had COVID-19 (33.8% and 38.2% respectively had flu-like symptoms). Fatality rates by region were higher than those observed in the general population. The main reported critical issues were lack of personal protective equipment (77.2%), inability to perform swabs (52.1%), absences of health personnel (33.8%), and difficulties in isolating (26.2%) and transferring residents (12.5%). All these factors resulted significantly associated with the spreading of COVID-19 in the NHs.

Conclusions:: The low response rate limits the generalizability of results, that were probably underestimated in terms of mortality and hospitalization rates, according to ad hoc analysis. This survey was the first major attempt to highlight critical issues and needs in NHs.
COVID-19 AND DEMENTIA: RECOMMENDATIONS FROM THE ITALIAN DEMENTIA NATIONAL PLAN WORKING GROUP

Marco Canevelli¹,², Ilaria Bacigalupo², Giulia Remoli², Emanuela Salvi³, Teresa Di Fiandra⁴, Nicola Vanacore²
¹Sapienza University of Rome, Department Of Human Neurosciences, Rome, Italy, ²National Institute of Health, National Center For Disease Prevention And Health Promotion, Rome, Italy, ³National Institute of Health, Pharmacoepidemiology Unit, National Centre For Drug Research And Evaluation, Rome, Italy, ⁴Ministry of Health, General Directorate For Health Prevention, Rome, Italy

Background and Aims:: Worldwide, about a fifth of those who died with COVID-19 were affected by dementia. A high number of excess deaths among people with dementia living in Italy was documented during the first wave of the epidemic. Based on such data, the Italian Dementia National Plan Working Group produced a report addressed to caregivers and healthcare professionals for the management and support of patients with dementia during the pandemic.

Methods:: Between September and October 2020, 11 online meetings were organized by the members of the Working Group. Documents produced by national and international Organizations were collected and analyzed together with the specific scientific literature on dementia and COVID-19. After reaching a consensus, recommendations for different health care settings were provided.

Results:: The report is structured into four sections: 1) reorganization of clinical and social care activities (e.g. swab execution procedures, management of behavioral disorders, accessibility to invasive treatments); 2) assistance in home settings; 3) care and support in day centers and residential structures (e.g. management of group activities in full safety, visits by family members); 4) training for health and social personnel (e.g. training on frequent atypical presentation of COVID-19 like delirium). The report “Interim guidance for the appropriate support of people with dementia in the current COVID-19 pandemic scenario” was sent to 4,609 representatives of outpatient dementia care services. Additional videos and iconographic materials were released to improve the diffusion of the main contents (https://www.epicentro.iss.it/demenza/demenze-covid19-report-ISS-2020).

Conclusions:: The impact of the report will be assessed throughout the pandemic with dedicated initiatives.
Background and Aims:: There is a wide variety of viruses that can predispose to longitudinal-transvers myelitis in humans and COVID-19 seems to be no different. Here we would like to present the case of a 45-year-old male, COVID-19 convalescent, with family history of sclerosis multiplex. He was admitted to the Department of Neurology and Neuroimmunology in late October 2020 after being hospitalized on Internal Diseases ward due to urine congestion, constipation and progressive lower limbs palsy.

Methods:: A series of tests and imaging studies led to the diagnosis of longitudinal-transverse myelitis of undetermined cause. We run cerebrospinal fluid and serology tests to search for immune background, however we have not found any specific antibodies present nor any other typical cause. The patient denied any COVID-19 related symptoms in recent past, and he had no record of positive COVID-19 PCR test. We run another blood test to determine whether had he underwent COVID-19 infection asymptotically. The man turned out to be seropositive for anti-SARS-CoV2 and anti-SARS-CoV2 IgG antibodies that confirmed our suspicion. We introduced treatment with steroids after which neurologic symptoms subsided.

Results:: There are known cases of myelitis in COVID-19 patients and convalescents, however, there usually is a history of previously detected and symptomatic infection and myelitis onset begins between day 7-10 after first COVID-19 symptoms.

Conclusions:: In present era it would seem to be crucial to screen patients with myelitis for anti-SARS-CoV2 seropositivity.
THE RISK OF CORONAVIRUS DISEASE (COVID-19) TRANSMISSION TO HEALTH WORKERS IN THE NEUROLOGY MEDICAL SERVICE AT DR. CIPTO MANGUNKUSUMO NATIONAL HOSPITAL, JAKARTA

Ahmad Yanuar Safri, Riwanti Estiasari, Kartika Maharani, Astri Budikayanti, Ediva Pradiptaloka, Jovita Stephanie, Darma Imran, July Kumalati
University of Indonesia, Neurology, Jakarta, Indonesia

Background and Aims:: Background and Aims COVID-19 transmission in the hospital environment is a serious threat to the patients and health or non-healthcare workers. Previous research identified changes in patients' status to COVID-19 positive during the treatment period reached 10.06%; indicated the high risk of transmission, including in neurology treatment area. This study aims to identify COVID-19 risk factors in the neurology medical service of Cipto Mangunkusumo General Hospital.

Methods:: Methods Health workers and non-health workers in non-COVID 19 neurology medical services went through a serial serological examination of total COVID-19 antibodies (day 1 and 30) or PCR test if clinical manifestation was found. Demographic, clinical, dan risk factors were assessed using a questionnaire (day 0, 7, 14, 21,30). Identification of risk factors classified as internal and external, which assessed the activities and contact history within or outside the hospital.

Results:: Result Among 103 subjects, seven subjects are diagnosed as COVID-19 based on PCR or seroconversion in antibody test. The significant internal risk factor identified were worked in shift (p = 0.045; OR 1.12), ate together (p = 0.002; OR 18), contacted within ≤ 1 meter (p = 0.029 ; OR 1.125), and performed procedures that involved physical contact (p = 0.004; OR 1.17). The significant external risk factor was going to public places on weekends (p = 0.029; OR 1.125).
Conclusions: The main risk factor for transmission of COVID-19 in the neurology medical service of Cipto Mangunkusumo hospital is public spaces usage outside of health service hours, namely the habit of eating together.

A STUDY ON NEUROLOGICAL PROBLEMS ARISING DUE TO COVID-19

Sheekha A, Shivam Mishra
EGC, Department Of Pharmacology, Mehsana, India

**Background and Aims::** The COVID-19 pandemic, caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), has been predominantly a respiratory manifestation. Currently, with evolving literature, neurological signs are being increasingly recognized. Studies have reported that SARS-CoV-2 affects all aspects of the nervous system including the central nervous system (CNS), peripheral nervous system (PNS) and the muscular system as well. Not all patients have reverse transcription-polymerase chain reaction positive for the virus in the cerebrospinal fluid, and diagnosing the association of the virus with the myriad of neurological manifestations can be a challenge. It is important that clinicians have a high-index of suspicion for COVID-19 in patients presenting with new-onset neurological symptoms.

**Methods::** The neurological manifestations can broadly be categorized into CNS and PNS. The neurological manifestations are commonly observed in older age and critically ill patients. We are reporting a clinical data of 200 patients with COVID-19 over a three-week period showcasing neurological or psychiatric disease in Gujarat, India.

**Results::** Notably, cerebrovascular event in (46%) patients, ischaemic stroke in 57 (62%), intracerebral haemorrhages in nine (7%) and CNS vasculitis in one (<1%) patients were documented. This study also reported altered mental status in 31 per cent of patients, encephalopathy (13%) and neuropsychiatric diagnosis (18%).

**Conclusions::** The neurological manifestations in patients with COVID-19 are varied and can emerge standalone or during the clinical course. Upholding a high-index of suspicion for COVID-19 in patients presenting with new-onset neurological symptoms will expedite an early diagnosis. Further studies are desired to unravel these varied neurological manifestations, treatment in COVID-19 patient.
COVID-19 IN PATIENTS WITH MYASTHENIA GRAVIS: WHICH PROGNOSIS?

Bissene Douma1, Ines Bedoui2, Mariem Elfekih3, Hajer Derbali4,5, Anis Riahi5, Mariem Messelmani5, Malek Mansour5, Jamel Zaouali5, Ridha Mrissa5
1Military Hospital of Instruction of Tunis, Department Of Neurology, sousse, Tunisia, 2CHU, Tunis Military Hospital, tunisia, Tunisia, 3CHU, Neurology, nabeul, Tunisia, 4Military Hospital of Instruction of Tunis, Department Of Neurology, tunis, Tunisia, 5Military Hospital of Tunis, Neurology, Monfleury, Tunisia

Background and Aims:: Coronavirus disease 2019 (COVID-19) is now the major public health concern worldwide. It can cause neurological complications and increase risk of exacerbations of chronic neurological disorders.

Methods:: We report a series of patients with myasthenia gravis who developed COVID-19 and referred to the neurology department of the Military Hospital of Tunis. Clinical characteristics and outcome of these patients are described.

Results:: Four patients with previously stable Myasthénia Gravis, had myasthenic exacerbation and were hospitalized in our department. One patient presented diplopia and two patients had dysphagia and limb weakness. One of them developed hypoxemic respiratory failure and required Intensive care unit admission and intubation. Three patients were treated with intravenous immunoglobuline. Increasing steroid doses was necessary in two cases. The outcome was favorable for all patients.

Conclusions:: Clinical course and outcome in patients with Myasthenia gravis and COVID-19 are variable. Early treatment is necessary in order to improve the prognosis of these patients.
COVID-19 IN PATIENTS WITH MYASTHENIA GRAVIS

Yosr Kooli¹, Asma Nasr¹, Salma Naija¹, Emna Jarrar¹, Anis Hassine², Sana Ben Amor¹
¹University hospital of Sahloul Tunisia, Neurology, Sousse, Tunisia, ²University Hospital Sahloul, Neurology Departement, SOUSSE, Tunisia

Background and Aims:: Coronavirus disease 2019 (COVID-19) has rapidly become a global pandemic, but little is known about its potential impact on patients with myasthenia gravis (MG).

Methods:: We studied the impact of COVID-19 infection on the clinical course of three hospitalized patients with acquired myasthenia gravis.

Results:: The first patient with previously stable MG had severe pneumonia. He required intubation for hypoxemic respiratory failure. He died within 48 hours. Whereas the two others required significant supplemental oxygen (high-concentration mask and non-invasive mask ventilation alternately). They were treated with cefotaxim, fluoroquinolone and then with tazocilline and received intravenous immunoglobulin, leading to full recovery.

Conclusions:: Our findings suggest that COVID 19 give rise to severe acute respiratory illness in patients with MG. They are at greater risk of poor prognosis.
**Background and Aims:** The World Health Organization (WHO) declared the coronavirus, a severe respiratory distress syndrome, Sars Cov 2 a global health emergency because of its rapidly transmissible nature, increasing mortality rate. Long-term sequelae of SARS-CoV-2 infection have become increasingly recognized and need huge effort to prevent and care.

**Methods:** We set up a 3 months follow-up of 160 patients, 82 women and 78 men, admitted in the Emergency Medicine Covid from October 2020 to March 2021. The mean age was 60. Asthenia, fever, cough myalgia, headache, anosmia, and ageusia are the most common primary symptoms.

**Results:** All the patients performed blood test, neuroimaging, respiratory and neurological assessment. We noticed a decrease in the laboratory findings inflammatory response. The Chest CT showed significant pulmonary fibrosis in 70 patients. 80 patients had a neuropsychological consequences, associated with depression, sleep impairment, anxiety, loss of memory and concentration, ageusia, anosmia, headache and global asthenia. Patients with pre-existent disease experienced a worsening, especially those with cognitive decline.

**Conclusions:** Currently, as we are still experiencing the pandemic and its effects, it is too early to describe the full clinical picture of post Covid syndrome. We need for more long-term clinical follow-up data to prevent long-term sequelae and Post Covid Neurological Syndromes. We need ongoing neurological cognitive and affective monitoring of all cases of Covid 19 to formulate relevant prevention and intervention strategies. Finally, the economic impact of this disorder, together with patient care, must be worked out in advance.
THE AFTER-COVID SYNDROME: A SURVEY OF POSTTRAUMATIC STRESS SYNDROME IN 111 RESIDENTS IN MOROCCO

Raymond Klevor¹, Khalid Ait Taleb², Najib Kissani³, Mohamed Chraa³
¹Mohammed VI University Medical Center, Marakesh, Neurology, Marrakesh, Morocco, ²Mohammed VI University Medical Center, Marakesh, Psychiatry, Marrakesh, Morocco, ³Mohammed VI University Medical Center, Marrakesh, Neurology, MARRAKECH, Morocco

Background and Aims:: The aim of this study was to investigate the incidence of symptoms of posttraumatic stress in a survey of infected and non-infected respondents in Morocco, and determine the risk factors.

Methods:: An online survey was conducted in 111 respondents and required them filling out a posttraumatic stress screening form.

Results:: Of 111 respondents, (average age: 24.3 ± 3.7 years; male-to-female ratio: 0.6), 18.9% reported having been infected by the Covid-19 virus. 64.5% said they had an infected close relation; 26.1% report knowing a close person who passed away from Covid. 55% frequently suspected being infected. The majority of respondents (56.8%) never got tested. Overall, 64.5% respondents met the criteria for possible posttraumatic stress syndrome. 42.3% respondents reported having had intrusions about experiences during the pandemic, 40.5% reported avoiding things or situations that reminded them of past Covid experiences, 38.7% reported having negative moods and thoughts concerning Covid, 29.7% reported having sleep or some other behavioral disturbances. Females reported relatively more symptoms than males (82.3% versus 69.0%) but the difference did not reach statistical significance (p = 0.092). Factors associated with symptoms were whether one was a Moroccan or a foreigner (p= 0.026), whether one knew a person who died from Covid infection or not (p= 0.026), or whether one was infected by Covid or not (p= 0.002).

Conclusions:: Posttraumatic stress syndrome is a frequent sequela of the Covid-19 pandemic and should be recognized as such by all in order for people to seek help to ensure a smooth return to normal life again.
Background and Aims:: The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is focusing primarily on respiratory complications. A comprehensive review of the neurological disorders reported during the current COVID-19 pandemic demonstrates that infection affects the central nervous system (CNS), the peripheral nervous system (PNS) and the muscle.

Methods:: In this retrospective, observational study, we enrolled 748 patients, with laboratory confirmed diagnosis of severe acute respiratory syndrome from coronavirus 2 (SARS-CoV-2) infection. Data were collected from March to May 2020 and from October to April 2021 and were extracted from electronic medical records. Neurological symptoms included central nervous system headache, dizziness, impaired consciousness, acute cerebrovascular disease, and epilepsy, peripheral nervous system symptoms, hypogeusia, hyposmia, hyposia, and neuralgia, and skeletal muscle injury. Data of all neurological symptoms were checked by a multidisciplinary team.

Results:: 814 patients admitted to the Urgency Medicine ward 284 were severe and 530 were nonsevere patients. Severe patients were older, and showed less typical symptoms. 633, 78% patients had neurolologic manifestations hypoageusia, hyposmia, neuralgia, headache, 29 patients had stroke, 2 Myastenic syndrome, 2 Guillaume Barre, 1 encephalitis

Conclusions:: The SARS-CoV-2 pandemic has implications for all areas of medicine. SARS-CoV-2 infection is associated with an increased incidence of neurological manifestations. Involvement of the nervous system carries a poor prognosis. The pathobiology of these neuroinvasive viruses is still incompletely known, and it is therefore important to explore the impact of CoV infections on the nervous system.
COVID-19 PRESENTING AS NEUROLOGICAL MANIFESTATIONS, RARE CASES IN NEUROLOGICAL DEPARTMENT.

Shadi Zamanian, Ebrahim Pourakbar
Social security organization, Mashhad, Iran, Neurological, Mashhad, Iran

Background and Aims:: Coronavirus disease 2019 caused by severe acute respiratory syndrome coronavirus 2 infection, is associated with coagulopathy causing venous and arterial thrombosis. SARS-CoV-2 infection is linked to a prothrombotic state causing venous and arterial thromboembolism and elevated D-dimer levels.

Methods:: A 50-year-old male taking warfarin for AF, presented 2 days after COVID-19 symptom onset (ARDS) with acute confusion, incoordination and drowsiness; GG pattern was reported in HRCT. CT brain confirmed acute large left cerebellar and left occipital infarcts. D-dimer was increased and the (INR) 3.6 at the time of stroke symptoms. A 67-year-old man with hypertension, presented with dysarthria and left hemiparesis. MRI brain showed an acute right MCA infarct. D-dimer was 27,000µg/L. A days following admission, he developed respiratory symptoms. RT-PCR confirmed SARS-CoV-2 infection.

Results:: The 45-year-old patient had severe muscle pain and had a mild cough and low grade fever. Groud glass was reported in HRCT tests and mild lymphopenic but increased enzyme creatinine kinase levels (4500) were significant improved. It lasted for two consecutive weeks. A 25-year-old previously healthy female was admitted with generalized tonic-clonic seizure in our hospital. The patient complained of dry cough 2 days before the admission. Brain MRI was normal and chest CT revealed focal ground-glass opacities. The respiratory specimen was positive for COVID-19 using real-time PCR assay. The symptoms of the patient improved with anticonvulsive and antiviral medications.

Conclusions:: Severe COVID-19 is associated with proinflammatory cytokines which induce endothelial and mononuclear cell activation with expression of tissue factor leading to coagulation activation and thrombin generation.
NEUROLOGICAL PRESENTATION OF COVID-19: EXPERIENCE FROM A TERTIARY CARE HOSPITAL OF BANGLADESH

Md Rashedul Islam¹, Tanbin Rahman²
¹BIRDEM General Hospital, Neurology, Dhaka, Bangladesh, ²Dhaka Medical College, Hematology, Dhaka, Bangladesh

Background and Aims:: Neurological manifestations of COVID-19 are being recognized day by day although predominant presentation is of respiratory illness. Understanding of impact of the virus on nervous system is important for selection and evolution of treatment now and in the future. The aim of the study was to describe the manifestations of COVID-19 affecting nervous system in a tertiary care hospital of Bangladesh

Methods:: This cross-sectional study was carried out in Department of Neurology, (BIRDEM) General Hospital from March, 2020 to October, 2020. Total forty patients who were admitted under neurology department were included in the study. Clinical syndromes associated with COVID-19 were classified broadly as a cerebrovascular event, altered mental status and peripheral nervous system disorders.

Results:: Median age of the patients was 58.6 years (range 22–73). Among those, 26(65%) were male and 14(35%) were female. Twenty two (55%) of 40 patients presented with cerebrovascular event, of whom 15 (68%) had an ischaemic stroke, 5 (23%) an intracerebral haemorrhage. 2(9%) patients were diagnosed as cerebral venous sinus thrombosis. Apart from cerebrovascular events, 14 (35%) of 40 patients presented with altered mental status, comprising 9 (64%) patients with unspecified encephalopathy and 5 (36%) patients with encephalitis. Four (10%) patients were diagnosed as peripheral nervous system disorder among those 2(50%) as Guillain-Barré syndrome (GBS) and 2(50%) as Bell’s palsy.

Conclusions:: We have found cerebrovascular disease, encephalopathy and peripheral nervous system disorder as presentation of COVID-19 in our study. Further nationwide study is needed to quantify the association and disease burden.
CEREBRAL VENOUS SINUS THROMBOSIS AND CORONA VIRUS INFECTION (COVID-19): A MULTICENTER ASIAN STUDY

Sajid Hameed Shaikh
Aga Khan University, Stadium Road, Karachi., Neurophysiology Department, Consulting Clinic-1, Karachi, Pakistan

Background and Aims: Coronavirus disease 2019 (COVID-19) has an increased propensity for systemic hypercoagulability and thromboembolism. An increase in cerebrovascular diseases has also been reported among these patients. The objective of the present study is to identify risk factors, presentation, and outcome of CVST in COVID-19 patients.

Methods: It is a multicenter and multinational prospective observational study. Ten centers in four countries, Pakistan, Egypt, Singapore, and the United Arab Emirates, participated in the study that included patients (aged > 18 years) with symptomatic CVST and recent COVID-19 infection.

Results: Twenty patients (70% men) were included. Mean age was 42.4 years. Headache (85%) and seizures (65%) were the common neurological features with a mean admission GCS of 13. Respiratory symptoms were absent in 45% of the patients. The most common MRI finding was ischemia (65%) followed by hemorrhage (20%). Superior sagittal sinus (65%) was the most common site for thrombosis. Acute inflammatory markers were raised with abnormal serum D-dimer (87.5%), erythrocyte sedimentation rate (69%), and C-reactive protein (47%) levels. Homocysteine was elevated in half of the cases. Mortality rate was high (20%). A good functional outcome was seen in the surviving patients with a mean discharge mRS score of 1.3.

Conclusions: COVID-19 patients are at high risk for CVST secondary to the high incidence of systemic thromboembolism. A low threshold for brain imaging should be kept for COVID-19 patients presenting with headache or seizures. Presuming a high prevalence of asymptomatic cases, all patients with newly diagnosed CVST should undergo testing for COVID-19 infection.
KNOWLEDGE, ATTITUDES, AND IMPACT OF COVID-19 PANDEMIC AMONG NEUROLOGY PATIENTS IN JORDAN: A CROSS-SECTIONAL STUDY

Mohammad Athamneh¹, Qais Sa’Di², Belal Aldabbour³, Yousef Khader⁴, Waleed Batayha²  
¹Yarmouk University Faculty of Medicine, Neuroscience, Irbid, Jordan, ²Princess Basma Teaching Hospital, Neurology, Irbid, Jordan, ³King Abdullah University Hospital, Neuroscience, Irbid, Jordan, ⁴Jordan University of Science and Technology, Public Health And Community Medicine, Irbid, Jordan

Background and Aims:: The impacts of COVID-19 pandemic on health services offered to patients with non-communicable diseases, including chronic neurological illnesses, are diverse and universal. This study aims to investigate these impacts on neurology patients in Jordan and assess their knowledge and attitudes towards the pandemic.

Methods:: We administered a paper-based, self-reported survey to neurology outpatients at a community hospital in the north of Jordan. The survey included demographics as well as disease-specific questions related to multiple sclerosis, epilepsy and migraine or tension headache. Knowledge and attitude towards the COVID-19 pandemic were also assessed.

Results:: Most respondents had positive attitudes towards COVID-19 pandemic, with 96% reporting they believed in the seriousness of the pandemic and adhered to prevention measures. Nearly 97% resorted to the internet and media outlets for medical information about the pandemic. About one in five clinic visitors had their appointments delayed due to interruption of health services. A similar portion of patients with MS, epilepsy and migraine or tension headache reported medication interruptions during the pandemic. One in two patients reported new events or worsening illness since the start of the pandemic, and sleep disturbances were reported by nearly one in three patients who had epilepsy or headache.

Conclusions:: Most surveyed neurology patients had positive attitudes towards COVID-19 pandemic. Also, the negative impacts of the pandemic on patients with neurological illnesses in Jordan were evident and diverse.
NEUROLOGICAL SYMPTOMS IN PATIENTS WITH COVID-19 AS MANIFESTATION OF SEVERITY AND PROGNOSIS, THE CASE OF ANOSMIA AND DYSGEUSIA

Luis Del Carpio-Orantes¹, Sergio García-Méndez², Ishar Solís-Sánchez¹, Miguel Arnulfo Perfecto-Arroyo³, Nancy Patricia Moreno-Aldama³, Jesús Salvador Sánchez-Díaz¹
¹Instituto Mexicano del Seguro Social, Internal Medicine, Veracruz, Mexico, ²Hospital Regional de Alta Especialidad de Oaxaca, Internal Medicine, Oaxaca, Mexico, ³Instituto Mexicano del Seguro Social, Neurology, Veracruz, Mexico

Background and Aims:: With the COVID-19 pandemic, attempts have been made to use various tools for prognostic purposes, however, the clinical manifestations that can act positively or negatively have not been taken into account.

Methods:: Descriptive and retrospective study carried out from April to June 2020 in Veracruz, Mexico, which analyzes adult patients with a diagnosis of COVID-19 pneumonia confirmed, in which the most prevalent neurological symptoms are evaluated, in order to find symptoms that act as severity and prognosis factors.

Results:: We analyzed 100 patients with COVID-19 pneumonia; 46 women and 54 men, with a mean age of 49.4 (± 19.3). The most frequent neurological symptoms were: headache (83%), anosmia (75%), dysgeusia (75%), myalgia (68%) and somnolence (50%). Somnolence and anosmia were more frequent in severe pneumonia than in mild pneumonia [(67.4 VS 35.2%; p = 0.002) and (84.8 VS 66.7%; p = 0.041); respectively]. By simple and multiple logistic regression analysis, it was found that the neurological manifestations associated with severe pneumonia, risk of intubation and death were: anosmia, somnolence, encephalopathy and age over 70 years, in contrast to neurological manifestations with a protective effect against severe pneumonia, intubation and death were: dysgeusia and age under 40 years.
Odds Ratios (OR) of the neurological variables for the development of severe pneumonia in patients with COVID-19.

* Multiple logistic regression analysis performed with Wald’s step-forward method.
Conclusions:: The presence of anosmia, drowsiness, and encephalopathy is associated with greater severity of the disease and with intubation requirements and death, while dysgeusia has a protective effect against severity, intubation and death associated, acting as prognostic factors and severity of the disease.
SUBCLINICAL MYOPATHIC CHANGES IN COVID 19

Davide Villa1, Gianluca Ardolino2, Linda Borellini2, Filippo Cogiamanian2, Maurizio Vergari2, Sergio Barbieri2
1Foundation IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Centro Dino Ferrari, University of Milan, Milan, Italy, Neurophysiology-neurology, Milan, Italy, 2Foundation IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy, U.o. Neurophysiology, Milan, Italy

Background and Aims:: Coronavirus disease 2019 (Covid 19) is associated to neuromuscular symptoms in up to 10.7% of hospitalized patients. The prevalence and the characteristics of intensive care unit acquired weakness (ICUAW) in patients affected by Covid 19 have been extensively assessed, although no distinctive pattern was found. ICUAW has been described as a potential confounding factor during the identification of severe acute respiratory syndrome coronavirus 1-related myopathy. In order not to incur this potential bias, we focused on a subset of non-severe cases. Our aim was to precisely assess the extent of primary neuromuscular involvement with neurophysiological investigation in Covid 19 patients.

Methods:: From April through May 2020 a total of 70 patients were hospitalized in the Internal Medicine Ward of the Fondazione IRCCS Ospedale Maggiore Policlinico in Milan, Italy. After excluding patients who underwent invasive ventilation and steroid treatment, 12 patients were evaluated. Neurological examination, nerve conduction studies (NCS) and concentric-needle electromyography (EMG) were performed.

Results::
While nerve conduction studies were unremarkable, needle electromyography showed myopathic changes in 6 out of 12 subjects. All patients were asymptomatic for muscular involvement. Clinical features and laboratory findings did not show relevant differences between patients with and without myopathic changes.

**Conclusions:** Our data show that in SARS-CoV-2 infection muscular involvement can occur despite the absence of clinical signs or symptoms and should be considered part of the disease spectrum. The application of muscle biopsy to unravel the mechanisms of myofiber damage on tissue specimens could help to clarify the pathogenesis and the treatment response of coronavirus-mediated injury.
Background and Aims:: There is emerging evidence that COVID-19 can trigger thrombosis because of a hypercoagulable state, including large vessel occlusion ischemic strokes. Bi-hemispheric ischemic stroke is uncommon and is thought to indicate an embolic source.

Methods:: We performed a retrospective cohort study at a quaternary academic medical center between March 1st and April 30th, 2020. We identified all patients with laboratory-confirmed SARS-CoV-2 infection who presented with simultaneous bi-hemispheric ischemic strokes.

Results:: Of 637 COVID-19 admissions during the two-month period, 13 had a diagnosis of acute ischemic stroke, including 5 who developed with bi-hemispheric cerebral infarction. Three (60%) were female, median age was 54 (range 41-67), and all five were being managed for severe COVID-19 related pneumonia complicated by acute kidney injury and liver failure before the diagnosis of cerebral infarction was established. Five presented with elevated ferritin, lactate dehydrogenase, and interleukin-6 (IL-6) levels, and four had lymphopenia and elevated D-dimer levels. All patients underwent neuroimaging with CT for persistent depressed mentation, with or without a focal neurologic deficit, demonstrating multifocal ischemic strokes with bi-hemispheric involvement. Outcome was poor in all patients: we discharged two to a rehabilitation facility with moderate-to-severe disability, and three (60%) patients died.

Conclusions:: Stroke is implicated in SARS-CoV-2 infection. Multifocal ischemic strokes with bi-hemispheric involvement should be considered in COVID-19 patients with severe infection and poor neurologic status and may be associated with poor outcomes.
THE EFFECT OF COVID-19 PANDEMIC ON PATIENTS WITH NEUROLOGICAL DISORDERS CONSULTING TELEMEDICINE OPD

Ruchika Tandon, Sushant Aildasani
Sanjay Gandhi Postgraduate Institute of Medical Sciences, Neurology, Lucknow, India

Background and Aims:: Electronic or telemedicine OPDs (e-OPDs) are being utilized for providing outpatient care to neurology patients during Severe Acute Respiratory Syndrome Corona virus-2 (SARS COV-2) or COVID-19 pandemic.

Methods:: We assessed knowledge, attitude and practices of 300 neurological e-OPD patients with regard to COVID-19 pandemic and perceived effect of this pandemic on their neurological problems via questionnaire.

Results:: Out of 300 patients (60% males), people between 20 and 40 years of age (35.3%) and those with seizures (28%) and strokes (17.3%) were most frequent visitors. Though 96% of all individuals were aware of the COVID-19 disease, only 34% patients fully followed disease preventive measures. Maximum numbers of patients were aware of airborne (54%) route of disease transmission and greatest number of people used face mask (88%). Follow up patients (71.3%) most frequently utilized e-OPDs and 56.1% of these patients contacted earlier than scheduled visits. 17.3% felt that there was a delay in emergency visit. The commonest reason for delay in emergencies as well as in follow-ups was government restriction (53.8% and 40.2%, respectively) and most common reason for arrival was regular follow up in 55.1% and reasons other than emergency or insistence from caregivers in 46.7% first visits. The e-OPD interaction satisfied most of the patients as well as doctors.

Conclusions:: In spite of good awareness of disease, very few patients were fully following COVID-related precautions. Fear of Government was motivating factor for most patients. There was a delay in very few neurological emergencies. Impact of COVID-related restrictions on neurological patients, was not significant.
ADEM POST SARS-COV-2 INFECTION IN A PAEDIATRIC PATIENT WITH FISHER EVANS SYNDROME

Maria Laura Manzo, Cristina Galati, Cristina Gallo, Giuseppe Santangelo, Antonio Marino, Fulvio Guccione, Vincenzo Raielli, Renata Pitino
University of Palermo, Child Neuropsychiatry School, Palermo, Italy

Background and Aims:: Introduction: Sars-CoV-2 is a single-strained RNA virus belonging to Coronaviridae's family. In paediatric age the majority of patients are asymptomatic, however several neurological manifestations associated with Sars-CoV-2 infection have been detected in a percentage of cases ranging from 17.3% to 36.4%. Acute Disseminated Encephalomyelitis (ADEM) has been recently included among the potential complications of Sars-Cov2 infection. The available data regarding paediatric patient show only one case.

Methods:: Case report: We present a case regarding a six-year-old child suffering from Fisher Evans Syndrome treated with Sirolimus and Thalidomide therapy and affected by Sars-CoV-2 infection.

Results:: Case report: We present a case regarding a six-year-old patient suffering from Fisher Evans Syndrome who was given Sirolimus and Thalidomide therapy. After ten days since the first positive nasopharyngeal swab for Sars-CoV-2, in which he had no symptoms, he presented an episode of generalized tonic-clonic seizure with spontaneous resolution. The patient underwent MRI which showed the typical picture of Acute Disseminated Encephalomyelitis. His clinical course was favourable, with a good response to cortisone therapy and a progressive improvement of the neuroradiological and electroencephalographic picture.

Conclusions:: according to our knowledge, this is the second case of an Acute Disseminated Encephalomyelitis following SARS-CoV-2 infection in a paediatric patient, characterized by monosymptomatic onset, in which the immunosuppressive therapy practiced for the Fisher Evans Syndrome has probably contributed to a favourable evolution of ADEM, in contrast to other case described in the literature.
Background and Aims:: Coronavirus Disease 19 (COVID-19) was declared a pandemic by the World Health Organization (WHO) in March 2020. Since the outbreak, neuropsychiatric presentations such as delirium and confusion have been developing. Our aim is to describe the differences between inpatients cursing with Acute Confusional Syndrome (ACS) with and without COVID-19 pneumonia.

Methods:: This is an observational-descriptive study. All patients attended by the liaison psychiatry service of Hospital del Mar, between February and April 2020, with ACS diagnosis were included. The sample was divided in 2 groups (with and without COVID-19 pneumonia). Sociodemographic and clinical variables including sex, age, admission duration, previous somatic or psychiatric history and risk factors associated with ACS were compared. Chi-square and U Mann Whitney tests were used for comparisons.

Results:: The total sample was 62 patients. 43.5% were women with a mean age of 71.7 (SD 11.3). Covid pneumonia group mean age was lower (69, SD=8.4) (p=0.033) Covid pneumonia group included 26 patients. There were significant differences between Covid pneumonia group and ACS in relation to a previous diagnosis of: Ischemic Heart Disease (p=0.007), Heart Failure (p=0.029) and Nephropathy (p=0.022). Risk factors associated with ACS such as cognitive impairment or hypoxemia were compared. There was a higher percentage of Hypoxemia in Covid pneumonia patients (p<0.001)

Conclusions:: In this sample, patients with ACS and Covid pneumonia had a bigger rate of hypoxemia and a previous history of Ischemic Heart Disease, Heart Failure and Nephropathy compared to the rest of ACS patients. More studies would be necessary to assess the significance.
Background and Aims:: Initially barely affected by the Covid 19, the African continent suffered a second violent wave this winter. Neurological manifestations worldwide are increasingly reported, dominated by encephalitis, stroke and polyradiculoneuritis. We report the Senegalese experience of NeuroCovid through a series of 9 patients.

Methods:: This is a prospective study of patients hospitalized in the neurology department of Fann. Were included patients who had neurological manifestations during or following an COVID-19 infection defined by a positive PCR or a recent infection with ELISA serology or typical chest imaging.

Results:: We collected 9 patients (6 men and 3 women), aged 7 to 80 years. Diagnoses were: 3 encephalitis, 4 polyradiculoneuritis, 1 hemorrhagic stroke and 1 chorea. 4 patients had comorbidities. The delay for neurological signs appearance was 11.1 days. A nasal swab was positive on 5/8 patients. Antibodies were found in all 3 negative patients. The LCR study showed hyperproteinorrachia in 7/9 patients. 5 patients underwent CT chest scan, showing ground glass opacities. Brain imaging was normal in 3 and pathological in 2, showing a parietal temporo hematom
in one and mesencephalic and parietal hypersignal in the other.
50% of patients with polyradiculoneuritis had an ENMG that showed an AIDP. One patient had an electroencephalogram that showed an overall slowing of the pattern with diffuse pseudoperiodic complexes.
Evolution was good for 6 patients but we noticed 3 deaths.

**Conclusions:** Neurological manifestations most often occur in post-infection. The creation of a multidisciplinary team will allow a better understanding of the sequelas of patients with COVID-19.
VISUAL HALLUCINATION IN DELIRIUM ASSOCIATED CORONAVIRUS DISEASE 2019 (COVID-19): A CASE SERIES

Rocksy Fransisca V. Situmeang¹, Aristo Pangestu²
¹Siloam Hospital Lippo Village, Memory Clinic, Neurology Department, Tangerang, Indonesia, ²Siloam Hospital Lippo Village, Neurology, Tangerang, Indonesia

Background and Aims:: The increasing number of COVID-19 confirmed cases is also accompanied by an increasing number of reports of atypical symptoms, one of which is delirium. Visual hallucinations as a symptom of delirium are rarely reported in COVID-19.

Methods:: We report 3 COVID-19 confirmed patients with symptoms of delirium accompanied by visual hallucinations.

Results:: All patients were male, 2 were elderly patients (66 and 72 years) and 1 patient was relatively younger (29 years). All patients denied the use of substance abuse and do not have neuropsychiatric comorbidities. Complex visual hallucinations were found in 2 patients and 1 mixed visual hallucination was found in 1 patient. The visual hallucination features found are typical of delirium. We proposed two mechanisms for visual hallucinations in delirium associated COVID-19, namely the involvement of the reticular activating system and dysregulation of neurotransmitters, especially dopamine.

Conclusions:: Visual hallucinations can be an atypical presentation of delirium associated COVID-19 in patients without comorbid of neuropsychiatric illness. Further research is needed to determine the impact of outcome and severity as well as the pathomechanisms for visual hallucinations in delirium associated COVID-19.
POOR OUTCOME OF MYASTHENIA GRAVIS IN COVID-19: A TERTIARY PUBLIC HOSPITAL EXPERIENCE

Godard Artajos, Marissa Ong
EAST AVENUE MEDICAL CENTER, Neurosciences, QUEZON CITY, Philippines

Background and Aims:: The COVID-19 Pandemic has caused a great concern worldwide. Myasthenia Gravis is known to be a challenging disease on its own. Most of the time the management of MG would include immunosuppression which could lead us to think that these patients may be at higher risk of contracting an infection or experience severe manifestations of COVID-19. [3] Current data might be biased toward poor outcome of patients with myasthenia gravis with COVID-19; more likely to be hospitalized, have disease exacerbations, and have a higher risk for mortality than the general population with COVID-19.

Methods:: This case series will present how a concurrent COVID 19 infection affected the outcomes of patients with Myasthenia gravis.

Results:: In our observation, other factors that may contribute to a poorer outcome are pregnancy and presence of other co-morbidities. The first case was pregnant. The second patient was undergoing treatment for pulmonary tuberculosis. The third case had more than two chronic illnesses and risk factors. In our setting, additional factors like accessibility to a health facility, proper patient education and availability of medications and equipment need to be considered. Despite improvement of myasthenic symptoms, there was progression of respiratory infection leading to poor outcome of the patients.
Conclusions:: For third-world countries like the Philippines, patient education and monitoring is very important for the prevention of hospitalization due to myasthenic crisis or COVID-19 infection. Further studies are recommended to establish the effects of pregnancy and other co-morbidities in the poor outcome of MG in COVID-19.
A CASE OF COVID-19 ENCEPHALITIS WITH ANTI-GFAP ANTIBODY-POSITIVE MENINGOENCEPHALOMYELITIS

Fan Cheng, Ker Tang  
Hull University Teaching Hospitals NHS Trust, Department Of Neurology, Kingston upon Hull, United Kingdom

**Background and Aims::** Neurological manifestations are increasingly recognised in COVID-19, caused by SARS-CoV-2. Anti-glial fibrillary acidic protein (GFAP) antibody (Ab)-mediated astrocytopathy can have parainfectious aetiologies.

**Methods::** We describe a patient with COVID-19 and adenovirus encephalitis preceding anti-GFAP meningoencephalomyelitis.

**Results::** A woman, 49, was admitted with headache, fever and positive SARS-CoV-2 nasal PCR. Over 72-hours, she developed drowsiness and confusion. CT head was normal. Cerebrospinal fluid (CSF) showed leukocyte 28/mm^3, protein 0.8g/dL and glucose 2.2mmol/L. She started empirical intravenous aciclovir and cefotaxime. MRI brain following improved agitation demonstrated right temporal T2 hyperintensities. On Day 10, CSF returned positive SARS-CoV-2 and adenovirus PCR (HSV, VZV, enterovirus PCR and microbial culture negative). COVID-19 and adenovirus encephalitis was diagnosed. 5-days dexamethasone and 14-days total aciclovir were given with clinical improvement. However, on Day 20, she developed new quadriparesis, myoclonus and fluctuating consciousness. Repeat MRI revealed new right temporal and parietal T2 hyperintensities, patchy enhancing cord lesions, and cauda equina and conus medullaris meningeal enhancement. Repeat CSF showed leukocyte 185/mm^3 (90% lymphocytes), protein 1.9g/dL, glucose 1.3mmol/L, with negative SARS-CoV-2 and adenovirus PCR. Serum and CSF anti-GFAP Ab were positive (titres: 1:128 and 1:64). Other autoimmune encephalitis/paraneoplastic/connective-tissue Abs and infective/malignancy screens were negative. After 5-days high-dose methylprednisolone with steroid taper, power and cognition began improving. CSF parameters and meningeal enhancement resolved when repeated after 1-month. She started mycophenolate, further improving at 3-months follow-up. .
Conclusions:: We report the first case of COVID-19 encephalitis preceding anti-GFAP meningoencephalomyelitis, supported by characteristic imaging-findings and steroid-responsiveness. We postulate COVID-19 and adenoviral infections immunologically precipitated anti-GFAP astrocytopathy.
COVID-19 INFECTION WITH ANTI-BASAL GANGLIA ANTIBODY-POSITIVE MOVEMENT DISORDERS AND PRESENCE OF SARS-COV-2 IN CEREBROSPINAL FLUID

Fan Cheng, Ker Tang
Hull University Teaching Hospitals NHS Trust, Department Of Neurology, Kingston upon Hull, United Kingdom

Background and Aims:: Movement disorders have been reported in COVID-19 infection, although underlying mechanisms are poorly-defined.

Methods:: We describe a case of COVID-19 with reversible myoclonus, dystonia and Parkinsonism associated with positive anti-basal ganglia antibodies (ABGA) and SARS-CoV-2 in cerebrospinal fluid (CSF), improving post-immunotherapy.

Results:: A man, 42, was admitted with cough, fever and positive SARS-CoV-2 nasal PCR without desaturation. Symptoms improved with supportive management. On Day 5, he developed jaw and faciobrachial myoclonus with involuntary sudden brief jaw, face and upper limbs jerks without seizure markers. He had no Parkinsonism at this point. Septic, metabolic, toxic and hypoxic causes were excluded. MRI head and electroencephalogram were unremarkable. Myoclonus continued daily despite multiple anti-epileptics. He developed gradual progressive cervical, bilateral hand and laryngeal dystonia from Day 9. Repeat MRI showed bilateral caudate and putamen T2 hyperintensities. CSF showed leukocyte 8/mm^3, protein 0.9g/dL, glucose 3.1mmol/L and negative viral PCR including SARS-CoV-2. Myoclonus and dystonia continued. Over the next 2-weeks, he developed bilateral bradykinesia and rigidity. DaTscan showed bilaterally reduced striatal tracer-uptake. Repeat CSF showed leukocyte 17/mm^3, protein 0.8g/dL, glucose 2.5mmol/L and positive SARS-CoV-2 PCR. Serum ABGA was positive. Anti-DNaseB, anti-Streptolysin-O, other encephalitis/paraneoplastic antibodies, metabolic/heavy-metal/malignancy screen, and Parkinsonism/dystonia genetic panel were negative. Given ABGA-positivity and mild CSF inflammation, he received high-dose methylprednisolone and, subsequently, intravenous immunoglobulin. Myoclonus, dystonia and Parkinsonism resolved over 5-months.
Conclusions: We report the first case of COVID-19 with ABGA-positive movement disorders and CSF SARS-CoV-2 presence, without hypoxia, suggesting cerebral entry of SARS-CoV-2 could induce movement disorders by precipitating ABGA-positive autoimmune encephalitis, which improves post-immunotherapy.
PHANTOMSIA AS A RARE NEUROLOGICAL MANIFESTATION IN PATIENT INFECTED WITH COVID-19: A CASE REPORT

Septi Rahmy, Catur Setianto, Badrul Munir
Universitas Brawijaya, Neurology, Malang, Indonesia

Background and Aims:: SARS-CoV-2 is a new strain of coronavirus, responsible for respiratory illness known as the COVID-19 pandemic, which has spread to several countries worldwide. Numerous otolaryngologists reported sudden event of anosmia or hyposmia as one of the symptoms of COVID-19 disease. Phantosmia often undetected because it only diagnosed through the patient's history. The diagnosis often missed because these symptoms were not specific.

Methods:: Man, 39-years old, presented with a 7-day history of chill and fever of unknown cause with no other symptoms, nor had a history of travels abroad. Rapid Test SARS Antibody examination was negative on the fourth day after his fever symptom with laboratory result was leukocytopenia and slight thrombocytopenia and diagnosed as Dengue fever. The chest x-ray examination result is pneumonia, which performs after 7-days of fever and after 1-day of dry cough. The fever's symptoms did not resolve even though he had fluid therapy and antibiotics. He began to complain about olfactory hallucination seven days from his fever symptom, which he always smelled of bitter medicine, and complained about shortness of breath, especially when he was doing activity even just for walking. His nasopharyngeal and oropharyngeal swab after ten days of the symptoms was positive.

Results:: His symptom of fever, dry cough, and olfactory hallucination wholly resolved after two weeks since initial symptoms without taking any specific medication.

Conclusions:: There are many other diseases has symptom like COVID-19. Here, we reported phantosmia as rare neurological manifestation in patient infected with COVID-19. The mechanism of phantosmia needs further study.
Background and Aims:: The competition model of the COVID19 virus and effector cells without and with vaccination is a two-cell interaction model that takes the form of a non-linear system of differential equations. The presence of vaccination may affect the behavior of the number of both cell populations. Based on the above problems, this study aims to analyze the stability of the equilibrium point of the differential equation model system and determine the dynamics of effector cells by the COVID19 virus without and with vaccination. But before that, in order to know the origin of the formation of the model, the model of the process of attacking the COVID-19 virus on the body's immunity will be analyzed.

Methods:: This study uses library research by presenting scientific reasoning arguments that describe the results of the literature review and the results of the researchers' thinking regarding the problem of the COVID19 virus model and effector cells.

Results:: The results of this study indicate that the difference in parameter values causes differences in the stability of the infection-free equilibrium point, but remains stable for the infected equilibrium point in the model without vaccination. Meanwhile, the presence of vaccination, with a fairly small value, has a significant effect on the behavior of both of them.

Conclusions:: And several types of vaccinations and changes in parameter values formed varied viral behavior, namely the logistic model and the chaotic model.
CEREBRAL VENOUS THROMBOSIS WITH NEW ONSET THROMBOCYTOPENIA AFTER ASTRazeneca’s VACCINE IN A PATIENT WITH A POSSIBLE AUTOIMMUNE DISEASE – A CASE REPORT

Miguel Miranda¹, Alexandre Fernandes², Sandra Sousa¹, Fernando Pita¹, Cátia Carmona¹, Vera Montes¹
¹Hospital de Cascais Dr. José de Almeida, Department Of Neurology, Alcabideche, Portugal, ²Hospital de Cascais Dr. José de Almeida, Physical Medicine And Rehabilitation Unit, Alcabideche, Portugal

Background and Aims:: Cases of cerebral venous sinus thrombosis (CVST) after Sars-Cov-2 vaccination, presenting with vaccine-induced immune thrombotic thrombocytopenia (VITT) have been reported in patients receiving ChAdOx1 nCoV-19 (AstraZeneca/Oxford) and Ad26.COV2.S (Janssen/Johnson&Johnson) vaccines.

Methods:: A case of a 27-year-old woman diagnosed with VITT related CVST is presented.

Results:: A 27-year-old female patient with asthma and eczema, chronically medicated with prednisolone, was admitted at the emergency department due to a left cervical and temporal pulsatile headache, worsening on Valsalva maneuver, without focal neurological deficits or papilledema. Initial laboratory work-up showed mild thrombocytopenia and a CT venography revealed a CVST of the left transverse and sigmoid sinuses and left jugular vein. The patient was started on anticoagulation and transferred to the Neurology ward for clinical vigilance, where she was further diagnosed with a pulmonary embolism. Additional work-up revealed a positive HLA-B51/B52 test and elevated C3/C4 levels, pointing to a possible autoimmune disease. Notwithstanding, further anamnesis revealed a first inoculation with ChAdOx1 nCoV-19 vaccine 10 days before headache onset, suggesting a VITT related CVST, later confirmed by a positive ELISA test for detection of PF4/heparin antibodies.

Conclusions:: In the era of vaccination against COVID-19, the presence of classical risk factors for CVST should not rule out an eventual diagnosis of VITT-related CVST. Correct and early identification of this clinical entity is vital for guiding therapeutic approaches, with direct implications over choice of acute and chronic anticoagulant drugs (non-heparin drugs preferably) and thrombocytopenia management (with immunoglobulin if persistent and severe).
NEUROLOGICAL MANIFESTATIONS OF COVID-19; A NARRATIVE REVIEW

Etedal Ibrahim¹, Ramah Hassan², Elmuntasir Salah³, Khabab Mohamed Ahmed⁴, Mohammed Eltahier Omer⁵
¹Al-Neelain University, Faculty Of Medicine, Khartoum, Sudan, ²International University of Africa, Faculty Of Medicine, Khartoum, Sudan, ³National Ribat University, Faculty Of Medicine, Khartoum, Sudan, ⁴University of Khartoum, Faculty Of Medicine, Khartoum, Sudan, ⁵Gadarif University Faculty of Medicine and Health Sciences - Sudan, Medicine, Omdurman, Sudan

Background and Aims:: Many studies done during this pandemic revealed several neurological manifestations related to coronavirus disease 2019 or COVID 19 infection. The aim of this narrative review is to discuss the neurological manifestations and complications of COVID-19 disease.

Methods:: Data were retrieved from: PubMed, Scopus, Science direct in addition to manual search using Google scholar from December 2019–May 2020. Keywords were used in the search such as COVID-19; Neurological manifestations; Cranial nerves; Motor system.

Results:: Neurological manifestations and complications are common and increase with the severity of the respiratory involvement. It ranges from 34% to reach 80% in some studies. It involves the central and peripheral nervous system leading to cranial nerves palsies and limbs paralysis.

Conclusions:: Neurological complications of COVID-19 is an important determinant for the severity and mortality of patients. The virus can lead to Headache, Convulsion, Mental and Psychic changes, Delirium and Insomnia (the most affected cranial nerve is the olfactory nerve leading to anosmia), Stroke (mainly infraction), Encephalitis, Meningitis, Guillain-Barre Syndrome, Relapse of Multiple Sclerosis and Transverse Myelitis.
IMPACT OF COVID-19 RELATED DELAYS OF BOTULINUM TOXIN INJECTIONS ON THE QUALITY OF LIFE OF PATIENTS WITH DYSTONIA OR SPASTICITY

Yvonne Teuschl, Michaela Pinter
Danube University Krems, Department For Clinical Neuroscience And Preventive Medicine, Krems, Austria

Background and Aims:: Botulinum toxin A (BoNT-A) is considered a safe and effective treatment for spasticity and dystonia. Individual interinjections intervals are critical for the maintenance of the effect. In Austria, BoNT outpatient clinics were shutdown from November to December 2020 during COVID-19 control measures, leading to rescheduling of BoNT-A injections. This survey aimed at investigating the influence of injection delays on symptoms, physical functioning and quality of life (QoL) of the affected patients.

Methods:: Between April and June 2021, 31 outpatients (20 females, mean age: 63.7 ± 12.2 years) treated ≥12 months at the BoNT outpatient clinic Horn (Austria) and experiencing ≥2 weeks injection delays completed a structured face-to-face questionnaire.

Results:: Indications were dystonia (35.5%), spasticity (41.9%) and hyperhidrosis (3.2%). Injections were delayed by 10 weeks (median, range: 2-15). Muscle cramps increased in 94% of patients with spasticity, muscle contractions in 91% of those with dystonia, pain in 9% and 59% for dystonia and spasticity, respectively. Overall, 79% reported functional worsening, and reduces in QoL by 61% ± 17 (mean ± SD). The impact on QoL correlated with the subjective global improvement induced by BoNT-A (Rs:0.676; p<0.001). For 76%, long-term assurance of BoNT-A therapy was very important, and 79% felt their patient rights not respected.

Conclusions:: COVID-19 related delays in BoNT-A injections illustrate the importance of this therapy for symptom relief, functional outcome and QoL in patients suffering from movement disorders. BoNT-A therapy is essential and has to be guaranteed even in circumstance such as the COVID-19 pandemic.
THE EFFECT OF VIRTUAL LEARNING ON SEIZURE CONTROL AMONG EPILEPSY PATIENTS IN SAUDI ARABIA

Bashaer Alharbi¹, Muruoj Almaghrabi¹, Amal Alkhotani², Moayad Iskandar¹, Wejdan Alshehri¹, Doaa Baashar¹, Abdulaziz Alnemari¹
¹Umm alquraa university, Mbbs, Makkah, Saudi Arabia, ²Umm alquraa university, Internal Medicine, Makkah, Saudi Arabia

Background and Aims:: The COVID-19 pandemic has resulted in multiple precautions to control the infection. One of which is transforming student’s schools into virtual classrooms. This study aimed to determine the effect of virtual learning in seizure control among epilepsy patients.

Methods:: This is an online-based cross-sectional study that performed between 17 February to 27 June 2021 among patients with epilepsy who attend virtual learning classes. We included all patients aged between 12 to 30 years and living in KSA.

Results:: A total number of 70 patients were included in the study. The participants’ gender was nearly equally distributed between the two groups with females predominant (51%). Before the pandemic of COVID-19, only seven patients reported an average number of times of seizures experienced per year, while during the pandemic of COVID-19, the number were increased to 14 patients. More than have of the patients reported an increased levels of anxiety and stress due to the pandemic (43, 61.4%), and forty patients have complained of sleep disturbances due to the pandemic of COVID-19 (57.1%).

Conclusions:: Virtual learning has increased the seizure frequency in a subset of patients with photosensitive epilepsy as they are spending more time on devices.
IMMUNIZATION RELATED FOCAL NEUROLOGICAL SYNDROME AFTER CORONAVAC VACCINATION

Nijasri Suwanwela¹, Naruchorn Kijpaisalratana¹, Supatporn Tepmongko², Pongpat Vorasayan², Chutibhorn Charinnarong¹, Jaturon Tantivatana², Wanakorn Rattanawong¹, Sirigunya Roongruang¹, Tatchaporn Ongphichetmetha¹, Wasan Akarathanawat⁴, Aurauma Chutinet¹
¹Chulalongkorn Stroke Center, King Chulalongkorn Memorial Hospital, Chulalongkorn University, Neurology, Bangkok, Thailand, ²Chulalongkorn University, Radiology, Bangkok, Thailand, ³Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, Chulalongkorn Stroke Center, Bangkok, Thailand, ⁴King Chulalongkorn Memorial Hospital, Chulalongkorn Stroke Center, Bangkok, Thailand

Background and Aims:: We report patients with focal neurological symptoms after receiving inactivated virus vaccine, CoronaVac (Sinovac Biotech, China).

Methods:: Patients who reported acute focal neurological syndrome to the hospital post vaccination surveillance program were studied.

Results:: Among 13,194 individuals who received first doses and 4,064 second doses of the CoronaVac, 49 (0.37%) reported focal neurological symptoms. Patients were age 24-48 years and 90% were female. Unilateral sensory disturbance was the most frequent symptom (92%). 66% occurred at the same side of injection. The sensory symptoms typically started in the hand and progressed to ipsilateral arm and face and/or leg. Four patients had significant hemiparesis on physical examination. Headaches were reported in 61%. Onset of symptoms was within 24 hours after vaccination in 70% and within 7 days in all. Symptom duration most commonly was for 2-4 days and resolved within 2 weeks. Of the 49 cases, 8 presented to the emergency department and received further investigations. MRI and MRA of the brain were normal in all 8 patients. Regions of hypoperfusion and concurrent smaller regions of hyperperfusion contralateral to the symptomatic side on brain SPECT imaging were seen in all studied cases while symptomatic.

Conclusions:: We propose the term Immunization Related Focal Neurological Syndromes (IRFN) for this novel clinical entity. The transient nature of the symptoms, progressive sensory impairment involving the typical areas of migraine aura together with abnormal findings on SPECT suggest cortical spreading depression as a contributing mechanism of this syndrome. Further investigations are required to understand the pathophysiology of this condition.
CEREBRAL AMYLOID ANGIOPATHY – RELATED INFLAMMATION AFTER COVID 19 VACCINATION: CASE OR CAUSALITY?

Francesco Rossato\textsuperscript{1}, Gianmarco Gazzola\textsuperscript{1}, Valentina Carlucci\textsuperscript{1}, Antonio Bisogno\textsuperscript{1}, Stefano Crivellari\textsuperscript{1}, Stefano Mozzetta\textsuperscript{1}, Federica Boso\textsuperscript{2}, Annachiara Cagnin\textsuperscript{3}

\textsuperscript{1}Neurology Clinic, Department Of Neuroscience, Padova, Italy, \textsuperscript{2}A.P.S.S. Trento, Neurology, Trento, Italy, \textsuperscript{3}University of Padova, Padova Neuroscience Center, Padova, Italy

Background and Aims:: Cerebral amyloid angiopathy (CAA) is characterized by microangiopathy with increased susceptibility to hemorrhages. Some patients may develop an inflammatory form presenting with focal deficits, seizures and alterations of vigilance (CAA-related inflammation episodes-CAA-ri). To report on clinical and biological findings of a case of CAA-ri after Covid 19 Tozinameran vaccination.

Methods:: CSF exam and brain MRI were done.

Results:: A 77 year-old male with recent brain hemorrhage in an established probable CAA presented to ER for fever and confusional state 14 days after Tozinameran first dose vaccination. Neurological examination found the patient alert, confused, with hypertonia and action tremor but no meningeal signs. Blood investigations revealed inflammation without microbiological findings. CSF study showed increased proteins, lymphocytic pleocytosis (122 cells/\textmu L) and mirror pattern. CSF Beta42 amyloid level was reduced (158 ng/L), t-Tau level increased. ApoE haplotype resulted E3/E4. The patient had refractory convulsive status epilepticus. MRI confirmed known subacute occipital hemorrhage, multiple microbleeds and occipito-parietal and frontal white matter vasogenic oedema. After a diagnosis of probable CAA-ri, high dose steroid therapy was started followed by clinical improvement and CSF normalization. Anti SARS CoV 2 antibodies were found in serum and CSF before and after steroid therapy.

Conclusions:: Following Tozinameran vaccine, a patient with probable CAA developed a systemic inflammation with neuroimaging signs of CAA-ri and persisting positive CSF anti-spike protein antibodies. We suggest that systemic inflammation evoked by anti-COVID vaccination may have induced CAA-ri in a patient with subacute intracerebral hemorrhage. Cross-reaction of anti-spike antibodies with endothelial antigens in amyloid microangiopathy should be further studied.
NEUROLOGICAL MANIFESTATIONS IN PATIENTS WITH COVID 19 AFFECTED WITH BLACK FUNGUS "MUCORMYCOSIS" : INDIA

Kunkala Lavanya1, Radhakrishna Pedapati2, Shankar Venkatasubramanian1,2, Sundar Shanmugam1,2, Philo Hazeena1,2
1SRI RAMACHANDRA INSTITUTE OF HIGHER EDUCATION AND RESEARCH, Neurology, CHENNAI, India, 2Sri Ramachandra Institute of Higher Education and Research, Neurology, Chennai, India

Background and Aims:: TO INVESTIGATE VARIOUS NEUROLOGICAL MANIFESTATIONS IN PATIENTS WITH COVID 19 AFFECTED WITH MUCORMYCOSIS
Methods:: METHODS : We analysed details of patients with mucormycosis and covid 19, admitted in Sri Ramachandra hospital, chennai from june1, 2021 to July 10, 2021 who developed various neurological features. We collected and analysed demographic features, severity of covid, comorbidities, treatment received, neurological manifestations that were present.
Results:: RESULTS: Overall, 22 cases of mucormycosis have been reported in covid patients, of which 11 cases had various neurological manifestations. Analysis showed most commonly affected were males (7(63.6%), preexisting diabetes was present in (9(81%)) cases. Various neurological features included were intracranial bleeds (2(18.2%)), orbital involvement(5(47%)), stroke(3(27.3%)), PRES(Posterior reversible encephalopathy) (1(9.1%)), cerebritis(2(18.2%)), cavernous sinus thrombosis(2(18.2%)). Surgical debridement was done in 7 patients(63%) , 2 patients died (18.2%) and 2 patients (18.2%)
discontinued the treatment.
Conclusions: Mucormycosis have been reported more from India. Mucormycosis in COVID 19 patients associated with various neurological features, due to direct invasion and systemic inflammatory syndrome. Conclusion in our study was, majority of patients had orbital apex syndrome, followed by stroke. Patients with intracranial bleed and large vessel stroke had fatal outcome. Early surgical intervention had good outcome. Patient who had moderate to severe pneumonia received anticoagulation, in spite of it, some developed stroke and treating intracerebral bleed cases was quite challenging. Further studies with larger number of patients and with control groups should be done to understand the interplay between covid 19 and mucormycosis and resulting neurological syndromes.
WORSENING OF NEUROPSYCHIATRIC SYMPTOMS AFTER SIX MONTHS FROM THE ACUTE COVID-19 INFECTION IN 1183 SUBJECTS

Beatriz Amorim Da Costa, Clarissa Yasuda, Fernando Cendes, Italo Aventurato
University of Campinas, Department Of Neurology/neuroimaging Laboratory, Campinas, Brazil

**Background and Aims:** Little is known about the longitudinal evaluation after COVID-19 infection. Here, we longitudinally evaluated a large group of recovered patients to analyze the changes of systemic and neuropsychiatric symptoms.

**Methods:** We collected self-reported symptoms (twice) from 1183 patients (79% women, the median age of 41 years [range 12-77]) with confirmed Covid-19 diagnosis (1046 (88%) domiciliary treatment, 50 (4%) intensive care and 87 (7%) infirmary treatments). We conducted a longitudinal analysis, comparing the proportion of symptoms between two interviews. The analyses were performed with in-house Python scripts.

**Results:** The median interval between diagnosis and the first interview (V1) was of 75 days [range 15-395]). The median interval between the V1 and second form filling (V2) was 101 days [range 30-261]. Only 9% reported being asymptomatic on V2. Between the V1 and V2, there was an increased proportion of self-reporting fatigue (49% to 55%), memory problems (43 to 55%), motor difficulties (10 to 33%), headache (30 to 42%), and insomnia (1 to 21%), anxiety (1 to 42%), depression (1 to 19%), cardiac problems (1 to 13%), and abnormal sexual desire (0 to 22%). Some symptoms remained stable: hyposmia (27%), dysgeusia (23%), and sleepiness (36%). There was a reduction of some symptoms, including musculoskeletal pain (7 to 1%) and shortness of breath (12 to 0%).

**Conclusions:** As expected, shortness of breath improved. However, this group of patients (mostly non-hospitalized) presented worsening neuropsychiatric symptoms. Multimodal investigation with neurophysiological tests and neuroimaging will help to clarify the neural substrates of these symptoms.
MOTOR SKILLS DYSFUNCTION AND FATIGUE PERSIST AFTER MILD INFECTION BY SARS-COV 2

Maria Julia Mendes, Fernando Cendes, Clarissa Yasuda, Lucas Scardua Silva, Marina Alvim, Italo Aventurato, Mateus Henrique Nogueira, Rafael João, Beatriz Amorim Da Costa

1University of Campinas, Department Of Neurology/neuroimaging Laboratory, Campinas, Brazil, 2State University of Campinas, Neurology Department, Campinas, Brazil, 3State University of Campinas (UNICAMP), School Of Medical Sciences, CAMPINAS, Brazil

Background and Aims:: Although neuropsychiatric manifestations have been reported after COVID-19, little is known about fine motor difficulties after mild infection. We evaluate fine motor impairment, fatigue, depression, anxiety and somnolence after COVID-19.

Methods:: We applied the 9-hole peg and the "box and blocks" tests to fine motor skills; and Hanoi tower test to evaluate executive functions. Individuals answered the Beck Depression Inventory (BDI), Beck Anxiety Inventory (BAI), Chalder fatigue questionnaire (CFQ) and Epworth sleepiness Scale (ESS). We used SPSS26 with Mann-Whitney U-test to compare variables between groups and partial correlations to correlate the continuous variables.

Results:: We evaluated 23 subjects recovered from COVID-19 (after 4 months from diagnosis) (16 women; median of 39 years)) and 35 healthy controls (23 women; median 33 years) balanced for sex (p=0.8), age (p=0.3) and education (p=0.6). COVID group presented excessive sleepiness (ESS, median 10 points (range 0-18)), and fatigue (CFQ, median 18 points (range 0-32)). Fatigue correlated with depression symptoms (r=0.5; p=0.018), with anxiety (r=0.49; p=0.021), and with sleepiness (r=0.4; p=0.06). COVID group was slower on the 9-Hole Peg Test for dominant (p=0.004) and non-dominant hands (p=0.002), and performed poorer on Box and blocks test (p=0.047). They were slower on the Hanoi Tower test with 3 pieces (p=0.04).

Conclusions:: We identified persistent neurological symptoms (mainly fatigue and somnolence) motor slowness and difficulties in patients with mild infection and without hospital treatment. Fatigue associated with other neuropsychiatric symptoms. The longitudinal evaluation and neuroimaging correlations in a larger sample may clarify the duration of deficits and the associated cerebral abnormalities.
Background and Aims:: The ongoing Covid-19 pandemic has led to a lot of deaths worldwide and has been responsible for major pulmonary as well as extra-pulmonary complications. Recently, mucormycosis has come up as an important epidemic in Covid recovered immunosuppressed patients in India. It has mainly been attributed to steroid use during Covid illness and particularly in diabetic individuals. While classical presentation includes headache, nasal crusting, orbital cellulitis and multiple cranial nerve deficits, varied unusual presentations are also witnessed. One such interesting case is discussed.

Methods:: A 51 year old diabetic male underwent treatment for Covid-19 illness. After around 20 days of discharge from hospital, he developed complaint of diplopia. Examination revealed nasal crusting, mild tenderness over left cheek with left sided lateral rectus palsy with no other cranial nerve involvement.

Results:: MRI revealed orbital soft tissue thickening, inflammation of ethmoid, maxillary and sphenoid sinuses with extension of abnormal soft tissue till left superior orbital fissure. Nasal endoscopic biopsy confirmed mucormycosis. Patient was successfully managed with liposomal amphotericin B and surgical debridement.

Conclusions:: Rhino-orbital-cerebral mucormycosis is an important recent complication of COVID-19 infection which can manifest with unusual presentations like isolated lateral rectus palsy.
POST COVID-19 RHINOCEREBRAL MUCORMYCOSIS PRESENTING WITH STROKE

Shubham Dubey, V Ramakrishnan, C Mutharasu
MMCH & RI, Department Of Neurology, Kanchipuram, India

Background and Aims:: COVID-19 may present with a variety of clinical features and complications like pulmonary thromboembolism, acute myocardial infarction, arrhythmias, acute stroke and other secondary infections. Mucormycosis is a dangerous invasive fungal infection characterized by vascular invasion, thrombosis and necrosis of tissues. We report an interesting case of COVID-19 infection, who developed rhinocerebral mucormycosis during the course of illness.

Methods:: A 90 year old female got admitted for treatment of COVID-19 illness. During the course of her stay, she developed left hemiparesis with left upper motor neuron (UMN) type facial palsy. This was preceded by left sided facial pain, nasal discharge and crusting.

Results:: CT head and paranasal sinuses was done which showed right MCA territory acute infarct with few hyperdense areas in left maxillary sinus with obliteration of left maxillary ostium suggestive of fungal sinusitis. Biopsy of paranasal sinuses was done which showed broad, ribbon-like non-septate hyphae consistent with mucormycosis. Surgical debridement was done and antifungals were given.

Conclusions:: Mucormycosis is an emerging important complication of COVID-19 infection. Prompt diagnosis of this life-threatening condition is needed for early initiation of treatment for improved survival.
DIAGNOSIS OF THROMBOSIS OF CEREBRAL VESSELS AND VENOUS SINUSES IN PATIENTS WITH MAXILLOFACIAL COMPLICATIONS AFTER COVID-19

Dilnoza Bobamuratova¹, Shukhrat Boymuradov¹, Alibek Kazimov², Yokubjon Kurbanov¹
¹Tashkent Medical Academy, Otolaringology & Stomatolgy, Tashkent, Uzbekistan, ²“Profmedservis” clinic, Maxillofacial Surgery, Tashkent, Uzbekistan

Background and Aims:: It is known that with Covid-19, blood clotting increases, the coagulopathy is the cause of thrombosis of the vessels, also of the brain, face. Diagnostics of thrombosis of cerebral vessels and venous sinuses in patients with maxillofacial complications after Covid-19

Methods:: In the multidisciplinary clinic of the Tashkent Medical Academy, 78 patients were diagnosed with thrombosis of the cavernous sinus, osteomyelitis of the upper jaw. The average age of patients was 60 ± 8 years, of which 41 were women (51.3%) and 37 were men (48.7%). All patients underwent MSCT / MRI of the brain with angiography

Results:: MRI imaging aids in the identification of thrombosis, either through direct visualization of a thrombus/filling defect in the cavernous sinus, or through indirect signs including proptosis, dilation of drainage tributaries, and abnormal strengthening of the dura, which well demonstrated in contrast-enhanced studies. According to analysis, thrombosis of A. oftalmica in 60% (p≤0,05)(Fig. 1.2)
thrombosis of the cavernous sinus 22% (Fig. 3), thrombosis of the A. Maxillaris
A. Sphenopalatina) 7%, narrowing of the internal
Carotid artery 24% of cases ... In addition, orbital lesion, which is indicated by abnormal orbital fat density by signal intensity, is well indicated along with other features such as narrowing of carotid artery, intraparenchymal abnormalities such as cerebral infarction, empyema, meningitis, cerebritis, and abscess.

Conclusions: CT / MRI shows the presence of heterogeneous and asymmetric defects, tributary thrombosis, dura mater sinuses, and cerebral veins, which is important to this condition, deciding on the need for anticoagulation and surgical treatment.
Guillain Barre Syndrome and Subsegmentary Pulmonary Embolism Associated to SARS COV 2 Infection. Case Report and Review of Current Literature.

Andrea Rodriguez Herrera¹, Max Linares², Samantha Rivas², Indira Contla², Diego Cafaggi², Mario Rojas³, Jose Juarez², Ana Hernandez Gallegos⁴

¹La Salle University, Internal Medicine, Ciudad de México, Mexico, ²La Salle University, Internal Medicine, Mexico City, Mexico, ³Nuevo Sanatorio Durango, Neurology, Mexico City, Mexico, ⁴Nuevo Sanatorio Durango, Internal Medicine, Mexico City, Mexico

Background and Aims:: There’s emerging evidence on the association of GBS with SARS-CoV-2 infection. Neurotropism by coronavirus has been documented as well as various neurological manifestations such as encephalitis, stroke, encephalopathy and peripheral nerve disease.

Methods:: A 67-year-old male, no comorbidities presents three weeks prior to admission with fever, cough, taste and smell disturbances, myalgias, asthenia, clumsy hand movements and progressive lower limbs weakness. 15 days prior to admission: difficulty swallowing, diaphoresis. At admission: breathing difficulty and palpitations. Glasgow 13 E4 V5 M4, bulbar compromise, bradylalia, diminished gag reflex, sternocleidomastoid and trapezius weakness, MRC scale upper and lower limbs: proximal 3/5 distal 2/5, generalized areflexia, distal diffuse hypoesthesia

Results:: Ferritin 519 LDH 236 D Dimer >10,000 Hgb 19 WBC 11590 L 12% N 80% P 241,000 CK 111 CK MB 17. Chest CT: COVID19 pneumonia, CO-RADS 3. Pulmonary angiography: Posterior right lower lobe segmental PE. Scores: PESI 108, Geneva 10. SARS-COV-2 PCR negative, SARS-COV-2 IgG/IgM: Positive. Lumbar puncture not performed due to PE. Met Asbury GBS criteria, HUGHES 4, mEGOS 8 at admission, EGRIS 4. Progression of ascending symmetrical bilateral flaccidity with respiratory failure requiring mechanical ventilation for 10 days, tracheostomy and gastrostomy were performed. Discharged at day 60 with muscle strength recovery, upper limbs 4/5 and lower limbs 3/5, Sensitivity recovery, diminished lower limb reflexes. Therapy: Enoxaparin 60mg every 12h, Immunoglobulin 0.4mg/kg/day/5 doses. Discharge HUGHES 3.
Conclusions: GBS is caused by an anomalous response of the immune system to an infectious agent. This particular patient presents with a GBS associated with SARS-COV-2 infection and PE.
EFFECT OF INACTIVATION MODE ON SECOND-GENERATION ANTIPSYCHOTIC TDM UNDER COVID-19

Yan Zhang, Jing Ding
Xi'an Mental Health Center, Pharmacy Lab, Xi'an, Shaanxi, China

Background and Aims:: To study the effect of heating at 56 °C for 30 min on the monitoring of five second-generation antipsychotics (aripiprazole, quetiapine, risperidone, clozapine and olanzapine).
Methods:: After the plasma samples were treated with protein precipitation, the concentrations of aripiprazole, quetiapine, risperidone, clozapine and olanzapine were determined by LC-MS method before and after inactivation of plasma quality control substances and clinical samples. Bland-Ahman method was used to evaluate the difference between the inactivated and non-inactivated determination results, and the correlation between the determination results was analyzed by Passing-Bablok regression and linear regression.
Results:: The five second-generation antipsychotics could remain stable after inactivation, and there was no significant difference in matrix effect before and after inactivation of serum quality control substances, and the concentration percentages before and after inactivation were all within the normal range.
Conclusions:: the combination of 56 °C for 30 min inactivated protein precipitation treatment method of plasma samples of LC - MS determination made pp, quetiapine, risperidone, clozapine, olanzapine plasma concentration is affected, the determination results have good consistency and relevance, o can be used to make pp, quetiapine, risperidone, clozapine, olanzapine routine therapeutic drug monitoring.
LOW STROKE ADMISSIONS AND MORTALITY DURING COVID-19 LOCKDOWN; LINK TO AIR QUALITY INDEX

Sajid Hameed Shaikh
Aga Khan University, Stadium Road, Karachi., Neurophysiology Department, Consulting Clinic-1, Karachi, Pakistan

Background and Aims:: Air pollution is one of the leading causes of mortality and morbidity. It accounts for 21% of stroke-related deaths and about 170 million disability-adjusted life years. Both long-term and short-term exposures to air pollution are markedly associated with ill health effects. COVID-19 pandemic and the subsequent global lockdown have led to a reduction in air pollution levels.

Methods:: All admitted stroke patients during the five months of lockdown from March to July 2020 are included and compared to the number of stroke admissions during the same five months in the previous two years, i.e. 2019 and 2018. The patients were further stratified into gender, stroke type, and mortality rates. Available online air quality index (AQI) of Karachi, Pakistan was also accessed.

Results:: 182 stroke patients were admitted compared to the 355 and 299 stroke patients admitted during the same months in 2019 and 2018, respectively. No gender or stroke type differences were noticed. However, a disparity was seen in the mortality rates (2.74% in 2020 vs 8.16% in 2019 and 12.04% in 2018). The average AQI of Karachi in the last nine days of May 2019 was 1.6 times higher than the same period in 2020 (102.11 vs 64.33). Similarly, average AQI was higher in 2019 compared to 2020 during the months of June (87.13 vs 73.03) and July (89.64 vs 65.09).

Conclusions:: Approximately 50% reduction in stroke cases is noticed during the lockdown. One of the suggested contributing factors is a reduction in air pollution, although further studies are needed to confirm.
PARANEOPLASTIC NEUROLOGICAL SYNDROME ASSOCIATED WITH ANTI-AMPHIPHYSIN ANTIBODIES MISLEADE THE DIAGNOSIS OF CREUTZFELDT-JAKOB DISEASE

Giuseppe De Santis, Lucia Merico, Angelo Zenzola, Antonio Carbone, Gerardo Ciardo
"Card. G. Panico" Hospital, Department Of Neurology, Tricase (LE), Italy

Background and Aims:: Creutzfeldt-Jakob disease (CJD) and neurological paraneoplastic disease may present similar clinical features. Establishing the correct diagnosis has practical relevance in the care management for these patients. The objective of the present study is to determine how the diagnosis of Creutzfeldt-Jakob disease may be differentiated from several rapidly progressive neurological syndromes.

Methods:: Here we describe a case of Creutzfeldt-Jakob disease associated with anti-amphiphysin antibodies. In July 2016 a 66-years old female patient was admitted to our acute neurological department with progressive walking disturbances for two months. Neurological examination showed cerebellar syndrome characterized by gait, truncal and limbs ataxia, tremor towards the end of upper limbs movements, absent deep tendon reflexes, bilateral nystagmus with impaired up- and lateral gaze.

Results:: Biochemical and serological investigations were unremarkable except of the presence of anti-amphiphysin autoantibodies both in serum and cerebrospinal fluid (CSF) (Yo, HU, Ri, PNMa2, CRMP5 autoantibodies were negative). Brain MRI (Fig. 1) and electroencephalogram (Fig. 2) reported findings suggestive for CJD. Cerebrospinal fluid was unremarkable but protein 14.3.3, tau-protein (> 2350 pg/ml) and RT-QuIC test were positive. Prion protein gene studying revealed heterozygosity Met/Val polymorphism at codon 129. After plasmapheresis, despite the removal of anti-amphiphysin autoantibodies the patients progressed to deteriorate and she died 5 months after symptoms onset. Brain autopsy confirmed sporadic sCJD.
Conclusions:: To our best knowledge, this is the first report about the association of anti-amphiphysin antibodies and CJD and the coincident of onconeural autoantibodies seems not to correlate with sCJD pathogenesis.
ACUTE ONSET GENERALIZED WEAKNESS: A RARE VARIANT OF MULTIFOCAL MOTOR NEUROPATHY

N. T. Wijesinghe¹, P Manokaran¹, Sp Mohotti², S Bandusena¹, A Fernando¹, K Gunaratne²
¹National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka, ²National Hospital of Sri Lanka, Clinical Neuro-electrophysiological Department, Colombo, Sri Lanka

Background and Aims:: Multifocal motor neuropathy (MMN) is a slowly progressive asymmetrical focal demyelinating neuropathy. We present a patient consistent with acute multifocal motor neuropathy with conduction blocks (AMMNCB).

Methods:: A 69 year old woman presented with acute onset generalized weakness in 2009, 2013, 2016 and responded to intravenous immunoglobulins (IVlg). In 2020, she presented with acute onset bilateral lower limb weakness, evolved very rapidly causing generalized weakness within a day. She had asymmetrical lower limb weakness and symmetrical upper limbs involvement with global areflexia. Cranial nerves, sensory, autonomic or sphincter involvement was not present.

Results:: Nerve conduction study (NCS) disclosed wide spread motor CBs in non-compressive sites with diffuse F wave abnormalities with normal sensory conduction. Serology revealed positive anti-GM1 antibodies without cyto-protein dissociation in csf done after 2 weeks. She responded to IVlg. Follow up NCS after a month revealed persistent motor CBs despite clinical improvement.

Conclusions:: Acute motor axonal neuropathy (AMAN), acute inflammatory demyelinating polyradiculopathy (AIDP) and chronic inflammatory demyelinating polyradiculopathy (CIDP) were considered in this clinical context. Definite CB is not usually seen in AMAN apart from rare form, AMAN with reversible conduction block variant. AIDP shows definite CBs which disappear with IVlg and also upper limb sensory involvement with sural sparing is classical. Sensory sparing and motor CBs observed alone without any other features of demyelination are against the diagnosis of CIDP. Therefore, the presentation with acute onset generalized weakness with above described electrophysiological evidence and serological confirmation are consistent with AMMNCB, a rare presentation of MMN.
PROGRESSIVE MYELOPATHY DUE TO TREATABLE INTRACRANIAL DURAL ARTEROVENOUS FISTULAE

Amedeo De Grado¹, Chiara Manfredi², Elisabetta Gropppo¹, Marco Scarabello³, Luca Valvassori², Federica Cencini¹, Francesca Bartesaghi¹, Alessandra Erbetta⁴, Elisa Ciceri⁴, Tommaso Bocci¹,⁵, Alberto Priori¹,⁵, Emma Scelzo⁴
¹III Clinical Neurology Unit, Department Of Health Sciences, University Of Milan, Polo Universitario Ospedale San Paolo, Asst Santi Paolo E Carlo, Milan, Italy, ²III Clinical Neurology Unit, Department Of Health Sciences, University Of Milan, Polo Universitario Ospedale San Paolo, Asst Santi Paolo E Carlo, Milan, Italy, ³ASST Santi Paolo e Carlo, Department Of Neuroradiology, Milan, Italy, ⁴Fondazione IRCCS Istituto Neurologico Carlo Besta, Head Imaging Radiology And Interventional Neuroradiology, Milan, Italy, ⁵“Aldo Ravelli” Center for Neurotechnology and Experimental Brain Therapeutics, Department Of Health Sciences, International Medical School, University Of Milan, Milan, Milano, Italy

Background and Aims:: Intracranial dural arteriovenous fistulae (DAVF) can rarely have a perimedullary venous drainage (Cognard Type V) resulting in an aggressive but potentially treatable and reversible myelopathy. Early diagnosis is often challenging.

Methods:: A 52 years-old man has come to our attention 8 months after the onset of a stepwise progressing myelopathy. Neurological examination showed quadriaparesis, ankle clonus, urinary retention and bowel incontinence along with abolished pain, temperature and statokinesthetic sensations below D10.

Results::

Spinal MRI showed cervical spinal cord swelling with T2-weighted sequences hyperintensity (previously interpreted as expression of myelitis - the patient was started on steroids without significant improvement) and tortuous flow-voids behind the spinal cord, expression of congested medullary veins. Brain MRI
demonstrated T2/FLAIR hyperintense lesions in the pons and in the right cerebellar hemisphere with focal hemosiderin deposits along the inferior cerebellar sulci. CSF analysis (with isoelectrofocusing), serum autoantibodies, a total body CT were negative. Brain angiography revealed a DAVF of the inferior wall of the straight sinus draining into the perimedullary venous plexus. Despite the successful endovascular treatment, the patient showed a mild improvement of the strength in his upper limbs but after 6 months he was still confined to the wheelchair.

**Conclusions:** DAVF are often under-recognized and misdiagnosed as infective myelitis, transverse myelitis, Multiple Sclerosis, Neuromyelitis Optica Spectrum Disorder or neoplasms. We thus suggest performing an angiography of cerebral vessels in the few cases of progressive myelopathy in which routine tests for myelitis are inconclusive, closely looking for perimedullary flow voids and/or serpiginous vessels on spinal cord MRI.
HYPNOSIS AND VIRTUAL REALITY IN PSYCHOTHERAPY

Salvatore Bellissima
ASP 3, Catania, Italy, Psychology, Catania, Italy

Background and Aims:: Hypnosis and virtual reality are already used separately in psychotherapy, but the associated effect of both techniques increases the influence of each, as virtual reality favours the narrowing of the field of consciousness induced by hypnosis, amplifying its effects: it is an all-encompassing experience that all users report as very engaging. It has been observed that the trance sometimes develops even without induction.

Methods:: The work is conducted through the use of a visor and the induction of the trance after the start of various videos, of varying duration. At the setting of hypnosis (armchair, adequate environmental temperature, attenuation of external stimuli) we add the use of the viewer in which first abstract videos such as geometric representations, lights and colors are transmitted to hinder the projections of the subject, and then concrete videos, depicting naturalistic scenarios associated with brief stimulus stories, used as a metaphor to guide the subject towards more appropriate behavioural styles. The therapist observes simultaneously on another screen what is transmitted by the viewer, so as to gradually follow the subject and accompany him with suggestions. The state of trance is maintained and it is not interrupted by the visual and auditory stimuli to which he is subjected.

Results:: At the moment everyone has experienced a drop in anxiety and reinforcement of the ego.

Conclusions:: The work started a few years ago, but the relative effects are encouraging, with the participants who do not develop any idiosyncrasies, but instead they are very satisfied with the experience and motivated.
COVID-19 PANDEMIC IN LOMBARDY: RISK PERCEPTION AND COPING STRATEGIES OF AGING PEOPLE

Claudia Toppo¹, Erika Guastafierro¹, Francesca Magnani¹, Rosa Romano², Carla Facchini³, Rino Campioni³, Ersilia Brambilla³, Matilde Leonardi³
¹Fondazione IRCCS Istituto Neurologico Carlo Besta, Neurology, Public Health, Disability, Milan, Italy, ²Auser, Regionale Lombardia, Milan, Italy, ³University of Milano-Bicocca, Sociology, Milan, Italy

Background and Aims:: During the COVID-19 pandemic, older adults are the segment of the population at higher risk for health and isolation. Exploring aging people needs and reactions to the situation it’s crucial to plan appropriate interventions and supporting strategies. The present study aimed to investigate risk perception and coping strategies in older adults during the COVID-19 pandemic in Italy.

Methods:: 514 people over 65 years, residing in the Lombardy region of Italy, were administered with a structured online interview collecting socio-demographic information, sources of information used, daily actions undertaken to avoid the contagion, risk perception related to COVID-19 and other threats, and coping strategies used to face the situation.

Results:: Risk perception related to COVID-19 was significantly lower than the perceived risk associated with other threats, and it was correlated to the number of sources of information used. Most of the sample relied on avoidant coping strategies with a tendency to accept the situation by avoiding stressors more than rebelling to the situation with approaching strategies.

Conclusions:: Participants put into action most of the possible behaviors aimed to avoid contracting the COVID-19, showing a tendency in using avoidance strategies. This confirmed that the choice of the best strategy to use depends on the features of the situation a person must face. Regarding risk perception, it is necessary to take into consideration its link with the perception of control: the lockdown condition lets older adults to feel safer and less vulnerable to the virus.
PROGNOSIS OF EARLY ONSET OF ALZHEIMER’S DISEASE UP 6 YEARS IN ADVANCE BY A CONFORMATIONAL VARIANT OF P53 (U-P53AZ)

Simona Piccirella¹, Daniela Uberti², Christopher Fowler³, Paul Kinnon¹
¹Diadem srl, Diadem Srl, Brescia, Italy, ²University of Brescia, Department Of Molecular And Translational Medicine, Brescia, Italy, ³The University of Melbourne, The Florey Institute, Melbourne, Australia

Background and Aims:: Recently, a conformational variant of p53 (U-p53AZ) has been identified as a lead biomarker for Alzheimer’s Disease (AD). A highly sensitive, specific and reliable IP-SACI-MS (described as AlzoSure® Predict) was used to detect U-p53AZ in plasma samples from AD-individuals at different stages of the disease to validate its AD-dementia prognostic value.

Methods:: 262 plasma samples from 225 participants (70y average in age) at different cognitive stages from Australian Imaging, Biomarkers, and Lifestyle (AIBL) retrospective longitudinal cohort were selected. Clinical groups included Cognitively Normal (CN; n=75) and Mild Cognitive Impairment (MCI; n=30) participants not progressed to AD or dementia over 6 years, CN (n=42) and MCI (n=49) who progressed to AD at different follow-up time points over 6 years, and AD (n=18) and other disorders (OD, n=10). AZ 284™ peptide, from U-p53AZ was quantified by IP-SACI-MS method (AlzoSure® Predict).

Results:: Preliminary cutoff of AZ 284™ to predict AD-dementia, were calculated using optimal Youden Index, 95% CI. U-p53AZ prognostic performance to AD-dementia (CDR>0.5) was evaluated by AUC, PPV, NPV and they were >90% for both Subjective Memory Compliants (SMC) (CDR=0) and MCI-non demented (CDR=0.5) progressed to AD (CDR>0.5) in a follow-up period from 1.5y to >6y. U-p53AZ showed an high AUC value =95% to diagnose individuals CDR ≥1, PiB-PetPOS and diagnosed as AD. By a regression model combining U-p53AZ with PiB-Pet data, age/ gender, APOE4 it was demonstrated the covariates didn’t significantly improve U-p53AZ AD-prognostic value.

Conclusions:: This study the U-p53AZ AD-Dementia prognostic value and its utility in the pathway of AD prognosis.
EVALUATION OF BLOOD PRESSURE VALUES IN PATIENTS WITH TRANSIENT GLOBAL AMNESIA: A SINGLE CENTER EXPERIENCE.

Giulia Fiume, Francesco Grillo, Giuseppe Vita, Carmela Casella, Paolo La Spina, Antonio Toscano, Rosa Fortunata Musolino
AOU Policlinico G.Martino, Clinical And Experimental Medicine, Messina, Italy

Background and Aims:: Transient Global Amnesia (TGA) is a syndrome characterized by a sudden anterograde and often a retrograde amnesia lasting less than 24 hours, in absence of other neurological focal signs. Its pathophysiologic mechanism is still unclear, but different hypotheses and trigger factors have been proposed. This study aimed to assess blood pressure values in patients diagnosed with the TGA at admission and at 24 hours after the onset of symptoms and to identify the degree of hypertension during and after the TGA attack.

Methods:: We retrospectively examined data of patients affected by TGA, who were admitted to our center from December 2012 to December 2020. The clinical diagnosis has been based on Hodges and Caplan criteria. BP values have been classified according to 2020 International Society of Hypertension classification.

Results:: We included 54 patients, 24 males (44%) and 30 females (56%). The mean age at the TGA attack was 62.7 years. 31 patients had a history of hypertension and 27 were in pharmacological treatment. Valsalva or Valsalva-like maneuvers were associated with the onset of TGA symptoms only in 3 patients. At admission 18.5% had normal BP values; 1.8% had high normal BP; 29.7% had grade 1 hypertension and 50% had grade 2 hypertension. At 24 hours from the onset of AGT 51.2% had a normal BP; 27.9% had high normal BP; 20.9% had grade 1 hypertension and no one had grade 2 hypertension.
Conclusions:: Our study suggests hypertension as possible TGA trigger factor, but we need more patients to determine its causative role.
THE TREND OF INCIDENCE AND BURDEN OF NEUROLOGICAL DISEASE IN IRAN BETWEEN 1990 AND 2017: BASED ON THE GLOBAL BURDEN OF DISEASE ESTIMATIONS

M. Hossein Harirchian¹, Hedayat Abbastabar², Sama Bitarafan¹
¹Tehran University of Medical Sciences, Iranian Center for Neurological Research, Neurology, Tehran, Iran, ²Advanced Diagnostic and Interventional Radiology Research Center, Tehran University of Medical Sciences, Radiology, Tehran, Iran

Background and Aims:: Neurological disease contributes significantly to morbidity and mortality in different ages and geographic areas around the world. The purpose of the current study was to investigate the incidence and disability-adjusted life years (DALYs) trend of neurological disease in Iran 27 years ago.

Methods:: We used the data of the Global Burden of Disease (GBD) Study to estimate the incidence and DALYs of neurological disease in Iran in different age groups between 1990 and 2017. Age groups were defined into 5 groups including < 5 years, 5-14 years, 15-49 years, 50-69 years, and ≥ 70 years.

Results:: The incidence number of neurological diseases from 1990 to 2017 increased from 7.5 million to more than 12 million and the incidence rate grew as much as 1400 per 100000 populations in Iran. Totally, headache, epilepsy, and Alzheimer's disease were the most common neurological diseases according to incidence and had the most values of DALY in Iran. The highest incidence and DALY of neurological disease was observed in the age group of 15-49 years.

Conclusions:: This study showed that the incidence and burden of neurological diseases had a dramatic increasing trend 27 years ago in Iran. Consequently, it is necessary to investigate the causes of the growing trend in future studies.
Background and Aims:: SSPE is chronic progressive encephalitis affecting children and young adults which usually presents with cognitive decline and behavioural changes followed by periodic myoclonic jerks, seizures, vision loss and ataxia. High degree of suspicion is required as the presentation can be variable and can have many differentials. We aim to study various presentations of SSPE.

Methods:: Retrospective study was done to analyse various presentations in patients diagnosed with SSPE as per modified Dykens criteria from a tertiary care centre over a period of 2 years (1st January 2018-31st December 2020).

Results::

![EEG showing slow sharp wave generalised quasiperiodic discharges](image-url)
6 cases of SSPE were identified. Case 1 - 22 months old presented with subacute history of ataxia, multifocal myoclonus and developmental regression. Gradually myoclonus worsened to involve trunk and developed drop attacks. Case 2 - 17 years boy presented with single episode of seizure. Case 3 - 25 years female with 5 months gestation presented with sub acute vision loss followed by progressive cognitive decline, behavioural changes, Parkinsonism, Dystonia and stimulus sensitive myoclonus. Case 4 - 28 years female presented with rapidly progressive cognitive decline and behavioural changes. Case 5 - 32 years male presented with history of myoclonic jerks and dropping of objects. Gradually developed progressive behavioural changes and cognitive decline and became vegetative. Case 6 - 9 year old child presented with faciobrachial seizures (myoclonic jerks) and scholastic backwardness.

**Conclusions::** SSPE can manifest with varied presenting complaints. Also, Results of EEG, MRI and CSF examination can change during the disease course. Therefore, high degree of suspicion is required for early diagnosis of this challenging entity.
HUFFER’S NEUROPATHY: A CASE OF ACUTE-ONSET TETRAPARESIS MIMICKING GUILLAIN-BARRÉ SYNDROME.

Valentina Tommasini¹, Mauro Catalan¹, Lucia Antonutti¹, Giulia Mazzon¹, Marta Cheli¹, Mariana Ridolfi¹, Tiziana Cavallaro², Salvatore Monaco³, Massimo Bovenzi⁴, Paolo Manganotti¹
¹University of Trieste, Neurology Unit, Department Of Medical, Surgical And Health Sciences, Cattinara University Hospital, Asugi, Trieste, Italy, ²Università degli Studi di Verona, Department Of Neurosciences, Biomedicine, And Movement Sciences, Verona, Italy, ³University of Verona, Neurosciences, Biomedicine, And Movement Sciences, Verona, Italy, ⁴University of Trieste, Clinical Unit Of Occupational Medicine, Department Of Medical, Surgical And Health Sciences, Trieste, Italy

Background and Aims:: N-hexane is a well-known neurotoxic agent causing chronic peripheral neuropathy with predominant motor involvement. Originally described as a result of occupational exposure in various industrial settings, only few reports exist on polyneuropathy due to recreational inhalation of glues and solvents.

Methods:: We herein report an unusual case of a 40-year-old woman presenting to the emergency department with acute-onset tetraparesis due to inhalation of chemical solvents containing n-hexane. The clinical picture, a mild albumin-cytologic dissociation and the demyelinating features on nerve conduction study initially mimicked the presentation of Guillain-Barré syndrome (GBS), but the patient failed to respond to intravenous immunoglobulin treatment and plasma exchange. Diagnosis of hexane-induced neuropathy was then confirmed by means of sural nerve biopsy, showing axonal enlargement with secondary retraction and thinning of the myelin sheath (Figure 1 and 2).
**Results:** We highlight the challenges faced in the differential diagnosis of acute-onset polyneuropathy as well as the electrodiagnostic and neuropathologic features of hexane neuropathy.

**Conclusions:** N-hexane polyneuropathy should be considered a possible differential diagnosis of GBS in patients with poor response to appropriate treatment and a history of substance abuse.
QUALITY CONTROL IN BIOBANK SAMPLES: THE IMPACT OF PRE-FREEZING STORAGE TIME AND TEMPERATURE ON GENE EXPRESSION OF BLOOD COLLECTED IN EDTA TUBES

Paola Valentino\textsuperscript{1,2}, Serena Martire\textsuperscript{1,2}, Fabiana Marnetto\textsuperscript{1,2}, Luca Mirabile\textsuperscript{1,2}, Antonio Bertolotto\textsuperscript{1}
\textsuperscript{1}Neuroscience Institute Cavalieri Ottolenghi, Neurobiology Unit, Orbassano, Italy, \textsuperscript{2}Neurologia - Centro di riferimento regionale sclerosi multipla (CRESM), Neurobiology Unit, Orbassano, Italy

Background and Aims:: Blood gene expression profiling is taking hold in research, diagnosis and monitoring of human diseases. Blood is vulnerable to pre-analytical variables that may alter gene expression ex vivo. Although RNA stabilization systems have been shown to reduce such influence, traditional EDTA tubes are still widely used since they are less expensive and enable to study specific leukocyte populations. Nevertheless, studies on the impact of short bench times on gene expression are lacking.

Methods:: Nine EDTA tubes were collected from 10 healthy donors. One tube from each donor was immediately processed for mononuclear cell isolation, while the others were kept at either 4°C or room temperature for 2, 4, 6 and 24 hours. RNA yield and quality and the expression level of 4 housekeeping (B2M, CASC3, GAPDH, HPRT1) and 8 target genes (CD14, CD19, CD20, IL10, MxA, TNF, TNFAIP3, NR4A2) were evaluated.

Results:: RNA yield, quality and integrity did not vary significantly with time and temperature. B2M was the most stable housekeeping gene, while the others were increasingly influenced by storing time, especially at 4°C. Even when normalized to B2M, the expression level of some target genes, particularly TNFAIP3 and NR4A2, was highly affected by delays in blood processing at either temperature, already from 2 hours.

Conclusions:: Pre-analytical processing has a great impact on transcript expression from blood collected in EDTA tubes, especially on genes related to inflammation. Storage at low temperature does not prevent gene expression alteration. Standardized procedure of blood collection and manipulation are needed to obtain reliable results.
EAN GUIDANCE FOR DEVELOPING AND REPORTING CLINICAL PRACTICE GUIDELINES ON RARE NEUROLOGICAL DISEASES

Background and Aims:: Rare diseases affect up to 29-million people in the EU, and almost 50% of them affect the nervous system or muscles. Delays in diagnosis and treatment onset, and insufficient treatment choices are common. Clinical Practice Guidelines (CPGs) may improve the diagnosis and treatment of patients and optimize care pathways, delivering the best scientific evidence to all clinicians treating these patients. We set recommendations for developing and reporting high-quality CPGs on rare neurological diseases (RNDs) within the European Academy of Neurology, through a consensus procedure.

Methods:: A group of 27 experts generated 93 initial items that were evaluated through a two-step
Delphi-consensus procedure and a face-to-face meeting. The final list of items was reviewed by an external-review group of 58 members.

**Results:** The consensus procedure yielded 63 final items. Items are listed according to the domains of the AGREE instruments and concern scope and purpose, stakeholder involvement, rigour of development, and applicability. Additional items regard reporting and ethical issues. Recommendations are supported by practical examples derived from published guidelines and are presented in two tables: 1. items specific to RND-CPGs, and general guideline items of special importance for RNDs, or often neglected; 2. items for guideline development within the EAN.

**Conclusions:** This guidance aims to provide solutions to the issues specific to RNDs. We consider this consensus document, produced by many experts in various fields, to serve as a starting point for further harmonization and increasing the quality of CPGs in the field of RNDs.
CARPAL TUNNEL SYNDROME IN CLEANERS AT GENERAL HOSPITAL FOR STATE SPECIAL SERVANTS

Munguntsetseg Tumurbaatar
General hospital for state special servants, Neurology, Ulaanbaatar, Mongolia

Background and Aims:: Carpal tunnel syndrome (CTS) is caused by pressure on the median nerve. When the median nerve is compressed, the symptoms can include numbness, tingling and weakness in the hand and arm. The anatomy of your wrist, health problems and possibly repetitive hand motions can contribute to CTS. Anamnesis and clinical examination are important for diagnosis, but electrophysiological tests play a key role in confirming the diagnosis and determining the severity of the neurological damage. The reason for conducting this study is that there is no study in our country that confirms CTS by electrophysiological analysis and identifies severe and mild disorders. We aimed to diagnose CTS among hospital cleaners through anamnesis, clinical and electrophysiological tests, identify risk factors, and determine the degree of nerve damage based on clinical criteria and electrophysiological tests.

Methods:: All female floor cleaners of General Hospital for State Special Servants were enrolled. Clinical and electrophysiological severity of CTS were evaluated with standardized scales and symptoms were assessed with self-administered Boston Questionnaire; risk factors and durations of current and previous rise occupations were recorded. Univariate analysis of risk factors was performed in workers with and without CTS.

Results:: Out of a total of 28 cleaners, mean age 39.2 years (23-56 years) were enrolled in the study; 9(32.14%) had CTS (diagnosis based on clinical and electrophysiological findings). Univariate analysis showed that cleaners with CTS were older and higher BMI of high risk of developing carpal tunnel syndrome than those without CTS.

Conclusions:: These results indicate a high occurrence of CTS in cleaners.
CLINICAL CASE STUDY: PIECING THE PUZZLE OF A PRESSURE ULCER.

Aisling Egan
University Hospital Limerick, Elderly Medicine/geriatrics, Dooradoyle, Limerick, Ireland

**Background and Aims:** Patient male, 49 years, presented to the Emergency Department (ED) with fever and lethargy (3/7) on a background history of Spina bifida with myelomeningocele and paraplegia. On examination of the patient, a severe sacral pressure ulcer was noted. As noted by Moore et.al., pressure ulcers are common. The mean prevalence is estimated at 16% in acute and long stay settings in Ireland (Moore, Johanssen, & van Etten, 2013). Pressure ulcers are a particular complication for patients with myelomeningocele (Plaum, Riemer, & Frøslie, 2006).

**Methods:** After examination of the patient, a number of differential diagnosis were noted including trauma, osteomyelitis, moisture associated dermatitis and unstageable pressure ulcer. The patient was diagnosed with a grade 4 pressure ulcer.

**Results:** The orthopaedics and plastics MDTs assessed the patient and debridement of the wound was done by the orthopaedic team and grafting of the wound by plastics. The infectious disease team advised that the patient be put on, long-term antibiotics.

**Conclusions:** With the combined efforts of the MDT in Ballinasloe hospital, the MDT in GUH and the community MDT, this patient had a medically successful outcome and was discharged home.
NAPROXEN-INDUCED ASEPTIC MENINGITIS

Rajarajan Rajendran¹, Senthilvelmurugan Veeraputhiran², Saranya Manickavasagam², Chitralekha Sivaprasakam², Jos Jasper⁴
¹Kauvery Hospital, Neurology, Tiruchirappalli, India, ²Kauvery Hospital, Radiology, Tiruchirappalli, India, ³Kauvery Hospital, Critical Care, Tiruchirappalli, India, ⁴Kauvery Hospital, Kauvery Brain & Spine Centre, Tiruchirappalli, India

Background and Aims:: Drug-induced aseptic meningitis is an uncommon side effect of certain widely prescribed drugs. Several non-steroidal anti-inflammatory drugs (NSAIDs) have been linked to aseptic meningitis, especially in patients with immune dysfunction. Drug-induced aseptic meningitis is difficult to diagnose, and infectious causes must be ruled out. NSAIDs should be considered in the differential diagnosis in evaluating meningitis of unclear etiology.

Methods:: Case Report

Results:: A 33-year-old young woman with a history of mixed connective tissue disease had been suffering from headaches for the past five days and had developed altered sensorium one day before admission. She had been self-medicating for arthralgia with naproxen (250 mg/day) for 6 months and had recently increased the dose to 500 mg/day 4 days prior to admission. She was restless and irritable in the emergency room. Her vital signs were within normal limits. Neurological examination revealed severe neck stiffness. CSF analysis showed lymphocytic pleocytosis, low sugar and elevated protein levels. An empirical treatment of ceftriaxone and vancomycin was initiated. CSF viral, bacterial and fungal studies yielded negative results. MRI brain was unremarkable. Based on her CSF profile, her history of mixed connective tissue disease and the temporal relationship between naproxen use and symptom onset, her symptoms were thought to be due to Naproxen-induced aseptic meningitis. The antibiotics were stopped after 3 days. She was discharged on her seventh day of admission without any neurological sequelae.

Conclusions:: The clinician should keep the diagnosis of drug induced aseptic meningitis in the differential diagnosis, when there is a temporal association with a culprit drug.
IS THERE AN IMPORTANT EFFECT OF THE TYPE OF POLYNEUROPATHY ON RESULTS OF ELECTROMYOGRAPHY AND PAIN

Nilufer Cetisli Korkmaz¹, Tuba Can Akman², Mehmet Duray³, Furkan Bilek⁴, Cagdas Erdogan⁵
¹Pamukkale University, School Of Physical Therapy And Rehabilitation, denizli, Turkey, ²Pamukkale University, School Of Physical Therapy And Rehabilitation, DENİZLİ, Turkey, ³Suleyman Demirel University, Faculty Of Health Sciences, Department Of Physiotherapy And Rehabilitation, Isparta, Turkey, ⁴Fırat University, School Of Health, ELAZIĞ, Turkey, ⁵Pamukkale University, Department Of Neurology, Medical School, DENİZLİ, Turkey

Background and Aims:: The patients with polyneuropathy (PNP) have serious complaints such as sensory, motor, and pain problems. The type of PNP may also be an important factor on these symptoms in patients with PNP. The aim of this study was to research the presence of difference in terms of sensory, motor and pain outcomes in patients suffered from PNP dependent to diabet, chemotherapy or other causation.

Methods:: Thirty-six patients suffered from PNP (12 female, 24 male; 12 PNP dependent to PNP, 10 PNP dependent to chemotherapy, 14 PNP dependent to other reason) were included in our study. Participants' nerve conduction characteristic including amplitude and velocity and pain assessment including pain levels and severity of neuropathic pain were assessed by Electromyography, Visual Analogue Scale (VAS), Leeds Assessment of Neuropathic Symptoms and Sign (LANSS), respectively.

Results:: The mean age of participants was 58.33 ± 15.29 years. When the groups were compared in terms of electromyography and pain evaluation results, It was seen that the groups had similar properties in terms of nerve conduction amplitude, rate, pain level and severity (p>0.05).

Conclusions:: It was determined that the type of PNP has no important effect on nerve conduction and pain properties in patients with PNP. The current findings indicate that similar treatment may be applied in managing these symptoms in all type of PNP.
Background and Aims:: Dural arteriovenous malformation (AVM) is rare but is the commonest vascular malformation encountered in the spinal cord. They cause progressive tetraplegia or paraplegia and significant morbidity. Spinal AVMs are treatable. We present a case of an acute cord compression in a young teenage girl due to a spinal AVM.

Methods:: An 18 year old girl presented with acute onset right lower limb weakness and left lower limb numbness with urine retention. Examination revealed wasted but spastic right lower limb with absent proprioception. Muscle power was MRS grade 0 on the right side and MRS grade 4 on the left. She had a sensory level at T2 on the left for pain and temperature, a band of pain and temperature loss in right side from T2 to T10. Plantar was extensor in right side, equivocal in left side. Other systemic examinations were normal.

Results:: Her MRI pan spine showed a dural arteriovenous malformation (AVM) extending from T6 to T10 with cord oedema up to T1 level bilaterally. Her MRI brain did not show any vascular anomalies. Her haematological evaluation was normal. She was treated with intravenous steroids and was subjected to a digital subtraction angiogram (DSA). The DSA confirmed the AV malformation with a feeding artery arising at T11. She underwent endovascular coil embolization and made a remarkable recovery following the intervention.

Conclusions:: Dural AV malformation is a rare but a treatable cause of progressive tetraplegia or paraplegia even in the young. Clinical presentations can be varied. Early diagnosis and appropriate intervention significantly reduces morbidity.
Background and Aims:: Globally heat stress is the silent health peril which gain attention when the body means of handling its thermoregulatory function starts to fail. The present study has been designed to investigate the nephroprotective potential Green Tea Extract (GTE) & Hesperetin in Heat Stress Induced Nephropathy (HSN).

Methods:: There were five groups in the present study and each group was comprised of six animals. Lacca mice was exposed to heat (39.5 degree C for 30 min, 2 time’s day) with DNP for 10 days. After 30 minutes’ exposure to heat mice were returned to their cages. This cycle was repeated twice a day for 10 days except the weekend. Renal histology, Biochemical parameters (BUN & sCr) & Oxidative parameters (TBARS, SOD, GSH) were performed. The experimental protocol reg. No. is USPS/IAEC/CPCSEA/2020/Protocol No. 49.

Results:: Pretreatment with GTE & Hesperetin (50mg/kg) for 10 days' results nephroprotection. It was noted that GTE and Hesperetin significantly restored the oxidative stress which was assessed by TBARS, SOD and GSH. Moreover the nephronal damage was assessed by histopathological examinations. However, the combination of GTE and Hesperetin showed the synergetic nephroprotection by decreasing oxidative stress followed by upregulation of eNOS in HSN.

Conclusions:: The nephroprotective potential of GTE & Hesperetin may be due to upregulation of eNOS followed by downregulation of ROS. The combination of GTE & Hesperetin showed additive effect which may be good potentiate for pre-clinically as well as clinically upcoming research specially targeting on Vascular endothelial dysfunctioning.
POSSIBLE POTENTIAL OF GLIMEPIRIDE WITH ORAL AMINO ACIDS IN TYPE 2 DIABETIC RATS

Nihal Nihal, Nikhil Jolly, Gurfateh Singh
UNIVERSITY SCHOOL OF PHARMACEUTICAL SCIENCES, RAYAT-BAHRA UNIVERSITY, SAS NAGAR, PUNAB, INDIA 140104, Pharmacology, KHARAR-SAS NAGAR (MOHALI), India

Background and Aims:: Diabetes Mellitus (DM) is a major threat to global public health since the number of diabetic patients is rapidly increasing worldwide. According to International Diabetes Federation, DM will affects about 592 million by 2035. The present study has been designed to investigate the possible potential of Glimepiride with oral amino acids in type 2 DM

Methods:: Six groups were employed and each group comprised six Rats. DM induced by high fat diet (HFD) followed low dose of Streptozotocin (STZ) (35mg/kg i.p). Type 2 DM was assessed by measuring the blood glucose level. Moreover, the body weight, triglycerides, total cholesterol, high density lipoprotein, very low density lipoprotein and oxidative stress were also measured.

Results:: HFD-STZ showed significantly increased in blood glucose, body weight, triglycerides, total cholesterol, low density lipoprotein, very low density lipoprotein and oxidative stress in the present study. Moreover, HFD-STZ treated rats significantly decreased the high density lipoprotein and antioxidant enzyme. Treatment with Glimepiride (1mg/kg and 2 mg/kg, i.p.) and amino acids (250mg/kg, p.o) for 21 days produced the antidiabetic potentials dose dependently in diabetic rats. Moreover, treatment significantly increased the reduced form of glutathione, superoxide dismutase and high density lipoprotein level dose dependently.

Conclusions:: The oral amino acids in combination with Glimepiride showed synergistic antidiabetic may be due to increase the activity of insulin receptor tyrosine kinase and reducing the conductance of ATP sensitive K+ channels by acting on pancreatic β cell membrane may be a novel therapeutic approach for the management of type 2 DM.
Background and Aims:: Sensory ganglionopathy (SNN), is a disease of dorsal root ganglia and usually associated with paraneoplastic syndromes (anti-Hu associated), Sjögren syndrome, chemotherapeutic agents and paraproteinemia. Spinal MRI shows dorsal column involvement mimicking subacute combined degeneration of the cord. We present 3 cases of confirmed SNN with characteristic MRI findings.

Methods:: Case 1: A 17-year-old girl presented with difficulty in walking, recurrent falls, hand and right-facial numbness for 2 months. Case 2: A 50-year-old male presented with lower limb weakness, numbness and fecal incontinence for 4 years duration. Case 3: A 43-year-old female presented with recurrent falls and lower limb numbness for 1 year. All had areflexia with flaccid paralysis and impaired proprioception, vibration with a positive Romberg’s test. NCS were suggestive of sensory ganglionopathy and MRI spine (Figure 1) revealed dorsal column hyperintensity without contrast enhancement. Serum B12 level was 113pmol/l (140-650) in case 1. All biochemical investigations including paraneoplastic antibodies, Hep B, C serology, Anti SSA/SSB antibodies and chest/abdominal/pelvic imaging were negative in all three patients.

Figure 1: Axial (A, B) and sagittal (C) images showing characteristic pattern of symmetric bilateral hyperintense signals in the dorsal columns affecting the cuneate fasciculus as well as gracile fasciculus without contrast enhancement.

<table>
<thead>

</thead>
<tbody>
<tr>
<td>Case 2</td>
<td>Idiopathic sensory ganglionopathy with pudendal neuropathy causing fecal incontinence</td>
</tr>
<tr>
<td>Case 3</td>
<td>Idiopathic neuronopathy</td>
</tr>
</tbody>
</table>

Table 1: Final diagnosis
Results: SNN is a treatable peripheral nerve disorder which presents with sensory ataxia. Early diagnosis and treatment is of paramount importance to prevent disability. Underlying sinister pathologies like malignancy needs exclusion. NCS can be inconclusive initially making the spinal MRI very important in making an accurate diagnosis.

Conclusions: It is important to include sensory neuronopathy/ganglionopathy as a differential diagnosis in dorsal column lesion in addition to vitamin B12 and copper deficiency.
LONG-TERM DYNAMIC CHANGES OF NMDA RECEPTORS FOLLOWING AN EXCITOTOXIC CHALLENGE

Manuela Bomba¹, Marco D’Aurora², Valentina Gatta², Marco Onofri¹, Stefano Sensi¹, Alberto Granzotto³
¹University “G. d’Annunzio” of Chieti-Pescara, Department Of Neuroscience, Imaging, And Clinical Sciences (dnisc), Chieti, Italy,
²University “G. d’Annunzio” of Chieti-Pescara, Department Of Psychological, Health And Territorial Sciences (disputer), Chieti, Italy,
³UC Irvine, Neurobiology And Behavior, Irvine, United States of America

Background and Aims:: Excitotoxicity is the neuronal death produced by the aberrant and sustained activation of N-methyl-D-aspartate receptors (NMDARs) and the neurotransmitter glutamate. NADPH-diaphorase neurons [also known as nNOS (+) neurons] are a subpopulation of aspiny interneurons, largely spared in excitotoxic conditions. Previous findings from our group have indicated that, unlike nNOS (-) cells, nNOS (+) neurons lack the production of reactive oxygen species (ROS) in response to NMDAR activation. This is a critical divergent step in the excitotoxic cascade; however, additional mechanisms underlying the reduced vulnerability of nNOS (+) neurons to NMDAR-driven neuronal death have not been explored.

Methods:: This study evaluated the functional, genetic, bioinformatics, and molecular events related to NMDAR activity in cultured striatal nNOS (+) neurons challenged with an excitotoxic stimulus.

Results:: nNOS (+) neurons exhibited fewer but fully operational NMDARs, nNOS (+) cells undergoing chronic exposures to excitotoxic hits failed to respond to NMDA after a second challenge produced 16-20 hours after. The downregulation was limited to the distinct and selective activation of NMDARs. No changes were found in response to AMPA agonists or depolarizing conditions set to activate voltage-sensitive calcium channels. This data set indicates that nNOS (+) neurons exhibit highly dynamic responses upon variable excitotoxic conditions.

Conclusions:: Our results indicate intriguing plasticity levels and the presence of dynamic control of NMDAR activity in the subset of striatal neurons that show the abundance of nNOS synthase.
Background and Aims:: Cerebral amyloid angiopathy (CAA) is a cause of spontaneous intracerebral hemorrhage, occurring in normotensive elderly subjects. Ischemic micro or macro lesions or vascular leukopathy are frequently found on magnetic resonance imaging (MRI), supporting this hypothesis of CAA.

Aim: To report that CAA can be revealed by mild head trauma in a normotensive elderly subject.

Methods:: We report the case of a patient who was treated in the neurology department of the Principal military hospital Tunis. He consulted for heaviness of the left hemisphere and dysarthria following a head injury.

Results:: A 72-year-old man, with a history of dyslipidemia, was referred to our hospital for left hemispheric heaviness with dysarthria of abrupt onset 3 days after a mild head injury. Clinical examination showed fluctuant temporoparietal disorientation, dysarthria, total and proportional left hemiplegia including the face and left hemi hypoesthesia. CT scan showed 2 intracerebral hematomas, one in the right fronto-parietooccipital and the other in the right temporal regions. FLAIR weighted images revealed a grade 2 Fazekas leukoaraiosis. T2* weighted images in addition to the 2 intracranial hematomas, 2 subcortical microbleeds of left occipital location.

Conclusions:: CAA is a cause of hematoma and ischemic stroke. In normotensive elderly patients, the possibility of a CAA-related hemorrhage should be considered in the presence of a lobar or subcortical hematoma.
Background and Aims:: Hypertrophic pachymeningitis (HP) is a rare entity characterized by inflammation and thickening of the dura mater leading to varied manifestations. We sought to characterize the clinico-radiological spectrum and treatment outcomes in hypertrophic pachymeningitis.

Methods:: It was a single center retrospective study conducted at a tertiary care center in India. A keyword search of “pachymeningitis” was carried to identify patients diagnosed to have HP admitted during the period of 2015 to 2020. Details of clinical, laboratory, radiological, treatment profile and outcomes both clinical as well as radiological were gathered.

Results:: A total of 31 patients were identified out of which 18 were classified to have idiopathic HP. Mean age of onset of symptoms was 40.6±15.7 years. Headache was the most common symptom irrespective of etiology (27/31, 87%). Majority of the patients had multiple cranial nerves palsies (26/31, 83.8%). Oculomotor nerve was the most common nerve involved (21/31, 67.7%). Presence of constitutional symptoms and extra neurological involvement was seen in secondary HP. On imaging, focal thickening of the duramater was seen in 70.9% of the patients. Cavernous sinus and tentorium cerebelli were the most common sites of involvement (22/31, 70.9%; 18/31, 58.1%). Steroids were given in all but one patient. More than half of the patients (58.1%) had complete resolution of symptoms with treatment.

Conclusions:: Hypertrophic Pachymeningitis is a clinically heterogeneous entity. Headache and cranial dysfunction are the most common symptoms. One should thoroughly evaluate for systemic involvement as it can help to delineate the etiology. Empirical ATT should not be given blindly.
ROLE OF QUERCETIN IN ATTENUATED CARDIO-PROTECTIVE EFFECTS OF ISCHEMIC POST-CONDITIONING IN STZ INDUCED HYPERGLYCEMIC RAT HEART

Daya Luxmi, Priyanka Sen, Gurfateh Singh
UNIVERSITY SCHOOL OF PHARMACEUTICAL SCIENCES, RAYAT-BAHRA UNIVERSITY, SAS NAGAR, PUNAB, INDIA 140104, Pharmacology, KHALAR-SAS NAGAR (MOHALI), India

Background and Aims: The cardio protective effects of Ischemic Post-Conditioning (IPOC) are abrogated in Hyperglycemic condition. The present study has been designed to investigate the effects of Quercetin in abrogated cardio-protective effect of IPOC against I/R injury in hyperglycemic rat heart.

Methods: Six groups were employed in the present study and each group comprised seven animals. The experimental duly approved by IAEC and protocol no. is 50. Hyperglycemia induced by Streptozotocin (50mg/kg/i.p). Quercetin pretreated (100mg/kg/day, orally) for 7 days and Quercetin (10µm) perfused for 8 min in hyperglycemic rat. I/R Injury induced by 30 min global ischemia followed by 120 min reperfusion. Myocardial Injury was assessed by Lactate dehydrogenase (LDH), and creatine kinase isoenzyme (CK-MB), coronary flow rate (CFR) and Infarct size. Moreover, oxidative stress was measured by estimation of TBARS, SOD and reduced form of GSH.

Results: The level of glucose, oxidative stress and myocardial injury were significantly increased and coronary flow rate significantly decreased in hyperglycemic rat heart subjected to I/R. The IPOC afforded cardio-protection in normal rat heart. However, the IPOC mediated cardio-protection against I/R injury was markedly abolished in hyperglycemic rat heart. Quercetin treatment significantly restored the abrogated cardio-protective potentials of IPOC in hyperglycemic rat heart subjected to I/R as assessed in term of reduction in myocardial infarction, TBARS, LDH, CK-MB level, infarct size and increased SOD, GSH and CFR.

Conclusions: Treatment with Quercetin for oral and perfusion markedly restored the cardio-protective potential of IPOC in hyperglycemic rat hearts may be due to the downregulation of NF-kB and over activation of ROS.
RIColinostat induces microtubule acetylation and neurite regeneration in cellular models of diabetic and chemotherapy-induced neuropathy

Daniele Cartelli1, Samanta Mazzetti2, Raffaella Lombardi3, Daniele Cazzato1, Mima Andelic1, Margherita Marchi3, Erika Salvi3, Ilaria D’Amato2, Graziella Cappelletti2, Giuseppe Lauria4

1Fondazione I.R.C.C.S. Istituto Neurologico Carlo Besta, Neuroallogogy Unit, Milano, Italy, 2Università degli Studi di Milano, Biosciences, Milano, Italy, 3Foundation IRCCS Carlo Besta Neurological Institute, Neuroallogogy Unit, Milan, Italy, 4IRCCS FONDAZIONE ISTITUTO NEUROLOGICO CARLO BESTA, Clinical Neurosciences, Milan, Italy

Background and Aims:: Peripheral nerves have unique regenerative capability, but two questions are still unanswered: what are the underlying mechanisms and why do some patients show higher spontaneous nerve fibers regeneration than others. Here we investigated if microtubule posttranslational modifications (PTMs) impact on neuronal regeneration in in vitro models of small fiber neuropathy (SFN) and predict intra-epidermal nerve fibers regeneration density (IENFD) in patients.

Methods:: We used differentiated F11 cells to mimic either diabetic- or chemotherapy-induced neuropathies. We challenged cells with Ricolinostat (ACY-1215), an inhibitor of HDAC6, and evaluated neurites length and microtubule PTMs. Confocal microscopy assay was performed to investigate acetylated and tyrosinated tubulin positive intra-epidermal nerve fibers, reflecting mechanical stress resilient and dynamic microtubules, respectively, in baseline and follow-up skin biopsies from SFN patients.

Results:: In F11 cells, glucose overload or chemotherapy drugs treatment impacted on microtubule organization and induced neurites shortening. Ricolinostat inhibited HDAC6 activity leading to a significant increase of acetylated microtubules, which allowed microtubule regrowth and neurites regeneration. In agreement with these findings, baseline biopsies of SFN patients showing improved follow-up IENFD revealed 2-fold increase of acetylated positive/PGP9.5 negative fibers compared to patients with worsened innervation density.

Conclusions:: Our results show that ricolinostat-induced microtubule acetylation is associated to neurite regeneration in F11 cells and that acetylated positive/PGP9.5 negative skin fibers could predict fiber regeneration in patients. These findings could drive innovative strategies of intervention in which ricolinostat administration can modulate microtubule acetylation and induce neuroprotective effects in diabetic or chemotherapy-treated patients.
CARDIOPROTECTIVE POTENTIAL OF HESPERETIN ISCHEMIC PRECONDITIONING AGAINST ISCHEMIC REPERFUSION INJURY IN RAT HEART

Harveen Kour, Kirti Kaushal, Gurfateh Singh
UNIVERSITY SCHOOL OF PHARMACEUTICAL SCIENCES, RAYAT-BAHRA UNIVERSITY, SAS NAGAR, PUNAB, INDIA 140104, Pharmacology, KHARAR-SAS NAGAR (MOHALI), India

Background and Aims:: Worldwide, Coronary heart disease (CHD) is the leading cause of mortality which reduced the quality of healthy human life. The present study has been designed to investigate the cardioprotective role of hesperetin with ischemic preconditioning (IPC) against ischemic reperfusion injury in rat heart.

Methods:: There was five group in the present study and each group comprises six rat. The protocol was duly approved by IAEC Reg. No. USPS/IAEC/CPCSEA/2020/Protocol No. 47. In Ischemia/Reperfusion (I/R) injury, 30 min of ischemia followed by 120 min of reperfusion produced myocardial injury which diagnosed in terms of elevated level of lactate dehydrogenase (LDH) and creatinine kinase-myocardial band (CK-MB) in the coronary effluent. In addition, the increase level of thiobarbituric acid reactive substances (TBARS), decrease level of superoxide dismutase (SOD) and reduced glutathione (GSH) was the clear indicators of oxidative stress.

Results:: I/R Injury induced myocardial damage and oxidative stress by significantly increased LDH, CK-MB, Infarct size, coronary flow rate and oxidative stress. In the present study, IPC comprised four episodes of ischemia followed by reperfusion (5 min each) and treatment with Hesperetin (100mg/kg, oral gavage) showed the cardio-protection which were assessed by reduced release of LDH and CK-MB, Infarct size, coronary flow rate and oxidative stress against I/R injury.

Conclusions:: Treatment with Hesperetin-IPC showed cardio-protective potentials in the present study may via activation of phosphatidyl inositol-3 kinase-Akt/protein kinase B and endothelial nitric oxide synthase.
RESEARCH ON THE MECHANISM OF WUZI YANZONG PILL EXCLUDING FOLIC ACID INTERFERENCE IN THE PREVENTION AND CONTROL OF NEURAL TUBE DEFECTS

Hui Jie Fan1, Zhi Chai1, Chan Juan Yang1, Yan Rong Li1, Meng Ying Sun1, Wu Shuai Xiao1, Xin Liang Wang1, Yi Ru1, Jian Jun Huang2, Jie Zhong Yu3, Bao Guo Xiao4, Cun Gen Ma1,3

Background and Aims:: Wuzi Yanzong Pill (WYP) has a potential prevention effect on neural tube defects (NTDs) Mice, but the mechanism is not clear. To determine the content of FA in WYP, compare the effect of FA and WYP which eliminate the interference of FA and research on its mechanism.

Methods:: LC-MS was used to determine the content of FA in WYP. The pregnant mice were divided into normal group, model group, FA group and WYP group, drug intervention was given at the same time. NTDs model was established by atRA at 7.5 days of pregnancy. The levels of PI3K, Akt, P-Akt, Nrf2, Bax and Bcl-2 were detected by Western Blot.

Results:: Compared with the model group, the neural tubes in FA group, WYP group closed obviously (P<0.05 and P<0.01 respectively), while the apoptosis rate decreased significantly (P<0.05 and P<0.01 respectively). The expressions of p-Akt and Bcl-2 increased after FA treatment (P<0.05 respectively), while the content of Bax decreased (P<0.05). After WYP intervention, the levels of PI3K, p-Akt, Nrf2 and Bcl-2 increased (P<0.01, P<0.01, P<0.01 and P<0.01 respectively), but the Bax showed the opposite trend (P<0.01). The preventive effect of WYP is better than FA.

Conclusions:: WYP which eliminate the interference of FA can effectively reduce the incidence of NTDs, which may be related to the PI3K/Akt signaling pathway. CEREBRAL AMYLOID ANGIOPATHY-RELATED INFLAMMATION DURING BEVACIZUMAB TREATMENT FOR METASTATIC CERVICAL CANCER

Tatiana Koudriavtseva, Svetlana Lorenzano, Vincenzo Anelli, Domenico Sergi, Annunziata Stefanile, Carlo Piantadosi

1IRCCS Regina Elena National Cancer Institute, Department Of Clinical Experimental Oncology, Rome, Italy, 2Sapienza University of Rome, Department Of Human Neurosciences, Rome, Italy, 3IRCCS Regina Elena National Cancer Institute, Department Of Research, Advanced Diagnostics And Technological Innovation, Rome, Italy, 4“San Giovanni-Addolorata” Hospital, Neurology, Roma, Italy

Background and Aims:: Bevacizumab is an anti-angiogenic monoclonal antibody targeting Vascular Endothelial Growth Factor (VEGF). Bevacizumab inhibits cancer angiogenesis fundamental for either cancer development, its exponential growth, or metastatic spread.

Methods:: A 72-year-old woman with metastatic cervical cancer presented a worsening confusional state after 6 cycles every three weeks of chemotherapy (cisplatin, paclitaxel, bevacizumab) and following two maintenance bevacizumab administrations. MRI showed bilateral temporo-parieto-occipital hyperintensity with numerous cortical microbleeds suggestive of a Cerebral Amyloid Angiopathy-Related Inflammation (CAARI).

Results:: Patient’s blood pressure values were normal as well as routine blood tests, autoantibodies, onconeural antibodies, and virology screening. Bevacizumab was interrupted and intravenous methylprednisolone (120 mg/day for 7 days) was started, followed by oral prednisone (25 mg/die with gradual reduction during two weeks) leading to rapid improvement of symptoms and a remarkable reduction of MRI lesions. Gadolinium-enhanced lesions have never been observed on MRIs at any timepoint. The patient resulted to be heterozygote (ɛ3/ɛ4) for apolipoprotein-E ɛ4 that increases the risk of sporadic Cerebral Amyloid Angiopathy (CAA) characterized by beta-amyloid accumulation and fibrinoid necrosis in cerebral vasculature leading to micro/macrohemorrhages and dementia. The subsequent 2-year oncologic follow up was negative for both recurrence and metastasis.

Conclusions:: To our knowledge, this is the first report on CAARI development during bevacizumab treatment. Inhibition of VEGF, which has anti-apoptotic, anti-inflammatory and pro-survival effects on endothelial cells, impair their regenerative capacity and increases expression of proinflammatory genes leading to weakened supporting layers of blood vessels and, hence, to damaged vascular integrity. In our patient, bevacizumab could further increase permeability of cerebral microvasculature likely impaired by an underlying, asymptomatic CAA.
CLINICAL OUTCOME OF YOUNG AND MIDDLE-AGED PATIENTS WITH FIRST-EVER ISCHEMIC STROKE

Georgi Dimitrov¹, Maya Danovska¹, Yoana Simeonova², Emilia Ovcharova¹
¹Neurology Clinic, University Hospital, Pleven, Neurology, Medical University, Pleven, Plevens, Bulgaria, ²Faculty of Public Health, Social Medicine, Medical University, Sofia, Pleven, Bulgaria

Background and Aims:: Prognostic evaluation of ischemic stroke (IS) outcome is of great clinical importance because of the increasing number of young and middle-aged IS patients with unfavorable outcome on the 3rd month. Aim: To assess the outcome of young and middle-aged patients with first-ever IS on the 3rd month

Methods:: A prospective study of 101 patients with first-ever IS, admitted to the Neurology Clinic of University Hospital Pleven from 2019 to 2020 was done. The patients were subdivided into two groups: Group A of young patients aged 18-44 years and Group B middle-aged 45 – 59 years. Clinical outcome was assessed on the 3rd month as favorable (modified Rankin scale; mRs 0-2) and unfavorable (mRs 3-5). The statistical analysis was performed with the Statistical Package for Social Sciences version 24.0.

Results:: Although male gender prevailed in both of the groups, it was not found statistically significant (p=0.060). Middle-aged patients (n=75) had higher rates of risk factors: arterial hypertension (88,0%), diabetes (29,3%), dyslipidemia (65,3%) and smoking (73,9%), but the majority of them (64%) showed favorable outcome (mRs 0-2). Though young patients (n=26) tended to have lower rates of risk factors, 69.2% demonstrated unfavorable outcome on the 3rd month (mRS 3-5), found statistically significant (χ²=3.631, df=1, p=0.003).

Conclusions:: Our data demonstrate a poorer outcome of younger IS patients on the 3rd month compared to the middle-aged ones, that implies the necessity of future studies on some rare risk factors and effective therapeutic prevention.
CLASSIFICATION OF EYE CONDITION BASED ON ELECTROENCEPHALOGRAM SIGNALS USING EXTREME LEARNING MACHINES ALGORITHM (ELM)

Rifaldy Fajar, Sahnaz Putri
Yogyakarta State University, Computational Biology And Medicine Laboratory, Sleman, Indonesia

Background and Aims:: Electroencephalography or EEG signals is a biosignal that is rife in current research topics. EEG signals have many benefits such as the detection of epilepsy, sleep disorders, or input in a computer application. One input that can be detected based on EEG signals is the state of the eye. However, to be used as input in an application a classification with adequate performance is required. Therefore a study was conducted in which one method of learning Artificial Neural Networks, Extreme Learning Machine (ELM) will be implemented to classify eye conditions based on EEG signals.

Methods:: The dataset used to train and test the model is an eye-state dataset donated by Oliver Roesler combined with a dataset from the University of California repository website, IrvineI (UCI). There are seven corpus which consist of EEG recording done to four different people, then one corpus is added, which is a combination of all other corpus.

Results:: From the test results it was concluded that ELM can be used for the classification of eye conditions with an accuracy of 97.95% with training time of only 0.81 seconds if each data is used separately, whereas the merging of the whole dataset only reaches an accuracy of 78.94% with 5.71 seconds training time.

Conclusions:: By getting a model with good accuracy with training time that tends to be fast, the ELM algorithm can be utilized as a Brain-computer Interface by previously conducting training based on the person's EEG signal with a short amount of time to build the model.
Background and Aims:: Transient global amnesia (TGA) is a rare and benign amnesic syndrome. It manifests as a sudden onset of anterograde amnesia that spontaneously resolves within 24 hours. It affects middle-aged people between the fifth and seventh decades of life. This study discussed the proposed mechanisms, clinical and radiological characteristics of TGA.

Methods:: We report the cases of three patients who presented an episode of TGA.

Results:: The three patients were aged 64 years (case 1), 59 years (case 2) and 54 years (case 3). Two of them were males. Their medical history includes depression (case 1 and 2), arterial hypertension (case 2), type-2 diabetes mellitus (case 3). They suddenly developed acute onset of disorientation to time and space but they remained conscious. Their memories prior to these episodes were fully preserved. Accordingly to their families, an emotional trauma had preceded the episode in two cases. Symptoms gradually and spontaneously resolved over the course of 14 hours (case 1) and 6 hours (case 2 and 3). No focal abnormality was noted on neurological examination except for lacunar amnesia. Brain MRI was normal in two patients and revealed hippocampal DWI (diffusion-weighted imaging) lesions in one patient.

Conclusions:: MRI findings can support the diagnosis of TGA and may be particularly valuable in situations of low clinical certainty. It is considered a useful adjunct to the diagnosis of TGA, when performed with a minimum delay of 20 hours.
NEUROFIBROMATOSIS TYPE 1 PRESENTING AS PROGRESSIVE PROXIMAL MUSCLE WEAKNESS: AN UNCOMMON PRESENTATION MIMICKING PROXIMAL MYOPATHY

Kasun Udenika, Bimsara Senanayake, Vithoosan Sahathevan
National Hospital of Sri Lanka, Institute Of Neurology, Colombo, Sri Lanka

Background and Aims:: There are three clinically and genetically distinct forms of neurofibromatosis (NF), NF type 1, type 2 and schwannomatosis. The hallmarks of NF type 1 are the multiple café-au-lait macules and associated cutaneous neurofibromas. There are various causes for generalized muscle weakness in neurofibromatosis. But progressive proximal muscle weakness is rare in NF type 1. We present an unusual case due to neurofibromas in multiple nerve roots and nerve plexuses.

Methods:: A 27 year old female presented with progressive proximal muscle weakness in both lower limb and upper limbs over one year. Her family history was unremarkable. She did not have features of connective tissue disorders or features of endocrine abnormalities. Examination revealed waddling gait, MRC grade 4 proximal muscle weaknesses in both upper and lower limbs without sensory impairment. She has multiple café-au-lait macules on her back and axillary freckles. No cutaneous neurofibromas or iris Lisch nodules were detected.

Results:: Basic blood and urine investigations and the inflammatory markers were within normal values. Serum creatine phosphokinase level was normal. The EMG was normal with no myopathic changes. Her MRI pan spine showed multiple neurofibromas and plexiform neurofibromas involving almost all neural nerve roots in varying sizes including both brachial and lumbosacral plexuses. MRI brain did not show bilateral cerebellopontine angle shwanomas. Her pure tone audiogram was normal.

Conclusions:: NF 1 presenting as progressive proximal muscle weakness without sensory signs mimicking a myopathy is exceptionally rare. Neurofibromas involving the nerve plexuses and roots are the cause and appropriate neuro-imaging confirms it.
TRACE AMINE-ASSOCIATED RECEPTORS AND ADULT NEUROGENESIS

Raul Gainetdinov
St Petersburg State University, Institute Of Translational Biomedicine, St Petersburg, Russian Federation

Background and Aims:: Trace amine-associated receptors (TAARs) are a class of sensory G protein-coupled receptors that detect amines, products of decarboxylation of amino acids. The majority of TAARs (TAAR2-TAAR9) have been described in the olfactory epithelium and considered to be olfactory receptors sensing innate odors. However, there is evidence that one of the members of this family, TAAR5, is expressed also in the limbic areas of the brain receiving projection from the olfactory system and involved in the regulation of emotional behaviors.

Methods:: In this study, we further characterized a mouse line lacking TAAR5 (TAAR5 knockout, TAAR5-KO mice) that express beta-galactosidase mapping TAAR5 expression.

Results:: We found that in TAAR5-KO mice the number of dopamine neurons, the striatal levels of dopamine and its metabolites, as well as striatal levels of GDNF mRNA, are elevated indicating a potential increase in dopamine neuron proliferation. Furthermore, an analysis of TAAR5 beta-galactosidase expression revealed that TAAR5 is present in the major neurogenic areas of the brain such as the subventricular zone (SVZ), the subgranular zone (SGZ), and the less characterized potentially neurogenic zone surrounding the 3rd ventricle. Analysis of neurogenesis by using specific markers doublecortin (DCX) and proliferating cell nuclear antigen (PCNA) revealed a 2-fold increase in the number of proliferating neurons in the SVZ and SGZ of TAAR5-KO mice, but no such markers were detected in mutant or control mice in the areas surrounding the 3rd ventricle.

Conclusions:: These observations indicate that TAAR5 is not just providing olfactory input into limbic brain areas but is also involved in processes related to adult neurogenesis.
AN OBSERVATIONAL ANALYTICAL STUDY OF PATIENTS WITH CEREBRAL VENOUS SINUS THROMBOSIS (CVST) TO IDENTIFY CRITICAL PROGNOSTIC FACTORS IN SOUTH COASTAL STATE OF KARNATAKA INDIA

Sankar Prasad Gorthi1, Sandeep Gurram2, Magith Thambi2, Ashwini Naik2
1Bharati Vidyapeeth (DTU) Medical College & Hospital, Neurology, PUNE, India, 2Kasturba Medical College, Neurology, Manipal, India

**Background and Aims::** Background CVST presents with a wide variety of neurological symptoms in various combinations and has a high mortality up to 50%. Recent advances in neuroimaging and therapeutic interventions have brought it down to 20% AIM To identify critical prognostic factors associated with poor outcome in patients with CVST.

**Methods::** Methods All cases of CVST of both genders and age >18y from July 2015 to July 2020 who were not terminally ill and bed ridden were evaluated at entry point for various risk factors and after 30days for outcome assessment with Modified Rankin Scale (mRs). Outcome is dichotomized applying mRs <3 as good outcome and analyzed with chi Square test or Fischer exact test in a bivariate analysis to identify associated variables.

**Results::** Results A total of 149 subjects were studied and GCS <9(p<0.001), focal neurological deficits (p-0.05), presence of mass effect (p-0.001) and the need for decompressive hemicraniectionomy (p-0.001) were associated with poor outcome. Age, gender, diagnostic delay, seizures at onset, papilledema, parenchymal lesions, deep sinus involvement and multiple sinus thrombosis were not associated with poor outcome.

**Conclusions::** Conclusion In present era, Early diagnosis and therapy of patients with CVST is associated with a favorable outcome in the face of conventional risk factors except four critical factors.
Background and Aims:: People who care for patients affected by neurocognitive disorders are at increased risk of developing stress and burnout. The workload has experienced a notable increase during the pandemic. In our observational study, we assessed the presence of anxiety, burnout and compassion fatigue in caregivers (family members and health professionals (HCW)). We also evaluated the presence of mental disorders as well as anxiety and depressive disorder.

Methods:: We recruited 67 caregivers (41F; 26M; mean age 43.63 years) (family members and health workers) of elderly people in residential rehabilitation facilities or observed in an outpatient office. Observation period: February-March 2021. All caregivers were administered the following scales: ProQoL; CBI. The SAVE-9 scale was used for the assessment of anxiety and work stress in viral pandemic.

Results:: The data obtained showed a significant increase in all mean scores of anxiety and burnout in pandemic periods. Family caregivers have higher scores on the CBI scale and lower scores on the Satisfaction Compassion subscale of ProQoL than other HCW; nurses had higher scores on ProQoL and CBI (31.37% on the ProQoL Secondary Trauma subscale). SAVE-9 scale showed high percentage scores in all factors (Total mean score: 21.10; 55.22%; Factor I: 13.91; 52.23%; Factor II: 7.19; 64.17%).

Conclusions:: The COVID-19 viral pandemic is having a major impact on the psychological and occupational well-being of caregivers of people with Alzheimer’s disease. However, family caregivers have a greater burden of work-stress. Our small study confirmed this incidence observed in previous studies, also highlighting high levels of anxiety and stress in HCWs.
LONG DURATION PROGNOSIS OF HYPERTROPHIC PACHYMENINGITIS

Akihiro Ueda, Mayumi Senda, Kunihisa Kato, Syunske Adachi, Konoka Esaka, Yuji Tsujimura, Syuko Nakano, Kazutaka Hayashi, Fumihiko Banno, Koichi Kikuchi, Atsuhiro Higashi, Ryunosuke Nagao, Toshiki Maeda, Tetsuharu Kako, Seiko Hirota, Tomomasa Ishikawa, Yasuaki Mizutani, Sayuri Shima, Mizuki Ito, Shinji Ito, Tatsuro Mutoh, Hirohisa Watanabe
Fujita Health University School of Medicine, Neurology, Toyoake, Japan

Background and Aims:: The aims of this study is to reveal details of long-term treatment and prognosis of hypertrophic pachymeningitis (HP).

Methods:: We investigated 10 HP patients experienced in our hospital from April 2015 to June 2020. As a diagnostic criterion for HP, the patient presented with some neurological symptoms and showed abnormal dural thickening by MRI Gd enhanced T1 weighted image.

Results:: The results of these 10 HP cases were as follows; the average age of onset was 61.5 years(range 29-79), four males and six females, underlying diseases (idiopathic 3 cases, ANCA-related vasculitis 3 cases, Aspergillus infection 2 cases, IgG4-related disease 1 case, ulcerative colitis 1 case), part of dural thickening (only supratentorial 6 cases, including infratentorial 4 cases), the form of dural thickening (linear type 6 cases, nodular type 4 cases), headache in 7 cases, pyrexia in 3 cases, lesion part of cranial nerve (upper cranial nerve 7 cases, lower cranial nerve 3 cases), maximum PSL dose 0.79 mg/kg/day, PSL maintenance daily dose 0.18 mg/kg/day, only 2 cases could end immunotherapy, 3 cases of the immunosuppressive drug combination, mRS decreased from 3.1 to 1.4 before and after treatment, Some sequelae remained in 8 cases, recurrence occurred in 3 cases, and 2 cases died.

Conclusions:: Idiopathic HP and HP associated with immune disorders responded to steroids and immunosuppressive drugs and recovered well, but it was difficult to terminate steroids. Secondary HP associated with Aspergillus infection could not use steroids pathologically, and recovery was poor.
RELATIONSHIP OF TNF-Α AND CRP WITH ELECTRONEUROPHYSIOLOGICAL PARAMETERS IN PERIPHERAL DIABETIC NEUROPATHY PATIENTS

Larisa Shchepankevich¹, Marina Pervuninskaya², Irina Gribacheva¹, Tatyana Popova¹, Ekaterina Petrova¹, Maria Shchepankevich¹
¹Novosibirsk state medical university, Neurology Department, Novosibirsk, Russian Federation, ²Novosibirsk state medical university, Neurology, Novosibirsk, Russian Federation

Background and Aims:: Diabetic peripheral neuropathy (DPN) is the most common complication of diabetes mellitus type 2 (DM2). The mechanisms of inflammation can damage effect on the nerve fiber. Aim was to assess the relationship between the inflammatory markers TNF-α, CRP and electroneurophysiological (ENMG) parameters depending on the duration of DPN.

Methods:: 76 patients with DM2 were evaluated (target HbA1c level <8%). The mean age was 62.6 ± 0.7 years, the duration of DM2 was 6.8 ± 0.5 years. There were two groups depending on the duration of the PDN: 1 (n = 34) - less than 2 years, 2 (n = 34) - more than 2 years. We used the American Nicolet Viking IV for a quantitative assessment of the speed of conduction along the nerve. TNF-α and CRP was carried out using immunological methods.

Results:: There was a speed decrease of the motor and sensory peripheral nerves. The conduction was significantly lower in group 2 (p <0.05), with more severe damage to the motor fibers. Correlation analysis showed a direct relationship between CRP and nerve conduction velocity (p <0.05) in both the 1 and 2 groups. Similar changes were revealed between TNF-α and the sensorimotor dysfunction according to ENMG, a direct relationship was noted between TNF-α and the speed of conduction along the nerve (p <0.05) both in the 1 and 2 group.

Conclusions:: The high level of inflammation markers TNF-α, CRP in patients with DM2 and a long history of DPN confirms the hypothesis of a possible contribution of nonspecific inflammation to the development of neuropathy.
AN INTERESTING CASE OF CEREBRAL AVM

Shubham Dubey, V Ramakrishnan
MMCH & RI, Department Of Neurology, Kanchipuram, India

Background and Aims:: Vascular malformations in brain can present with varied symptoms like focal or generalised seizure, severe headache, focal neurological deficits and sudden loss of consciousness. Approximately one-third to one-half of patients with newly diagnosed previously unruptured brain Arteriovenous Malformations(AVM) present with seizures. One percent of unprovoked first seizures are caused by brain AVMs.

Methods:: A 52 years old post-menopausal female with emotionally grief condition and prolonged crying due to loss of a family member came with complaints of sudden focal seizure without aura or automatism involving right upper limb and lower limb with deviation of head towards right side, tonic in nature, lasting for 2 minutes with impaired awareness without any postictal weakness or confusion, with no previous history of seizures or any comorbidities.

Results:: MRI Brain showed cluster of multiple T2 flow voids in left frontal region measuring 5.2*5.3 cm without surrounding edema & mass effect suggestive of Arterio-Venous Malformation in left frontal lobe (Spetzler-Martin grading 2) (Bag of black worms appearance).

Conclusions:: The mass effect of the brain AVM nidus or associated venous pouches may be responsible for triggering seizure activity. First focal seizure whether its provoked or unprovoked, irrespective of age, sex and systemic comorbid condition and previous normal neurological status, necessitates detailed and urgent neuro-imaging to rule out major life threatening causes of any etiology like vascular, neoplastic, infective, inflammatory, immune mediated, CSF flow disorders and congenital anomalies in brain.
A STUDY OF USING BARIA ZASAL THERAPY AS A TREATMENT METHOD OF CONCUSSION

Orgilbayar Ganbat¹, Oyuntugs Byambasukh², Soyol Erdene Tsend Ayush³, Tserendagva Dalikh⁴, Byambasuren Dagvajantsan⁵
¹Mongolian National University of Medicine, Department Of Physical Therapist, Ulanbator, Mongolia, ²Mongolian National University of Medical Sciences, Department Of Endocrinology, Ulaanbaatar, Mongolia, ³Mongolian National University Of Medicine, Department Of Neurology, Ulaanbaatar, Mongolia, ⁴Mongolian National University Of Medicine, Department Of Mongolian Medicine International School Of Medicine, Ulaanbaatar, Mongolia, ⁵Mongolian-Japan hospital, Mongolian National University of Medical Science, Department Of Neurology, Ulaanbaatar, Mongolia

Background and Aims:: In Traditional Mongolian medicine the baria zasal therapy has been inherited for hundreds of years due to the Mongolian lifestyle and nomadic culture. TMM's Baria zasal therapy hasn't lost it's value even the modern medicine, developing rapidly nowadays and still using as a main treatment of concussion. To study the factors in choosing the baria zasal treatment in concussions.

Methods:: A total of 400 hundred people was surveyed in our study and asked what would they do if their child had a concussion. The questionnaire also included the demographics and religions of the respondents.

Results:: The average age of our survey respondents is relatively young (average age 35.3±9.1) and 86% (n=354) highly educated. In terms of religions 59.6% (n=186) were Buddhists and 25.8% were non-religious people(n=80). When asked to how they treated concussion at that time, 62.3% of them answered they went to the bariachi which known as massagist. Using regression analysis to study the factors to why people chose to visit bariachi it shows based on their own beliefs [OR; 95%CI=2.21; 1.23–2.63, p=0.04], based on their previous experiences (2.36; 1.38–4.03, p<0.001) were statistically true. After experiencing the concussion, there are no difference found in age, religion or education between those who chose to visit bariachi and those who did not.

Conclusions:: Most parents and guardians seek treatment from a bariachi's their first choice in when their child suffers a concussion and the choice of visiting bariachi does no depend on their age, education level or religion but on their own beliefs.
THE EFFECT OF BRACHIOCEFALIC ATHEROSCLEROSIS TO THE CEREBRAL CIRCULATION INSUFFICIENCY

Doston Sultonov¹, Satima Kuranbaeva², Sevara Kalandarova², Sardorbek Khakimov¹, Gulnora Rakhimbaeva¹
¹Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan, ²Tashkent Medical Academy, Neurology, Farabi str., Tashkent, Uzbekistan

Background and Aims:: The aim of the study was to examine the structural features of atherosclerotic lesions of the brachiocephalic arteries and their relationship with the severity of cerebral circulation insufficiency.

Methods:: The study included 77 patients, 38 of them were subsequently operated on the brachiocephalic arteries, 39 were continued conservative treatment. In terms of gender, men were 67 (87.0%), while women were 10 patients (13.0%). The average age was 57.7 ± 7.8 years. Duplex scanning of blood vessels was performed using Ultramark-9 (ATL) and Sonos-1800 (Hewlett Packard) devices with sensors operating at 7-12 MHz.

Results:: The asymptomatic character of the cerebral ischemia with lesions of the brachiocephalic arteries was 29.6% of all patients included in the study. The clinic of transient ischemic attacks was revealed in 59.3% of patients included in the study (75.3% in operated patients and in 43.1% in patients receiving conservative treatment). The expediency of a comprehensive examination of patients with atherosclerosis of the branches of aortic arch has been substantiated, including a clinical assessment of symptoms and the use of additional imaging methods (duplex scanning of arteries, transcranial Doppler, computed tomography of the brain), simultaneous participation in the treatment were cardiovascular surgeons, neurologists and cardiologists.

Conclusions:: The study data indicate the role of early diagnosis of atherosclerotic lesions of the brachiocephalic arteries, which makes it possible to carry out complex measures aimed at stabilizing the course of the disease, improving the prognosis, including the timely determination of indications for surgical treatment of this disease.
CONSUMPTION OF OPIOID ANALGESICS IN THE PRIMARY HEALTH CARE IN ALBANIA, 2010-2019

Laerta Kakarriqi¹, Gentian Vyshka², Jera Kruja³,⁴
¹Faculty of Medicine, UMT, Section Of Pharmacology, Biomedical And Experimental Department, Tirana, Albania, ²Faculty of Medicine, UMT, Biomedical And Experimental Department, Tirana, Albania, ³Faculty of Medicine, UMT, Neurology, Tirana, Albania, ⁴UHC Mother Teresa, Neurology, Tirana, Albania

Background and Aims:: Authors discuss the use of opioid drugs (morphine, fentanyl, oxycodone, pethidine, and tramadol) in Albania, mainly at the primary health care level; and differences of prescription patterns over a period of 10 years.

Methods:: The data were assembled from Health Insurance Institute in Tirana, Albania and analyzed for the period 2010-2019. The consumption of drugs was expressed as a number of Defined Daily Dose (DDDs)/1000 inhabitants/day. We also analyzed the data of imported and domestically produced drugs, which represent the total consumption of opioid analgesics in the country.

Results:: The consumption values of opioid drugs in Albania are comparatively low. An important part of the opioid drugs flows out from the reimbursement scheme. A comparative analysis in the consumption of opioids between Albania and other countries suggested also important differences in the overall consumption values.

Conclusions:: The consumption values of opioid drugs in Albania are comparatively low. An important part of the opioid drugs flows out from the reimbursement scheme. A comparative analysis in the consumption of opioids between Albania and other countries suggested also important differences in the overall consumption values.
DIAGNOSTIC DIFFICULTIES AND CROSS-IMMUNOREACTIVITY OF PML. CASE-REPORT.

Olga Vorobeva, Darya Sitovskaya, Yulia Zabrodskaya
Polenov Russian Scientific Research Institute of Neurosurgery – branch of Almazov National Medical Research Centre, Pathology, St. Petersburg, Russian Federation

Background and Aims:: To describe the difficulties clinical diagnosis of progressive multifocal leukoencephalopathy (PML) not associated with HIV.

Methods:: MRI, PET, stereotactic biopsy, open surgery, histology, histochemistry, immunohistochemistry, PCR.

Results:: A 70-year-old man, not suffering from HIV, had progressive neurological symptoms. Then he underwent MRI and PET-CT of the brain: differential diagnosis of multifocal autoimmune, inflammatory disease or tumor. The patient is referred for stereotactic biopsy. The biopsy was analyzed in 3 medical institutions, in some of them anaplastic ganglioglioma was diagnosed, in the other demyelinating disease, in the third PCR method excluded herpetic encephalitis, tick-borne encephalitis, borreliosis and toxoplasma. Two months after the biopsy, craniotomy was performed with the removal of one of the nodes. On histological examination, PML was diagnosed.

Conclusions:: From a clinical point of view, differential diagnosis was complicated by the absence of a confirmed cause of immunodeficiency in the patient. Difficulties in the histological diagnosis of PML in this case were due to the small volume of material in the case of stereotaxic biopsy. Also in this case, due to the activity of the viral process, a large number of large bizarre cells were identified. Particularly difficult to diagnose was nuclear cross-reactivity of large bizarre cells with antibodies to ki-67, p53, Vim and NF, due to active replication of the virus in tumor cells. Based on our clinical experience, we can assume that the spectrum of antibodies with cross-reactivity and its severity in the case of PML is dependent on the viral replication activity.
POSTERIOR REVERSIBLE ENCEPHALOPATHY SYNDROME (PRES) WITHOUT HYPERTENSION, A CASE REPORT

Meri Papajani¹, Blerta Qazimllari², Serla Grabova³, Denis Qirinxhi⁴, Arben Rroji⁴, Jera Kruja²
¹UHC Mother Teresa, Neurology, Tirana, Albania, ²Faculty of Medicine, UMT, Neurology, Tirana, Albania, ³UHC Mother Teresa, Neurophysiology, Tirana, Albania, ⁴UHC Mother Teresa, Neuroimaging, Tirana, Albania

Background and Aims:: PRES is a disorder manifested by various neurologic symptoms, such as headache, visual and consciousness disturbances, seizures and focal neurological deficits. It is associated with a number of conditions, leading to white matter edema.

Methods:: We present the case of a young woman with headache and generalized tonic-clonic seizures in the early postpartum stage.

Results::

![Brain MRI Image](image-url)
A 22-year-old woman primigravida was sent to ER after 2 episodes of bilateral tonic-clonic seizures one hour after caesarean section under spinal anesthesia at her 39-40 week of an uncomplicated pregnancy. She never smoked or consumed alcohol. On arrival, she was alert and oriented, reported occipital headache, there were no evidence of meningeal signs, neither focal neurologic deficits. Visual field testing, cranial nerve examination and vital signs were normal. Laboratory findings were significant for an elevated WBC, LDH, RF, CRP, and hyponatremia of 129 mmol/l. Urinalysis was remarkable for proteinuria, glucosuria, and the presence of WBC and RBC. Renal and hepatic function, ANA, ANCA resulted normal, as well as EEG and brain CTA. Brain MRI showed bilateral multiple cortical lesions at the frontoparietooccipital regions with signal restriction in DWI, consistent with PRES. MRI performed one week later revealed resolution of lesions. The patient's headache resolved on the 3rd day of hospitalization, no more seizures were recorded. She was discharged home with no neurologic deficits.

**Conclusions:** PRES should be always suspected in a patient which presents in the postpartum period with seizures and headache. It is essential to treat PRES promptly in order to prevent permanent neurological deficits.
THE USE OF A NEW DIAGNOSTIC METHOD IN PATIENTS FOR THE DIFFERENTIAL DIAGNOSIS OF ALZHEIMER'S DISEASE (AD)

Dilshod Toliboy, Gulnora Rakhimbaeva
Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Background and Aims:: Selection of biomarkers incoming contact to the selected diagnostic complex is dictated by the participation of these proteins in the pathogenesis of AD, including at early asymptomatic stages of AD.

Methods:: Selected 147 patients with verified diagnosis of presenile type of Alzheimer's disease (n=17) – 1-group, senile type of Alzheimer's disease (n=30) - 2-group and chronic brain ischemia (n=100) - 3-group. Determined the dehydroepiandrosteron sulfate (DHEA-s) in blood serum of patients.

Results:: The average age of patients was 71,05±1,15 years in 1-group, 57,2±0,92 years in 2-group, 67,18±1,06 years 3-group. Determination of biomarker DHEA-s showed that the level of DHEA in 1-group and 2-group has not changed or has changed slightly, but in 3-group the level of DHEA-s increased by 2 or more times (concentration in norm - 2.6 mmol / l)

Conclusions:: The high diagnostic efficiency of biomarker was asserted, including determination of serum of patients DHEA-s for the early diagnosis and monitoring the effectiveness of therapy and to identify high-risk groups Alzheimer's disease, and chronic brain ischemia.
Background and Aims:: Typical chronic inflammatory demyelinating polyneuropathy (CIDP) is a symmetric sensorimotor polyneuropathy. We report three cases with motor predominant CIDP and phrenic nerve palsy.

Methods:: Case reports:

Results:: Case 1 : A 39-year-old woman had quadriplegia without any sensory deficit associated with areflexia and orthopnea. ENMG (electroneuromyography) showed motor demyelinating polyneuropathy with prolonged distal motor latencies of phrenic nerves. Respiratory function tests disclosed a decreased forced vital capacity (FVC). She was treated with IVIg and cyclosporine, and progressively improved after requiring non invasive ventilation (NIV). Case 2 : A 25-year-old man diagnosed as having Guillain-Barré syndrome and treated by IVIg. 4 years later he presented with worsening limb weakness and dysphonia. Examination revealed severe weakness and atrophy. ENMG testing showed abolished distal motor responses. Patient was treated with IVIg+prednisone+azathioprine. However, he developed worsening respiratory function (FVC at 30%) and later died following a bronchopulmonary infection. Case 3 : A 69-year-old male patient was admitted with progressive motor weakness. The neurological findings were symmetrical weakness with no sensory deficits. ENMG showed motor predominant CIDP. 2 years later, a flaccid quadriplegia and respiratory failure occurred, treated with tracheostomy, IVIg, azathioprine and prednisone. His clinical status slowly improved. he removed tracheostomy then remained fully independent. However, he died in 2015 of pulmonary embolism.

Conclusions:: Our patients illustrate the rarely reported association of motor predominant CIDP and phrenic nerve palsy. ENMG of the phrenic nerve and respiratory function measurement in different subgroups of CIDP patients may clarify the frequency and prevent more severe features of respiratory failure.
STROKE-LIKE EPISODES REVEALING SEVERE HYPERTHYROIDISM IN A MIDDLE-AGED WOMAN: A CASE REPORT

Meryem Moro¹, Mohamed Chraa², Najib Kissani¹
¹Mohammed VI University Hospital Center, Neurology, Marrakech, Morocco, ²Mohammed VI University Medical Center, Marakesh, Neurology, Marrakesh, Morocco

Background and Aims:: We report the case of a middle-aged woman who presented to the ED with stroke-like symptoms and normal brain imaging, ultimately revealing thyrotoxicosis with severe hyperthyroidism.

Methods:: A 49-year-old diabetic woman presented to the emergency department with a 5 day history of headaches and left sided weakness. She had a similar episode 3 months prior treated as a "minor stroke" from which she had fully recovered. She reported significant weight loss (30kg) over 6 months. On examination, she had a mild left-sided hemiparesis with decreased tone, flexor plantar responses and slightly diminished deep-tendon reflexes. She had a diffuse goiter with a bruit and her hearbeat was irregular. Lab tests found hyperthyroidism with low TSH <0.005 and elevated T4 levels >100. She had 2 EKGs 24hours apart: the first one unremarkable while the second one showed atrial fibrillation.

Results:: She was hospitalized with a working diagnosis of stroke due to paroxysmal atrial fibrillation in the context of thyrotoxicosis. Subsequent brain MRI however was completely normal. Further investigations revealed markedly elevated TPO levels >1000 Ul/ml, slightly elevated anti TSHR at 2.6 Ul/ml and thyroid sonography was compatible with thyroiditis. CSF examination also found anti TPO at low levels (2.85 Ul/ml). She was started on methimazole and propanolol, with anticoagulation. Her left-sided weakness resolved completely over the next two weeks.

Conclusions:: Stroke-like episodes have been rarely described with thyroid disease, mostly in the context of Hashimoto's encephalopathy. This patient however had no seizures or altered mental status and her symptoms resolved upon treating her thyroid disease.
FULMINANT IDIOPATHIC INTRACRANIAL HYPERTENSION AND REVERSIBLE SPLENIAL LESION SYNDROME (RESLES) : A CASE REPORT

Meryem Moro, Najib Kissani, Nissrine Louhab
Mohammed VI University Hospital Center, Neurology, Marrakech, Morocco

Background and Aims:: Reversible splenial lesion syndrome (RESLES) is a rare clinico-radiological entity characterized by transient lesions involving the splenium of the corpus callosum (SCC). It has been described in a broad spectrum of conditions. We report the case of a RESLES in a young woman ultimately diagnosed with fulminant idiopathic intracranial hypertension (IIH). To the best of our knowledge, this is the first such association reported.

Methods:: A 29 year-old woman with chronic kidney disease was admitted to the emergency department with a two-week history of severe headaches, nausea and rapidly progressive vision loss. On admission, the patient had no light perception in both eyes, bilateral stage 3 papilledema and bilateral sixth nerve palsies. Brain MRI with MRV was completely normal apart from a 1 centimeter lesion of the splenium of the corpus callosum. A lumbar puncture was performed: CSF composition was normal but the opening pressure was elevated at 43 cmH2O. The rest of her workup was normal apart from elevated creatinine at 15 mg/L. She was diagnosed with fulminant IIH.

Results:: The patient underwent ventriculoperitoneal CSF shunting with initial relief of symptoms but no visual recovery. Three days later however, her headaches reappeared. A repeat MRI showed extensive cerebral venous thrombosis and the patient was started on anticoagulants. Repeat MRI at 6-month follow up showed complete regression of the splenial lesion and thrombosis.

Conclusions:: Whether a coincidence or not, we report a case of an association between fulminant idiopathic intracranial hypertension and reversible splenial lesion syndrome. The physiopathology remains unclear.
TELENEUROLOGY DURING THE COVID-19 PANDEMIC: EXPERIENCES AND CHALLENGES

Ashraf Gango
University Hospitals Leicester, Neurology, Leicester, United Kingdom

Background and Aims:: This survey aimed at providing a comprehensive assessment of the rapid implementation of Teleneurology services at University Hospitals of Leicester in England in response to the Covid-19 pandemic. The twin surveys explored the experiences of both patients and clinicians.

Methods:: A target of 10% of patients who had audio consultations in the department of neurology was set for the patients’ survey. The total number of patients was 1100 during the month of May. A simple randomised procedure was followed for patient’ selection; every 10th patient in the list was contacted by phone by the auditors.

Results:: 44% of patients rated their experience as similar to their face-to-face appointments; whilst 18% rated their experience as better. 42% (19/45) of patients would prefer a face-to-face appointment over a phone appointment as opposed to 38% (17/45) who prefer audio consultation. Clinicians identified subspecialties such as movement disorders, neuromuscular and dementia clinics as particularly challenging to conduct over the phone as opposed to headache and epilepsy clinics. When asked to rate their experience of audio clinics, no clear preference was expressed.

Conclusions:: Data from these twin surveys suggests teleneurology under the unique circumstances imposed by the Covid-19 pandemic has cautious positive reception from patients and a careful welcome from clinicians. Teleneurology is feasible and effective method for service delivery in appropriately selected patients. Careful patient selection, implementation of validated protocols and introduction of bidirectional videoconferencing would help address some of the shortcomings and enhance the experience of both patients and clinicians.
Background and Aims:: Guillain-Barré Syndrome (GBS) is an acute immune-mediated polyradiculoneuropathy with diverse clinical phenotype and functional outcome. In this study, we tried to evaluate clinical profile and outcome of GBS patients admitted in a tertiary care centre of Bangladesh.

Methods:: This prospective observational study was conducted in the department of neurology from 1st January 2016 to 31st June, 2020 in BIRDEM General Hospital. Fifty adult patients who fulfilled the diagnostic criteria of GBS admitted in the neurology department were included in the study.

Results:: Majority of the patients were male (64%). Mean age of the study population is 31.5 years ranging from 19 to 60 years. The most common presenting symptom at entry was ascending paralysis that occurred in 24 patients (48%). Twenty four (48%) patients had GBS disability score of 4 at entry. 39(78%) had GBS disability score of 4 at nadir. Diarrhea was reported in 14(28%) and respiratory tract infection was reported in 9(18%) cases. Majority of the patients had Brighton criteria level 1 certainty of diagnosis (62%) in our study. GBS variants according to nerve conduction studies were AIDP (54%), AMAN (34%) and AMSAN (12%). CSF protein was raised in 72% cases. MRC score at entry was significantly lower at entry and nadir in AMAN and AMSAN group of patients. Patients diagnosed with AMAN and AMSAN had worse outcome after 3 months.

Conclusions:: AIDP was the commonest variant in our study with comparatively good outcome. We recommend further multicentre prospective studies among patients with GBS to determine their long-term prognosis.
ALCOHOL USE PATTERNS DURING COVID-19 PANDEMIC IN INDIA: AN EXPLORATORY ONLINE STUDY

Gayatri Bhatia
All India Institute of Medical Sciences, Psychiatry, Ghaziabad, India

Background and Aims:: Background: The COVID 19 pandemic and the nation-wide lockdown presented unique challenges to the population. Initial ban over sales of alcohol which was later lifted affected the availability and prices of alcohol. Combined with restriction of movement and disruption in daily routine, change in alcohol use patterns of the population can be anticipated. While studies have indicated a surge in the number of patients presenting to emergency services with alcohol withdrawal symptoms, data from healthy, non-treatment seeking population is sorely lacking. Aims: This study aimed to assess alcohol use patterns during COVID 19 pandemic in India via an online survey with participants inducted using snowball sampling technique.

Methods:: An online survey was created using Google forms. The link was shared with investigators’ associates and participants were inducted using snowball sampling techniques. Responses were obtained from 379 individuals.

Results:: Findings suggest that 65% of the participants who had consumed alcohol at least once in the previous year had continued alcohol consumption during the pandemic. More than 60% reported an increase in the money spent on alcohol consumption. While 17.5% reported problematic alcohol use and more than 30% had attempted cut-down/cessation, help/treatment seeking was extremely low. The most common reasons for continuing alcohol use during the pandemic were stress reduction and mood upliftment.

Conclusions:: These findings indicate a need for further detailed assessment of substance use and psychological issues which may influence alcohol use patterns during the Pandemic. The authors recommend adaptation of treatment services to match the changing requirements of the current situation.
IS THE PREHENSION BEHAVIOR TEST REALLY USEFUL? NORMATIVE DATA FOR THE SLIMMER FRONTAL ASSESSMENT BATTERY (FAB15)

Ciro Rosario Ilardi1, Sergio Chieffi2, Chiara Scuotto1, Nadia Gamboz3, Alessandro Iavarone4
1University of Campania “Luigi Vanvitelli”, Department Of Psychology, Caserta, Italy, 2University of Campania “Luigi Vanvitelli”, Department Of Experimental Medicine, Naples, Italy, 3Suor Orsola Benincasa University, Laboratory Of Experimental Psychology, Naples, Italy, 4CTO Hospital, AORN “Ospedali dei Colli”, Neurological Unit, Naples, Italy

Background and Aims:: The Frontal Assessment Battery (FAB) is a neuropsychological screening tool for exploring executive functions at bedside and in the outpatient clinical practice. Many studies found a marked ceiling effect for the prehension behavior test (PBT, environmental dependency) in the healthy and clinical populations, which affects the psychometric robustness of the battery. Aim of the current study was to provide norms for a shortened version of the FAB without PBT (FAB15).

Methods:: The normative sample included 1,187 individuals (655 women; age, M=52.75, SD=17.07; education, M=10.55 years, SD=4.82). PBT had near-zero variance (M=3.00, SD=0.02), poor content validity (r vs total FAB score=0.01, p>0.05), and no discrimination power (item-total correlation=–0.02). Internal consistency also increased (Cronbach’s alpha=0.69 vs 0.72) when PBT was excluded. FAB15 factorial structure and reliability were assessed. Normative data were extracted using a regression-based approach according to sex, age, and education.

Results:: The factorial analysis revealed a single component (variance explained=53.80%) with strong loadings (all>0.50). Interrater (ICC=0.99) and test-retest reliabilities (ICC = 0.98) were excellent. The regression analysis showed that sex (low-educated women did worse than low-educated men), higher age, and lower education affected FAB15 score. Cutoff value and correction grids were computed.

Conclusions:: The prehension behavior is a “relative” of the grasping reflex, with an elicitation method less effective in triggering the motor response. Moreover, the observation of a ceiling effect in healthy subjects makes PBT not suitable for inclusion in a neuropsychological battery. The more severe FAB15 may successfully replace the conventional FAB.
IMPACT OF SQUARE STEPPING EXERCISES ON MOBILITY AND BALANCE IN OLDER ADULTS - AN EXPERIMENTAL STUDY

Ekta Kharde, Nawaj Pathan, Varsha Mishra, Rohan Thombare
MGM Campus, Department Of Physiotherapy, Aurangabad, India

Background and Aims:: Background: A fall is described as a life event in which an individual comes on the ground, floor which is mostly accidental in nature. During ageing, physiological changes set back many changes such as mitochondrial dysfunction and dropped hormonal production. These physiological events result in gradual decreased bone density, decreased muscle mass and strength in lower limbs. Aims: The intent of this study is to explore the impact of Square Stepping Exercise (SSE) in older adults to enhance balance and mobility to reduce fall risk.

Methods:: This is an experimental study in which (N-96) senior populations over sixty years were randomly divided into SSE and conventional exercise groups using a simple random sampling procedure. The interventions lasted for four weeks. Berg balance scale (BBS) and a Timed Up and Go (TUG) test were used to assess pre and post interventional effects.

Results:: Paired and unpaired t tests were used for statistical analysis. In SSE both balance and mobility showed statistically significant improvement (P < 0.001).

Conclusions:: Conclusion: Square Stepping Exercise has potential to serve as effective intervention among elder population with a high risk of fall.
CERVICAL MYELORADICULOPATHY WITH HYPOGLOSSAL SCHWANNOMA MIMICKING AMYOTROPHIC LATERAL SCLEROSIS

Sathyajith Ambawatte¹, Dulmini Weerathunga¹, Athula Dissanayake², Surangi Somaratne¹, Piyumi Wijewickrama¹
¹Ministry of health, Sri Lanka, Health Department, Colombo, Sri Lanka, ²Teaching hospital Karapitiya, Sri Lanka, Neurology, Karapitiya, Sri Lanka

Background and Aims:: A presentation of upper and lower motor signs without sensory impairment in multiple regions may suggest Amyotrophic Lateral Sclerosis(ALS). However, the co-existence of two or more other pathologies can give rise to a clinical picture similar to ALS. We report a case of co-existent hypoglossal schwannoma and cervical myeloradiculopathy presenting as ALS.

Methods:: A 45-year-old Sri-Lankan lady presented with slowly progressive painless right upper limb weakness for 6 months and mild left upper limb weakness for 2 months associated with muscle twitching, associated with slurred speech. Asymmetrical wasting and fasciculations were noted in upper limb proximal muscles with reduced power on right more than left. Her biceps and supinator jerks were normal with exaggerated triceps jerks and a positive Hoffman sign. Both lower limbs were hypertonic with exaggerated reflexes, without clonus or Babinski sign. Sensory examinations were unremarkable. Her tongue deviated to right side with fasciculations and wasting of the right side. Palatal movements and jaw jerk were normal. She was clinically diagnosed with possible ALS.

Results:: Electromyography showed denervation changes in deltoids and biceps with right predominance and right genioglossus muscle too showed denervation changes. Magnetic-resonance imaging revealed a right-sided hypoglossal schwannoma and degenerative disk disease with cervical cord compression.

Conclusions:: Pure motor symptoms with a mixture of upper and lower motor signs may suggest a clinical diagnosis of ALS. This case is an eye-opener to be open-minded about the presence of dual pathology as above, giving rise to a similar clinical picture, in order to avoid misdiagnosis.
AN EVALUATION OF DIGITISED NEUROFEEDBACK - THE FUTURE OF PERSONALISED MENTAL HEALTH CARE?

Karanjot Chhatwal, Viraj Shah, Elina Tanskanen
Imperial College London, Faculty Of Medicine, London, United Kingdom

Background and Aims:: Neurofeedback is a method of brain self-control via measurement of brainwaves and provision of a feedback signal. Previous literature has identified potential for neurofeedback as alternative treatment for neuropsychiatric conditions including stress and anxiety. The SPHERE tool aims to digitise neurofeedback for mobile devices. This study evaluated whether SPHERE was more effective in improving the common symptoms of stress and anxiety than the most popular alternative digital tool available.

Methods:: 39 participants were recruited opportunistically. Participants were randomly assigned to 3 groups to test either SPHERE, the widest-used digital tool or the widest-used digital tool with a pre-session artificial stressor applied. Participant heart rate was recorded pre- and post-session. 1-tailed Mann-Whitney U Tests or Welch's tests were used to assess significance between cohorts with p<0.05 denoting significance throughout.

Results:: A significantly larger decrease in heart rate pre- and post-session was observed amongst the SPHERE cohort compared to both other cohorts: 11.6% decrease for SPHERE, 3.02% increase for the widest-used digital tool and 1.72% decrease for the widest-used digital tool with a pre-session artificial stressor applied (p<0.01).

Conclusions:: SPHERE's digitised neurofeedback tool was significantly more effective in improving symptoms of stress and anxiety compared to the widest-used alternative digital health tool ± pre-session artificial stressor applied, indicating the benefits of accessible neurofeedback therapy. More investment is necessary in comparing digital therapies to pharmaceutical treatments for stress and anxiety and for exploration of net changes in brain frequency pre- to post-session to enhance the effectiveness of this tool.
Background and Aims:: Idiopathic intracranial hypertension (IIH) is a disorder typically affecting young and obese women. It may be associated with several pathologies. The involvement of coagulation abnormalities in the genesis of IIH remains debated.

Methods:: We report a case of a 45 years old man with a body mass index of 20.8 kg/m², followed up for IIH that was resistant to therapies. He had diffuse headaches with stage II papilledema. The intracranial pressure (ICP) was 47 cmH₂O, CSF composition was normal and so was the cerebral MRI. Two years later, the patient presented a deep venous thrombosis of the right lower limb. A complete thrombophilia work-up was performed, finding activated protein C resistance. The search for a factor V Leiden gene mutation was not performed. The patient was put on heparin therapy with a spectacular improvement of his IIH.

Results:: The association of IIH and the factor V Leiden mutation is rare; it is attributed to a prethrombotic state leading to the formation of microthrombi in the arachnoid villi reducing the reuptake of CSF and thus leading to the increase of ICP. Thrombophilia workup is requested in the setting of secondary IIH only if the patient presents episodes of thrombosis.

Conclusions:: IIH can be idiopathic or secondary (associated with different pathological conditions). Activated protein C resistance is a coagulation abnormality often linked to factor V Leiden mutation. To our knowledge, the association of IIH and factor V Leiden mutation has been reported only in 5 cases.
PECULIARITIES OF CEREBRAL HAEMODYNAMICS IN PATIENTS WITH PROLONGED DISORDER OF CONSCIOUSNESS

Olena Kuryk1, Dmytro Mankovsky2, Lyubov Cherkasova3
1Bogomolets National Medical University, Department Of Pathological Anatomy №1, Kyiv, Ukraine, 2State institution “Heart Institute of the Ministry of Health of Ukraine”, Intensive Care Unit, Kyiv, Ukraine, 3Bogomolets National Medical University, Ukraine, Radiology Department, Kyiv, Ukraine

Background and Aims:: Structural and functional changes of the central nervous system in patients with postcomatose prolonged loss of consciousness (PPLC) remain insufficiently studied. Aim -to study the features of cerebral hemodynamics in patients with permanent and persistent PPLC.

Methods:: A comparative examination of 34 people with persistent and 67 - with permanent vegetative state (VS) was performed to clarify the state of cerebral hemodynamics. Ultrasound duplex scanning of extra- and intracranial arteries was performed using the method of extra- and transcranial Doppler on the instrument VOLUSON 8 General Electric Med. Sist. (USA).

Results:: A dissociative character of blood supply was discovered: unlike patients with a persistent VS, in those with a permanent VS the above blood supply takes place (p≤0.05) as a result of an increased circulatory resistance in the territories of blood supply by the middle cerebral artery, common cerebral artery, vertebral artery (VA) and basilar artery (BA) with a simultaneous deceleration (p≤0.05) of the maximum blood flow in the common carotid artery (CCA), internal carotid artery (ICA) and its acceleration (p≤0.05) in VA and BA. That is, unlike patients with a permanent VS, those with a persistent VS develop functional incoordination of vascular responses, this fact manifesting an impairment of the central mechanisms of vascular tone regulation.

Conclusions:: Assessment of vascular changes in cerebral hemodynamics in permanent VS revealed a significantly higher level of disorder of regulatory mechanisms than in persistent VS. Comparative analysis of functional disorders of blood flow revealed that vascular-reflex reactions have differential diagnostic and prognostic value.
